Construction of Spatial Memory Demolished Historic Architectural Context after 1972 Earthquake in Managua, Nicaragua

Romer Altamirano Guerrero, Martín Alfredo Majewsky García

(Arq. Romer Altamirano Guerrero, Universidad Centroamericana, Managua, Nicaragua, raltamirano@ns.uca.edu.ni, ronalt01@yahoo.com)
(Arq. Martín Alfredo Majewsky García, Universidad Centroamericana, Managua, Nicaragua, arquitectura@ns.uca.edu.ni, majewskym@yahoo.com)

1 ABSTRACT

In commemoration of the 40th anniversary of the earthquake in the city of Managua, proposes the construction of historical spatial memory with survivors of the tragedy, taking as reference the enhancement of the architectural context earthquake demolished after December 23, 1972 to facilitate the exchange of social imaginary urban generation.

It has a collection of little known historic architectural context demolished by the earthquake of 1972 affected, allowing the assembly of an Urban Observatory in digital format by creating a Web site featuring virtual reconstruction of demolished buildings, located within demolition area given by the National District regulator urban management at the time.

This research is developed in an interdisciplinary context, between the Faculty of Science, Technology and Environment comprising areas of Architecture, Information Systems and Graphic Design, in conjunction with the Institute of History of Nicaragua and Central America (IHNCA) all these instances of the Central American University (UCA).

It is conceived as a retrospective cross-sectional study, which modeled an architectural context that ceased to exist shortly after the 1972 earthquake rebuild oriented so volumetric demolished buildings, adding personal experiences occurred in them. Also considered a documentary research methodologies associated with qualitative, to show the historical memory of a natural event that shocked the residents of Managua.

Resumption four dominant theoretical elements, such as the architectural context, comprising the built product of socio-cultural development of a historical moment, conditioned by the natural and urban environment that surrounds (Silfa, 2009); historical spatial memory, as a reference for the symbolic construction of historic centers (Rodriguez, 2008) which is an imaginary scenario, understood as the accumulation of experiences that facilitate the exchange of various generational residents as the work of Cornelius Castoriadis and finally the concept of urban observatory proposed by UN-HABITAT (the UN Programme for Human Settlements) that guides the generation of information and comprehensive analysis stimulates actors to boost sustainable urban processes.

1.1 Objectives

(1) Establish criteria for the analysis and presentation of digital information to demonstrate the construction of historical memory of the architectural context demolished after the 1972 earthquake.

(2) Develop georeferenced information with volumetric three-dimensional models of architectural context demolished after 1972 earthquake in Managua.

(3) Collect the urban experiences of the people who interacted in the architectural context demolished after 1972 earthquake in Managua, as a contribution to the construction of historical memory of the city space.

(4) Create a virtual space that contains an urban observatory, for the interaction of the people of Managua, in the construction of historical memory of vanished architectural context by the 1972 earthquake.

2 METHODOLOGICAL DESIGN

The investigation concerns four phases, namely: exploratory, inquiry, operational and digital processing. Each is different corresponded procederes, which are explained below, see figure.

2.1 Exploratory phase

Announced by different authors to recognize the capabilities to produce a product for virtual disclosure of information processed ..

2.2 Phase of Inquiry

It includes the development of documentary research, highlighting the processing and analysis of bibliographic information, journalistic and photographic detected in the acquis IHNCA, 10 buildings were selected taking into account:

- Buildings should be studied within the demolition area given by the National District regulator urban management of the time in the city of Managua.
- Socially recognized urban facilities by reference in the city, demolished between 1973 to 1974.
- Most photographic resources, which facilitate virtual reconstruction.

2.3 Operational Phase

Corresponds with the rise of georeferenced data in the context of the study area using specialized equipment lifting (GPS) processing in Arc Gis program, activity in parallel with the development of virtual volumes, modeled Sketch-up program.

As part of the construction of a social imaginary of the inhabitants of the city destroyed by the seismic event, we propose two focus groups, the first, is to record the experiences arising from the interaction with the buildings analyzed by participants.

The second focus group aimed at validating the results of the research presented in digital format in order to recognize whether the processed information is accessible and manageable from handling personal Web site.

2.4 Phase Digital Processing

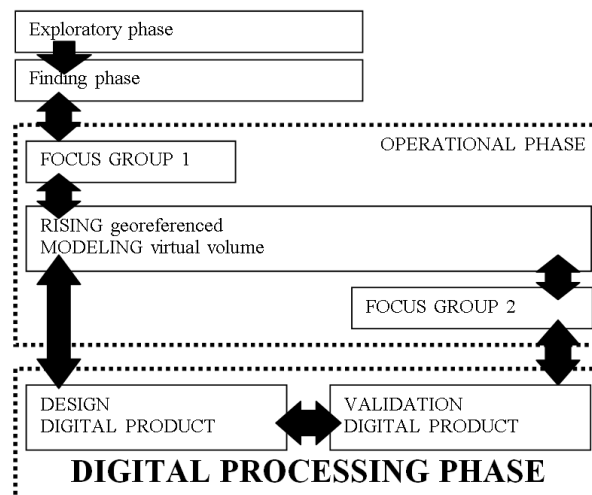
This phase consists of virtual product design from the processed data product of documentary research, as designated technical specifications for programming Web page, and the design requirements of the line of sight.


Fig. 1: Graphic of the research process

3   CONCLUSION

The Urban Observatory is organized by presenting the context of the city of Managua before, during and after the earthquake in 1972, resumed technical documents and documentary evidence the organization of the city, its seismic characteristics, audiovisual collects information from damage caused by the earthquake and proposals for rebuilding the city, adding newspaper articles from major newspapers of the city that evidence of the demolition process and specifically the city of the buildings in study, then describes the content of each of these sections in the urban observatory.

1972 Urban Context

Accurately set forth the context, sociopolitical, socioeconomic, sociocultural Managua earthquake to date, this highlights the city as the capital of Nicaragua, home of state powers, the main commercial and financial center of country as well as the setting for the dissemination of national culture.

Reference is made to the buildings covered in the research, within its urban context highlighting, where land uses are located in urban regulatory function of the time and the same location in their respective neighborhoods and its location in the urban pointing streets and avenues. This evidenced by aerial photos showing accurately tabulated data.

The section addresses an urban context where the network equipment characterizes the city concentrated in the area affected by the quake, highlighting public spaces recognized by villagers. The city was provided with drinking water supply, storm drainage, mains, telephone and telegraph, many of these services were modernized with the cotton boom in the 1950s.

3.1 Seismic Context

Are given as contrasted two PDF documents, which provide the geological environment of the city of Managua, "Seismology and tectonics of Nicaragua", lecture by Mr. Freddy Marin Bendaña in 1974 and "Seismic microzonation of Managua" by National Institute of Territorial Studies (INETER) in June 2000, which present the seismic history and current seismicity, and an analysis of the geology and tectonics. The latter is reflected in the study of soil amplification and seismic hazard Managua and illustrates the numerical simulation of earthquakes.

Exposed in PDF format refers to the technical analysis presented by Carlos Santos Berroteran, which highlights the occurrence of a seismic event of major involvement in the center of the city of Managua, it is noteworthy that the document would begin to publish in the newspaper La Prensa on December 23, 1972 day the quake struck.

3.2 Managua Earthquake

Displays the seismic event as natural disaster from a technical perspective, showing the natural physical affectations in the environment, through the reports submitted comments. Also presented showing resilience to earthquake legal action in urban governance dictate the time during the first six months for the recovery of the city, are highlighted here the management of international aid, demolition debris and supposed reconstruction of the city.

We report annotated so the damage report, from a quantitative and qualitative, of the damages, this is evidenced by the presentation of audiovisual material submitted by Mr. Nicolás López Maltez, which evaluates only human pain in seconds it caused, and the transformation of the city from a dynamic urban center, by virtue of their national capital, a destroyed environment, vacuum, inert.

Incorporated in PDF format from the daily news of the period March 1973 to October 1974, the newspaper La Prensa, stands out as the historical media, political opposition to the Somoza government of the time. But the daily news, official organ of the Somoza government, presented in terms of meeting agenda by the national government, the intervention process of the historical center of the city affected by the quake. Both emphasize the process of insertion into everyday life by people in the city and the demolition of the various buildings.

3.3 Historical Memory Space

We describe the buildings in study, by presenting technical work name, location in the central area of Managua, to recognize access roads, main location photos, pre and post earthquake, and now, also the stylistic , that define it. The following table presents the studies highlighting buildings, city location, usage and stylistic nomination:

No.	Buildings	Location	Us3	Nomination Stylistics
01	Club Managua	Core Foundation	Recreative	Neoclassical
02	City Hall	Core Foundation	Municipal Government	Neoclassical
03	Office of Pacific Railroad	Core Foundation	Administrative	Eclectic
04	Calasanz College	San Sebastián	Education	Funcionalist
05	Church San Antonio	San Antonio	Religious	Eclectic
06	Divina Pastora College	San José	Education	Funcionalist
07	Boer Market	Boer	Trade	Funcionalist
08	Casa Mantica	Trade Mall	Trade	Funcionalist
09	Male College "La Salle"	Trade Mall	Education	Neoclassical
10	Central Institute Ramirez Goyena	El Caimito	Education	Funcionalist

Table 1: Location of buildings in study as location, usage and stylistic nomination

It shows a different lane period photographs that show the works from the beginning, highlighting some remodeling over time, are photographs of the damage by the earthquake, and the evidence of the demolition process. These photographs were supplied by the Institute of History of Nicaragua and Central America (IHNCA).

Each building shows a virtual model, based on observation of photographic resources, it is about building a qualitative assessment based on the interpretation of each of the items that we offer photos, taking up elements of architectural composition and structural logic.

The building-product of a virtual modeling is georeferenced Mercator coordinate system with WGS84 datum, currently used at official level in Nicaragua. These are located in the updated maps of Goole Earth, allowing for a virtual tour of the center of Managua, integrating the buildings disappeared in the quake, the current environment of the city.

3.4 Annotated Bibliography

In order to provide information to the researchers on the subject of Managua earthquake in 1972, the Institute of History of Nicaragua and Central America (IHNCA) shows his collection, organizing it according to the number of titles by subject, are set out below: Nicaragua -History, Planning, Engineering, Geology, Seismology, Geography, Economics, Literature, public health, Testimony, Tourism, Education, Architecture.

(Dipl.-Ing. Martin Fabisch, TU Kaiserslautern CPE, martin.fabisch@ru.uni-kl.de)

1 ABSTRACT

Every era had its specific building culture and infrastructures that need continous monitoring to sustain it. In order to be able to do that, a reliable database is required but is not available up to date. Many buildings of the sectors of transport infrastructure for example were built 50 years ago and are now requiring massive investments for maintenance. The problem is even more relevant in regions close to the border, because infrastructures like streets are cross-border, legal regulations and data sources differs from country to country. To find a solution for this problem, this is the aim of the project CURe MODERN. This project, supported by the European program INTERREG IVa, aims to show, by which approaches a comprehensive monitoring of these buildings by non-destructive methods could be deployable. Project partners besides the department CPE of the University of Kaiserslautern are Fraunhofer Institute, Centre d'Études Techniques de l'Équipement de l'Est, European Research and Project Office GmbH (Eurice), Rogmann Ingenieure, Landesbetrieb Straßenbau Saarland and the Eurodistrict SaarMoselle. Focus of content is to develop different monitoring approaches for spatial infrastructures. On a local scale, this embraces various kinds of non-destructive testing. Potential testing methods are terrestrial surveyings and laserscanning as well as airborne photography are used for inventory and 3D-modelling. The regional scale needs a webbasesd GI-system analysis in order to achieve a comprehensive database as well as a tool to visualize the data for decision makers. Furthermore, the aim of this project is the foundation of a regional competence network even for innovative technolgical approaches and for regional classification in the aspect of planning.

2 REGIONAL CONTEXT

The issue of monitoring infrastructure became increasingly more relevant in recent years in the perspectives of planners. This is especially true for cross-border areas, because the relevant infrastructures embrances national and administrative boundaries. However, there is often a lack of data for the respective objects in these areas. The INTERREG IVa project "CURe MODERN" is using new and innovative technologies to develop both regional and local approaches to testing and monitoring of infrastructure and cultural structures. The consortium for this project is made up of the Department of Computer-aided planning and design methods at the TU Kaiserslautern (CPE), in cooperation with the Fraunhofer Institute for Nondestructive Testing (IZFP) in Saarbrücken, the French authority for roads in Lorraine (CETE de l'Est) in Metz, the state office for roads in the Saarland (Landesbetrieb für Straßenbau), Rogmann Ingenieure and the Eurodistrict SaarMoselle. Besides the technical and methodological approaches also an intensive knowledge exchange is planned. In this perspective, a joint competence center for cross-border cooperation between research and industry and public authorities will be initiated.

3 PROJECT

The project will focus on exemplary objects, which are relevant in the regional context for developing new and innovative monitoring approaches. There has to be a common understand for the situation of the infrastructure as well as for comprenhensible collection of the different legal circumstances from the planning and building sector. The used technologies include a variety of innovative recording techniques such as airborne photogrammetry with UAVs (Unmanned aerial vehicle), photogrammetry or terrestrial laser-based scanning. Furthermore, some concepts about how to share this information with relevant decision takers will be examinded.

The test subjects were picked in order to achieve as complementary as possible approaches of testing methods. For the representative cultural buildings, a church in Metz/France (Eglise Ste. Thérese) as well as a restored castle in Manderen/France (Château Malbrouck) was chosen. Both are reflecting a different building style which is exemplary for monitoring purposes. The focus for monitoring transport infrastructure was especially put on bridges in the project area. The first examination objects are the "Grumbachtalbrücke", which is placed on a German highway and a bridge on a national street in Rosbruck/France. The first project

focus lies on the examination of the two bridges. In a first step, a model of the object will be developed out of the various data sources (electronical property data and innovative non-destructive surveying methods) in order to use it for further elaborations of the potential damages. This data will available on a self-developed, web-based information system.

3.1 Non-Destructive testing methods for the bridges

The subsequent pictures show the first object for the examination. Based on legal property data, a 3D-model was built. In a next step, an UAV (Unmanned aerial vehicle) will be used to take detailed pictures of damages at the construction. Furthermore, the Fraunhofer Institute will conduct some concrete testings in order to get information about performance of the pre-stressed concrete. These results will be visualized with the 3D-model for politicians and decision takers to have a fundament, how to act on further reparations of the object.

Fig. 1: 3D-Model with a sufficiently level of detail for a damage localisation (Own source)
Fig. 2: Screenshot from Autodesk Navisworks for visualizing construction damages (Own source)

3.2 Web-Based-GIS & Database for project buildings

Parallel to the tests of the various objects, a web-based plattform with a common database is developped. The web interface allows besides the official website (www.cure-modern.eu) access to geographical information of the project area as well as relevant information for the test objects. The goal is to develop a common tool which gives information about the local conditions of the different buildings. Besides security-critical data, all data could be downloaded as geographical dataset or as textfile.

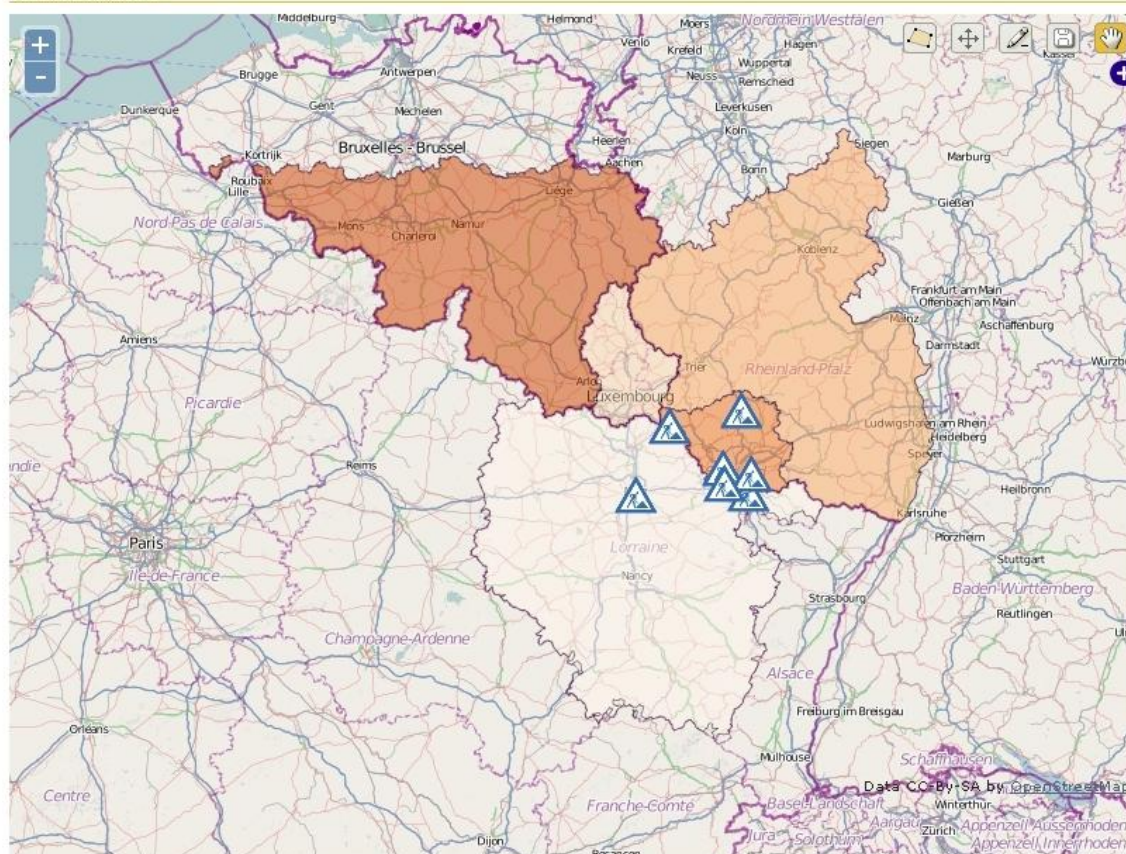
The technical realisation is completly founded on open-source-sofware. Geodata and attributes are store in a PostgreSQL/PostGIS-database, witch is richly equipped with geoprosessing funcitonality. Furthermore geoserver renders and provides our data as WMS, gives a writeable acces through WFS-T and enables an flexible data. On the clientside, openlayers ist configured as a web-based interface. It's javascript-library is able to allow various kinds of requests. Both Geoserver and Openlayers are developed and promoted as OSGeo-projects. The subsequent picture shows the web-plattform with its basic functionalities which will be extended in the future.


Fig. 3: Web-Interface CURe MODERN (Own source)

4 CONCLUSION

The important fact of this project is the cross-border approach for the monitoring methods. Whereas innovative testing methods for various kinds of buildings have been previously developed, the situation in the project region with many partners is much more complicated. Hence, aim is besides new technical solutions and potential benefits for homogenization of legal regulation is to learn from each other and develop cross-border monitrong approaches.

For the upcoming project time, more innovative and non-destructive test methods will be realized with the presented and planned study objects. In addition, new testing methods (airborne laser and radio scanning for example) will be developed. The common cooperation should be strengthened by cooperative work at a Wiki as fixpoint for the project related knowledge. Based on this, the foundation of the regional competence network will be accelerated and the scientific discourse will be pushed forward by a conference in Nancy (France) in March 2014.

Visit www.cure-modern.eu for further information.

Data Representation Dynamic Model for Distributed Urban IGIS

Andrey Pankin, Natalia Zhukova

(Dr. Andrei Pankin, SPIIRAS, 39, 14th Line, V.O., St. Petersburg, 199178, Russia, pankin@oogis.ru)
(Dr. Natalia Zhukova, SPIIRAS, 39, 14th Line, V.O., St. Petersburg, 199178, Russia, gna@oogis.ru)

1 ABSTRACT

In the article a dynamic distributed model of data presentation for creation of municipal economy distributed managment systems on the base of intellectual GIS technologies is offered. Decisions on submission of actual data for solving end users tasks, organization of data processing, data analysis, supporting interaction of various system components taking into account structure of municipal economy data and its great volume that meet modern standards are described.

2 INTRODUCTION

Hic et nunc (with lat. Here and Now). The modern computer user does not want to wait for a long time, does not want to enter initial data received from different places, does not want to look for a place where he (or she) can solve his problems. Information systems serving these users must comply with the principle of semper et ubique (with lat. Always and everywhere). Modern systems should not only provide decision support, but also a set of following possibilities. To extract necessary information from newly appearing data sources. To integrate information immedeately into existing information space. To transfer results to any place wherever a user can be. To predict his intentions and prepare the result in advance and with maximum quality. To such systems municipal services management systems undoubtedly refer. Functions that are carried out by the system are various and thus they are implemented in different subsystems. The majority of them have been developed during a long period of time, without any general idea or a plan. Because of functions distrubution and absence of the system management concept it is extremely difficult to provide hight quality solution of main tasks, such as rational use of city resources, coordination of city services work, safety of different types of human activity in conditions of dynamically changing situation. All this, finally, defines effectiveness of modern cities and megalopolises management. There is an objective need for development of a urban system that allows to integrate separate components by building a uniform data and knowledge space, and a need in universal tools for processing and analysis of continuously received diverse information. All this, finally, defines effectiveness of modern cities and megalopolises management.

3 GOALS AND REQUIREMENTS

The managment system of municipal services belongs to category of decision-making support systems. The main goal of such systems is to help users, that make decisions in difficult conditions, in complex and objective analysis of subject activity in the form of decision making process support [1]. Life cycle of a decision is a set of processes which are carried out from the moment of situation emergence to its permission. Life cycle of a decision consists of the following top level stages:

(1) Initiation – a stage that realizes the mechanism of decision making start point. As a cause for the beginning of the stage situation emergence is considered.

(2) Planning. Stage of decision making.

(3) Implementation. Stage of decision implementation.

(4) Assessment of results. Stage of implementation completion, analysis and storage of results.

At the same time several interacting cycles can be realized. New cycles are build on the basis of in advance prepared templates, but there is an opportunity to change the structure and contents of the cycle stages in dynamic when cycles are executed. The course of life cycle is considered as changes of state of the decision information model. As methodology of system development IDEF standards [2] are used.

For effective management of municipal services a system must be able to solve the following tasks:

(1) To execute continuous modeling of managed object; it allows at each timepoint to provide qualitative estimations of object current and predicted states for timely identification of various situations.

(2) To support interaction with various sources of information for maximum decreasing of the degree of uncertainty about managed objects states and providing results obtained by the system to other consumers of information.

(3) To provide adequate representation of information about managed objects states and about possible development of the situation to the user.

For the successful solution of the system tasks the following requirements are to be fullfilled:

(1) The system and all its components have to be distributed. Duplication of connections with information sources is to be provided for continuous obtaining of information. For operative modeling of unexpectedly arisen situations it is necessary to involve maximum amount of computing resources. To allow users working in various places client applications of the system have to function on various platforms, including mobile platforms.

(2) The system has to be adaptive. The main directions of system adaptiveness are defined by features of managment systems. First of all it is necessary to carry out newly arising tasks with minimum expense. Besides, depending on completeness, volume and features of analysed data the system has to apply various mathematical models. There also must be an opportunity to provide interaction with new sources of information in the shortest possible time at the expense of automatic information search that satisfies information requirements.

(3) The system has to be safe. It is necessary to provide mechanisms of the system stable continious functioning. The system has to reveal constantly internal and external threats and to use software and hardware solutions for effective prevention of threats and restoration of the system functionality and integrity. For this purpose a plan [3] has to be made. The plan is realized by aprocess that includs: analysis of functionality threats, updates of restoration strategy, adaptation of threats prevention and system restoration mechanisms, testing and state analysis.

The enumerated problems can be solved by the system at the expense of continuous situation modeling. The modeling is base on application of dynamic information model.

4 DYNAMIC INFORMATION MODEL

Dynamic information model reflects existing business processes of objects life cycle related to situations and allows to receive adequate estimates of situations at each timepoint. The situation is considered as a certain change in time and space of objects properties state and relations between objects that demand attention of the system [4]. Dynamic information model implements top levels of JDL model. Modeling is carried out not on the request of an operator, but continuously in case computing resources are available. Depending on degree of uncertainty of situation objects state and requirements to operationability more rough or exact mathematical methods are used. Methods can be applied if correct input data and parameters are defined [5].

Dynamic information model is based on three subsystems (Fig. 1).

(1) Subsystem of static information model. The subsystem is intended for providing access to business objects. It contains all set of objects, their properties and relations between objects [6]. The model is constructed on the basis of ontologies.

(2) Subsystem of business processes. The subsystem is intended for organization of decisions life cycle. It allows describing and carrying out sequence of interacting tasks. Interaction between functions is provided by making changes in business objects. It is build according to Business Process Definition Metamodel [7].

(3) Modeling subsystem. The subsystem is used for building models that reflect managed objects states and allows making estimates of situations development. Models are represented in a form of business process scenarios. Modeling subsystem contains two components:

(3.1) Simulation modeling subsystem. One of the subsystem's tasks is visualization of progress of spatial distributed business processes. The subsystem represents business logic platform providing uniform integrated framework for managing rules, working streams and processing events. As an example of such framework Drools [8] can be considered.

(3.2) Mathematical modeling subsystem. The main objective of the subsystem is organization of a cycle of situations assessment at the expense of use of scientific based mathematical concepts and heuristic

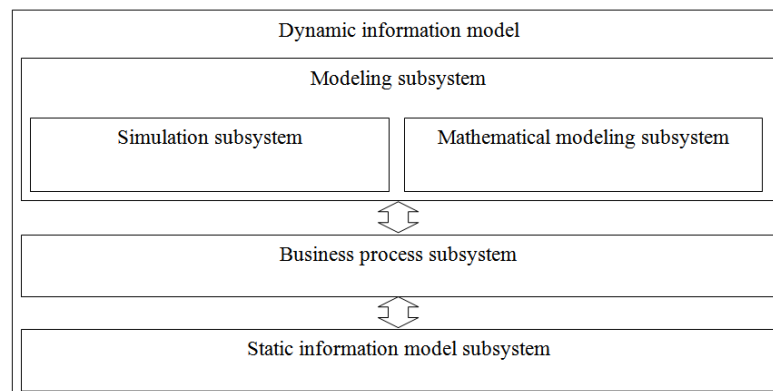
algorithms. The cycle represents a process of organization of interacting methods performance (the output data of one is input for another) that solves the task of identification and quantitative assessment of the situation.


Fig. 1. Structure of dynamic information model

4.1 Static information model

The base of static information model is a unified model of information presentation (UMIP) [9]. The model provides access to all business objects that are used in applied business logic of the system. The structure of the model is based on the known principles of object-oriented paradigm. UMPI is a structure of entities describing subject domain in a form of a set of classes and objects, each of which possesses a set of properties that characterise them. A class represents a description of set of objects with similar behavior inherited from parent classes and extanded. These objects are called instances of a class. Objects of a class are described by a set of properties. For each property following characteristics are usually defined: name, type and value. Instances of classes are objects possessing all properties defined in a class. An object can belong to several classes and, respectively, it possesses all characteristic properties of the classes. Each property (object property or class property) has a complicated structure that contains: property unique identifier, property name, property description, set of property values. Property value can be multiple and single, contain simple data and links to other objects. Key types of objects of static information model are given in Fig. 2.

4.2 Business-process model

The subsystem of business processes defines an order of business functions execution. The subsystem allows describing and carrying out sequences of interacting functions. Interaction between functions is organized by modifying business objects. Process is a basic element of life cycle stages. It represents a set of interconnected tasks aimed to change a decision information model. Processes implement a unified interface providing methods to process and analyze input and output data, management and control mechanism and mechanism for interaction with other processes. Business processes are built on the basis of the following elements and relations connecting them:

1.   Objects of management flow

1.1.   Activities

1.2.   Events

1.3.   Gateways

2.   Relations between objects of management flow

2.1.   Flow sequence

2.2.   Flow message

2.3.   Association

3.   Objects of life cycle products

3.1.   Main product

3.2.   Management product

3.3.   Information product

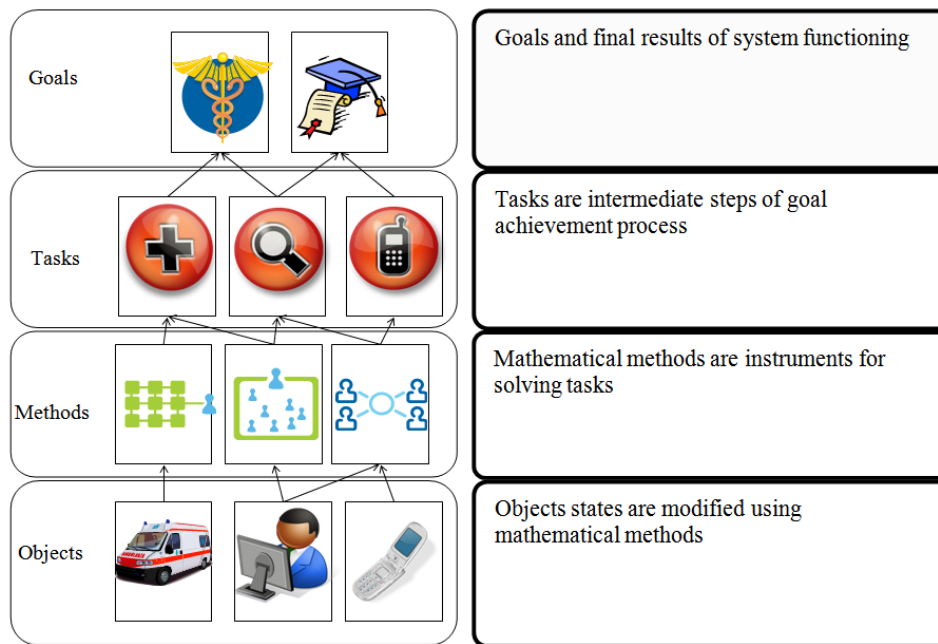
4.   Associations of objects


Fig. 2. Objects types of static information model

Activity is a basic element of a business process. It is an operation of generation, modification of state and destruction of life cycle products. Activities can be executed sequentially or in parallel, they can be dependent and independent.

Event is an element of process management that impacts on a process flow. Two types of events are considered – external and internal. External events are caused by factors that are outside of a process model. Internal events are results of changes in a management product state.

Gateway is an element that defines dependences in activities sequence. Using gateways consecutive and parallel activities are defined, selection of activities execution sequence is supported.

Flow sequence defines relations between activities and events connecting them in one sequence of activities. Flow sequence set describes an order of activities performance.

Flow message defines external actions which lead to event generation. It is a relation connecting management product or external object and an event.

Association is a relation connecting set of objects that is not an interaction or management relation.

Product is a result of activities execution. It is a container that changes its state while performing activities. It must match the information model of the product.

Information product is a product, which state does not influence a decision life cycle course.

Management product is a product a defined states of which can cause occurrence of internal events.

Main product is a result of performance of decision life cycle. It is an object generated in the beginning of decision life cycle. Main product can be considered as management product.

On the basis of dynamic information model decision-making support system is developed.

4.3 Modelling subsystem

Modeling subsystem supports two modeling approaches – simulation approach and mathematical modeling approach. Simulation approach assumes definition and execution of simulation scenarios [10]. Scenario can be formally defined as an algorithm that is a sequence of stages and solutions. Algorithms can be executed by expert systems. Stage is an aggregate of elementary actions executed sequentially or concurrently. Solution is a point where the process flow can alter to one or another direction depending on some conditions emerged at the given moment. Scenarios can alter the state of the information model objects. Scenarios are

represented as texts written in special scenarios' language, and scenarios repository is a documentary data base. An aggregation of developed scenarios is considered as a part of knowledge base.

Mathematical modeling subsystem is aimed to process large volumes of heterogeneous data, including quantitive and qualitive data, as well as measurements time series. Data can be successfully (at the desired time and with the desired precision) processed only if automated adaptive data processing approach is used, that means that processes are built in dynamics taking into account all available related information. For building adaptive processes on the base of IGIS two components are required. The first essential component is a library of algorithms that must be sufficient for solving user problems. It is also necessary to provide possibility to performed algorithms in an automatic mode. To support automatic execution of algorithms functions for defining algorithms input parameters and functions for results estimation must be defined. The second component is a library of exploratory data analysis algorithms that provide additional priory information about structure and characteristics of the data being processed. It is used together with the knowledge available to system for selecting algorithms for building processes. Both components include a wide range of statistical and data mining algorithms.

5   INFORMATIONE INTERACTION MODEL

Effectiveness of decision-making support system significantly depends on possibility of interaction with external information sources for the maximum decrease of degree of uncertainty about managed object and possibility of trasfering results of tasks solutions to the place where a user is located. In modern conditions there is a huge number of various systems potentially capable to be suppliers and consumers of necessary data. There is a number of problems that have to be solved. The first problem is that initially interaction of all these systems was not supposed. The second problem is the organization of the optimal (on time and cost) route of information passing. The third problem is that suppliers of information can be switched off, faulty, occupied with solving other tasks. To overcome the specified problems the system has to be designed in the following way.

Lets connsider a set of existing information nodes. A node carries out one business function. Business function can be realized on the base of information that is available in the node or is received from any other node. It is important to note that quality of such information can be different. A knot can have information necessary for other knot for executing its business function. Such information is received from sensors that are connected with the node or is earlier received from other nodes. A node can transform information when new information is received, make harmonization, integration and merge of data [11]. A node can transfer information to any other node connected to the supplier node by channels. Nodes and channels can be switched on or switched off, be occupred solving other tasks. For information transfer, storage and transformation certain resources are spent. It is necessary to organize information exchange between knots so that spent resources for business function execution with necessary quality will be minimized (Fig. 3).

Resources consist of the following costs and times parameters with defined weights (quality of information and probability of the corresponding task solving is taken into account):

(1) building rout for information transfer;

(2) information transfering;

(3) information transformation;

(4) information storage;

(5) possibilities of a node.

Weight coefficients are recalculated for each node proceeding from success of the previous operations.

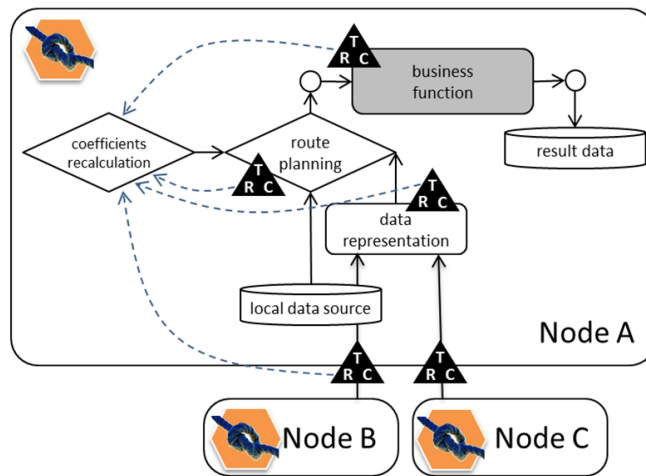
Dynamically changing routes of information passing between nodes can balance system loading and provide its fault tolerance.


Fig. 3 Information interaction of nodes

6   SYSTEM STRUCTURE

Decision making support system contains following components (Fig. 3):

(1) Management organization component;

(2) Mathematical methods library;

(3) Simulation and modeling component;

(4) Situations management component;

(5) Component for support of external relations and interactions;

(6) Settings and audit component;

(7) Decision information model access bus.

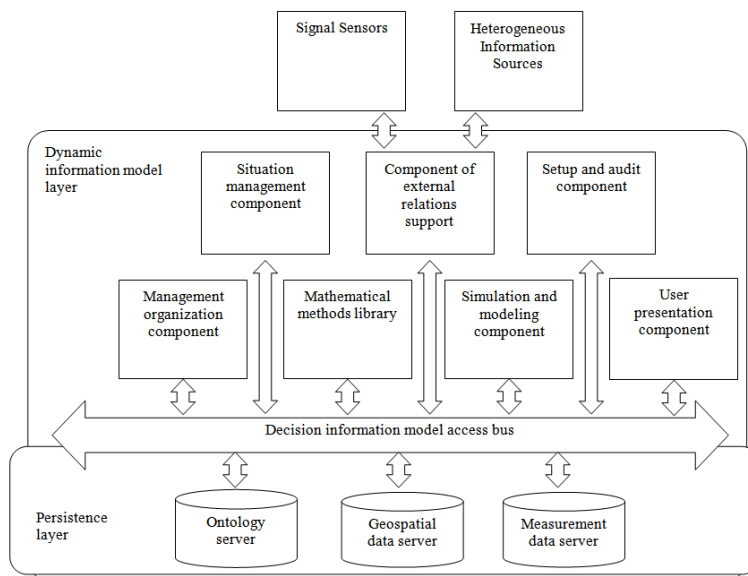
Functional subsystems are realized in the form of program modules that interact only with decision information model access bus.


Fig. 3. System structure

7   CONCLUSION

Application of dynamic information model of data presentation along with intellectual GIS technologies for development of municipal economy distributed management systems provides:

(1) Integration at information level of various subsystems, each of which solves one or several tasks of municipal services management. It will allow creating a uniform system of municipal services.

(2) Access to the actual data on municipal economy in conditions of dynamically changing situation at the expense of continuous data acquisition from all accessible data sources and operative data processing.

(3) Possibility of making full and objective analysis and estimation of situations, arising in the sphere of municipal services, and also formation of well-founded decisions on situations management at the expense of application of mathematical and simulation modeling methods.

(4) Convenient working environment for end users due to using GIS technologies.

It is suggested to develop municipal economy distributed management systems on the base of ONTOMAP [11] System that is Surveillance & Recognize Systems for information Support and Automation of Activity Information Centers` Staff that is based on IGIS technologies and nowadays is efficiently used in naval bases, command and information centers.

Development of the Border Territories within the Framework of National Development Plan for the Republic of Kazakhstan

Turlybek Mussabayev, Karlygash Muldagaliyeva

(Professor Turlybek Mussabayev, KazRPICA JSC, 6 Pushkin Str., Flat 15, Astana city, Kazakhstan, tmusabayev@rambler.ru)
(Karlygash Muldagaliyeva, KazRPICA JSC, 1 Aspara Str., Flat 40, Astana city, Kazakhstan, muldagaliyeva@gmail.com)

1 ABSTRACT

Kazakhstan is located in the Central Asia and borders with CIS countries (Russian Federation, Kyrgyzstan, Uzbekistan, Turkmenistan and Azerbaijan) and with People's Republic of China.

12 provinces from 14 in the republic are border territories, acting as the potential centers of economic activity and integration of Kazakhstan into world economic system.

Capacity of border territories of the Republic of Kazakhstan, first of all, is based on the strong state support aimed at their program purposeful development.

The conducted research was undertaken within the limits of the development of the first National Development Plan of the Republic of Kazakhstan (hereinafter – National Development Plan). Development of the border territories, transboundary infrastructure, management of transboundary natural elements (e.g. water and mineral resources) in the conditions of open economic activity, external economic processes has a direct impact on both functional and spatial planning structure of population distribution, environmental management, distribution of production forces, etc.

The border territories of the Republic of Kazakhstan were studied and analyzed, while aiming the transition to integrative model of cooperation of border territories on the basis of implementation of joint territorial projects. This demands modernization of the developed system of planning on the basis of consolidated sustainable development of the border territories of the Republic of Kazakhstan.

2 INTRODUCTION

2.1 Description

The Republic of Kazakhstan is located in the Central Asia and borders with CIS countries (Russian Federation, Kyrgyzstan, Uzbekistan, Turkmenistan and Azerbaijan) and with People's Republic of China (Fig.1).

12 provinces from 14 in the republic are border territories, acting as the potential centers of economic activity and integration of Kazakhstan into world economic system.

Capacity of border territories of the Republic of Kazakhstan, first of all, is based on the strong state support aimed at their program purposeful development.

The conducted research was undertaken within the limits of the development of the first National Development Plan of the Republic of Kazakhstan. Development of the border territories, transboundary infrastructure, management of transboundary natural elements (e.g. water and mineral resources) in the conditions of open economic activity, external economic processes have direct impact on both functional and spatial planning structure of population distribution, environmental management, distribution of production forces, etc.

3 DEVELOPMENT OF THE BORDER TERRITORIES AND THE ISSUE OF POPULATION DISTRIBUTION IN THE REPUBLIC OF KAZAKHSTAN

One of the main objectives of the development of the border territories is an improvement of the system of population distribution. Proceeding from the big extent of the border territories and the need of preservation of their familiarity, it is necessary for the Republic of Kazakhstan to realize the measures for preservation and development of economic potential and infrastructure of border settlements, to increase the administrative importance of large settlements of border areas that has to stop outflow of the population and in the long term to strengthen external immigration from neighbouring countries: Russian Federation and states of Central Asia.

For achievement of this purpose in average and long-term prospect it is necessary to solve such problems as prevention and minimization of negative consequences of migratory processes; provision and protection of the rights and interests of migrants; stimulation of inflow of foreign experts with high innovative potential by simplification of an order of attraction of foreign labour of high qualification and regulation of qualitative structure of attracted foreign labour; stimulation of return of ethnic Kazakhs, former citizens of Kazakhstan living abroad; assistance and help in the accelerated adaptation and integration of immigrants and another.

Fig. 1: The borders of the Republic of Kazakhstan

Important steps in the solution of migratory policy are suppression of illegal migration, introduction on boundary posts and other points of the modern technical means providing monitoring of illegal stay of immigrants in the territory of the country; harmonization and systematization of the national legislation with CIS countries in the field of migration.

The first step on a way of the development of border territories of Kazakhstan within the National Development Plan is overcoming of existing information gap with border territories of neighboring countries. In this regard the defining role is played by formation of information networks and creation of the general cross-border databases on the basis of use of Systems of Support of Planning which will promote in the long term creation of new forms of cross-border systems of population distribution.

Subsequent development of the border networks of settlements in the status of objects of self-government will allow having a number of social and economic effects, including:

development of the cultural cooperation;

common use of the settlements entering into a uniform complex of demographic, cultural and educational and industrial potential of a network of settlements;

formation of a uniform labor market and optimization of placement of infrastructure objects, educational and scientific centers;

formation of effectively working transport system.

For the realization of the above described positive results as a basic planning elements of network information integration of border systems of population distribution in the Republic of Kazakhstan and adjacent countries allocation of two basic frameworks organizing territorial border interaction of the country with adjacent areas are offered:

social-and-ecological information framework;

infrastructure and economic information framework.

The social-and-ecological framework is aimed at the allocation of optimum population distribution where rational use of planning conditions allow sufficient use of human and natural resources at which further economic development can be reached.

There are three city-forming elements showing efficiency criterion of the population distribution of the border systems:

placement environment;

social density of population distribution;

ecological interaction of the settlements.

The first city-forming element of a social-and-ecological framework is an environment of placement of border settlements which allows allocating nodal from the point of view of natural stability of the settlement. Environment affecting on the placement of border settlements can be considered on the basis of such indicators as their neighbourhood in relation to existing protected natural territories, water, mountain and forest systems – in turn bearing key natural risks of formation of emergency situations.

In practice of environmental management around the world a great value gets an allocation and development of the systems of special protected natural territories and objects which play an important role in the sustainable development of the regional systems of population distribution. In whole or in part withdrawn of economic use, they represent special spaces of natural self-restoration of environment of dwelling.

The indicator of the neighbourhood of protected natural territories can include a number of components, such as the area, extent of use for a pasture of cattle, tourist and recreational activity, the importance for environment self-restoration, etc.

The infrastructure and economic framework is aimed at information of allocation of the basic centers of economic activity and the need of development of their binding key lines of transport and infrastructure interaction, thus the main analytical role of this framework is monitoring and regulation of process of involvement of border territories of Kazakhstan in economically effective cross-border interaction with border territories of the adjoining countries, namely:

information identification of not populated territories and their definition in the status of "An ecological reserve" will allow to make revaluation of value of land resources: provided with infrastructure, a manpower (population) and natural territories and also to create the common long-term goals of border cooperation in the environmental protection sphere;

information support of complex long-term decrease in anthropogenous pressure upon natural complexes, at the expense of development "A unified plan of rational management of environmental management of a border network of settlements", directed on:

decrease in the level of all types of pollution of the main natural components – water, air, soil and subsoil;

rational use of all types of natural resources;

recultivation and improvement of the broken lands, etc.

On the basis of the historical analysis for a sustainable development of settlements a need of the accounting of specifics of formation of certain border territories of Kazakhstan was revealed.

4 ECOLOGICAL CONDITIONS OF THE BORDER TERRITORIES OF THE REPUBLIC KAZAKHSTAN, THE ISSUE OF CROSS-BORDER POLLUTION

Within the complex development of the National Development Plan special attention is paid to the development of planning proposals of the development of the border territories, as one of the key vectors of improvement of the organization of the territory of the country, including ecological condition of border territories of Kazakhstan, development of measures for the solution of problems of cross-border pollution.

Disintegration of the Soviet Union in 1992 led to considerable deterioration of the situation in the field of environmental protection. Division of an economic mechanism led to a stop or to considerable deterioration of technical and financial conditions of a set of the enterprises. In the conditions of the rigid crisis of investments and operational means, nature protection measures and technologies were significantly weakened.

At the same time there was a disintegration of a control system by environmental protection. Besides, before the countries there was a number of problems of environmental protection in border territories and cross-border basins of the rivers where remained, and often – environmental problems became aggravated, but the institutional basis for their effective decision was lost.

Specific feature of cross-border problems is the impossibility of their permission efforts of the certain state, or higher efficiency of joint actions, in comparison with autonomous national, or bilateral activity.

Within complex development of the National Development Plan the main cross-border problems of the Republic of Kazakhstan and adjacent countries for justification of recommendations about the perspective measures, submitted on the solution of problems of cross-border pollution are considered.

Realization of the following nature protection actions for the stabilization of an ecological condition of border territories of the Republic of Kazakhstan and the adjacent countries is necessary for the solution of cross-border environmental problems:

expansion of the international relations in the field of improvement of an ecological situation of cross-border territories;

implementation of interstate control in the field of the protection of the land and water resources, behind observance by subsoil users of rules of ecological safety;

implementation of interstate control in the field of protection of land and water resources, behind observance by subsoil users of rules of ecological safety;

development of the documents on introduction of the general quotas of environment pollution for the border territories of the adjacent countries in the conditions of carrying out geological exploration;

formation of the general network of environmental monitoring behind the preservation of the cross-border archaeological and natural monuments and development of joint documents on the organization of cross-border reserves.

At the expense of the state and local budget of adjacent territories of the states to develop a system of steady financing of nature protection actions in the cross-border territory.

For the solution of environmental problems of the border territories of the states fully realize accepted regional programs on rational environmental management and environmental protection. Development of a joint program of economic development of the border areas of the states.

Creation of the conditions necessary for providing normal life and activity of inhabitants of border regions of the states, maintenance of historically developed communications and contacts in production, social, cultural, household and other spheres by means of introduction of the simplified procedure of crossing of border on the basis of special admissions of long using.

5 CONCLUSION

As a world experience shows, the key advantage of the developed border territorial associations is their influence on spatial optimization of the territory, including:

Intensification of joint development of border infrastructure, transport, trade and other service systems;

Integration of the market of consumers that promotes an increase of economic capacity of the border territories of the both countries under the condition of joint efforts on the directed investment orientation.

Transition to the cooperation model of cooperation aimed at the development of the border territories on the basis of implementation of joint territorial projects, demands modernization of the developed planning system on the basis of offered approach of consolidated sustainable development of the border territories of the Republic of Kazakhstan.

Disaster Prevention Planning and Disaster Preparedness for Earthquake

Shabnam Farboud, Anahita Mahmoudi

(Shabnam Farboud, shabnamfarboud@yahoo.com)
(Anahita Mahmoudi, anahita.mahmoudi@gmail.com)

1 ABSTRACT

There are differences between earthquakes and other natural disasters:

- Enormous damage

- Occurrence of a very short time (as much as a few seconds) to allow the deal to eliminate

- Destruction of vast areas, sometimes hundreds of square kilometers covers

- Threats of aftershocks, which often takes more than one year

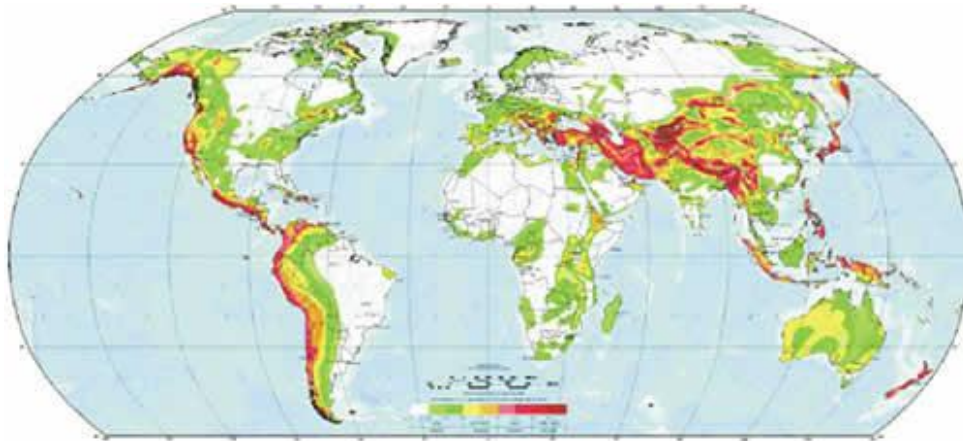
Causes of loss and damage in Iran

- Increasing number of cities in Seismic areas,

- Uncontrolled development of cities, so many faults in urban areas have been

- The city's population density increased the number of earthquake victims,

- Increase the quality and quantity of municipal installations and facilities increasing financial losses due to earthquake

- Despite the lack of planning for placement in seismic active regions of the world,


While the earthquake is much more than building blocks. City Form, The spatial distribution

Spatial and landuse compatibility and performance of building systems, appropriate network access and efficient hull design of streets and city views, open space ratio of width to height distribution are effective in reducing the vulnerability of the earthquake.

1.1 Disaster Management

Disaster management is a continuous and dynamic science. It's branch in management so includes planning organizing leadership and control.

Disaster management is usage sciences by the systematic observes of disasters and analysis them, and consider tools that can be prevented by disasters. (if it's possible) and reduced its impact, quick responsed and improved. Cycle of disaster includes 3 parts.

Before disaster, during disaster and after disaster. Each part includes some actions such as prevention reduction, Preparation, relief, organizing and improvement.

1.2 Planning in different stages of disaster

Natural, social, finance, skeletal differences in different communities likelihood of disaster has caused that different countries different experiences.

For achievement useful plane model in disaster management in a city must be done:

(a) Definition of overall goal and other operational objection consider:

- Immunizations must be provided in the side against earthquakes.

- control the situation after the earthquake, such as health status or utilities provided to victim and survivors of the disaster and secondary control and vulnerability.

- Safety and social and economic organization of survivors.

- Suitable ground for post-crisis measures including regulation of regeneration and redevelopment and job creation.

(b) identifying current situation of organs such as identifying all organs and resources of them.

(c) identifying barriers and environmental aid and organizations to deal

(d) determine necessary actions and operational goals and forecasting methods, time and location and person ,department and organization and necessary resources with the maximum flexibility to deal with potential incidents occur.

Planning is done in 3 stages.

1.2.1   Before the crisis

Prevention: This planning is not possible for all kind of disaster such as earthquake then it means reduce adverse effects.

Reduction effects: This kind of planning includes package of acts to minimize the damage caused by an accident and the purpose of it is reducing adverse effects of the crisis. For example limitation of landuse in harmful fields or development techniques building Strength against earthquake Specific regulation to encourage the use of new techniques of building construction

Static actions: Action such as the development or application of the building code criteria such as classification buildings and zoning of urban and regional planning, Landuse, tall Building Safety Laws.

Dynamic actions: Action such as public education, Develop programs to improve the quality of housing

Safe movement of people in vulnerable areas and diversification of economic activities to find substitutes for those who are vulnerable to accidents include

Disaster preparedness planning:Disaster preparedness planning will underpin all responses after crisis and Includes an estimate of immediate needs and identify resources to meet those needs that Urban management organizations, governments and citizens to act with speed and efficiency are necessary in the present.

1.2.2   during the crisis

First aid plan (the immediate short-term actions): this stage begins 3-7 days after earthquake

Temporary Housing (expending steps): begins After 1 month

1.2.3   after the crisis

Immediate Relief: includes survive injuries, Nutrition, shelter

Reorganizatin: from fifth day to third month after earthquake

Reconstruction: of the third month after earthquake

1.3 Disaster management and Urban planning

Crisis management is the process of urban planning in the five periods are:

First moments of disaster of its time scale is in seconds or at most minutes.

Second stage: the escape and refuge. Sustained physical injuries caused destruction and loss of life.

Third stage: the relief and rescue operations in the early hours of the onset and persists for weeks

forth stage: the establishment of the interim period from the first day until many months.

Fifth stage: Elimination of the destruction caused by the earthquake and reconstruction operations and involves purge.

1.4 The role of urban design in crisis

"Singer" and "Lynch" more flexible forms of urban open spaces are compact.

"Banerjee": More on transportation networks, infrastructure, municipal services and facilities, the city is safe.

But most urban form of flexibility, in terms of efficiency or fairness is the best option. As a result,

Looking through the process of research and urban design professionals may be treated in three ways:

(a) The concept of vulnerability in the broader social and ethical dimensions, etc. The traditional method of estimating earthquake hazard maps in terms of economics and engineering go beyond saving.

(b).Earthquake scenario developed and determines the relative vulnerability of different regions of the human dimensions of hazards and estimated damages to be considered And priorities for action or improvement are identified and are given in the form of increased resistance

(c) Implementation strategy, in terms of improving existing programs, building and land use regulations are proposed and evaluated.

2 ACTING FAST IS MOST IMPORTANT IN DISASTER MANAGEMET AND IT CAN BE USEFUL TO REDUCE INJURY AND DAMAGE.

I want to show how locations of some of strategic building can be useful to reduce time chart.

2.1 Management and police unit

Municipal Building is located at the center.

If there is enough open space around the building.

The location of the building has good access to the region.

Electricity and water tower is not located within the zone.

Large-scale industrial users of chemicals plants and nuclear reactors, and have a great distance.

Authorized to establish land uses in the vicinity of residential, commercial and hospital.

Natural edges and cut the gap to be deep.

Municipal building a simple plan (in terms of geometry) to allow escape in case of disaster relief assistance to clients and the access is easier.

The building is situated in a grade 2 arterial approach.

Construction site on a secure site with the earthquake risk is low.

In high-risk sites should be located as far away from them.

The atmosphere is building in the center.

Structure is associated with wide sidewalks.

Space the side walls of the staircase should be retrofitted.

Long corridors inside the building as possible and not be easy to open and access.

Municipal buildings and open spaces for public parking near the temporary settlements is

2.2 Fire Station

Tower of Power and Water Resources aerial firefighting services right away have.

Away from hazardous sites have.

Arterial streets are associated with the fire services degree.

Shows the degree of fire in a street collection centers are located.

Open fire in the center, there is enough for helicopter landing.

Fire services are built on low-risk sites.

Access to a range of 5 to 8 minutes to have its hinterland.

Resource for emergency water storage and its hinterland have size scales

The edges are the natural and urban cuts.

Centers, clinics and hospitals have easy access to the fire.

Priority neighborhood centers, fire and police administration of the land.

2.3 Health centers

The low tissue density in urban centers (with respect to scale and its hinterland) is placed.

Tower of Power and Water Resources Center right away have

Scale industrial centers of heavy industry and chemical plants and nuclear reactors have a great distance.

Neighboring residential treatment centers, the first priority should be utilized. The neighborhood, education, commercial, cultural, administrative function whereas the same is not permitted.

Approach confirms a positive gathering centers communicate.

Centers are located in the passageway collector grade.

Stay away from high-risk sites.

Centers to be built in place of low-risk sites.

Edges, and cuts away from the city.

Nodes aren't located busy urban centers.

Find it in the middle of the land allocated to be built around them to be completely open and

Construction of the center is not connected to another building.

Centers have easy access to the fire.

The center is located in the stairwell space.

Side wall of the staircase space is retrofitted.

Inclined planes and ramps instead of stairs is used.

Wide stairs and into the main building of the hospital is simple

Adjacent to outdoor centers are enough to destroy the possibility of the use of this space is used for center field.

Open space near the helicopter landing centers exist.

2.4 Open space

Open spaces have a minimum area of 2500 square meters in extent, depending on the area of hinterland can be changed.

Open spaces with high dimensions are scattered across the region.

The edges of the cuts are urban.

Open spaces are located adjacent to the water tower and electrical biographies.

Regarding open space, texture and appearance of the city, the fighting identity.

Open spaces in the neighborhood of the battle.

The streets are open spaces rides between locations.

Health facilities within the open spaces are considered.

Network of open spaces with water and electricity, and sewage disposal facilities are.

2.5 Residential buildings

The maximum occupancy rate of the building 50.

Building height to length ratio is equal to one yard minimum.

Building staircases and corridors to reach the open air .

The centers are located in the stairwell space.

Cavity side walls of the staircase are retrofitted.

Tower of power and water supplies, air space be reserved.

Away from Utilization of industrial-scale heavy industry and chemical plants and nuclear reactors.

Away from the natural edges.

Regulations, building codes and retrofitting buildings to be considered.

Uneven and not plating material and may not be used in any way harmful.

Outside of the building is the perfect escape.

The intermediate spaces such as hallways at least used to be.

Away from construction sites is prohibited (due to earthquake, nearby faults and soft alluvial sediments and soils in terms of soil type and groundwater level above).

Hydrant installations such as power stations and substations to be close.

Easy access to building and window openings.

3 CONCLUSION

Order to locate a suitable model, the characteristics which must affect the vulnerability of a city, and how performance can be identified and their impact must be examined.

In addition, the user's position and the reasons for their vulnerability and the wider Nhvhbaztab (damaging the land adjacent to the other users) must also be determined. Combination of these sets of factors can be found in the user-specific strategies. Primary factor affecting the level of vulnerability is the location. In this regard, various parameters such as the location of faults, slope, soil type, water table, topography and ground motion (seismic potential) are introduced, which measures the vulnerability of any kind involved.

These indicators can be summarized in the following table that the weight of the index, the importance of user variables:

Recognition	Strategy	Criteria
Identify the location of the user according to nearby seismic faults and potential	-Geology -Seismic studies -Studies to determine faults	Compliance boundary faults (according to the type of use case will be provided) Avoid construction in areas that have high seismic potential. Such areas devoted to green space. Strict avoidance of high population density in the areas of construction land
Natural characteristics of the location	-Studies of soil material - Studies slope - Studies of ground water level	Avoid construction in areas where there is the possibility of liquefaction
Radius of influence cognitive user access based on	- Distance of the radius of access and proximity to the center - To determine the influence of land - Determine the location of any user	Adopt the broad, central and convenient for easy access
Understanding how specific user access. Related pathways were late (roads between cities)	Determine optimal routes to access Criteria: . Safe routes (heterogeneous differentiation pathways and risk factors) . Short route (time and space) . Pleasant paths (mental peace) . Pathways readability (comprehension location)	-Given the importance of land use planning is the main route selection. - Separate access off the roadway and determine specific Hrymhay - Avoid mixing tracks user access with heavy transit traffic - Avoid creation of the access tortuous
Identify of the specific pathways	- Criteria of buildings away from the wide thoroughfares Ykdygrnsbt - Criteria of buildings setback from the sidewalk to the street width	-Sidewall height to width ratio of way - Use the wide thoroughfares
Identify of the adjoining land	- In terms of land adjoining or contaminates that can cause interference to the following terms are going to be difficult and the adjacent land. - Traffic congestion (volume-using population.	Create a central area and Prevention and community center on the same land
Recognition of enclosed land (Floor -Area)	Evaluation of internal conditions and the placement of physical (density and storage space built into a piece of land)	During the height of the building is a courtyard in North homes Pass on the south side of the wall is the width of a ford
Identify materials used in the manufacture of building land	Evaluate the strength of materials, construction and design of the user	- Compliance with Building Regulations 2800 or any new e-Syn is available for resisting earthquakes. - Structural provisions for retrofitting
For determining the location	To give priority to the rescue	Evacuation and sheltering of quick and easy access to nearby open spaces and safe

Stages of analysis of applications Vrsydn criteria for reducing the seismic vulnerability

(Karlygash Muldagaliyeva, KazRPICA JSC, 1 Aspara Str., Flat 40, Astana city, Kazakhstan, muldagaliyeva@gmail.com)

1 ABSTRACT

The problems of mono-towns, unfortunately, are very urgent for many countries of the former Soviet Union area. Mono-town is the city or town where the main part of its industrial production and working population is concentrated on one or several city-forming enterprises. These enterprises tend to have single profile and raw material orientation which define all economic and social processes happening in the city.

The main reasons of mono-towns' issues are the decrease in output and stop of activity of city-forming enterprises as a result of exhaustion of a source of raw materials of the extracting enterprises, low competitiveness of production, outdated technologies at the city-forming enterprises, and the rupture of technological chains connected with disintegration of the Soviet Union.

The major objective of the development of mono-towns is an achievement of their sustainable social and economic development in average and long-term prospective. In order to tackle these issues there is a need to develop complex measures taking into account specific problems of mono-towns and features of their branch orientation affecting production and social aspects of their development.

Planning decisions should be about improvement of the existing system of population distribution and modernization of production capacity of mono-towns which result from negative consequences of transitional and crisis processes of economy.

Planning development decisions of mono-towns would constitute major spatial elements of the organization of the country which promote modernization of the general planning framework within the National Development Plan for the Republic of Kazakhstan.

2 INTRODUCTION

2.1 Description

The problems of mono-towns, unfortunately, are very urgent for many countries of the former Soviet Union area. Mono-town is the city or town where the main part of its industrial production and working population is concentrated on one or several city-forming enterprises. These enterprises tend to have single profile and raw material orientation which define all economic and social processes happening in the city.

The major objective of the development of mono-towns is an achievement of their sustainable social and economic development in average and long-term prospective. In order to tackle these issues there is a need to develop complex measures taking into account specific problems of mono-towns and features of their branch orientation affecting production and social aspects of their development.

Planning decisions should be about improvement of the existing system of population distribution and modernization of production capacity of mono-towns which result from negative consequences of transitional and crisis processes of economy.

2.2 Brief history

The main reasons of mono-town' issues are the decrease in output and stop of activity of city-forming enterprises as a result of exhaustion of a source of raw materials of the extracting enterprises, low competitiveness of production, outdated technologies at the city-forming enterprises, and the rupture of technological chains connected with disintegration of the Soviet Union.

Emergence of mono-towns in Kazakhstan happened in various ways. For instance, the mining centers during the development usually acquired the manufacturing industry enterprises and therefore some of them turned into mono-towns.

At the moment mono-towns in Kazakhstan is possible to group in the following way:

- the towns with primary development of a mining industry;

- the towns with primary development of manufacturing industry;

- the towns with primary development of electricity generation;

- the towns with primary development of mechanical engineering, construction, light and food industry;

- the towns industrial and transport centers;

- the towns which are carrying out functions of the improving centers, tourism;

- the towns of scientific and experimental centers;

- the towns with primary development of processing agricultural production;

- the towns which have lost industrial and nonindustrial function

2.3 Analysis of mono-towns' conditions

Industrial production in mono-towns is characterized by specialization on one-two branches, and other branches are developed slightly, or the industrial enterprises in general are absent. Decrease in output or stop of the city-forming enterprises led to the general deterioration of social and economic situation in the towns.

Owing to disintegration of a common economic space of the former Union and market transformations, the majority of mono-towns fell into decay, their production base was completely destroyed, former city-forming enterprises are closed and declared by bankrupts.

During the years of reforms in many mono-towns industrial production was curtailed or reduced to a minimum. Especially it concerns the towns of the extracting profile which situation considerably worsened owing to decline in production, exhaustion of stocks of minerals, decrease in demand for production.

The mono-towns in the areas of the development of new oil and gas fields in the west of Kazakhstan have the highest growth rates of industrial production, large volumes of investments and the relatively high income of population.

At the same time the depressive small towns of the extracting profile which situation was considerably worsened owing to decline in production because of exhaustion of stocks of minerals, decrease in demand for production are allocated.

Future development of the towns of the industrial direction is connected with improvement of structure of economy by diversification and expansion of structure of their functional specialization. In the towns with an extracting industry where production of raw materials is already inefficient, it is expedient to develop new productions which would compensate reduction of workplaces in the main production.

Requirements of modern industrial production to technology, the equipment, existence of the qualified labor, infrastructure became complicated. In this regard mono-towns with manufacturing industry, as a rule, have no conditions for the organization of large modern industrial enterprise. In these towns it is necessary to develop the small enterprises with high level of particular and technological specialization.

The smallest industrial outputs per capita have the centers of agricultural areas.

The manufacturing industry enterprises in mono-towns stand idle or are partially loaded because of low competitiveness of products, lack of demand, remoteness of sales markets and high tariffs for transportation. Their situation is aggravated physically and the obsolete equipment, loss of qualified personnel as a result of migration.

Development of small business in mono-towns with depressive economy is interfered by a low production and consumer demand, inaccessibility of financial and credit resources caused by absence at businessmen of liquid mortgage property.

2.4 Employment and unemployment

Topical problem of many mono-towns is discrepancy of structure of production and economic base to requirements of market economy. Technological backwardness and wear of the fixed business assets of the majority of the enterprises of the small towns, accruing staff deficit, and their low professionalization slow down further development of the small cities. Stabilization in the industry and economy as a whole

demanded existence of professional shots, first of all technical officers, and introduction at the enterprises of new technologies led to increase of requirements to a skill level of workers.

On a labor market of mono-towns remains both quantitative and qualitative discrepancy of supply and demand of labor. Thereof there is a need of taking measures to reproduction of personnel potential on a new qualitative basis, proceeding from prospects and priorities of development of urban economics.

2.5 Production and social infrastructure

Unsatisfactory condition of production infrastructure is one of the key problems, constraining development of mono-towns. Especially sharply there is a problem of transport remoteness and bad condition of highways.

Remoteness from large sales markets, city agglomerations, a transport issues complicate development of such towns. They are connected with regional centers the highways demanding considerable rehabilitation works.

The low technological level of highways, accident rate of certain bridges and communications leads to decrease in high-speed opportunities of transport, increase in a transport component in the cost of goods and services, losses when transporting agricultural production.

Remoteness and bad quality of highways have except economic and social consequences, such as youth outflow, decrease in a cultural standard of living of the population.

2.6 Ecological situation

Ecological consequences of industrial development of mono-towns are pollution of atmospheric air, chemical infection of soils, surface fresh waters and fish stocks in reservoirs, increase of an incidence of the population.

Sources of ecological issues are:

congestions of cindery dumps, spontaneous dumps and lack of city treatment facilities;

bad condition of sewer networks and the fields of a filtration located near the towns;

large volumes of dumps and tailings dams of the mining enterprises;

emissions of polluting substances from the numerous small boiler rooms working at firm fuel.

3 MAJOR ISSUES AND DIRECTIONS OF THE DEVELOPMENT OF MONO-TOWNS

3.1 The main issues and factors constraining development of mono-towns

The analysis of economy and the social sphere of mono-towns allowed allocating the main problems inherent in them such as:

- lack of effective strategy and programs of development of the mono-towns;
- lack of funds for development, dependence on higher budgets;
- low level and quality of life;
- high unemployment rate;
- high dependence on the city-forming enterprises;
- high percent of wear of objects of production and transport infrastructure in combination with big remoteness of many towns from the regional centers;
- shortcoming of skilled workers and experts of all branches of economy;
- environmental problems.

3.2 General directions of development of mono-towns

The complete program of development of mono-towns has to define the main strategy of development of the mono-towns of the country, defining the financing sphere which finally has to be carried out from republican and regional budgets. Concrete measures for development of each town have to be provided in regional programs of development of the mono-towns.

The main directions of development of mono-towns are:

- improvement of structure of economy by diversification and creation of an optimum combination of the enterprises of various size and branch accessory;

- expansion of structure of functional specialization of the towns;

- development of mineral raw material resources available near the mono-towns;

- territorial organization of social infrastructure for availability increase to the population of main types of services;

- reproduction of the population and personnel potential;

- territorial organization of infrastructure of support of subjects of small business.

Each mono-town needs to be studied in details. The main directions of development of mono-towns have to be defined taking into account their mineral and raw and agrarian resources, the production and labor potential, a favorable geographical position.

Effective Usage of Short-Term Parking Zones by Offering Real-Time Information on the Utilisation of Parking Lots

Tina Uhlmann, Reinhard Hössinger, Peter Widhalm

(DI Peter Wiedhalm, Austrian Institute of Technology, peter.widhalm@ait.ac.at)

1 ABSTRACT

In many cities area-wide short-term parking zones were introduced to reduce traffic in search of a parking place and to enhance the life quality. Nevertheless, in many cities with parking restrictions the volume of traffic is still high and parking search traffic is one reason for this problem. Previous attempts aim to overcome this issue by guiding drivers to the next available parking space. These systems are expensive and politically controversial, because they indirectly encourage car use. On the other hand, a pre-trip information service informing road users prior to departure about the occupancy of parking spaces at the destination could have a higher steering effect and encourage people to use alternative transport means. Based on these assumptions a real-time information system for the occupancy of short-term parking zones was developed and tested in two areas in Vienna (Austria). Instead of relying on roadside infrastructure this system uses position data of the mobile phone parking service as an indicator of the occupancy of parking zones. In addition, the potential of two more data sources to improve the reliability of forecasts was tested: model-estimated traffic flow data and counts of short-term parking customers in parking garages. The prediction model was developed and validated with an empirical parking survey. This novel technology helps to administer the scarce resource of parking space in urban environments more effectively and supports people in choosing sustainable transport modes.

2 INTRODUCTION

In recent years the automobile industry and academic researchers developed numerous driver assistance systems (Pellecchia et al., 2005). For example, several techniques have been evolved, which provide drivers with real-time information on the occupancy of car parks. However, developing an analogous information service for on-street parking spaces is much more demanding, because entries, exits, and parking spaces are less well defined and inappropriate for counting. In table 1 different approaches are listed, which have been developed to provide this information.

System	Function	Disadvantages
Vehicle detection with panoramic street images	Use of laser-ranger finder and a line-scan camera taking epipolar-plane images	Delivers only static snap-shots, but no real time information. (Hirahara and Ikeuchi 2003)
Linked parking meters	Parking meters identify free parking spaces via infra-red sensors, the meters are connected with each other via radio frequency transceivers	Impractical system to cover large areas, electrical infrastructure necessary, high deployment and maintenance costs (Sifuentes et al., 2011)
Wireless sensor networks with autonomous sensor nodes	Sensors or induction loops identify free spaces and communicate via radio frequency transmitters; information is available on mobile devices or VMS,	High costs for equipment and maintenance (Federal Highway Administration, 2007; John Markoff, 2008)
Vehicle to vehicle (V2V) communication	Protocols can be used by vehicles to share information about available parking spaces via V2V communication	Only for cars equipped with the necessary expensive techniques
Community-based system	Enables users to indicate (release) free on-street parking spaces and to find these spaces via a mobile app	Requires high share of market penetration to provide a complete picture

Table 1: Approaches for the development of a real-time information system on the occupancy of on-street parking spaces

Up to now detection of on-street parking spaces relied on area-wide infrastructure on street or within vehicles, which causes high costs. Such systems are also controversially discussed, because they aim at navigating drivers quickly to the next free parking space and making car use more convenient. It is therefore more preferable to inform road users early about the current and predicted parking situation at the destination. A reliable forecast of the occupancy could support the use of other alternatives (public transport, Park & Ride) and reduce parking search traffic at the destination.

3 STUDY IMPLEMENTATION

The objective of the study was to develop a non-invasive real-time information system for the occupancy of short-term parking zones, which operates without the need for roadside infrastructure (see Figure 1). Instead of showing the status of individual parking lots, it aims to provide a sufficiently accurate description and reliable prediction of the parking pressure in a broader target area. Three existing real-time data sources were tested for their usability in such an information system:

- position data of short term parking customers, who buy their electronic parking ticket with their mobile phone using an SMS payment service;

- counts of short-term parking customers in car parks in or close to the target area;

- traffic flow volumes derived from more than 300 automatic counting sites in Vienna.

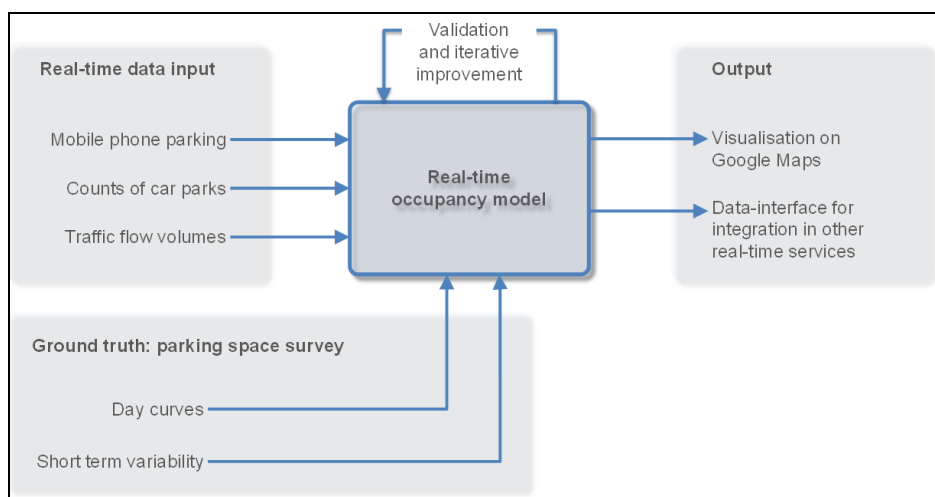
The city of Vienna was chosen as case study area. In the inner city district, parking search traffic amounts to 20 % of total traffic, at peak times up to 90 %. The city offers an SMS payment service for short-term parking fees, which is called "HANDY Parken". More than 40 % of all short-term parkers pay their ticket by using this service. Each electronic ticket generates information about the duration and location of a parking transaction and is therefore expected to provide an indicator for the number of parked vehicles and the total occupancy in an area. The two further real-time data sources were tested concerning their influence on the reliability of the forecasts. The real-time occupancy model was developed and calibrated with data of an empirical parking space survey in two test areas in Vienna. The study was to form the basis for an online prototype, equipped with a visualisation on Google Maps and a data-interface for integration into existing travel information services.


Figure 1: Data flow in the real-time occupancy model

3.1 Real time data sources

The HANDY Parken service has an agreement with mobile network operators (MNOs), the largest of which participated in the research project. Reading out all SMS-tickets booked in a given time interval is technically and legally feasible, but for the model also the coordinates of the active network cell from which the mobile phone sent the HANDY Parken SMS was necessary. Due to data protection concerns, the responsible officers of the MNO decided against a data transfer despite an initial agreement. As a consequence, the HANDY Parken data could be made available for calibrating the model, but is currently not available as real-time information source for operation. The counts of short-term parkers in the car parks were obtained by an agreement with five of the six car park operators in the test areas. The provided data included separate counts of long term and short term parkers entering and exiting the car park throughout the duration of the parking space survey. Traffic flow data is already collected at a central point, where they feed into a transport model. A data exchange protocol has been defined, enabling data exchange at any time.

3.2 Parking space survey

A parking space survey has been conducted in order to obtain a 'ground truth' for calibrating and validating the occupancy model and to estimate the day curves of vehicles, which have a permanent parking

permission, any other special permission, or no permission at all (fee dodgers). This survey was necessary because parkers without a HANDY Parken ticket leave no electronic trace for real-time indication. The survey was conducted in two test areas with a total of 3,000 parking spaces. The areas have different characteristics concerning the residents-visitors ratio, supply of on- and off-street parking, spatial functions, and demographic structure. The survey was carried out in three periods in February, March and April 2012. The demand of parking spaces was observed periodically every 30 minutes from 8 am to 10 pm. Each parked vehicle was registered along with the type of parking permission: permanent permission, fill-in ticket, or no visible permission. The latter could be fee dodgers or users of the mobile parking service. In order to distinguish between the two, we recorded the license plates of these vehicles and checked them against the HANDY Parken database, which allowed us to determine, how many cars in a certain part of the test area had valid electronic tickets during the observation period.

Based on this survey it could be shown that there are strong differences in the day curves for both test areas. The share of short-term parkers is approx. 40 % in the city centre (area 1), whereas it is only 20 % in the residential area (area 2). The occupancy in the city centre is highest during the day and during the opening hours of pubs in the evening, whereas the residential area shows the highest occupancy in the morning before the residents leave and in the evening when they are back.

4 RELATIONSHIP BETWEEN REAL TIME DATA AND OCCUPANCY RATE

4.1 Counts of short term parking customers in car parks

Several correlations of car park data with parking space occupancy were computed, but no systematic relationship between car park inflow and parking space occupancy were found. This indicates that the car park inflow is no suitable indicator of the occupany rate. The commonly held view that the garage inflow indicates an overflow of on-street parking demand was not confirmed by the survey data.

4.2 Traffic flow volumes

Traffic flow data from 830 major roads in the Vienna region was examined. The data were derived from a traffic model, which uses data of more than 300 automatic counting sites in the city. In order to check the suitability of the traffic flow data for predicting parking space occupancy, the correlation coefficients between the traffic flow and mean occupancy rates was computed. It turned out that there is no significant relationship between traffic flow data and parking occupancy rates. The flow data were therefore not included as input for the real-time occupancy model.

4.3 Mobile phone parking data

As mentioned earlier, the mobile network operator refused to provide the location data of mobile phone parkers for privacy concerns. However, for the vehicles observed in the parking space survey this information could be derived from the HANDY Parken database. The initial assumption was that mobile phone parkers are a congruent subset of all short term parkers, and that the latter can be added to the number of permanent parkers, which evolves according to its own independent day curve. Table 2 shows the relationships of the number of electronic tickets with other kinds of permissions and with the total occupancy rate.

Kind of permission	Area 1		Area 2	
	r	p	r	p
fill-in tickets	0.515	0.000	0.503	0.000
permanent permissions	-0.259	0.000	-0.269	0.000
cars without permission	-0.372	0.000	-0.418	0.000
all other permissions	-0.067	0.241	-0.238	0.000
total occupancy rate	0.659	0.000	0.115	0.043

Table 2: Correlation coefficients (r) and significance (p) between electronic parking tickets and other parking permissions in in 1st district (area 1) and 6th district (area 2)

Table 2 shows a strong positive correlation between the number of cars with electronic tickets and fill-in tickets, but a moderate negative correlation with permanent permissions as well as fee dodgers (without permission). As a result, the hypothesis that the number of permanent parkers evolves independently from short term parkers has to be rejected. Area 1 shows a high positive correlation between electronic tickets and total occupancy rate, whereas in area 2 the correlation is very low. The reason for this difference is the higher share of short term parkers in area 1, which results in a stronger relationship between electronic tickets and

total occupancy rate than in area 2. A linear regression model of the occupancy rate given the number of electronic tickets explains r² = 43.5 % of the occupancy rate variance in area 1 and only r² = 1.3 % of the variance in area 2.

4.4 Real-time model

In order to measure the improvement in prediction accuracy gained from the real-time information two reference models were defined. One was a constant average model, which is based on the assumption that the occupancy rate stays at a constant average level at any time; and the other was an average day curve model, which is based on the assumption that on all days the occupancy rate follows the average day curve. The second model accounts for 65.8 % of the variance of the occupancy rate in area 1 and 54 % in area 2, respectively.

Although, the real-time indicator has a lower explanatory value for the occupancy rate than the average day curve model, it might still improve the predictive power if added to the average day curve model. This was tested for estimations of the occupancy rate in a) the current time interval, b) in future time intervals, and c) in exceptional situations, where the occupancy rate differs strongly from the usual level.

A linear regression model taking into account the number of electronic tickets increases the fraction of explained variance of the occupancy rate in the current time interval by 10 % in area 1 and 1.7 % in area 2. The attempt to improve the prediction of the occupancy rate of a time interval in the near future was based on a linear model of the day curve of electronic tickets. A separate model was developed for both areas and subject to three cross-validation rounds. Within each round, two of the three survey weeks served for calibration, while the remaining week served for validation. The result was that the real-time indicator could in most cases not reduce the prediction error of the average day curve model.

However, the real-time model outperformed both reference models in exceptional situations. This could be shown for the Shrove Tuesday, during the first week of the parking space survey. In this particular case it turns out that the real-time model predicts the occupancy rate better than the average day curve model. The error improvement is strongest in the current time interval, but it still appears in predictions of future time intervals. This result indicates that the real-time information about electronic parking tickets might increase the accuracy of an occupancy model in situations, in which the demand of parking place deviates from the usual level.

5 CONCLUSION AND OUTLOOK TO MODEL APPLICATION

This paper reported on the development of a real-time occupancy model of short-term parking zones, which operates without roadside infrastructure. The following points can be concluded from the presented work:

- The number and location of electronic tickets of the HANDY Parken service can help to indicate and predict the occupancy rate in short term parking zones, whereas traffic flow data and counts of short-term parking customers in car parks show no significant correlation. Due to privacy concerns of the major mobile network operator this indicator is currently not available for online operation of the service.

- The occupancy rate of on-street parking spaces follows a recurrent pattern. An average day curve model thus predicts the occupancy at a given time interval very well and can hardly be outperformed by a real-time model which does not account for these daily patterns.

- However, unusual deviations from the day curve due to exceptional events can only be predicted by the real-time model.

The unavailability of the location data of electronic parking tickets is the result of data protection concerns of the Mobile Network Operator. However, the decision is subject to interpretation of the legal regulations, so that there is still a chance for a positive decision in a second attempt.

An elemantary way to make the information service available to the users would be a stand-alone webpage as shown in figure 2, where the user can choose the area and time for which the occupancy information shall be provided. A second option could be to integrate the service into existing information services. The end users' benefit of the information service is in either case a better knowledge of the current and predicted occupancy of on-street parking spaces at the destination in a short-term parking zone. It could also include recommendations for alternative options in case of high parking pressure such as off-street parking facilities,

intermodal transport, or public transport. It can serve as a role model for other cities, since mobile phone parking is state of the art in many European cities, and its use will increase elsewhere as well.

Energia e paesaggio al tempo dei cambiamenti climatici.

Marcello Magoni

(Professore, DASTu – Politecnico di Milano, via Bonardi, 3, magoni@polimi.it)

1 ABSTRACT

Ambiente e paesaggio sono concetti che tendono a sovrapporsi e che in genere subiscono effetti analoghi dalle azioni dell'uomo. Tuttavia, con l'attivazione delle politiche di contenimento dei gas climalteranti, conseguenti alla previsione e alla percezione di cambiamenti climatici globali di entità catastrofica, iniziano ad aversi effetti divergenti sull'ambiente e sul paesaggio. Spesso gli impianti che utilizzano energie rinnovabili, e che quindi hanno effetti positivi sull'ambiente, comportano delle trasformazioni del paesaggio che se non ben gestite possono portare a rilevanti effetti negativi. I parchi eolici, i grandi impianti fotovoltaici, gli impianti idro-elettrici e a biogas e le coltivazioni per la produzione di biomassa costituiscono elementi il cui armonico inserimento paesaggistico richiede notevoli sensibilità progettuali.

La Convenzione europea del paesaggio ha spostato l'attenzione dai soli paesaggi di grande valore ai paesaggi di tutto il territorio, per cui occorre governare l'insieme delle trasformazioni dovute all'insieme di impianti, manufatti e infrasrtutture necessarie alla produzione, alla trasmissione e al consumo di energia.

L'articolo affronta il tema delle trasformazioni del paesaggio conseguenti alla diffusione delle fonti di energia rinnovabile in territori urbani, rurali e naturali a partire dalla relazione tra energia e paesaggio e quindi dai caratteri che i sistemi energetici assumono nei territori. Successivamente vengono illustrati i criteri per analizzare tale relazione e viene proposto un approccio innovativo per governare le trasformazioni del paesaggio dovute alla realizzazione di impianti, manufatti e infrastrutture per l'utilizzo di energie rinnovabili.

2 L'ENERGIA NEL PAESAGGIO E I PAESAGGI DELL'ENERGIA

Non esistono attività o processi naturali o antropici senza che vi sia la presenza di energia e quindi non esistono luoghi, territori o paesaggi non interessati da flussi energetici. All'interno dei paesaggi, qui intesi come "parti omogenee di territorio i cui caratteri derivano dalla natura, dalla storia umana o dalle reciproche interrelazioni", l'energia opera in modi diversi e assume differenti connotazioni, in funzione anche del tempo.

Vi è innanzitutto l'energia che influenza in modo visibile il paesaggio, vedi i manufatti, gli impianti e le attività necessarie per l'estrazione di combustibili e la produzione, la trasmissione e il consumo di energia.

Vi è quindi l'energia che influenza il paesaggio in modo indiretto, dai differenti caratteri insediativi che si affermano in territori con condizioni climatiche diverse, per cui nei climi freddi vi sono edifici compatti e chiusi per trattenere il calore mentre nei climi caldi vi sono edifici leggeri e aperti ai venti, ai territori e ai manufatti dove viene prodotta e conservata l'energia biochimica necessaria al metabolismo umano, cioè gli alimenti, alle infrastrutture stradali, ferroviarie, navali e aeree necessarie per consentire gli spostamenti di uomini e merci.

Vi è infine l'energia che si trova "incorporata" nelle componenti di un paesaggio, vedi ad esempio l'energia utilizzata in passato per la costruzione di manufatti, insediamenti e infrastrutture territoriali o le energie che hanno dato forma ai territori, a partire dalle energie tettoniche e gravitazionali.

Sono in genere considerati paesaggi dell'energia quei paesaggi che sono interessati in modo rilevante da manufatti e impianti necessari all'estrazione di combustibili e alla produzione, trasmissione e consumo di energia. Le infrastrutture energetiche costituiscono un fondamentale supporto per la nascita e lo sviluppo delle civiltà e hanno influenzato in modo rilevante l'evolversi delle città, anche se nelle trasformazioni del paesaggio urbano esse incidono in modo poco rilevante.

I paesaggi dell'energia possono essere distinti facendo riferimento alle diverse fasi che caratterizzano i processi di utilizzo energetico da parte dell'uomo, distinguendo le fonti energetiche non rinnovabili da quelle rinnovabili poichè per le prime le fasi di estrazione e di lavorazione dei combustibili comportano rilevanti effetti sull'ambiente e sul paesaggio – vedi le piattaforme per l'estrazione di gas e petrolio di terra e di mare, le miniere di carbone e di uranio, le raffinerie, gli impianti di arricchimento dell'uranio -, mentre per le seconde la relazione tra produzione e consumo di energia è fortemente integrata. Inoltre, la produzione di

biomassa per utilizzi energetici, che costituisce il principale combustibile rinnovabile, avviene in genere in modo armonico o comunque non traumatico con il paesaggio (vedi coltivazioni e aree boscate).

Vi sono i paesaggi contraddistinti dalle centrali termoelettriche e nucleari, le quali modificano il paesaggio in modo profondo, in genere aree aperte in prossimità di corsi e bacini d'acqua necessari per il raffreddamento dei fumi, alterandone i caratteri identitari ed estetici.

Centrale termonucleare

Da circa un paio di decenni questi impianti non sono più oggetto di interventi di mitigazione dell'impatto paesaggistico attraverso meccanismi di camuffamento, ma vengono pensati sin dalla fase iniziale del progetto come elementi di elevata qualità formale capaci di caratterizzare il paesaggio come importanti landmark.

Termovalorizzatore a Brescia

Vi sono i paesaggi delle grandi e medie centrali idroelettriche, le quali modificano fortemente i paesaggi montani, vedi l'eliminazione delle cascate, la realizzazione di invasi e condotte forzate, la scomparsa di luoghi anche abitati, ma che con il tempo formano dei nuovi paesaggi che spesso diventano suggestivi.

Centrale idroelettrica in Lombardia

Vi sono i paesaggi interessati dalle reti di trasmissione energetica, che in modo più o meno visibile innervano buona parte delle terre emerse e che interessano alcuni fondali marini. Caratterizzano questi paesaggi gli elettrodotti, i gasdotti, i distributori di carburanti, ecc.

Elettrodotto a Messina

Infine, l'illuminazione diffusa di strade e case ha negli ultimi 100 anni sempre più influenzato i paesaggi notturni locali, portando a modifica rilevanti, vedi le immagini notturne della Terra.

Europa di notte vista dal satellite

La transizione energetica, che sta avvenendo in questa fase storica, da un modello basato sulle fonti energetiche fossili a uno basato sulla prevalenza delle fonti energetiche rinnovabili, apre a possibili scenari sul tipo di forma che questo modello assumerà nella sua fase matura: si avrà una presenza diffusa della produzione energetica, dovuta a un elevato utilizzo di impianti di piccole dimensioni integrati nei luoghi in

cui l'energia viene consumata, oppure si avrà soltanto un maggiore equilibrio tra produzione diffusa e produzione concentrata?

Poiché gli impianti che utilizzano energie rinnovabili hanno in genere una capacità di produzione per unità di superficie molto più bassa degli impianti a combustibili fossili o nucleari, la loro diffusione va a interessare quantità di territorio e quindi di paesaggio molto più ampie. Questo fenomeno lo si riscontra in conseguenza dell'attuale forte impulso dato allo sviluppo delle energie rinnovabili, poiché si sta assistendo alla modificazione di numerosi paesaggi e alla configurazione di nuovi. In particolare, la strategia dell'Unione Europea si prefigge tre grandi obiettivi: la riduzione dell'entità dei consumi globali di fonti energetiche; la riduzione delle emissioni di gas capaci di alterare il clima; l'aumento della presenza di fonti rinnovabili nel totale delle fonti utilizzate.

Gli impianti di maggiori dimensioni vengono collocati in aree dove è possibile catturare maggiori quantità di energia solare, eolica e idrica, dove ancora non utilizzata. Essi possono trovarsi anche molto distanti dai luoghi di consumo, vedi ad esempio i grandi impianti fotovoltaici previsti nel deserto del Sahara a servizio dei paesi europei e gli impianti eolici off-shore. Queste esigenze, assieme alla necessità di una maggiore integrazione delle reti di trasmissione dell'energia elettrica a livello nazionale e internazionale per ridurre i costi energetici e i rischi di black-out, stanno portando a numerosi interventi di potenziamento, razionalizzazione e diffusione delle reti di trasmissione dell'energia elettrica. Inoltre, poichè la maggior parte delle energie rinnovabili funzionano a intermittenza in relazione alla presenza o meno di sole, vento o acqua, la connessione energetica tra luoghi lontani consente di avere una fornitura molto più stabile. Infine, la generazione diffusa di energia elettrica richiede una rete di distribuzione che non solo porti energia alle utenze, ma che dalle utenze ne possa ricevere. Questo comporta il miglioramento dell'estetica degli elettrodotti, per cui sono state pensate forme differenti per rendere i tralicci più belli e in armonia con i diversi paesaggi.

Progetto di Rosenthal-Dutton premiato al concorso "Tralicci del Futuro, Terna spa

Se gli impianti eolici, solari e idrici di medio-grandi dimensioni trasformano in modo rilevante i caratteri dei luoghi, agendo sui valori scenografici, estetici e identitari delle comunità interessate, la produzione diffusa di energia tenderà a sovrapporsi ai luoghi e ai manufatti dove l'energia viene consumata e queste modifiche, meno controllabili, potrebbero comportare dei piccoli ma diffusi effetti negativi soprattutto per i luoghi caratterizzati da una buona qualità del paesaggio, vedi ad esempio i centri storici.

La produzione energetica diffusa può avvenire in tre diversi contesti paesaggistici. Nelle aree di nuova costruzione e urbanizzazione, dove vi è la possibilità di una buona integrazione di impianti e manufatti energetici. Nelle aree edificate (retrofitting), dove gli interventi possono compromettere l'aspetto di singoli o più edifici di interesse storico e/o architettonico. Questo richiede una elevata sensibilità e capacità progettuale parallelamente al miglioramento di forme e materiali degli impianti. Ad esempio, le sempre più ampie possibilità di produrre energia elettrica con la radiazione solare diffusa consente di limitare la necessità di rispettare pendenze e orientamenti rigidi. Inoltre, la possibilità di avere spessori molto sottili delle superfici fotovoltaiche consente di ottenere interventi poco invasivi. Nelle aree non edificate, dove si diffondono sul territorio in modo spontaneo numerosi piccoli interventi senza che ne venga fatta una opportuna valutazione degli impatti sul paesaggio.

Un fenomeno connesso al paesaggio urbano e che ne modifica l'efficienza energetica è l'isola di calore, la quale è causata dalla limitata presenza di vegetazione e alla prevalenza dei colori scuri e opachi nelle superfici di strade ed edifici. Nelle zone temperate essa ha effetti parzialmente positivi in inverno ma piuttosto negativi in estate. Per ottenere dei miglioramenti significativi del micro-clima urbano e nei conseguenti consumi energetici, occorre aumentare la vegetazione non solo lungo le vie e nei parchi, ma anche sulle facciate e sui tetti degli edifici.

In generale, nella progettazione dei sistemi energetici emerge una visione conflittuale del rapporto innovazione energetica e paesaggio. Le nuove tecnologie vengono trattate come elementi estranei al progetto dando adito a due tipi di approccio, entrambi insoddisfacenti. L'approccio conservativo, caratterizzato da soluzioni di tipo vincolistico che individua paesaggi buoni da conservare e paesaggi degradati che possono essere trasformati con maggior libertà, così come tecnologie accettabili, perchè facili da mitigare o integrare, e altre no; l'approccio tecnicistico, che per rispondere all'emergenza energetica legittima qualsiasi tipo di intervento, soprattutto sulle aree considerate di scarso valore paesaggistico.

3 I CRITERI DI ANALISI DEI PAESAGGI DELL'ENERGIA

Le azioni e le strategie di tutela e di qualificazione del paesaggio vanno espresse in rapporto ai caratteri degli interventi proposti e al grado di "sensibilità" del luogo, salvaguardando gli elementi di connotazione, le condizioni di fruizione e la leggibilità dei complessi paesaggistici. Le azioni di tutela del paesaggio devono porre l'attenzione alle diverse trame relazionali (ecosistemica, storica, estetico-visuale, sociale) esistenti e future, considerandole quali strutture portanti del contesto stesso. La condizione alla base di ogni azione corretta sul paesaggio è quindi la conoscenza dei caratteri, delle identità e delle potenzialità paesaggistiche.

La complessità dei paesaggi non consente il semplice utilizzo nel processo progettuale di codici, linguaggi e repertori prestabiliti, ma richiede anche la sperimentazione di soluzioni capaci di individuare nuovi significati paesaggistici, dando origine ai nuovi luoghi della produzione, della trasmissione e del consumo di energia rinnovabile. Va considerata la complessità dell'insieme, in quanto non è solo il gradimento di singoli componenti a essere importante, ma anche il loro comporsi e il loro configurarsi che conferiscono a quanto percepito una "forma" riconoscibile che determina il carattere di un paesaggio.

L'analisi dei caratteri dei paesaggi energetici, comparata con i requisiti prestazionali dei sistemi energetici rinnovabili, fa emergere nuovi significati e potenzialità progettuali, per cui occorre considerare la possibilità di modificare la percezione e l'identità dei luoghi, riconoscendo quelle spazialità inedite funzionali a realizzare sistemi energetici che utilizzano quantità di energie non rinnovabili irrilevanti.

La matrice identitaria di una comunità e di un territorio prende forma e si modifica nel suo svilupparsi in connessione con i processi storici e sociali. Il concetto di identità non è quindi un valore precostituito, ma un valore in continuo divenire. Il problema è comprendere quali sono i gradi di libertà di un luogo e quindi i gradi di trasformazione che un paesaggio può sopportare. Occorre considerare l'azione e l'evoluzione come fattori di progetto, per cui il progetto di un impianto o di una infrastruttura deve considerare la possibilità di inserire, con sensibilità e inventiva, un nuovo elemento, senza per questo ledere l'immagine storica o rinunciare alla sensibilità contemporanea. Un ruolo centrale lo gioca il tempo, poiché con il passare degli anni un elemento innovativo può diventare un elemento costitutivo dell'identità di un luogo.

Passaggio fondamentale e preliminare a qualsiasi scelta di localizzazione e progettazione di un nuovo impianto è la conoscenza dell'insieme dei valori che connotano un paesaggio e dei valori che le popolazioni riconoscono come caratterizzanti il proprio ambiente di vita da preservare. Le modalità di analisi di un paesaggio variano in funzione dei caratteri dei luoghi e degli impianti (estensione, dimensione, forma e caratteri tecnici). In generale è necessario:

- leggere la morfologia del contesto, i suoi colori dominanti e le tecniche costruttive utilizzate in edifici e manufatti;
- riconoscere la presenza di punti e percorsi panoramici, di relazioni visive significative tra il sito di intervento e il contesto;
- comprendere gli elementi e le relazioni di tipo sistemico che ne connotano assetto e funzionamento dal punto di vista paesaggistico-ambientale;

- comprendere le vicende storiche che hanno portato alla sua costituzione e coglierne le tracce ancora riconoscibili, i segni, le trame, gli allineamenti, le suddivisioni territoriali, le relazioni tra gli elementi e tra elementi e contesto;
- comprendere i significati culturali, storici e attuali attribuiti dalle collettività a quei luoghi;
- valutare le dinamiche di trasformazione in atto con una proiezione verso il futuro.

La lettura delle connotazioni del paesaggio è necessaria alla comprensione delle modifiche che il nuovo impianto può apportare all'assetto paesaggistico consolidato al fine di governarne con piena consapevolezza le trasformazioni indotte, tutelando per esempio la continuità dei sistemi di relazione di varia natura, evitando di occludere o interferire con visuali significative o di entrare in competizione e mortificare elementi connotativi di particolare significato.

L'analisi del contesto richiede di considerare più scale territoriali, passando dall'analaisi degli aspetti più generali a quelli più particolari e viceversa. Ciò che a una scala di dettaglio può apparire come singolo elemento isolato, a scala più vasta si scopre essere parte di un sistema più ampio. Viceversa, aspetti di dettaglio che a scala vasta non si colgono, a scala ravvicinata mettono in luce connotazioni molto significative del luogo.

4 ENERGIA E PAESAGGIO: APPROCCI E CRITERI DI INTERVENTO

La crisi energetica, la ricerca di sempre maggiori livelli di efficienza energetica e l'incentivazione all'uso delle fonti di energia rinnovabili richiedono forti innovazioni tecnologiche e infrastrutturali che hanno come conseguenza delle continue e importanti modificazioni del paesaggio. Occorre favorire e supportare queste innovazioni anche orientandole verso la costruzione di nuovi "paesaggi energetici", tenendo conto delle componenti naturali e culturali e delle risorse umane, energetiche e materiali.

Un buon paesaggio energetico è il risultato di un'integrazione sistemica tra i fattori energetici e il paesaggio in cui la tecnologia viene considerata come elemento costituente il paesaggio alle diverse scale che, con la necessità di ridurre l'inquinamento e gli squilibri ecosistemici, diventa una funzione ecologica e sociale. Occorre superare la realizzazione episodica e casuale di impianti e opere e adottare approcci dove l'energia diventa parte attiva e positiva per il paesaggio stesso. Questo richiede l'uso di metodi di analisi e di valutazione e di criteri di progetto basati su un rapporto integrato tra paesaggio ed energia. Al riguardo, possono essere adottati due tipi di approcci, entrambi innovativi.

L'approccio integrato si basa sulla reinterpretazione del rapporto tra energia e paesaggio, in cui ogni apporto specialistico viene indirizzato nelle diverse fasi del progetto verso una sintesi che porta a un valore aggiunto rispetto alla semplice addizione fra le parti. La creatività progettuale e il sapere tecnico definiscono i limiti e le potenzialità per la costruzione di luoghi energeticamente sostenibili. Il rapporto tra utenti e innovazione viene facilitato grazie a progetti che sostengono l'integrazione visiva, funzionale, produttiva, spaziale e gestionale delle nuove tecnologie energetiche con gli elementi materiali e immateriali del paesaggio.

L'approccio rifondativo è orientato all'elaborazione di nuove soluzioni non solo tipologiche, figurative, spaziali e materiali, ma anche sociali. Gli obiettivi e le trasformazioni energetiche diventano l'occasione per favorire la formazione di nuove pratiche dell'abitare, fondate sulla cooperazione degli utenti, sull'impiego condiviso delle risorse, sui comportamenti virtuosi di comunità energetiche. Ad esempio, i nuovi quartieri ecologici gettano le basi per una diversa concezione dell'abitare, così come l'uso di nuovi dispositivi rivoluziona la composizione volumetrica e la costruzione degli edifici.

Solar City, Linz, Austria, 1992-

In entrambi gli approcci occorre promuovere la cultura della progettualità energetica diffusa verso la definizione di nuovi assetti insediativi, in sintonia con le specificità locali, culturali, tecniche ed economiche. Ad esempio, gli impianti medio-grandi non solo dovrebbero limitare i loro effetti negativi sul paesaggio, ma potrebbere diventare un fattore di interesse paesaggistico, sia come land-mark che come elementi di interesse tecnologico. Ad esempio, le wind farm possono assumere elevati valori estetici per le loro forme snelle, aerodinamiche e scultoree, per la solidità e modernità del design, per il senso di ordine che viene dalla coerenza e ripetitività di elementi di grandi dimensioni. Così come dal punto di vista simbolico la turbina a vento, che richiama i mulini a vento che per numerosi secoli hanno caratterizzato i paesaggi sia europei che di altri continenti, è un esempio di manufatto in armonia con la natura capace di utilizzare una risorsa rinnovabile.

Altamont Pass Windfarm, Northern California

Per mantenere una elevata qualità paesaggistica dei centri storici occorre adottare degli opportuni criteri di conservazione nell'inserimento di impianti solari. Da una parte la conservazione di monumenti e zone storiche dovrebbe far proprio un approccio moderno allo sviluppo delle energie rinnovabili, dall'altra gli specialisti in energia dovrebbero garantire una gestione moderna del patrimonio architettonico. Tra l'altro, l'impiego diffuso di fonti energetiche rinnovabili può costituire un fattore di recupero di piccoli insediamenti, spesso di interesse storico-culturale, situati in aree marginali.

L'energia può essere acquisita o risparmiata agendo sulla struttura, sulle forme, sui materiali e i colori di una città. Vi è una forte correlazione tra la morfologia urbana, intesa come organizzazione fisica e funzionale, e il comportamento energetico degli insediamenti, per cui da qualche decennio si stanno ricercando forme urbane virtuose in termini di conservazione e di acquisizione di energia.

L'armonizzazione tra tecnica e paesaggio nei nuovi paesaggi energetici di tipo concentrato e diffuso dovrà passare attraverso la loro integrazione sia a livello pianificatorio che a livello progettuale, per cui i piani e i progetti energetici dovranno tener conto dei criteri di trasformazione del paesaggio mentre i piani e i progetti paesaggistici dovranno considerare le necessità dei processi di produzione, trasmissione e consumo di energia. Sulla base dei caratteri del paesaggio, degli obiettivi energetici e delle esigenze tecniche, occorre scegliere l'atteggiamento che si intende adottare nei confronti del contesto. Si può preferire un approccio conservativo, adeguandosi il più possibile al sistema di relazioni e alle connotazioni (morfologiche, materiche, cromatiche, ecc.) del contesto, ricercando così la minima incidenza possibile dei nuovi manufatti, oppure un approccio innovativo, reinterpretando in modo attento relazioni e caratteri del contesto e proponendo nuovi significativi elementi di riferimento, comunque nel rispetto dei valori consolidati.

Non è possibile indicare a priori quale scelta effettuare, in entrambi i casi occorre assumere un criterio progettuale coerente dall'impostazione alla definizione di tutte le scelte: localizzazione, posizionamento dei diversi componenti, soluzione architettonica e scelte materiche e cromatiche, sistemazione aree contermini ecc. Più il progetto si orienta verso soluzioni formali e compositive innovative, più deve farsi carico di comprendere a fondo quali siano le alterazioni indotte sui sistemi di relazione e di connotazione consolidati, nonché verificare che l'introduzione del nuovo porti comunque a un assetto convincente e condiviso dei luoghi, nel rispetto dei valori pre-esistenti. Qualunque sia l'approccio scelto, occorre seguire alcuni criteri generali:

- i progetti devono sempre confrontarsi con le indicazioni di tutela, valorizzazione e riqualificazione del paesaggio sviluppate ai diversi livelli dalla pianificazione paesaggistica, tenendo in attenta considerazione la salvaguardia degli elementi e dei sistemi di prioritaria attenzione. Inoltre devono essere organicamente sviluppate nel progetto le aree contermini e le sistemazioni accessorie agli impianti;

- gli interventi vanno collocati in scenari di medio-lungo periodo, verificando la possibilità di completa rimozione degli impianti e le possibilità di riqualificazione complessiva del luogo in caso di cessazione della loro funzionalità;

- gli interventi che hanno una minima incidenza paesaggistica devono comunque essere oggetto di una attenta progettazione dei manufatti, così come la formazione di un nuovo paesaggio non può prescindere dalla valorizzazione di quello preesistente. In tutti i casi, le scelte cromatiche sono determinanti per l'integrazione paesaggistica dei manufatti.

- gli interventi di razionalizzazione comportano spesso l'eliminazione di alcuni manufatti e l'accorpamento di altri in progetti di nuova concezione che devono tendere a concentrare le reti su corridoi preferenziali, gli impianti su poli di nuova concezione, i piccoli impianti domestici su soluzioni centralizzate;

5 CONCLUSION

Ciò che viene collocato sul territorio determina una trasformazione del paesaggio e questa trasformazione segnerà per un tempo significativo l'assetto di quei luoghi e il permanere o interrompersi di relazioni sistemiche, simboliche e visuali. La realizzazione di un intervento è quindi l'occasione per riflettere sulle opportunità di valorizzazione di un luogo e di proposta di nuovi elementi qualificati integrati nel paesaggio.

La piena comprensione dei caratteri connotativi dei luoghi e il rispetto dei valori da essi rappresentati costituiscono la base di ogni progetto paesaggisticamente appropriato. Pertanto, prima di pensare alla minimizzazione dell'impatto sul paesaggio occorre pensare un'opera come parte integrante del paesaggio in cui essa viene inserita.

Un sistema energetico deve avere un carattere multifunzionale, cioè avere la capacità di generare un paesaggio energetico che diventa fattore economico positivo poiché capace di incidere non solo sulla produttività di un territorio, ma anche sulla qualità della vita delle popolazioni che vi abitano. L'elaborazione di strategie integrate per lo sviluppo energetico e la qualificazione del paesaggio richiede, a monte, una pianificazione dell'uso delle risorse energetiche rinnovabili che consideri l'insieme degli interventi necessari al sistema energetico di un territorio e individui il livello di utilizzo delle risorse rinnovabile disponibili.

Energy Poverty: Considerations for Socially Sustainable Shifts Towards Renewable Energy Sources

1 ABSTRACT

Recent years have witnessed growing concern over a phenomenon long deemed extinct in Western Europe: energy poverty – a term referring to people's inability to sufficiently heat and light their homes – has re-entered the political agenda as an increasing number of people is affected all over Europe.

While this may be regarded as just one facet of poverty in an increasingly segmented society it is one deeply rooted not only in households' low recourses but also in high energy prices and insufficient energy efficiency of buildings. This triangle of drivers makes energy poverty a highly complex matter to deal with, starting from the very definition of the problem.

So far, no such definition is available in most of EU member states, let alone on European level. Accordingly, reliable statistical data on the scope of the problem is mostly missing. A scrutiny of existent propositions for the definition of energy poverty reveals that defining the problem in itself already implies a political statement on who is to be targeted in this respect.

This is even more so the case for the design of suitable measures of counteraction; While at the moment most of such measures aim at providing affected households with consultancy on energy saving behaviour this has to be regarded as just one step into tackling the overall problem.

Leaping further beyond, strategies against present and future energy poverty primarily have to aim at improving thermal standards of buildings as well as providing energy poor families respectively households with options to use renewable energy sources.

This paper investigates energy poverty in Austria with a special focus on gender issues and migrants.

2 BACKGROUND

Only recently, energy poverty has been recognized as an independent problem in the context of increasing energy prices in Austria. So far broad political and social discussion of this topic lacks existence. In Austria in 2010 313,000 people were not able to keep their dwellings sufficiently warm (STATISTIK AUSTRIA, 2011a), these are 3.8 % of the population of the twelfth richest country in the world.

„relative income poverty"is a generally aknowleged indicator of poverty risk. It refers to individuals living in households whose equivalised income is lower than 60 % of the national equivalised median income. In Austria around 1 million people, 12 % of the population, were at risk of poverty (after social transfers) in 2010 (STATISTIK AUSTRIA, 2011a). Deprivation is defined as an inability to participate in the reference society due to financial reasons. Financial deprivation is regarded as applicable as soon as two out of the following seven problems arise (Eurostat, 2013):

The household could not afford

- to face unexpected expenses
- to pay for mortgage, rent, utility bills or substantial instalments
- a meal with meat, chicken or fish every second day
- to keep home adequately warm
- visits to doctors and dentists
- to invite friends or relations to dinner once a month
- to buy new clothes

Even so income-based indicators of poverty and inequality are essential, they are not sufficient to satisfactorily reflect the diversity of living conditions. For that reason the EU portfolio of commonly accepted social indicators is extended to material deprivation measures. Material deprivation rate measures the percentage of the population which cannot afford at least three of the following nine activities and items:

- to face unexpected expenses

- to pay for arrears (mortgage or rent, utility bills or hire purchase instalments)

- a meal with meat, chicken or fish every second day

- to keep home adequately warm

- to go on holiday

- a television set

- a washing machine

- a car

- a telephone

People who can't afford at least four of these nine activities and items suffer from severe material deprivation.

Of course people at risk of poverty are confronted more often with an inability to afford fundamental needs than people who are not at-risk-of-poverty. Nevertheless, deprivation and poverty risks don't arise together automatically. Not all materially deprived people are at risk: around 45 % are in fact above the treshold of poverty risk. Therefore, factors other than low income seem to matter. One hypothesis is, that deprivation arises with a time lag to the occurrence of low income (savings are used up) and vice versa. On the other hand the current method for measuring poverty risk does not refer to the individual needs or costs of living.

In the absence of a specific definition for energy poverty in Austria, a household's inability to keep home adequately warm is used as an indicator for energy poverty.

Just like deprivation energy poverty – one of the nine features charcterizing material deprivation – is possible to occur in the absence of poverty risk. In Austria, 313,000 people suffer from energy poverty, but only 135,000 (43 %) of them suffer from severe material deprivation. Only 115,000 or 37 % of the people suffering from energy poverty are at-risk-of-poverty. 191,000 or 61 % have a middle income (60 % to 180 % of the median) an 7,000 or 2 % have a high income (STATISTIK AUSTRIA, 2011b).
Figure 1: Overlapping of poverty risk, severe material deprivation and energy poverty (Source: STATISTIK AUSTRIA, 2011a)

Energy poverty has to be recognized as a special case of poverty: 115,000 out of around 1 million people at risk of poverty are affected by energy poverty – hence 198,000 people are regarded as energy poor, but not at-risk-of-poverty. Thus the reduction or prevention of energy poverty needs specific approaches.

Figure 2 shows the development of the share of people who cannot afford keeping their home adequately warm within the period of 2003 to 2011. It also differentiates between the group of people having an income of less than 60 % of the median income and the one having a higher income. The share of people who cannot afford keeping their homes warm fluctuates between 2.1 % in 2004 and 4 % in 2008. Nevertheless, the share of energy poor amongst the population with low income is at least double as high as amongst people with 60 % of median income or more throughout this time period. Figure 2 also depicts the annual inflation for the same period. As it can be seen, energy poverty among people are at-risk-of-poverty pretty much follows the development of prices. This is not true for the population with an income of at least 60 % of median income. People at-risk-of-poverty are also facing a higher risk of becoming energy poor when prices generally rise, because they are unable to compensate rising energy prices through saving elsewhere.
Figure 2: Share of population not able to keep home adequately warm and annual inflation 2003 to 2011 (Source: Eurostat, Statistics Austria)

57.4 % of the people aged 20 years and older not being able to keep their homes adequately warm are women, in the age group 65 years and older even 76 % (STATISTIK AUSTRIA, 2011b). As income is one of the drivers for energy poverty, elderly women are affected by a higher risk of energy poverty as their pensions are comparably low. Due to lower incomes from employment because of educational and occupational gender segmentation, less working hours and longer absence from work because of care for children and elderly, women´s economic situation is worse than men´s. Women´s economic disadvantages exacerbate in high age. (BIFFL, 2010)

Migrants are vulnerable to energy poverty in a twofold way: Firstly, migrants often have lower educational attainment levels and less professional experience wich leads – in combination with certain migration specific challenges like language barriers – to difficulties with labour market integration. Furthermore, they often have to cope with low incomes. Secondly, due to constraints on the housing market, migrants often have to rent relatively expensive appartements or houses which further diminishes their capability to absorb rises in energy costs.

28 % of the people suffering from energy poverty don't have Austrian citizenship. Among Austrian total population, the share of foreign citizens was only 10.7 % in 2010. This means that around 3 % of all Austrian citizens are energy poor, but more than 10 % of foreign citizens in Austria. The share of people not able to keep the home adequately warm is especially high (14 %) among people with a citizenship from a so-called third country, namely from outside the EU or EFTA.

3 CAUSES AND POSSIBLE IMPACTS OF ENERGY POVERTY

3 main factors are generally acknowledged to drive energy poverty: high energy prices, low incomes and insufficient energy efficiency of residential buildings.

Global energy demand increases constantly and is expected to continue to do so for future decades (GEA, 2012). Associated energy price increases have been well above general index raises during the last decade and are likewise due to be going strong for foreseeable future. Thus, there is hardly any relaxation in sight for this important driver of energy poverty. Quiet contrary, overly increasing energy costs represent the cause why energy poverty is not just one further problem for impoverished households and a mere side effect of

general poverty. Instead, it may well cause an otherwise sufficiently equipped household to be unable to cover its further expenses.

Figure 3 shows the development of prices for gas and electricity for household consumption as well as the development of general prices, namely the total HCPI (Harmonized Consumer Prices Index) and the one for accommodation, water, electricity, gas and other fuels between 1997 and 2011. Prices of gas and electricity for household consumption both excluding and (especially) including taxes strongly increased in the respective period. The HCPI for goods and services relating to housing rose much higher than the total HCPI – the rise in energy prices (also rents etc.) was higher than the rise of general prices within the last couple of decades.
Figure 3: Gas and electricity prices for households and HCPI 1997 to 2011 in Austria (Source: Eurostat)

Of course low incomes also contribute significantly to energy poverty. The weakest social groups therefore are highest at risk of being energy poor; this especially refers to single mothers (and fathers), elderly (and chronically ill) persons and migrants. These groups tend to live on low income or even to rely solely on public subsidies and transfers. Expenses for heating and electricity as well as transport – a service which likewise strongly depends upon energy supply and pricing – therefore constitute a heavy burden for their budgets. But only 37 % of the people suffering from energy poverty are at-risk-of-poverty. This confirms that income is an important but just one out of three drivers for energy poverty.

Low income groups are often found to be living in urban rental districts as these settings tend to be the only affordable housing options for them. This is especially true for migrants who try to find jobs in urban industries. In many cases they find themselves excluded from social housing estates due to their foreign nationality. This only leaves private rental available to them as a housing market. These accomodations however tend to be located in buildings of minor quality, generally displaying insufficient energy efficiency. In Austria, less than a third of the total population lives in cities with 100.000 or more inhabitants. But among the people who are cannot afford keeping their home adequately warm, almost 50 % live in cities of the size of this category.

Badly insulated buildings represent the third important cause of energy poverty. Inhabitants of such buildings tend to spend more money on energy bills than other households do in relative terms. At the same time, these households have fewer opportunities to improve their situation as they lack legal means and financial resources for refurbishment. Such refurbishment of existent building stock, however, not only constitutes a

social necessity but also a highly desirable ecological measure in the light of green house gas emissions associated with leaky buildings.

Reducing their energy consumption often remains low income households' sole way of cutting expenses on energy. Cold homes and the associated health risks are a consequence; low temperature and moisture raise the danger of fungi formation, respiratory and chronic bronchial diseases are likely to inflict the affected inhabitants especially when very young or elderly. Increased winter mortality may partly be attributed to energy poverty. Furthermore, cold homes also further habitants' social isolation as it keeps them from inviting others and thereby revealing their actual living conditions which they often feel ashamed of.

4 DIFFICULTIES IN DEFINING ENERGY POVERTY

Properly defining the phenomenon of energy poverty constitutes a prominent prerequisite for an in depth analysis of the affected groups which is still missing today in Austria as well as in many other countries in the EU.

According to the most widely acknowledged definition (Boardman, 2012) a household has to be regarded as being energy poor if it has to spend more than 10 % of its household income on energy. There are discrepancies whether this includes heating only or whether lighting, warm water preparation and electricity are equally taken into account. No reference is made to mobility costs. However, a household's expenses on energy under this definition are not calculated on what is actually spent but rather what would have to be spent to keep it adequately warm. The term "adequately" herein makes reference to a WHO definition (WHO, 1987). Contrary, judging households by their actual bills would signify that those who already restrict their consumption in a way which might be unhealthy could be regarded as still not energy poor while in fact they clearly are.

This approach certainly leaves ample space for discussion; firstly, household's income resp. expenses have to be defined more clearly: Therein – to name just one point – it makes a significant difference whether housing costs (and public subsidies associated with them) are taken into account. Secondly, the limit of 10 % is based on rather empirical findings. In order to allow for comparison of different states with their respective socio economic situations the reference to national medians would be more suitable.

Finally, even the definition of "adequate" warmth is under discussion as it is argued that this may partly be an individual choice. More complex definitions of energy poverty therefore rely on a set of parameters to qualify not just energy costs but energy efficiency of buildings and heating devices alike. Furthermore, they may include indicators of how long and how severe people are affected by energy poverty (Mandl 2012).

The exact definition of energy poverty, complex as it might be, hence has to be regarded as a highly political issue which determines which groups of society are seen as most affected and which have to be chiefly targeted by alleviation strategies. Clearly, the energy poor are a highly heterogeneous group: it includes urban low income families in substandard rental housing as well as rural pensioners living in their own, depilating properties which they can't afford to improve.

As has been demonstrated above numbers on energy poverty for Austria and many countries in the EU are based only on individual appraisals of the persons affected. In the statistical investigation EU-SILC, the interviewees are asked, if they can afford to keep home adequately warm. No criteria are determined to categorize energy poverty in Austria according to objective aspects. The necessity of objective criteria is shown also by the volatile nature of the numbers of people not able to keep the home sufficiently warm in Austria, fluctuating from 313,000 in 2006 (3.8 %) to 214,000 in 2007 (2.6 %) to 333,000 in 2008 (4 %) to 237,000 in 2009 (2.9 %) and back to 313,000 in 2010 (3.8 %).

5 FUTURE CHALLENGES

For Austria a significant need in data ascertainment and research concerning energy poverty is identified. Only in the last years has this issue become a specific research field, mainly on the basis of qualitative studies and with a focus on energy consumption behaviour. A research gap concerning gender issues in the context of energy poverty in Austrian studies and projects exists. In international research projects on energy, poverty and sustainability, the application of the gender perspective is common issue as engendering necessitates being a common task for energy policies and for the fulfillment of social equity in sustainability and development. In general, the contexts of gender and energy are well elaborated on the international level,

but hardly for Austria. In terms of migrants' vulnerability to energy poverty in particular, little targeted research has been undertaken so far. Rather, it is generally assumed that comparably high energy costs due to inefficient housing and health problems related to cold and damp homes add up to their overall problems. Yet, this view fails to take into account the fact that future energy shortages will result in cost increases different from general inflation and thus will hit harder.

The interdependencies portrayed above clearly highlight the urgent necessity of increased energy efficiency in residential buildings. This necessity not only exists due to ecological considerations but very much so also for goals of social sustainability: keeping energy demands low due to increased energy effciency helps taking the burden of high energy bills off poor households' shoulders. Covering the remaining demand by renewable energy sources would imply to even go further: prices of energy from such sources may well be expected not to follow closely the prognosed increases in costs of fossil supplies.

Unfortunately however, things are not as simple as that; Firstly, as has been described above, low income groups tend to be those living in buildings least isolated

As Fig. 4 shows, 75.1 % of all people having more than 180 % of median income own either a house or a flat. Also within the group of middle earners, almost two thirds own their home. This picture looks totally different for people with low income (less than 60 % of median income): Less than a third of them is owner of the dwelling. More than a third lives in a rental house or flat. Another 16.7 % live in a public housing (council home). This is even more pronounced among those suffering from severe material deprivation (definition see above): 42.8 % of people suffering from severe material deprivation live in a rental house or flat and almost another third (27.7 %) lives in a council home.
Figure 4: Legal position of home by income group and severe material deprivation (Source: Statistics Austria, EU-SILC 2011)

For people with low income, there are barely measures to change the situation they are on. In most cases, mere renters of their flats, not entitled to decide about any major improvement in their buildings's construction. They also lack funds to invest into such measures. Should their landlords decide to refurbish the property the renters run danger of being unable to cope with consequently increased rents. In such cases, low income inhabitants often have to leave the refurbished building and to look for another cheap flat elsewhere – most probably in just another inefficient building with high running costs.

Even if they manage to stay after refurbishment it is found that increases in energy efficiency often do not trickle down to renters: renting costs tend to include many fractions which are independent of actual energy consumption and reductions in this consumptions are seldomly reflected in real overall cost reductions.

Therefore, not only has energy demand of affected households to be reduced but the price of energy has to be kept to a minimum for people suffering from energy poverty. It is argued that energy from renewable sources holds the potential of doing so in the future. At the moment however renewable energies are rather associated with and blamed for increases in (electricity) price increases.

6 POSSIBLE OPTIONS TO ELEVATE ENERGY POVERTY

Among the driving causes of energy poverty it is low incomes and lacking energy efficiency of buildings first and foremost which are tangible for national policy. As a first measure, linking public subsidies with the quality of buildings which receiving households inhabit serves as a starting point for interventions, thereby making sure that these households do not have to suffer from health risks associated with cold homes.

This, however, is adviseable only if integrated into a broader strategy which aims at refurbishing least energy efficient buildings. Thereby CO2 emissions and energy costs should be reduced.

Only few low income households profit from improved energy efficiency standards which have been established for electric devices in Europe over the last years: most of the affected households still stick to old or second hand equipment. It is therefore not enough to wait for more efficient devices to "trickle down" to these social groups by way of second hand.

Concerning energy billing so called "reverse block tariffs are proposed: these provide energy at a comparably low rate up to a certain limit allowing households to cover their basic needs at affordable costs. Only above this limit do tariffs increase, thereby setting incentives even for better offs to economically use energy.

The most common approach in tackling energy poverty nowadays consists in advising and coaching affected groups in their behaviour regarding energy consumption. This should be backed by supplying them with energy efficient equipment. Furthermore, this approach is limited to the extent that changes in consumption habits are only partly reflected in reduced energy costs due to accounting mechanisms which strongly rely on basic costs. Energy bills are often facturated on a quarterly or even yearly basis only which makes it difficult to track impacts of behavioural changes on energy costs. Finally, such changes at best only hold potential to reduce part of the overall energy consumption as reducing heating demands is hardly possible in rented residential establishments.

The energy poor do not possess resources neither to refurbish their buildings nor to implement systems to harness renewable energy sources such as photovoltaic cells. Public subsidies aiming at the promotion of such technologies therefore exclusively benefit the better off. In consequence a gap threathens to open up between them and the weakest social groups not only in terms of resources but also in energy efficiency of their living conditions. Hence, strategies against present and future energy poverty primaryly have to aim at improving thermal standards of buildings as well as providing energy poor families with options to use renewable energy sources.

FIFA World Cup 2018 – the Planning Challenge for Russian Cities

Alexander Antonov, Tatiana Badmaeva

(Alexander Antonov, Russian Urban Planning Association, P.O. 109028 Box 46, Moscow, Russia, alexfusion@rambler.ru)
(Tatiana Badmaeva, Russian Urban Planning Association, 109028 P.O. Box 46, Moscow, Russia, bbtt@bk.ru)

1 ABSTRACT

11 Russian cities were chosen to host FIFA world Cup 2018. Their starting positions 6 years before the championship are very different. It seems that the Megacity of Moscow may host almost any large event at any time. From the other hand the city has been suffering for years from infrastructural shortcomings and incorrigible traffic problems.

Sochi and Kazan are cities most prepared for FIFA world Cup due to other coming sport events: winter Olympics in Sochi (2014) and World student games in Kazan (2013). All sport facilities and infrastructural projects will be completed 4-5 years before World Cup 2018 starts. So these cities probably will face the problem of maintenance surplus sport objects.

Other 8 cities including one of the largest European city St. Petersburg face the challenge they haven't ever faced before in their 20-years post-soviet history.

City's approaches to the "challenge 2018" are common – the main idea of the preparation period is to obtain more federal investments into local transportation projects. Current priorities for almost all cities start from new stadium construction (or total reconstruction). The next issue is network development that focuses mostly on focal projects like a new airport, street crossings nearby the stadium or parking facilities.

The aim of Local organizing committee (LOC FIFA 2018) and the federal company "Arena' founded to coordinate all construction activity – is to ensure the championship itself. The FIFA's claim to provide the heritage of the tournament is taking into consideration rather on the theoretical level.

The core task for all cities – to integrate "World Cup oriented" infrastructural projects with federal financing into own planning strategies, to consider the FIFA tournament as a «catalytic agent» for post-soviet city transformation. This idea is rather new for cities. At the same time planning projects for future stadiums causes wide public discussions in some cities from the point of long-term development – not the championship preparation.

The legal issue is also claiming attention. All cities have general plans worked out a few years ago. New stadiums appointed by FIFA, were not planned. Is it necessary to correct the general plan? Or the serious project like FIFA World Cup may inspire the city to real strategic planning – more sustainable and more resilient than traditional soviet regulatory-based planning?

The paper overviews all FIFA world CUP 2018 host cities focusing on significant construction and infrastructural projects that may excite structural transformations of every city framework. The paper attempts to pay cities' attention on planning aspects of "sports objects development" and related issues (like renovation, mixed use, public spaces) beyond transit systems, hotels and fan areas. Various local long-term development projects that can be pushed hand by hand with championship-oriented ones are explored.

2 FIFA 2018 HOST CITIES – THE OVERVIEW

FIFA local organizing committee had grouped all cities into clusters according to their location. We prefer another approach: the importance of the World Cup for every city. Four groups were distinguished. The championship for Small cities is a great event, for cities-Millionaires (above 1 million citizens) is a chance, for "Sport" cities is out of agenda yet and is an ordinary event for Capital cities

2.1 Small cities

Kaliningrad – extreme western city of Russia, is an enclave surrounded by new EC countries. Centre of promising resort region on the Baltic Sea. Population – 431 500.

The stadium was built in 1892 now seats 14000 people. Airport Khrabrovo failed to become an international hub a few years ago. Now is 18th in Russia. Public transportation system includes bus, trolley and shrinking tram networks. Hotel network is well developed both in the city and surroundings.

Plans for 2018 includes: new Stadium on the Lomse island close to the city centre together with the whole island housing and commercial development, fast tram ring, the tram network and water passenger transport extension, street network extension around the Lomse island, including 4-5 bridges construction across Pregola river, new energy supply facilities. Railway extension to the airport is the issue for discussion.

Saransk – the capital of Mordovia – the region with a highest level of social and political stability in Russia. Population – 298 000.

New stadium that seats 11500 people was built in 2004. Small airport operate only one route to Moscow. The city is not on the transit railway – only 3 long-distance trains daily. Saransk has well developed trolley and bus network and a very low level of hotel service – insufficient to FIFA minimal demand.

Plans for 2018 includes: new Stadium on a new site near the centre of the city, temporary terminal construction at the Airport, new hotels construction (about 2000 rooms), street network extension, housing development project near the stadium. City centre redevelopment is also declared by city authorities.

World Cup 2018 – is the great challenge and opportunity both for Kaliningrad and Saransk. Former Keningsberg had lost al the greatness of the Prussian capital. The city gets a chance to start its spurt towards the modern one developing the Lomse Island like HafenCity in Hamburg or Västra hamnen in Malmo. Saransk is too small and too provincial. The city is realizing several housing projects now based on soviet "microrayon" and strong functional zoning approaches. Probably Saransk may switch to present-day planning concepts and rise its appeal, but it should start strategic planning immediately thinking not only about the FIFA event but planning its own future in the whole.

2.2 Millionaires

Nizhni Novgorod (former name Gorky) – industrial city on the bank of Volga river. Capital of the Povolzhsky federal district. Has a good rail connection to Moscow. Population – 1 254 600 (decreasing).

The main stadium "Lokomotiv" seats 17000 people. The city has a wide range of sport objects an plans to build new ones – like the largest hockey hall in Russia. Airport "Strigino" is situated at the south-west end of the city and connected by bus line with the metro station. Nizhni Novgorod has two metro lines, bus, trolley, tram network and a cable-way to the city of Bor on the other side of Volga River. Railway station in the centre of industrial part together with metro station forms the main transportation hub. The city is lacking for hotels.

Plans for 2018 includes: new Stadium on a very significant place on the bank of Volga in the central part of the city, railway terminal reconstruction, two metro stations (probably more), 3 cable-ways, street network extension, road junctions and a tunnel, 30 new hotels. Railway extension to the airport is discussing.

Samara – one of the largest cities on the Volga river, forms Samara-Togliatti agglomeration. The centre of space science and industry. Famous for its historical centre dated by late 1800-s. Population – 1 198 000

The stadium Metallurg is old and uncomfortable. Airport "Kurumoch" (in top-10 Russian airports) is situated 40 km far from the city. Samara has one metro line (9 stations) but it role in public transportation system is minor. The city has extensive bus and tram networks. Also trolleys and route taxis. Railroad doesn't used for inner-city connections. Hotel network fit minimal FIFA requirement but need extension.

Plans for 2018 includes: new stadium on a new site far from the centre of the city, tram network extension and water passenger transport development, new cable-way, street and outer road network extension, road junctions and railway crossings. A new metro line (12 stations) and alternate airport connection by existing railway extension or new LRT construction are issues for discussion.

Volgograd – (former name Stalingrad) – one of the longest cities of Russia, stretches for about 90 km along the Volga River. Industrial centre in the South of Russia. Population –1 018 739.

The Central stadium is situated in front of the main landmark of the city (downhill towards Volga) – "Mamaev Kurgan" with the statue of Motherland. Gumrak airport is located about 13 km from the city centre. Volgograd is the unique city in Russia with Metrotram system launched in1984. It has 22 stations on one line length of 17.3 km. The city has also a separate tram network, buses and trolleys. Hotel network includes 84 hotels that rooms more than 3000 people.

Plans for 2018 includes: the new stadium is "Victory" on the same place of the Central stadium on the Volga' riverfront in the north-central part of the city, training camp in Maslovo on the over bank of Volga river, airport complex reconstruction, fast tram (Metrotram) network extension, transit road network near the stadium and west cargo traffic bypass around the city, hotel network development.

Rostov-on-Don – the capital of the Southern federal district, a major industrial, scientific and cultural centre in the south of the country, is often informally referred to as the "Gateway to the Caucasus". Population –1 099 500.

The main city stadium now is "SKA" that seats 11000 places. Rostov airport located inside the city 8 km far from the centre. They plan to close it after the new one will be completed. Rostov-on-Don is the only city in Russia with European gauge system (1435 mm). It also has trolley, bus and route taxi network. The city counts more then 40 hotels, motels and resorts for 3500 rooms.

Plans for 2018 includes: the new stadium construction on the left-bank of Don river opposite the main city embankment, training fields in the suburbs, a new international airport, reconstruction of one bridge over the Don River and construction of another one, two new road bypasses for transit transport to the south and to the west of the city, cable-way over the Don River. New metro network construction is the question for discussion.

Yekaterinburg – the largest city, industrial and economical centre of Ural region. The city's brand is epy largest number of skyscrapers among all Russian cities. Population – 1 377 700.

The "Central" stadium was opened after reconstruction in 2009, now seats 27000 people. Situated close to the central part of the city from west side. The new airport is 5th in Russia and was included in top 100 European airport in 2012. Connected to the city by the railway and highway. The city has one metro line, bus, trolley and tram network and unique transport for Russia – the city railway. A lot of hotels were constructed during last years.

Plans for 2018 includes: total stadium reconstruction (The stadium couldn't be demolished due to historical significance), 4 stations on a new metro line, Fast tram line, Street network extension with a few road junctions. About 25 hotels may be build if necessary. No planning projects developed yet.

All cities except Yekaterinburg are situated on great Russian rivers determine the historical planning structure and claims for new extension. Key words for Rostov-on-Don and Samada are city expansion and agglomeration development. Airport and interregional transportation networks development play a great role, the stadium construction on a greenfield forms a new central place for the whole region.

The main idea for other millionaires-cities is reconstruction and road network development. Projects will be more local, more detailed. Planners and architects may pay attention on public spaces, parks, waterfront, spatial and visual links between stadiums and city centres.

2.3 Sport cities

Kazan – city on Volga River, the capital of Tatarstan Republic – one of the most populated and economically developed regions in Russia. Population – 1 161 300.

The city is almost ready for the Summer Universiade 2013 (started on July 6, 2013). More than 10 new sports objects were build during last few years. New Stadium for 45 000 people is among them. Many infrastructural projects were also dated for the Universiade including extended street network reconstruction, traffic interchanges construction and a new railway connection to the airport. Kazan has one metro line, bus, trolley and tram network and no route taxis (untypical for Russia). Hotel network is well developed.

Plans for 2018 includes: launching city rail ring project, new transportation Hub development (railway terminal Kazan-2), street and network extension, a new metro line of 5-6 stations.

Sochi – the main and the most popular Russian sea resort. The Great Sochi is stretched out 140 km along the sea-side and includes several living communities (Sochi is the largest) separated by natural landscapes and resort development. Population – 343 300 is increasing 3-5 times during the summer.

The city is going to host winter Olympic Games 2014. Sports infrastructure (stadium "Fisht" for 40000 people) and traffic network projects (transit streets and road bypass, rail connection to the airport, etc.) are

completed or in last stage of construction. City has only two really working types of public transport: bus and rout taxi. Hotel network is redundant for any sporting event bus still is extending.

Sochi has no Plans for 2018. All development projects are concentrated on Winter Olympics. Water and energy supply systems development, completing traffic bypass for cargo transit and launching the city railway are the main ones. Development plans beyond 2014 are not discussing yet.

World Cup 2018 is not the key issue for planning discussions not in Kazan no in Sochi now. While Sochi is focused on tactical issues of 2014 Olympics, Kazan is almost ready for Universiade and tries to widen its "planning horizon" to 2018 and beyond.

2.4 Capitals

St. Petersburg was the capital of Russia in 1712-1918. The northern, sea and cultural capital of the country. The most "European" city in Russia. Population – 5 028 313.

Stadium "Petrovski" – the home one for the richest Russian football club Zenit was built in 1925 now seats 21000 people. The airport "Pulkovo" (3th in Russia) is situated close to the city but connected with it only by road network. St. Petersburg has 5 railway terminals, marine passenger terminal, 5-lines metro network and all types of public transport. Hotel network is well developed and includes a lot of small hotels.

Plans for 2018 includes: new Stadium on the place of Demolished Kirov Stadium on the west end of Kirovsky Island (project by Kurosava) may form a significant landmark in the city's panoramic view from the seaside. New terminal construction at the Airport and connecting it with the city by rail, metro or LRT line, construction of 5 metro stations on 2 lines, Street and road network extension.

Moscow is the capital of Russia, The largest mega city in Europe and one of the top-10 in the world. Population of the city is about 12 million people. The Moscow agglomeration population runs up to 16-17 million.

Moscow is implementing a lot of projects now: Smart city Scolkovo, Moscow agglomeration and new south-west development, transportation projects including rail ring and fast tram lines construction, vast metro network extension, Industrial sites redevelopment, etc. FIFA 2018 is among them but not the main one. They plan reconstruction of the main Moscow stadium "Luzhniki" and the new stadium "Otkritie Arena" construction on the north-west of the city.

3 CHALLENGES AND OPPORTUNITIES

World cup campaign has already started. Stadium design comes first. Dozens of architects had worked out their concepts of fantastic sport facilities. Networks development dreams goes next, focused on airports, rail and metro construction, kilometres of new streets, highways and road junctions. The most tempting time – cost assessment comes now.

3.1 Federal investment race

City's approaches to the "challenge 2018" are common – the main idea of the preparation period is to obtain more federal investments into local transportation projects. First evaluation of World Cup cost for Russian budget was estimated as 10 billion Euros. Now it rises to 15 billions. Cities' requests are the flip side of the process. Samara region has calculate detailed demand as 5,5 billions – only for one city.

While analysing preparation plans one can see a lot of expensive projects. Only some of them would be accepted. For example currently only two of metro network extension projects would be financed by federals: in St. Petersburg and N. Novgorod. What are criteria for project selection? Is it provision of a few football matches or significance for long-term city development?

3.2 Local initiatives

The main stream of federal financing would go via the regional governments – not municipalities. And what are the real cities' needs? It's amazing but almost all cities do not really need new large stadiums. Average attendance of football matches in Russia is about 10 thousand fans. Top matches can attract 20-25 thousand – not more. Present-day cities' needs are housing and network's development: roads, public transport, gas and water supply systems, etc. Coming back to Samara region demand one can see that 70 % of 5,5 billions

is necessary for road networks development, 11,7 % – for sports facilities and only 9.5 – for city improvement.

Most plans not strategically but problem oriented. The main problem for almost all cities is traffic. If you have traffic jams – you mast build more roads. Another approach – to integrate "World Cup oriented" infrastructural projects with federal financing into own planning strategies as a «catalytic agent» for post-soviet city transformation – is rather strange idea for cities' authorities.

3.3 Planning challenges

What about strategies? All cities have general plans elaborated 6-8 years ago (long before crisis came) they are out of date now in principal statements. As a result – all new stadiums were located ignoring general plans – in Kaliningrad, Samara, N. Novgorod, Saransk. Yekaterinburg has a city development strategy adopted in 2009. Samara has started its strategic planning last year. That is all.

Bad roads and lack of housing have been traditional problems for Russia for years but they are not critical now. The main problem is referred to demography. Volgograd and N. Novgorod are shrinking cities (N. Novgorod was stated by UN as one of the most rapidly depopulating cities in the world), Samara, Kaliningrad and Saransk are stable, Kazan, Yekaterinburg and Rostov experience minor growth in the last 2-5 years after the fall in the end of XX century.

Stagnating and shrinking cities in Russia are entering the era of competition for skilled human resources. They must learn how to attract people not only by construction of social objects and dwellings or solving current infrastructural problems but by improving city environment, widening range of possibilities in workplaces, education and rest. Cities need to implement new planning methods and approaches using the wide range of instruments including participatory planning, professional discussions, competitions, international cooperation etc.

4   PLANNING STORIES

Two case studies offer more detailed view on cities' planning challenges. Kaliningrad is famous for the wide public involvement in city long-term development discussions. Rostov-on-Don seems to face most serious spatial transformation in the nearest future.

4.1 Kaliningrad

Kaliningrad – former Keningsberg was demolished during the 2 World War and still has been looking for its identity for more than 60 years. The city never faced strategic challenges like World Cup 2018. Probably this was the reason for wide public discussions both concerning the championship preparation and city development started immediately after the idea to host football championship was announced in 2009.

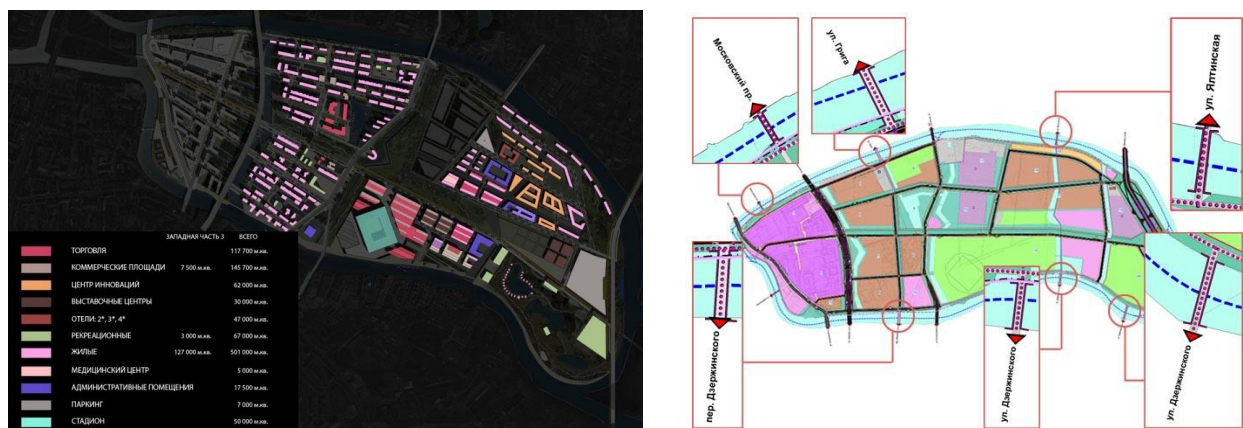
First of all location of a new stadium was discussed. The FIFA commission's decision adopted in 2011 is still an issue for debate. The Lomse island is a swamp with average height 1,5-2 meters above the sea level. According to the general plan developed in 2004 the whole island except the western part was the recreation zone. The new stadium was placed in the middle part of the island. Some experts worry about negative geological and hydrological conditions that can complicate the stadium construction and increase its cost.


Fig. 1: Concept of Lomse Island development (left). Transportation scheme in the „Project of Planning" (right)

At the same time the stadium construction can stimulate development of the large territory about 220 ha close to the city centre. The concept of Lomse island development was created in the beginning of 2012. An official document „Project of Planning" was developed half a year later and caused a new round of debates. Somebody may see that blocks-based structure of the Concept was transferred to typical "microrayon-based" scheme with a rare street network. „Project of Planning" was criticized by a group of Kaliningrad architects but vas adopted by city authorities in march 2013.

New development of Lomse island based on today principles of green building, public spaces priority, low carbon emission and multi-use planning approach may help the city to start its spurt towards the modern-looking city and get a unique identity among Russian cities. Probably Kaliningrad needs to explore successful housing projects in middle-sized European cities like Västra hamnen in Malmo (Sweden) or Port Marianne in Montpellier (France).

4.2 Rostov-on-Don

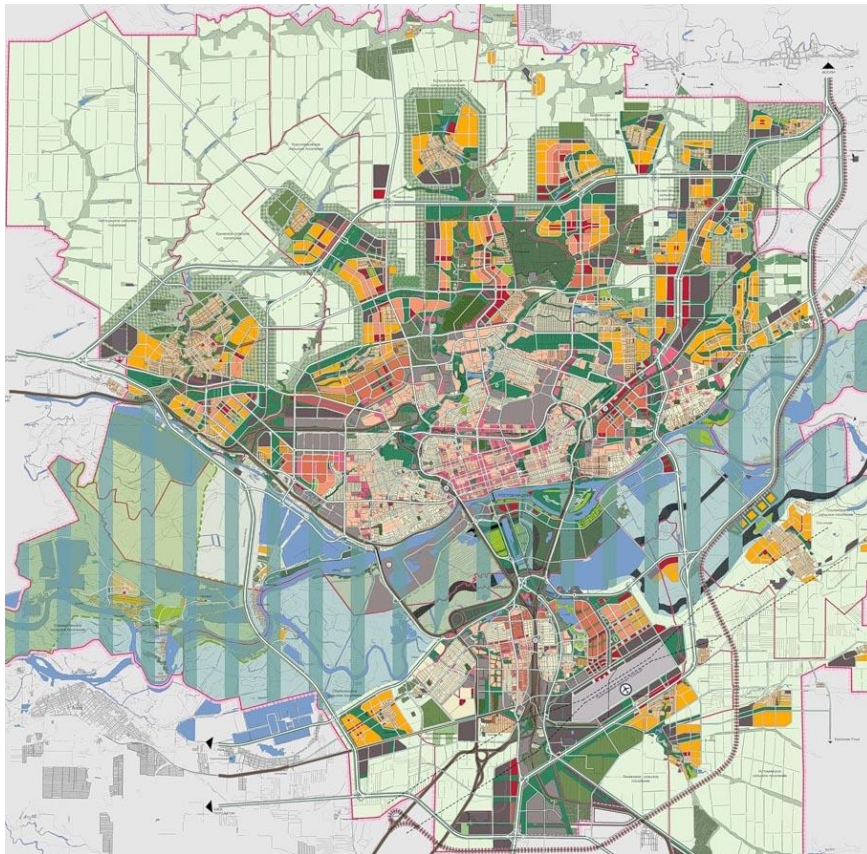
Rostov-on-Don has surpassed almost all host cites by the number of proposed infrastructural projects on the threshold of World Cup 2018: construction of the new metro line, a new airport, cable-way, of the northern bypass around the whole city, bridge reconstruction and of course the new stadium on the left bank of Don river. World championship will make a qualitative leap in the city's development. Moreover, this opportunity can be considered in the geopolitical competition in southern Russia. It is a chance to get ahead of Krasnodar (also was a candidate to host WC 2018 but lost) as a leading city in the region.


Fig. 2: Concept of the "Great Rostov" agglomeration

Investments in transportation network not only within the city but also in the adjacent municipalities will improve metropolitan planning structure of the "Great Rostov" and ensure the development of new "points of growth" for the harmonious territorial development. One of new focal points is the airport projected to the north-east from the city that can attract logistics and commercial development. Another one is a new stadium, whose active "life" would depend on the ongoing events.

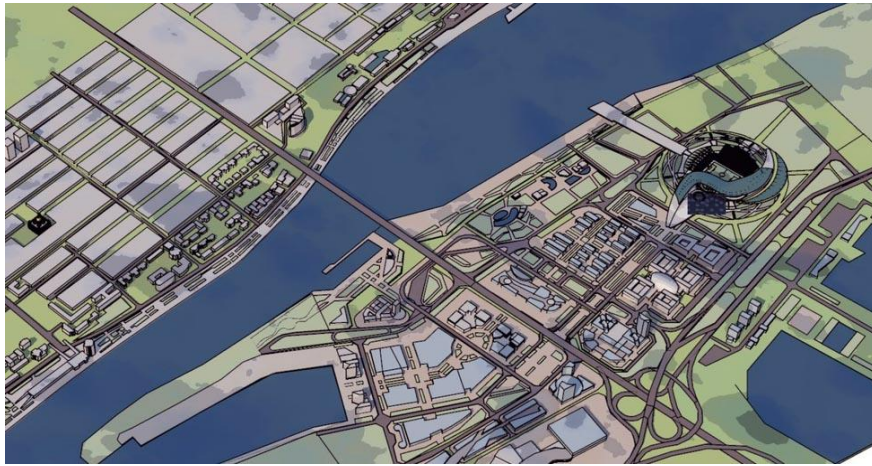
In case of successful "Great Rostov" development most of active functions related to business, sports and recreation will transfer to the left coast to create more balanced city's framework. At the same time challenges of the "Great Rostov" may face a various risks.


Fig. 2: 3-D model of new development around the stadium on the left bank of Don River

The left bank development conflict with the theory of a compact city and has a risk of limited connection between both sides of river by existing and planned bridges. Infrastructure development on the left bank may cause multi-stored economy class housing construction while most workplaces will remain on the right bank of the river.

Will "Great Rostov" slide to the notorious offering "affordable" housing in the new "active" areas, or the city can formulate the concept of a modern urban environment? What are the goals now and what is the vision? The question of urban policy focused on qualitative development remains open.

Globalization and Urban Land Use Planning: The Case of Lagos, Nigeria.

Leke Oduwaye

(Prof. Leke Oduwaye, Department of Urban and Regional Planning, University of Lagos, Akoka-Lagos, Nigeria, aoduwaaye@unilag.edu.ng)

1 ABSTRACT

Globalization and associated economic concepts are new directions of development raving the world. The concept will have enormous effects on all aspects of life ranging from economic, social, cultural and physical development of different regions of the world. It will however have more pronounced effects on large settlements especially in the cities. The mega-cities of the world of which Lagos is one will be influenced more than other categories of human settlements. This paper is a study of the emerging and potential effects of globalization on Lagos, the former Federal Capital of Nigeria until 1991 when the seat of national government was moved to Abuja in central part of Nigeria. Lagos is located along the Atlantic Ocean coastline in south-western part of Nigeria. It is also the most industrialized and the city with the highest population in Nigeria with a population of about 18 million on a built-up land area of about 22,000 Hectares. With the advent of globalization and privatization the land use system of Lagos has changed significantly, with the traditional land uses such as industrial premises reducing in floor areas, increase in religious land uses, public land use areas are reducing but with tremendous increase in commercial land use areas. Most of the commercial land use areas are in fragments and predominantly in form of small scale and informal commercial premises along major roads. The cityscape is engulfed with illegible streetscapes. This paper examines this physical growth trend of the city and offer explanation, upon which suggestions are offered on how to harmonize this changing city growth pattern with the advantages offered to human development by globalization.

2 INTRODUCTION

Most studies on urban land use planning are with emphasis mainly on city aesthetics administration, need for conservation and preservation of the city natural and cultural resources. Unfortunately there has been a dearth of research on the relationships between the city land use pattern and global economic policies. Among early studies on urban land use in Nigeria are the works of Falade and Kaigama (1992) who evaluated the urban landscape improvement strategy in Yola, Nigeria. The researchers investigated the contribution of the Yola Landscape Task Force (YLTF) to the improvement of Yola. Ademola's (2002) study was on the urban art aesthetics of Nigeria. He investigated the city as a work of art because like art it evolves as a means of enriching the quality of living by continually transforming the environment through creative organisation. Investigation of the outdoor communication media in Nigerian cities was carried out by Sheba (2002). The fact that the recent researches on urban structures in Nigeria have tended to dwell on the city aesthetics to the neglect of the economic forces shaping the city land use makes the need for an investigation on the economic variables influencing the city land use compelling.

Metropolitan Lagos is located in the southwestern part of Nigeria. It is the largest metropolitan area in Nigeria (Ayeni, 1979) consisting of 51 Local Government Areas. The Lagos Metropolis lies generally on low lands. Along the southern boundary of the study area is the Atlantic Ocean; in the west are Ojo and Ijanikin settlements. Lekki settlement forms the eastern boundary, while the northern boundary delineates the landmass of Ikorodu and Alagbado. The general structure of land use distribution shows that residential areas occupy the single largest proportion, 9,669 hectares (52.1 %), while commercial has 1,021 hectares (5.5 %), and industrial 1,448 hectares (7.8 %). Institutional and special uses constitute 2,784 hectares (14 %), transportation 3,340 hectares (18 %) and open spaces 520 hectares (2.8 %).

3 THE CONCEPT OF GLOBALISATION

Globalization is a concept which seeks to integrate various parts of the world into a global economic and global finance system has been a subject of considerable debate. The forging of a global economy is an intoxicating and momentous process, one of the major structural features of the contemporary age (Castells, 1992). The concept of globalization views the global economy as one, which works as a unit on real time on a plenary scale. It is an economic concept where capital flows, labour and commodity, markets, information, raw material, management and organization are internationalized and fully interdependent throughout the

planet. It corresponds to an attempt at contraction of space and time through development of new means of communication and information technologies across the planet (Hammouda, 2000). It is the process through which people, goods and services, trades, ideas and information flow across the borders of countries with ease (Asaju, 2002). Coincidentally urban planning is inescapably caught in this dynamics.

Globalization perceives the world as a trade unit without socio-political barriers and constraints. It is the process through which people; goods and services, trades, ideas and information flow across the borders of countries with ease (Asaju, 2002). This has been enhanced greatly by technological breakthroughs in the development of the computer and telecommunications. Globalization is characterized by liberalization of the world economies and economic activities to free them from institutional control and thereby foster and promote the free market mechanism, private enterprise, open competition, professionalism and excellence in corporate governance. It seeks to promote specialization and the principle of comparative advantage in the production of goods and services on a global scale. It is aimed at creating a new world economic order, efficiency, competitiveness, efficient allocations of resources, and speedy growth of the world economy. Generally the most pronounced effect of globalisation has been a shift in urban government policy from managerialism to enterpreneurism, which views the city as a product that should be marketed (Vliet, 2002). Therefore cities must appeal to global investors in urban planning. Unfortunately, cities that do not have the resources to attract outside interest and investment will even be more alienated and impoverished. Metropolitan areas such as Lagos arc the core areas for global competition; it is therefore necessary to strengthen them through greater authority and autonomy in land use resource allocation, through appropriate planning through innovative, more entrepreneurial and more participatory. Planning has a role to play by way of intervention, mediation and harmonization of the diverse interests attracted to the cities.

In the area of globalization little research work has been done in Nigeria. The little done so far has concentrated on the socio-economic dimensions of the concept. Since globalisation is implicated in the socio-economic variables of city development, economic variables it implied that globalization should have significant effects on the Lagos land use.

4 THE NATURE OF URBAN LAND USE PLANNING

Urban land use planning has a number of aspects which may be considered from different viewpoints. Therefore, any definition of planning that is adopted can only express one of the many aspects of planning activities. Planning is both a philosophy and a social technology; therefore it cannot be studied in isolation from other areas of social and pure sciences. Urban land use planning demands the study of variables representing different human efforts in achieving maximum opportunity for best biological and sociological environment for humanity. Its potential is a recurrent issue. The nature of problems confronting it is multi-disciplinary, thus to resolve these problems a multi-disciplinary approach is required (Oduwaye, 2006). It requires sharing of knowledge and skill on a scale which is still insufficiently appreciated. Planning as a discipline is a core area within overlapping fields of study. For example in the area of urban geography; planning inquires into spatial context while in urban economics and sociology the inquiry is non-spatial.

It is an attempt to reconcile the social and economic aims of private and public enterprises, Oia (1984), quoting from Keeble (1980) in "Principles and Practice of Physical Planning" defined physical planning as the act and science of controlling the use of land, the character and arrangement of buildings so as to achieve economy and secure convenience and beauty, Adeniyi (1978) defined physical planning as an act concerned with design, growth and management of physical environment in accordance with pre-determined and agreed policies whereby balanced social and economic objectives may be achieved. Planning is a science and art of movement of policies governing physical growth of towns. Generally, planning is traditionally concerned with the best use of land, maximum improvement of physical conditions that can be obtained within the limits of available resources, provision of beautiful and quality environment for habitation and conservation of natural resources, beauty, historical and architectural creations. These functions could be likened to the statement in Article II of the American Institute of Planners which describe the planning professionals sphere of activity as"... the planning of the unified development of urban communities and their environs and of the state, region and the nation as expressed through determination of the comprehensive arrangement of land uses and regulation thereof.

Urban planning, the object of discussion here involves the arrangement of spatial patterns overtime. Its fields impinge upon psychology, .scientific methods generally, upon general system theory, upon cybernetics, upon

operations research and logistics. Planning is future-oriented and thus optimistic, for it assures man's ability to control his own destiny, at least within certain limits. Planning involve man closeness with nature and with life. It is done by human beings for human beings. It is a human conception and seeks human decision and participation. The Nigerian Institute of Town Planners in her 1992 Information Handbook described town planning as an activity concerned with the spatial ordering of land use both in the urban and rural setting for the purpose of creating functionally efficient and aesthetically pleasing physical environment for living, working, circulation and recreation.

5   OBSTACLES TO FAR-REACHING ACHIEVEMENTS IN URBAN LAND USE PLANNING IN LAGOS.

Based on the level of urban planning in Nigeria, major obstacles confronting planning are discussed in this paper. First is ignorance on the part of government on the process involved in urban planning. This is fundamentally due to lack of plan upon which the environment should be managed. The use of plan as basic yardstick for planning has no alternative but this we have failed to accept. Towns and villages in Nigeria have no current master plan. Master plan will make the city efficient, increase economic viability, health, and build into it land use management strategies, it will draw up programmes to prevent flooding, embankment to protect flood plains, how to reduce ocean scourge among other issues on which government dissipate economic and financial resources (Oduwaye and Dekolo, 2005).

Political will on the part of the ruling class is a basic attitude for successful urban land use planning. Public ignorance and apathy are major obstacles' to the growth of urban planning awareness, protection and regeneration (Falade, 1999). Inadequate institutional frameworks, whereby there is over concentration of power in the hands of the federal government in determining the direction or evolution of policies for other levels of government is another problem. There is also multiplicity of agencies which most often degenerate into jurisdictional overlaps not only among the various levels of government but within the central government itself.

Non-implementation of existing planning laws to their fullest is another problem (Oduwaye and Ogundele, 2007). In many instances, existing laws are implemented based on how suitable they are to those who are in charge of their implementation at a particular point in time. Lack of equipment and fund is another problem. This is a recurrent problem in many areas of endeavor in Nigeria. Perhaps urban planning is having its own share of this national problem.

6   GLOBALISATION IN AFRICA AND SOME LESS DEVELOPED COUNTRIES

The global forces that impact upon African countries and cities have their origin in the historical relationships between the continent and the world economic system (Rakodi, 1997). This is further reinforced by the colonial control, which left an enduring political, economic and spatial legacy which influences city growth, administration and values. Despite these historical legacies, the global economic situation and globalisation in particular have started to evolve differential effects on African cities. Cities in Africa being relatively weak are unable to compete favourable with cities in developed countries in terms of productivity and foreign exchange capacities. As a result, indigenous people are unable to operate on large scale, and industrial capacity substantially weakened, forcing entrepreneurial migration to the service sector of importation of consumer products and retails sales. Africa generally exports mainly primary commodities, while a high proportion of manufactured goods are imported. This places Africa; development prospects at the mercy of the industrialized consumers of her primary export products. This reflects on the physical development of African cities. The dynamics of this economic influence on the city pattern have been documented in respect of Africa by O'Connor, (1983) and Simon (1997) and in the case of Latin America, Asia and the Caribbean by Potter (1993). European colonial influence was clearly of fundamental importance in this process, and especially in regions where decolonization is a recent event (Simon, 1997). It can be stated that the nature of urbanization in Africa has been strongly influenced by colonial policies. So also are the extent and dimensions of wealth or poverty, indebtedness or prosperity. The effect of this interplay of colonial and post-colonial experience in Africa is that Africa and in particular sub-Saharan African are rated as the world's poorest region. The rate of urbanization in sub-Saharan Africa in 1991 put at 31 percent was the least compared with other continents in the world, though there were considerable disparities among African countries.

The impact of globalisation on African cities has been examined by Rogerson (1995). He stated that most African cities have been left out of the globalisation process, the only notable exceptions being parts of North Africa and Mauritius. Effective participation in the globalised production system is determined by location and geopolitical significance, existence of strong and reliable state apparatus, technological and human resources, infrastructure and the ability of state to capture new opportunities. All these preconditions are not well established in sub-Saharan Africa. In the Arab world by the end of the twentieth century, five distinctive types of urbanization could be identified. The first class was the 'nouvcau riche' states which depended on oil exploitation such as Libya, Saudi Arabia, Bahrain, Qatar, Kuwait, the United Arab Emirate and Oman. These countries have about 90 per cent urban population largely due to high rate of immigration. However, cities in this region are mainly centres of consumption rather than production. About 75 per cent of employment in these states is in the service sector (Abu-Lugard, 1996). In Asia Indonesian economy initially depended on oil export. However, recent rapid expansions in manufacturing industries and large scale export of manufactured goods have had a profound effect on the level of spatial pattern of urbanization there (Hugo, 1991).

7   DISCUSSION OF FINDINGS

Despite remarkable history of planning laws and regulations from colonial period to the present time, coupled with appreciable public awareness on factors influencing land use in Lagos, yet Lagos presently lacks the basic conducive environment for globalisation to thrive. Lagos also lacks the competitive technology and human resource base necessary for a robust role in a globalised world. For Lagos, as for many cities in developing regions, the preconditions for global competition are unavailable. Such condition includes the capacity to develop "niche product", a capacity which requires flexibility in the production process. This can only be acquired through an appropriate organisational framework for technology and human resource.

Owing further to unstable and unreliable policy framework, poor state of infrastructure and security in Lagos, globalisation processes have been slow, with corresponding severe consequences for urban economies and environment. In terms of industrial investments and land use, Rakodi (1997) has noted that large foreign enterprises have continuously shunned Africa, with the result that while being devisely populated, African cities are not sufficiently industrialized. It is perhaps only the city of Johannesburg in South Africa that has any chance of attaining "world city" status in this decade (Rogerson, 1995). This derives in part from the city's conscious efforts at developing its financial and producer service sector; this also has to do with its interest in attracting offices of international organisations and developing a cultural strategy to image the city positively before foreign investors.

The formal economic sector in Lagos has been on a gradual decline due to need for restructuring created by globalisation. This is a common feature in sub-Saharan Africa, where regular urban wage employment opportunities constitute between 5-10 per cent of the urban work force (ILO, 1992). Recent studies show a decline from this range in Central African Republic (33.6 %) and Gambia (27 %). Similarly, formal wage employment in the public sector of these countries has been on the increase with massive retrenchments coupled with the declining absorptive capacity of the formal private sector. Abiodun (1997) has noted that at least 70 per cent of the unemployed in Lagos are aged between 15 and 29, while in Kenya according to House (1993), the age group mostly affected by unemployment fall between 20-29, or about 65 per cent of the unemployed.

Unfortunately for developing countries globalisation implies a new structure of global competition in a "global" market of "global" production complexes (Thirft, 1994). As a consequence, innovations in technology, such as micro-electronics, telecommunication, as well as other scientific discoveries are assuming even greater significance in world production systems than ever before. There has been tremendous growth in trans-national production and an increased openness and interdependence of national economies. Propelled by the momentum from advances in telecommunication and infrastructure, the total financial market has responded with a great leap forward. This can easily be noticed in Lagos where investment of trans-national companies particularly in telecommunication and transportation has positively impacted on, the Lagos urban economy and individual enterprises alike. At the national level the impact is evident in the intensification of international and local competition for markets and investments. It is also seen in the increase in the rate of employment into these new sectors. At the enterprises level, it has opened

up the need for adoption of new process technologies, a dynamic working system, and a shift towards flexible rather than mass production system.

The effects of globalisation on Lagos land use come as a mixed bag of positive and negative results. However, since it is a global trend it is better for Lagos to be well positioned to participate in it. Lagos within the context of African and particularly West African frame of reference is a leading city, which stands to benefit in the unfolding competition process through efficiency and job creation. Indeed, many cities in developing countries will be left out of the globalisation train because of their non-competitive status relative to their counterparts in the developed world. Naturally, this would affect development in the less developed regions negatively. The new character of international labour as a dichotomized realm of exporting and manufacturing economies means that the export oriented third world economies might increasingly be alienated in terms of industrialization. A further consequence of this would be the gradual depiction of industrial production land uses, import dependency of consumer nations of developing economies, and of course the dangerous socio-economic crises that possibly will result in future.

Specifically, the most noticeable effect of globalisation within Lagos cityscape is the radical shift in the land use pattern. The high dependency of the city economy on imported consumer goods, has led to a massive depletion, within a decade, of industrial enterprises with its attendant erosion of job opportunities. While industrial land uses are decreasing however, alternative uses, chief among which are religious in nature, are rapidly taking the place of industries, churches especially are in the forefront. It is thus a common phenomenon to see churches occupying entirely an area hitherto used as factory or partially occupying a significant portion of such premises. Such religious places have their peculiar complementary accompaniments such as weekly heavy traffic. Many commercial premises in different parts of the city have also given way to religious land uses. The reason for this is that churches seems in the prevailing circumstances, to be the land use capable of affording the rents demanded by property owners, the service sector having been economically weakened as it were, by forces of globalisation. This phenomenon can be described as change of use of existing buildings.

Change of use of existing land use zoning plan is also a common feature. The city landscape is now dotted with uncomplimentary land uses in many areas. This is common with uses such as multi-storey office blocks within residential neighbourhoods. This is contrary to basic urban land use theories, which discourage intrusion into the privacy of residential areas. This aside from being an intrusion in household's privacy is also a security risk. The heavy traffic which accompanies such invasion also violates residential neighbourhoods. Aside from multi-storey within residential areas, petrol filling stations and fast food outlets are other common infractions observable within the Lagos cityscape.

With the decline in the formal sector of industrial and formal service industries, the informal sector has emerged as the dominant feature of the city land use. Usually in the form of scattered small-scale service points. The bulk of the informal sector usually operates along major roads and within neighbourhoods. This sector has also assumed the services formally provided by supermarkets, furniture sales shops, electronic stores, hardware shops etc, following the demise of the formal sector, which these units of business were a part. It is important to reiterate here that the collapse of these formal service units is due to globalisation, which has eroded local industries, which used to produce the goods sold at these shops but which can no longer do so because of their non-competitiveness within a globalized economy. Since the informal sector can afford to offer similar services at lower prices made possible by relative lower overheads, of the doubtful quality of the goods, they become the only available avenues for consumers, even at the risk. The Lagos streetscape is dotted with small scale sales shops and points offering a wide range of services from household items, electronics, furniture, hardware, to cobbling, packaging and sundry cottage manufacturing industries. In the market sector, hawking, itinerant salesmanship and home trading thrive while in the service sector, catering, telephony service, hair-care, vulcanizing, motor mechanic etc dominate. The city landscape is in fragments of dirty production and service points with no regard for land use zoning.

Another major noticeable feature (on the positive side) induced by globalisation in Lagos is the emergence of trans-national companies especially in the area of telecommunication. Though some of the existing telecommunication companies are owned by Nigerians, their operations basically depend on the global network. With the liberalization of the telecommunication industry in Nigeria there has been a tremendous inflow of capital and services into Nigeria. The teledensity of the country and most especially of urban

centres has increased immensely from the situation prior to the telecommunication liberalization era. This has brought with it largely positive multidimensional effects, the most striking of which is the emergence of new employment opportunities. These opportunities within these telecommunication firms have activated a multiplier effect on other informal outlets in the form of outlets for sale of telecommunication components such as telephone handsets, batteries, among other components. It has also stimulated activity in the technical area of repairs, installations and sundry services.

The city has been significantly transformed by the installation, erection and conversion of existing buildings to fit into the new use of these global enterprises. This is more pronounced in the telecommunication sub sector where giant billboards are now corporate status symbols. This has generated bandwagon effects on other sectors by way of sharpening their sense of outdoor advertisement. Because these activities take place in space and specific locations, they have consequently contributed in opening up of hitherto undeveloped areas in the city. Inflow of capital into the country to support these services have been chiefly from foreign investors who possess the technology and the hard currency to make the desired impact on an increasingly reinvigorated domestic economy of towns and cities in Nigeria particularly Lagos.

8 RECOMMENDATIONS TOWARDS SUSTAINABLE LAND USE PLANNING IN LAGOS

Until recently, much of the development planning efforts in Nigerian rest largely on economic planning with very little regard to the implications of economic and social policies on physical planning (Adeniji, 1998). For few towns with master plans to guide their development there has been insignificant citizen involvement in the mist of rapidly changing socio-economic circumstances, thus making it extremely difficult to achieve the provisions of such plans. The results of this are settlements based on unsustainable yardsticks. This call for a more dynamic approach which will not only be the use of the plan-design but with adequate support of appropriate management strategies, such approach should be derived from the unique local situation from the area concerned. Based on this, the paper suggests the need to give consideration to the following in the attempt to achieve sustainable land use development in Lagos, in the era of globalization.

An area where a major effort has been made in the Lagos land use legislations is on provisions for public participation. What is presently lacking in that the public is not aware of these provisions. In order to benefit from the laudable efforts of governments through the various existing laws put in place to guide sustainable environmental development in general and enhancement of citizen participation, there is need to promote active participation of community leaders and planning advocacy practice.

There is no doubt that information revolution is sweeping across the globe. This will determine not only the way cities are managed but now they will proper and grow. Cities without the ability to cope with the modern age information system are destined to fall hopelessly behind and doomed to fail in an increasingly competitive world. This has serious implication on the growing information gap, between the "information rich" and the "information poor" nations. Access to information technology is important not only on how a city is managed but it is important on how local leaders communicate with their constituents. Lagos information strategies for development in the new global system must emphasize their connectivity, their information capacity and their ability to manage social integration. Cities switched-off the global information network system will be marginalized and ultimately impoverished.

Specific programmes such as "right to quality environment campaign" should be initiated at all levels of government to emphasis that quality environment is a right along with food, education, clothing and employment. Children environmental issue programmes and exhibitions in schools should be encouraged to tailor the minds of the children to their critical role in identifying solutions to environmental problems, thus influencing their development as they are highly vulnerable.

The concept of advocacy in planning should be given consideration in Lagos physical planning efforts especially through the formation of partnership by multidisciplinary group such as the town-planners, architects, surveyors and the lawyers coming together to form environmental advocate groups and consultants. This could also be done in form of non-governmental associations. Among the major merits of the advocacy planning concept are availability of richer ranges of plans, exposing government planners to expert criticisms, aiding the disadvantaged, education of the client and the government on planning. The politicians should be encourage by advocate group as the former could serve as invaluable planning agent because they form the bulk of representatives of the community at all levels of government decision making.

Thus, they are vital tools as advisers and presenters of planning information. Advocacy groups should also organize talk-shops with interests groups such as market women, drivers union, and other trade groups across the strata of the society during which people are to be educated about their roles, opportunities and how to contribute to make the environment livable. There is need to integrate the effort of theorist, government officials, private practitioners and private managers. These sectors will require a meeting point to exchange ideas. The thinkers whose theories are providing the intellectual brain for environmental planning and the investors whose investment affect and propel development should share ideas.

The process of capacity building should involve human resources development and institutional development in the area of urban governance, integrated environmental planning and management, awareness and involvement of local communities, promoting partnerships, capacity building of actors and stakeholders and replication of best practices. Also in order to make planning proposal acceptable to the people and carry them along it should be recognized that different environment are structurally different and cannot accommodate standardized formula or rigid methodologies.

A major step toward achievement of sustainable development in Lagos is the organization of sustainable practice exhibition through joint cooperation of the private sector and all levels of government. The exhibition will involve the identification, documentation and dissemination of best practices. Such best practice may be inform of actors initiatives or-projects that have led to tangible improvements in the quality of live and the living environments of the people in a sustainable way. Such exhibition will expose physical planning managers and communities to actors in other communities outside their areas and from this they will have opportunities to draw from such programmes that could be applied or adapted into their own communities.

There is need to identify and celebrate best practices in planning. This could be spearheaded by the Nigerian Institute of Town Planners in collaboration with allied professional groups and organizations. Also higher educational institutions may be in position as part of the organizers but the problem is that they too could be given awards in their area of planning practice which is teaching, research and publication. Such award should cut across many areas such as the best consultant of the year in environmental planning, best project proposal, best advocacy group, best government agency, best friendly environment, best sustainable environment, best new neighbourhood etc. This will go a long way in stimulating positive competition among players in the environmental planning within Lagos State.

To achieve, the basic aim of sustainable physical development in Nigeria the planning approval (permit) stage is a major determinant of the prospects of the environment. Though this has recently been termed planning permit; whereas the actual demand of the complex situation is that of management of planning approval or project for which permits are obtained since the planning permit is not the end in itself. It must be seen within the context of managing change in order to achieve the greatest benefit. Therefore the signifier of this new thinking is that development control (permit) should be changed and practiced as "development management". This should be supported with the adoption of the new practices that this change implies.

Land information is a critical element towards achieving sustainable physical environment; therefore there is need for free access to land information by the public at the touch of a computer button. This will provide invaluable information that will guide individuals, consultants, government and all stakeholders in environment planning and development. Like the Portal Planning merit, it will also eliminate human problems especially misinformation, delay and corruption.

9   CONCLUSION

This paper has presented the unfolding consequences of globalization on the land use fortune of Lagos. This has been done with emphasis on the influence of economic factors and policies on the structure and pattern of the city. It also presented the relationships between physical planning, the need for sustainable development and how appropriate planning can be used to enhance development. The paper present suggestions that will ameliorate the challenges unraveled.

Governance in the Metropolitan Region: The Vienna-Bratislava Case

Daniela Patti

(Daniela Patti, CEIT Alanova, Schwechat, Austria, d.patti@ceit.at)

1 ABSTRACT

The discrepancy between the de facto city and the de jure city has brought to the attention the pressing issue of metropolitan governance, either by instituting a specific body responsible for the whole territory or by strengthening cooperation among existing institutions.

The latter is currently the most preferred because of its flexibility and reduced operational costs, but how easy is it to implement?

The case of the Vienna-Bratislava metropolitan region, illustrates a particularly challenging example because of its cross-border condition, with no institution solely responsible for the management of the territory.

2 INTRODUCTION

It is widely known that 75 % of the population in Europe live in cities and that these have now sprawled beyond their administrative boundaries (EEA, 2006).

However, what is less known is that the new urban form that has been shaped, known also as peri-urban,[1] today nearly matches the surface of urban areas, with 48,000 km² against 49,000 km² (Piorr, 2011), which thus makes it at least statistically relevant.

This is why territorial cohesion, especially at the metropolitan level, has been strongly promoted by the European Commission from the European Spatial Development Perspective (1999) to the Territorial Agenda (2011). Cities need to look beyond their boundaries and towards their functional areas, cooperating with their neighbouring municipalities.

Metropolitan governance has therefore gained more importance over the past years, especially when having to manage projects of great interest to all parties, such as infrastructures (Forum of Federations and Committee of Regions, 2011).

But how does cooperation among municipalities work in metropolitan regions?

A very particular case in Europe is that of the Vienna-Bratislava region, a recently developed two-headed cross-border metropolitan system (Brzica, 2009), which covers 2 countries with 2 languages and 4 different spatial planning laws (Slovak, Viennese, Lower Austrian and Burgenland).[2]

But here is the big challenge: there is no sole institution managing this territory.

There is rather a 'Russian Doll' system of institutions responsible only for portions of the region and with different tools at their disposal for its management (STEP, 2005).

The paper will briefly outline some aspects of the current debate around governance; present an overview of the governance bodies acting on the territory and explain their competence and planning tools; conclude with considerations on the effects of metropolitan governance on the territory.

3 ABOUT META-GOVERNANCE AND GOVERNANCE

Governance can be so called when there is "interdependence between organisations; continuing interactions between network members; game-like interactions, rooted in trust and regulated by rules of the game negotiated and agreed by network participants; a significant degree of autonomy from the state" (Rhodes, 1997).

The European Commission's white paper on governance adds an additional perspective, promoting principles such as openness, participation, accountability, effectiveness and coherence (CEC, 2001).

---

[1] Various European studies have researched upon the definition and functioning of peri-urban areas, that we can therefore define as the territory part of the Functional Urban Area (considered mainly on the basis of the commuter area) without the Urban Core, with an average population of 40 persons per km².

[2] It needs to be clarified that the Vienna-Bratislava region includes also part of Hungary, but there is currently no relevant cooperation and therefore little available data. For these reasons the article will not include the Hungarian part in the description.

Therefore when looking into governance there are a series of stakeholders involved from public to private that are organised in a manner that takes the form of networks, defined by Sørensen & Torfing (2009, p. 236) as "a stable articulation of mutually dependent, but operationally autonomous actors from state, market and civic society, who interact through conflict-ridden negotiations that take place within an institutionalised framework of rules, norms, shared knowledge and social imaginaries; and contribute to the production of 'public value' in a broad sense of problem definitions, vision, ideas, plans and concrete regulations that are deemed relevant to broad sections of the population."

Although there is a degree of spontaneity in the governance processes that is usually given by the contingency that brings the actors round the same table, this is also fostered by a framework of policies and financial mechanisms often referred to as 'metagovernance'. According to Sørensen (2006) this must allow coordination, coherence and integration within the fragmentation of structures of governance allowing at the same time its autonomy and self-regulation.

Metagovernance can take mainly four forms, one consisting of the framework of policies, goals and financial mechanisms, therefore how; it can consist in the design of the actors' network, therefore who; it can define the management of tensions within the network or it can consist of network participation, where planners and politicians directly influence the decision making.

What we can see is that complexity science enters the decision making processes, developing what Innes and Boheer (2010) call 'collaborative rationality': "The complexity and rapid change in contemporary society have created an increasing awareness among policy leaders of the limits to hierarchical control by government agencies and to formal expertise in solving problems. This awareness leads to growing uncertainty about policy and a new focus on the need to manage uncertainty, rather than create programs and regulatory regimes that deny its existence. As society has become more culturally diverse, decision makers have to deal with an array of publics with different values, perspectives, cognitive styles and worldviews. Complexity is also reflected in growing interdependence among government players, as agencies find they cannot be successful, even on their own limited agendas if they continue to work unilaterally."

This opens also some reflection on the sustainability and resilience of decision making, no longer to be seen as end products but rather as an ongoing process.

How does this theory translate into practice?

4 THE METROPOLITAN GOVERNANCE BODIES IN THE REGION

The Vienna-Bratislava Region has been recognised as a functional entity by the European Union and studies from the OECD have been available for various years (Schremmer, 2003).

Now the two cities create a functional metropolitan region with 3.5 million inhabitants that, as both Austria and Slovakia are part of the European Union, is connected by labour market, housing and transport corridors. Although the cross-border collaborations are growing in number there still is no institution responsible for the coordination of the metropolitan region.

The challenge is that although the area works as a metropolitan region, the governance structures are not still too fragmented to coordinate actions easily.

The Region is characterised by different Länder on the Austrian side, each one having a different Urban Planning Law (Vienna, Lower Austria and Burgenland) and Bratislava following the Slovak Urban Planning Law.

Many super-national initiatives are active on the territory yet none of them have binding decisional power. Among the most relevant are:

- the Centrope Initiative[3] which brings together eight federal provinces, regions and counties that make up the Central European Region, with 6,5 million inhabitants.
- the PGO (Planungsgemeinschaft Ost)[4] is an organization for the administration of Burgenland, Lower Austria and Vienna to coordinate the preparation of regional planning issues, also in cross-border activities and regional networks.

---

[3] For further information on the Centrope Initiative : www.centrope.com

- the Danube Strategy[5] interests 14 countries in the river basin area relating to topics from transport and environment to society and culture, without financial support.

Although these are all very important initiatives, they do not directly intervene in the decision making of the land uses destined for the metropolitan region.

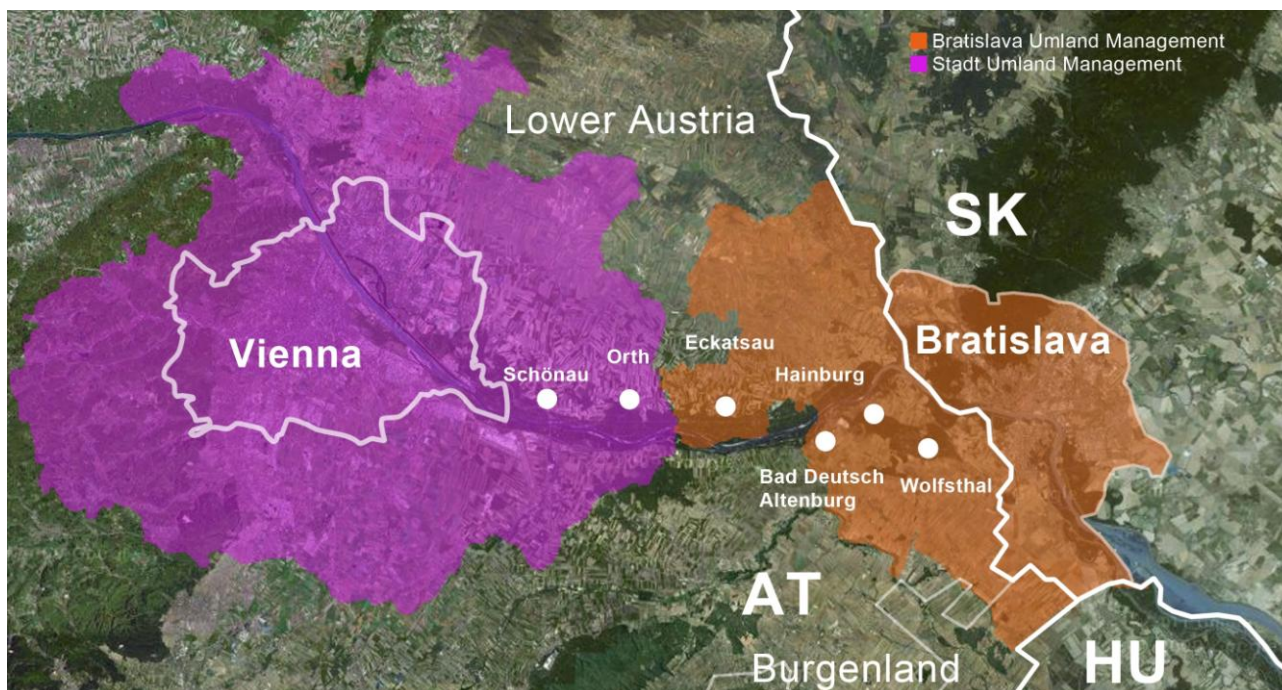
Very relevant initiatives in the coordination of actions in the metropolitan region are the Stadt Umland Management (SUM), an association of Municipalities of the Vienna Metropolitan Area, and the Bratislava Umland Management (BAUM), recently developed on the blueprint of the SUM, which is financed by a European cross-border program (Creating the Future), including Bratislava and the Austrian municipalities close to the border.


Image 1: The areas of influence of SUM and BAUM. Source: Image made by the author

Both SUM and BAUM are associations of the municipalities of the region that also include other relevant actors on their boards. They do not have budgets to enable the funding of projects in the Region nor do they have binding instruments that can enforce decisions, but rather they are responsible for the moderation and communication amongst institutions, mainly concerning projects such as transport infrastructures, water management and ecological corridors.

(a) SUM (Stadt Umland Management)[6]

Austria is a federation of States (Länder) of which Vienna is one of them and is surrounded by the Land of Lower Austria, each having a different Urban Planning Law. The city of Vienna, therefore, has the dual status of being a city and a State at the same time, but the functional area of the city goes beyond the administrative borders and covers parts of Lower Austria, especially in the southern part.

In Austria municipalities have to manage their planning activities, therefore each one of the approximately 100 municipalities surrounding the city of Vienna is responsible for their own plan.

Vienna and the municipalities of Lower Austria do not have a common inter-municipal planning body due to political reasons, economic prosperity and rivalry between the city and the suburban area. Regional planning and planning between the city of Vienna and the municipalities of Lower Austria is mainly based on single projects.

In 2006 an association was founded between the City and Land of Vienna and the Land of Lower Austria, whose jurisdiction would involve ensuring communication and coordination among the various institutions.

---

[4] For further information on the PGO: www.pgo.wien.at

[5] For further information on the Danube Strategy : www.danube-region.eu

[6] For further information on the Stadt Umland Management: www.stadt-umland.at

One may assume that this would end up being a large bureaucratic machine, but this is not the case, as SUM is formed by two people, one in charge of the northern part and one of the southern one.

SUM has no decision power as such, as funding coming equally from Vienna and Lower Austria covers maintenance expenses, but influences the process because of its communication facilitator's role in priorities recognised by involved partners, mainly being transport and environmental issues.

There are no planning tools for the SUM as it is an association, a network that is based on the skills of those people involved.

As SUM is initiated by Länder it can support planning issues that are under their competence, and not on land use for example, which is under municipalities. Though related to this scale is a tool that has been recently introduced with great involvement also by SUM: the Landschaftskonto. This is a planning tool for environmental compensation, based on the German instrument of the Ökokonto, and uses a system where municipalities can collect points according to environmentally sustainable projects they carry out (creating a park for example) that can then be exchanged also with other municipalities to compensate projects with a higher environmental impact (such as a housing project).

The durability of this initiative currently seems to be stable but the fragility of this system stands in the dependency on political will and personal capacities of those people involved.

(b) BAUM (Bratislava Umland Management)[7]

The Bratislava Umland Management is an EU funded project that involves the city of Bratislava, the Regional Management of Lower Austria and the Regional Management of Burgenland, which over a period of two years (2011-2013) aims at developing a Multilateral Expert Platform that will prepare an Urban and Regional Planning Concept.

The project is the current result of a need for cooperation and coordination among municipalities across the border that has developed since the fall of the Iron Curtain and first took shape in the Jordes+ project[8] between 2002 and 2004, then the KoBra project from 2003 to 2007 and now the BAUM project.

What is interesting about the evolution of these projects is that the city of Bratislava became more and more involved in them up until today where it is the Project's Lead Partner.

In fact, the Jordes+ project included a very vast area which is more or less the one of the Centrope initiative, whilst the KoBra project, which stands for Cooperation Bratislava, was a project that included various Austrian municipalities along the border but strangely enough only involved the City of Bratislava in a very limited way (Schaffer, 2008).

The project KoBra was started as a form of institutional cooperation among Austrian municipalities from different Länder but did not manage to really communicate nor establish a cross-border collaboration as the current project BAUM is doing.

Although the BAUM project is still not completed it is already possible to see some strategies being implemented.

The Multilateral Expert Forum, composed by representatives of the regions from Austria and Slovakia, has already had a series of meetings that have up to now focused on the development of the Urban Planning Study and will be assessed in the closing phase of the project (BAUM, 2011).

This study includes comprehensive aims and targets agreed upon by both sides for issues concerning transport, water management, landscape protection and cultural heritage.

The value of BAUM lies in the fact that it is bringing round the same table institutions for the metropolitan region of Bratislava but its durability is only granted until the end of the EU financing unless the actors decide to build a more permanent structure at their own expense.

Both SUM and BAUM communicate with one another as they have representatives on one another's boards, but there is no official collaboration agreement among them nor is the coordination of the whole area one of their aims.

---

5 CONCLUSIONS

In the case of the Vienna-Bratislava metropolitan region we can see that the network governance is still at an initial phase, often facing problems due to budget and communication among stakeholders, but nonetheless it must be also noted that this symbolises a great advancement in order to dim the traces of the Iron Curtain.

This is in fact an interesting governance condition as in the past century the geo-political relationship between the two cities has changed radically, from the times of the Austro-Hungarian Empire, where the two cities were governed under the same legislation but playing very different geopolitical roles, to the independence of Czechoslovakia after WWI, from the rise and fall of the Iron Curtain; from 1993, following the Velvet Divorce, when Bratislava became the capital of the newly formed State of Slovakia to the entry in the European Union; from the entry in the Shenghen area until today, when they are a functional metropolitan region.

If 'collaborative rationality' gives much value to the interaction among individuals, being that the more these are linked by various networks, the more they will be able to combine various interests, in can be noted that both SUM and BAUM are based on a collaborative model, but they still do not cover the whole metropolitan region.

Will there be a joint project in the coming years between SUM and BAUM?

1 KURZFASSUNG

Transformationsprozesse zu Smart Cities können nur mit dem Wissen um ihre spezifischen soziodemographischen Rahmenbedingungen, welche eine Leitlinie für die zu setzenden Maßnahmen darstellen können, einhergehen. Veränderungen in der demographischen Struktur und daraus resultierende Veränderungen der Nutzerinnen- und Nutzerzahlen und des Nutzungsverhaltens erfordern differenzierte Handlungsstrategien sowohl für das Re-Design von städtischen Strukturen als auch zur Implementierung von Smart-City-Maßnahmen. Gleichzeitig sind multiple Akteurinnen und Akteure und Stakeholder (z.B. Gemeinden, Planerinnen, Planer, Politikerinnen, Politiker, Verkehrsunternehmen, Ver- und Entsorgung) in diese Planungsprozesse und institutionelle Designs eingebunden, welche durch hohe Komplexität und Unsicherheit charakterisiert sind (vgl. de Roo et al, 2012). Ziel des Forschungsprojekts DemoSmart[1] war spezifisches Wissen für diese Akteurinnen und Akteure über den aktuellen Status und die Entwicklung von Stadttypen auf Basis ihrer aktuellen soziodemographischen Struktur und einer erwartbaren Entwicklung bereitzustellen. Für die unterschiedlichen Stadttypen wurden spezifische, adäquate Maßnahmen für Transformationsprozesse zu Smart Cities entwickelt.

2 AUSGANGSLAGE, ZIELE UND METHODE

2.1 Ausgangslage und Ziele

70 % der Europäerinnen und Europäer leben in Städten (vgl. Europäische Komission, 2011). Gleichzeitig verbrauchen auf globaler Ebene jene Städte 80 % der gesamten produzierten Energie und sind auch die größten Emittenten (vgl. OECD, 2010). Daher wird vor allem der Stadtplanung großes Potential für die Reduktion der negativen Auswirkungen des Klimawandels und Ressourcenknappheit im Kontext mit demographischem Wandel zugeschrieben. Innovative Lösungsansätze werden immer öfter mit dem Begriff Smart City in Verbindung gebracht, dessen Ausgangsidee auf der Annahme basierte, dass für die Effizienz von Städten nicht nur harte Infrastruktur, sondern auch die Verfügbarkeit und Qualität von Kommunikations- und sozialen Infrastrukturen eine Rolle spielt. (Vgl. Wiener Stadtwerke, 2011)

Gleichzeitig unterliegen Städte wesentlichen Veränderungen der Bevölkerungsstruktur, welche durch Wanderungsbewegungen bedingt sind und sich durch das Wachsen von Zentralräumen und das Stagnieren oder Schrumpfen von ländlichen Räumen äußern. Andererseits sind auch die Änderungen in der Altersstruktur der Bevölkerung wesentlich, die eine Vielzahl von Ursachen, wie beispielsweise den Rückgang der Geburten oder die zunehmende Lebenserwartung haben. Der soziodemographische Wandel und ein erwartbarer Anstieg des Durchschnittalters auf > 65 Jahren im Jahr 2030 (vgl. Proske, 2011; Statistik Austria, 2012) haben insbesondere Auswirkungen auf das Mobilitätsverhalten, die Entwicklung der Wohnformen, Energie, Ver- und Entsorgung und IKT. Aus diesen Rahmenbedingungen lassen sich folgende Forschungsfragen im Smart-City Kontext ableiten:

In welche Stadttypen lassen sich österreichische Städte anhand ihrer aktuellen und zukünftigen demografischen Entwicklung differenzieren?

Welche Maßnahmen sind für solche Stadttypen adäquat, um in Abhängigkeit von demografischer Entwicklung und Stadtgröße die Entwicklung in Richtung Smart City zu forcieren?

---

[1] Das Forschungsprojekt „DEMOSMART – Sociodemographic change and the dynamics of Austrian Smart Cities" wurde durch den österreichischen Klima- und Energiefonds in der Programmlinie Smart Energy Demo – FIT4SET mit den Mitteln des Bundesministeriums für Verkehr, Innovation und Technologie beauftragt.

2.2 Methodischer Zugang

Das Forschungsprojekt behandelt die Komplexität des Themas im Rahmen eines interdisziplinären Multimethodenansatzes, Einerseits wurden 78 österreichische Städte mittels einer statistischen Korrelationsanalyse typisiert. Das Sample umfasst alle Städte mit mehr als 10.000 Einwohnerinnen und Einwohnern, wobei Wien, als Extremwert, in die Analyse nicht integriert wurde. Um eine zeitliche Dimension in die Arbeit zu integrieren als auch um Stagnations- und Schrumpfungsprozesse abbilden zu können wurde der zeitliche Rahmen bis zur Volkszählung im Jahr 1971 aufgespannt und alle Städte, die in dieser Periode einmal den Wert von 10.000 Einwohnerinnen und Einwohnern überschritten, in die Stichprobe integriert. Ergebnis der Korrelationsdanalyse sind fünf Stadttypen. Die Nachfrageseite unter Bezugnahme auf das voraussichtliche zukünftige Nutzerinnen- und Nutzerverhalten wurde mittels einer qualitativen Delphi-Befragung bearbeitet. Von Expertinnen und Experten wurden Maßnahmen vorgeschlagen und anschließend bewertet, die eine Entwicklung in Richtung Smart City für die jeweiligen Stadttypen begünstigen (76 Expertinnen- und Expertenbefragungen, zwei Durchläufe). Diese Analyse wurde durch ein Literaturstudium ergänzt und in Smart-City-Handlungsoptionen für spezifische Städte verdichtet.

3 DEMOSMART

3.1 Demographische Typologie österreichischer Städte

Aus der Korrelationsanalyse kristallisierten sich drei Faktoren heraus, auf Basis derer fünf demographische Stadttypen für Österreich ermittelt wurden. Einer dieser Faktoren ist die Bevölkerungsdynamik, für die der Indikator der Bevölkerungsentwicklung von 2001 bis 2011 verwendet wurde. Als zweite wichtige Größe gilt die Bevölkerungszahl („kritische Masse"), für die die Absolutbevölkerung 2011 als Indikator verwendet wurde. Die Bedeutung dieses Kriteriums ergibt sich insbesondere daraus, dass viele Smart-City-Technologien erst ab einer bestimmten Stadtgröße wirtschaftlich zum Einsatz kommen können. Die Altersstruktur ist die dritte wichtige Funktion, für die der Anteil der über 60 Jährigen als Indikator gewählt wurde. Dieses Kriterium ist vor allem für Fragestellungen wie Technikaffinität, Mobilität und soziale Infrastruktur von Bedeutung.

Tabelle 1: Übersicht über Indikatoren und Schwellenwerte für die Stadttypologie (Darstellung: ÖIR)

Stadttyp	Merkmale	Städte (exemplarisch)
Wachsende größere Stadt (16 %)	Geringer Anteil an Personen älter als 45 Jahre Überproportionales Wachstum der Gruppe von Personen jünger als 45 Jahre Hohe Mobilität (Umzüge) zwischen den Städten und hoher Anteil an Singlehaushalte Hoher Anteil an nicht in Österreich geborener Personen	Graz Salzburg Innsbruck Stadtregion Rheintal
Wachsende junge, kleine bis mittlere Stadt (44 %)	Junge Bevölkerung; geringer Anteil der Bevölkerungsgruppe älter als 60 Jahre Überproportional starkes Wachstum der Beölkerungsgruppe jünger als 45 Jahre	Bischofshofen Wörgl Marchtrenk

	Hoher Anteil nicht in Österreich geborener Personen	
	Vergleichsweiser geringer Frauenanteil bei gleichzeitig hohem Anteil an weiblicher Erwerbstätigkeit	
Wachsende ältere, kleine bis mittlere Stadt (9 %)	Hoher Anteil der Bevölkerungsgruppe älter als 60 Jahre und Personen die nicht mehr im Erwerbsprozess stehen (Pesionistinnen und Pesionisten)	Klosterneuburg
		Krems
	Unterdurchschnittlicher Anteil an Erwerbspersonen	Baden
	Überdurchschnittlich hoher Anteil an Frauen bei gleichzeitig geringem Anteil von Frauen im Erwerbsprozess	Bad Vöslau
	Hoher Anteil an Singlehaushalten	
Stagnierende kleine bis mittlere Stadt (16 %)	Sehr geringer Anteil der Bevölkerungsgruppe jünger als 45 Jahre	Steyr
		Kapfenberg
	Hoher Anteil an Personen im Pensionsalter	Spittal an der Drau
	Starker Rückgang junger Bevölkerung	
	Geringer Anteil an Personen geboren in EWR Staaten und relativ geringer Anteil an in Drittstaaten geobrenen Personen	Baunau am Inn
Schrumpfende kleine bis mittlere Stadt (15 %)	Signifikant geringer Anteil der Bevölkerungsgruppe jünger als 50 Jahre	Leoben
		Eisenerz
	Hoher Anteil an Personen im Pensionsalter	Mürzzuschlag
	Starker Rückgang der Bevölkerungsruppe junger Personen	Zwettl
	Kaum Zuzug	Bruck/Mur
	Hoher Anteil an Personen die in Österreich geboren wurden	Judenburg

Tabelle 2: Charakterisierung der Stadtstrukturtypen auf Basis der Regressionanalyse (Quelle: ÖIR)

3.2 Maßnahmen für Transformationsprozesse zu Smart Cities

Aufbauend auf den unterschiedlichen Stadttypen wurden auf Basis der Delphi-Befragung, internationaler Best-Practise-Beispiele und von Literatur Maßnahmen für die Entwicklung in Richtung Smart City formuliert. Diese Maßnahmensammlung gliedert sich in folgende Smart-City-Themenbereiche: Stadtentwicklung, Gebäude und Freiraum; Ver- und Entsorgung: Energie, Wasser, Abfall; Verkehr und Mobilität; Informations- und Kommunikationstechnologien. Die Maßnahmen wurden den Expertinnen und Experten zur Einschätzung und Bewertung vorgelegt. Dabei spielen folgende Bewertungsparameter bei der Argumentation eine Rolle.:

Die Umsetzung mancher Maßnahmen setzt eine kritische Masse hinsichtlich Nutzerinnen- und Nutzeranzahl und innovationsbereiter Personen voraus, dies wird durch die Einwohnerinnen- und Einwohnerzahl und -struktur beeinflusst. Hier wird der Begriff im Zusammenhang mit der Auslastung technischer Infrastruktur, beispielsweise des öffentlichen Verkehrs, verwendet. Falls eine kritische Masse potenzieller Nutzer- und Verbreiterinnen und Verbreiter unterschritten wird, ist eine Maßnahme möglicherweise nicht mehr wirtschaftlich rentabel oder umsetzbar. Eine kritische Masse an Nutzerinnen und Nutzern der öffentlichen Verkehrsangebote, welche nicht nur von der Einwohnerinnen- une Einwohnerzahl einer Stadt, sondern auch von der Alterszusammensetzung der Bevölkerung abhängt, ist somit eine wichtige Voraussetzung für die Wirtschaftlichkeit der Verkehrssysteme. Gerade in schrumpfenden Städten stellen bedarfsorientierte Verkehrsangebote (z. B Anrufsammeltaxi) daher eine wirtschaftliche Alternative zum Linienbetrieb in Zeiten schwacher Verkehrsnachfrage dar. Der zweite wichtige Bereich, in dem das Vorhandensein einer kritischen Masse von Bedeutung ist, ist die Verbreitung und Akzeptanz neuer Technologien und Innovationen. Nicht nur die Verbreitung neuer Technologien, sondern auch die Etablierung innovativer Mobilitäts-, Wohn oder Energiekonzepte bedürfen einer gewissen Akzeptanz und Nutzungsbereitschaft innerhalb der Gesellschaft. Eine gewisse Größe der Nutzerinnen- und Nutzergruppe und ein bestimmter

Bekanntheitsgrad, sind also wesentliche Voraussetzungen dafür, dass sich neue Technologien und Innovationen in den Bereich Mobilität, Wohnen, Energie und IKT am Markt durchsetzen können und wirtschaftlich sind (vgl. BMVIT, 2011). [2]

Neben der kritischen Masse, die von der Nutzerinnen- und Nutzeranzahl abhängt, spielt auch das Nutzerinnen- und Nutzerverhalten eine wichtige Rolle, welches maßgeblich durch die Altersstruktur bestimmt wird. Insbesondere die langfristige Investitionsbereitschaft aber auch die Nutzung moderner Technologien hängen vom Alter ab. So werden beispielsweise bestimmte IKT-Maßnahmen bei einem hohen Anteil betagter Bevölkerung weniger schnell greifen als bei einem hohen Anteil Jüngerer. Grundsätzlich gliedert sich das Nutzerinnen- und Nutzerverhalten in das kurzfristige Ver- und Gebrauchsverhalten und das langfristige Investitionsverhalten, welche das Kommunikations-, Einkaufs-, Konsum-, Entsorgungs-, sowie hier besonders das Mobilitäts- und Umweltverhalten umfassen.

In Ergänzung zu den beiden oben genannten Bewertungsparameter ist auch der Handlungsdruck einer Stadt, welcher von der Bevölkerungsdynamik bestimmt wird, zu berücksichtigen. In einer schrumpfenden Stadt ist beispielsweise ein größerer Handlungsdruck gegeben als in einer stagnierenden Stadt, auch schnell wachsende Städte weisen einen höheren Handlungsdruck auf. Generell ist der Handlungsdruck also in jenen Städten mit extremeren Werten im Bezug auf die Bevölkerungsdynamik größer, unabhängig davon, ob ein starkes Wachstum oder ein starker Rückgang zu verzeichnen ist.

Ergebnis der Analyse ist ein Demografie-Maßnahmen-Profil für jeden Stadttyp, das Handlungsempfehlungen als Grundlage zur Orientierung für eine Entwicklung in Richtung Smart City enthält.

Maßnahmenbündel	Maßnahmen	wachsende größere Stadt	wachsende junge kleine bis mittlere Stadt	Wachsende ältere kleine bis mittlere Stadt	Stagnierende kleine bis mittlere Stadt	schrumpfende kleine bis mittlere Stadt
I	Barrierefreiheit, Aufwertung und Gestaltung im Öffentlichen Raum (z.B. Straßenraumgetaltung mit Shared Space) und in Gebäuden	X	X	X	X	X
	Aufbau smarter Ver- und Entsorgungsnetze und Anpassung an geänderte Nachfrage	X	X	X	X	X
	Mischnutzungen im Quartier mit kurzen Wegen, soziale Infrastruktur und Versorgung der zukünftigen Nachfrage anpassen	X	X	X	X	X
	Erneuerbare Energien nutzen, Energetische Sanierung, Aufbau smarter Ver- und Entsorgungsnetze und Anpassung an die geänderte Nachfrage	X	X	X	X	.
	Neue Wohnformen (z. B. intergenerationelles Wohnen, Variabilität der Nutzung von Gebäuden, Alterungsfähigkeit von Gebäuden	X	X	X	X	X
II	Innovative Mobilitätslösungen: Sharing Systeme (z.B. Car sharing, Fahrradverleih), Mitfahrsysteme mit multimodalen Informations-, Buchungs- und Bezahlsystemen	X	X	.	.	.
	Systemintegration (z.B. Smart Grids)	X	X	.	.	.
	Web 2.0 für Beratung, Information und Partizipation zu kommunalen Themen (z. B. Wohnstandortwahl, Leerstandsbörse, Stadtinformation, E-Partizipation etc.),	X	X	.		
III	E-Government	X	X	X	.	.
	Multimodale Verknüpfungspunkte (z.B. Schnittstelle ÖV, Car Sharing)	X	X	X	.	.
	Nach- und Innenverdichtung von Siedlungen besonders an Haltepunkten des öffentlichen Verkehrs, flächensparender Neubau und ‚smartes Bauen'	X	X	X	.	.

[2] Gleichzeitig gilt es hier auch anzumerken, dass es vor allem im Bereich der Beteiligung und Partizipation von Nutzerinnen und Nutzer Smart-City-Maßnahmen gibt, die für die erfolgreiche Umsetzung eine kritische Masse hinsichtlich der Höchstzahl an Nutzerinnen und Nutzern haben z. B. Arbeitsgruppen auf Quartiers- und Stadtteilebene.

Martin Berger, Martina Jauschneg, Sebastian Beiglböck, Tobias Panwinkler, Katharina Gugerell, Carina Diesenreiter

	(z.B. Plusenergiehäuser), Bestandssanierung von Gebäuden.					
	Ausbau smarten öffentlichen Verkehrs (Mikro-ÖV, Stadtbussysteme)	X	X	.	X	X
IV	Gezielter Rückbau bei Leerständen, schlechter Bausubstanz etc.				X	X
	Ambient Assistanted Living (= selbstbestimmtes Leben durch Technik)	.	.	X	X	X
Legende: X: besonders für den jeweiligen Stadttyp geeignet						

Tabelle 3: Auswahl Smart-City Maßnahmen für Stadttypen (Quelle: Green City LAB)

Alle vorgeschlagenen Maßnahmen für Transformationsprozesse in Richtung Smart City wurden grundsätzlich von den Expertinnen und Experten als positiv bewertet, jedoch sind einige für die jeweiligen Stadttypen besser oder weniger gut geeignet sind (vgl. Tabelle 3).

Maßnahmenbündel I wurde für alle Stadttypen als nachvollziehbar und sinnvoll eingestuft.

Maßnahmenbündel II bezieht sich insbesondere auf die Typen ‚wachsende größere Städte und ‚wachsende junge kleine bis mittlere Städte'. Angepasst an die Stadttypen, die sich insbesondere durch einen höheren Anteil junger Menschen, höhere Mobilität und Singlehaushalte auszeichnen, spiegelt dieses Maßnahmenbündel eine höhere Technikaffinität aber auch mehr Potential für real-time Systeme wider, wie beispielsweise dynamische Ridesharing-Systeme. Die in diesen Nutzerinnen- und Nutzer-Gruppen weit verbreitete Verwendung von Smartphones begünstigt diese Entwicklungen.

Das Maßnahmenbündel III stellt den Übergang zwischen den expandierenden, prosperierenden und den stagnierenden bis tendenziell schrumpfenden Städten dar. Hier gilt es „klassische" Maßnahmen aus dem Bereich der Stadtplanung hinsichtlich Nach- und Innenverdichtung von Quartieren oder Stadtteilen oder aus dem Bereich der Verkehrsplanung (z.B. Öffentlicher Verkehr), zu setzen.

Für die Gruppen der stagnierenden und schrumpfenden Städte, die in der Regel von einer zunehmend älter werdenden Bevölkerung bewohnt werden, ist die Schaffung und Sicherung der lokalen sozialen Infrastruktur und die barrierefreie Gestaltung des Öffentlichen Raumes auch im Rahmen der Gesundheitsförderung und -vorsorge von besonderer Relevanz. Maßnahmenbündel IV zeigt typische Spielräume für diese Stadttypen und umfasst dabei den gezielten Rückbau bei Leerständen oder schlechter Bausubstanz sowie Ambient Assisted Living als spezifische Handlungsansätze.

4 FAZIT

Zusammenhänge zwischen der soziodemografischen Entwicklung von Städten und ihrem Weg in Richtung Smart City mit entsprechenden Handlungsoptionen konnten aufzeigt werden. Der Wandel der Bevölkerungsstruktur und die damit einhergehenden veränderten Alltags- und Nutzungspraktiken erfordern spefizifische Handlungsstrategien.

Die Ausarbeitung der fünf demographischen Stadttypen mit unterschiedlichen Demographieprofilen bildete die Basis für die Entwicklung der spezifischen Maßnahmen, die von Expertinnen und Experten auf ihre Eignung für die unterschiedlichen Stadttypen geprüft wurden. Die Maßnahmen decken alle Themenbereiche ab, welche für Smart Cities als wichtige Kriterien gelten.

Die Studie hat gezeigt, dass für Transformationsprozesse zu Smart Cities und die damit einhergehenden Planungs- und Entscheidungsprozesse folgende Themen von zentraler Bedeutung sind: Dynamik und Geschwindigkeit des Bevölkerungswandels, da dieser Handlungs- und Entscheidungsdruck sowohl bei Planenden als auch bei Entscheidungsträgerinnen und Entscheidungsträgern erzeugt. Bevölkerungszahl und -struktur sind entscheidend hinsichtlich der Erzielung einer kritischen Masse, die für die Auslastung von Infrastruktur und die Verbreitung neuer Technologien eine wichtige Voraussetzung ist. Smart-City-Maßnahmen haben auch hinsichtlich des langfristiges Investitionsverhalten und des kurzfristigen Ver- und Gebrauchsverhalten unterschiedlicher Nutzerinnen- und Nutzergruppen spezifische Erfordernisse, welche bei den Entscheidungsprozessen ebenfalls berücksichtigt werden wollen.

Klima- und Ressourcenschutz sowie Energieeffizienz sind Ziele auf unterschiedlichen räumlichen Ebenen, die Implementierung und Umsetzung erfolgt aber – in Österreich – zumeist auf kommunaler Ebene. Daher rückt bei der strategischen Forcierung der Smart City die Ebene der Stadt in den Vordergrund, auf der die einzelnen technischen Systeme Energie, Mobilität sowie Informations- und Kommunikationssysteme mit unterschiedlichen Maßnahmen zu einem Gesamtsystem vernetzt werden sollten. Zur Konkretisierung der Maßnahmen sollten jedoch auch die jeweiligen Quartiere innerhalb einer Stadt differenziert betrachtet

werden, da sich hier Synergien einfacher erzielen lassen und die Nutzerinnen und Nutzer leichter eingebunden werden können. Quartiere können anhand typischer Bauformen, Freiraum-, Sozial-, Verkehrsstrukturen etc. abgegrenzt werden. Dies bedeutet, dass die vorgeschlagenen Maßnahmen zwar als Entscheidungsbasis für die jeweilige Stadt im Gesamten dienen können, deren Umsetzung jedoch auf kleinräumiger Ebene nochmals genauer geprüft werden sollte. So könnten Maßnahmen, welches für die Stadt im Allgemeinen als besonders passend eingestuft wurde, für einen bestimmten Stadtteil ungeeignet sein.

1 ABSTRACT

Mobilität spielt für die soziale Teilhabe von Menschen eine wesentliche Rolle und macht einen erheblichen Teil der Lebensqualität aus. Mobilität leistet aber auch einen Beitrag zur Inklusion der unterschiedlichen Bevölkerungsgruppen in die Gesellschaft. Jugendliche stellen die zukünftige Generation an Entscheidungsträgerinnen und Entscheidungsträgern dar – sie nehmen also einen gewichtigen Einfluss auf die zukünftige Lebensqualität in den Städten, die wesentlich davon abhängen wird, wie die Menschen mit ihren Mobilitätsbedürfnissen umgehen (Ruoss, 1999) und in welchem Maße es gelingt, die soziale Inklusion zu verwirklichen. Es gilt daher jene Voraussetzungen und Strukturen zu schaffen, die es den unterschiedlichen Bevölkerungsgruppen ermöglichen, in gleichem Maße am gesellschaftlichen Leben teilzuhaben. Im Rahmen des Forschungsprojektes „Jugendliche: Lebensqualität, Verkehr & Mobilität" (FWF Der Wissenschaftsfonds, P 23194-G17) wurde den vielfältigen Verflechtungen zwischen der Mobilität und der Lebensqualität von Jugendlichen (14-19 Jahre) in Österreich nachgegangen, um ein besseres Verständnis dieser komplexen Zusammenhänge zu erlangen. Es ist notwendig, mehr darüber in Erfahrung zu bringen, was für die Jugendlichen von heute Lebensqualität bedeutet und was ihnen für ihre Mobilität wichtig ist, um für die nachfolgenden Generationen qualitätsvolle Voraussetzungen für nachhaltige Mobilität zu schaffen. Zentrale Fragestellung war die Identifizierung von Bestimmungsfaktoren für eine nachhaltige Fortbewegung im öffentlichen Raum, die gleichzeitig auch hohe Lebensqualität bietet. Diese wurde durch eine umfassende Literaturstudie, Fokusgruppeninterviews mit Jugendlichen, einer österreichweiten Online-Befragung und Expertinnen- und Expertenworkshops zu beantworten versucht. Die Ergebnisse dieser Studie dienen als Entscheidungsgrundlage für Politikerinnen, Politiker, Stadt-, Raum- und Verkehrsplanerinnen, Raum- und Verkehrsplaner, damit diese Maßnahmen für nachhaltige Verkehrsmittelwahl junger Leute ergreifen können.

2 MOBILITÄT & LEBENSQUALITÄT

Mobilität und Lebensqualität werden unterschiedlich definiert, je nach Fachdisziplin werden andere Aspekte hervorgehoben. Inwieweit die betroffene Bevölkerung eingebunden ist, stellt einen wichtigen Indikator für die spätere Zufriedenheit und Nutzung (=Lebensqualität) dar.

2.1 Mobilität der Jugendlichen

Jugendliche weisen grundsätzlich ein nachhaltiges Mobilitätsverhalten auf, sie gehen häufig zu Fuß, nutzen den öV und das Rad. Mit Erwerb des Führerscheins, beim Eintritt ins Erwerbsleben oder im Zuge der Familiengründung ändert sich dieses Mobilitätsverhalten. Jugendliche sind eine sehr heterogene Gruppe; Alter, sozialer Hintergrund, oder die unterschiedlichen Lebenslagen beeinflussen ihre Einstellungen zur Mobilität. Jugendliche sind im Vergleich zur erwachsenen Bevölkerung hoch mobil. Die nachhaltige Fortbewegung der Jugendlichen sollte in vielfältiger Weise gestärkt werden, so dass sie auch als Erwachsene vorwiegend im Umweltverbund unterwegs sein werden. Da sich die Einstellungen zu Mobilität relativ schnell verfestigen, stellen Jugendliche eine entscheidende Zielgruppe für Bewusstseinbildung dar. Da die Phase des „Erwachsen-Werdens" eine sensible ist und alle Zeitbereiche, die eine Wende beinhalten auch Möglichkeiten für Informationsvermittlung und Beeinflussung darstellen, würde sich dies gut für die Thematik der nachhaltigen Mobilität eignen.

3 METHODOLOGIE

Im vorliegenden Projekt kamen zwei Methoden der Datenerhebung zur Anwendung – Fokusgruppen-Interviews (FGIs) und eine quantitative Online-Befragung.

3.1 Fokusgruppeninterviews (FGI)

Insgesamt wurden 4 FGIs mit Jugendlichen durchgeführt. Die Teilnehmerinnen und Teilnehmer (24 Personen) wurden anhand verschiedener Kriterien ausgewählt, wie etwa Alter, Geschlecht, Bildungsniveau, städtische vs. ländliche Herkunft. Mittels eines strukturierten Leitfadens zu den Themen Lebensqualität, Verkehrsmittelwahl und Zufriedenheit mit der eigenen Mobilität wurden qualitative Daten über Jugendliche in Wien und Niederösterreich erhoben.

3.2 Online-Befragung

Anschließend an die FGIs fand eine österreichweite repräsentativen Online-Befragung mit 14-19 jährigen Teilnehmerinnen und Teilnehmern statt. Insgesamt füllten n=800 Jugendliche den Fragebogen aus.

4 ERGEBNISSE

4.1 Ergebnisse der Fokusgruppeninterviews

Bekannte Lebensqualitätsdimensionen aus der Literatur, wie etwa Gesundheit usw. (Forward et al., 2004, CDV, 2004, Bein et al., 2004) konnten im Rahmen der Fokusgruppeninterviews um spezifische Dimensionen, die Jugendliche betreffen, erweitert werden. Die Aussagen der Jugendlichen in den FGIs wurden im Zuge der Auswertung zu verschiedenen Themenbereichen zusammengefasst, die wiedergeben wie Jugendliche den Zusammenhang zwischen Mobilität und Lebensqualität erleben:

- Respekt/Ernst genommen werden: Die Jugendlichen fühlen sich mit ihren Anliegen als Verkehrsteilnehmerinnen und Verkehrsteilnehmer häufig nicht ernst genommen bzw. von Erwachsenen nicht respektvoll behandelt.

- Selbstbestimmung/Unabhängigkeit: Dem Auto wird von den Jugendlichen große Bedeutung im Zusammenhang mit Unabhängigkeit, Eigenständigkeit und Erwachsenwerden beigemessen, wobei im Zuge rationaler Überlegungen der Besitz von Auto und Führerschein an Bedeutung (insbesondere in der Stadt) verliert.

- Sicherheit: Jugendliche haben ein hohes Sicherheitsbedürfnis. Verunsichernde Faktoren sind für Jugendliche im Verkehr u.a. sich auffällig verhaltende Personengruppen, Gruppen von (männlichen) Jugendlichen, Personen unter Alkoholeinfluss.

- Infrastruktur: Uneindeutige oder gefährliche Situationen im Verkehr hängen für die Jugendlichen oft mit der Verkehrsinfrastruktur zusammen. Vor allem die Radinfrastruktur wurde bemängelt. Jugendliche aus Niederösterreich kritisieren ferner das unzureichende Angebot an öffentlichen Verkehrsmitteln.

- Vorbildwirkung Erwachsene: Die Verkehrsmittelwahl bzw. die Einstellungen der Eltern oder der älteren Geschwister prägen die Jugendlichen, bspw. durch Bring- und Holdienste mit dem Auto (u.a. aus Sorge um die Sicherheit), durch Unterstützung beim Kauf eines eigenen Autos oder beim Erwerb des Führerscheins, durch Verbote mit dem Rad zu fahren oder nachts zu Fuß unterwegs zu sein.

- Mangelnder „Freiraum" im öffentlichen Raum: Die Jugendlichen geben an, dass „freie" Räume für sie fehlen, so wie es insgesamt an entsprechenden Freizeitangeboten mangele. Jugendliche in Wien haben dabei die Vorstellung, dass am Land mehr Freizeitangebote außer Haus bestehen. Jugendliche aus Niederösterreich wiederum empfanden das Angebot für Jugendliche, gerade was Indoor-Aktivitäten betrifft, in Wien weitaus attraktiver.

- Diskriminierung: Als sehr mobile Personen befinden sich Jugendliche oft im öffentlichen (Straßen-) Raum. Diskriminierung, die sie dabei von den Erwachsenen, aber auch von anderen Jugendlichen erfahren, beeinträchtigt ihre Lebensqualität. Sie haben das Gefühl, dass ihnen aufgrund ihres Alters oder ihrer Herkunft keine Chance gegeben wird.

4.2 Ergebnisse der Online Befragung

Ausgehend von den Themenbereichen aus den FGIs und Ergänzungen aus der Literatur wurden Hypothesen über die Zusammenhänge zwischen Lebensqualität und Mobilität entwickelt und anhand des Fragebogens geprüft. Ingesamt betrachtet weisen die Jugendlichen eine hohe allgemeine Lebenszufriedenheit auf (88,6 %

„sehr" oder „eher" zufrieden mit ihrem Leben). Entscheidend für ein gutes Leben für Jugendliche sind Freunde, Gesundheit, Familie und Ausbildung, sowie die Möglichkeit zur selbstständigen Entscheidung über die Freizeitaktivitäten. In Folge werden einige Ergebnisse der Hypothesenprüfung vorgestellt.

- Eingebundenheit in soziale Netzwerke: Jugendlichen ist Mobilität wichtig, damit sie ihre sozialen Kontakte pflegen können. Knapp über 86 % der Jugendlichen geben an, dass ihnen Mobilität vor allem wichtig ist, um Gleichgesinnte und Freundinnen und Freunde zu treffen.

- Soziales Verhalten: Jugendlichen ist es wichtig, dass sie im Straßenverkehr respektvoll behandelt werden. Die Aussage, dass Radfahrerinnen, Radfahrer, Fußgängerinnen, Fußgänger, Autofahrerinnen, Autofahrer etc. aufeinander Rücksicht nehmen sollten, erhielt von den Jugendlichen eine hohe Zustimmung (95,3 %).

- Sicherheit: Sich auf der Straße oder in den öffentlichen Verkehrsmitteln sicher fühlen zu können (vor „blöden Anmachen"), bewerten fast 90 % der Jugendlichen als wichtig. Als wesentlich erachten die Jugendlichen auch die Sicherheit vor Unfällen im Straßenverkehr – 94 % ist ihre Verkehrssicherheit wichtig.

- Infrastruktur: 88 % der befragten Jugendlichen ist es wichtig, ein gut ausgebautes Netz öffentlicher Verkehrsmittel nutzen zu können. 76 % erachten Gehwege als wichtig und 58 % finden ein ausreichendes Vorhandensein von Radwegen und Straßen als wesentlich für ihre Mobilität.

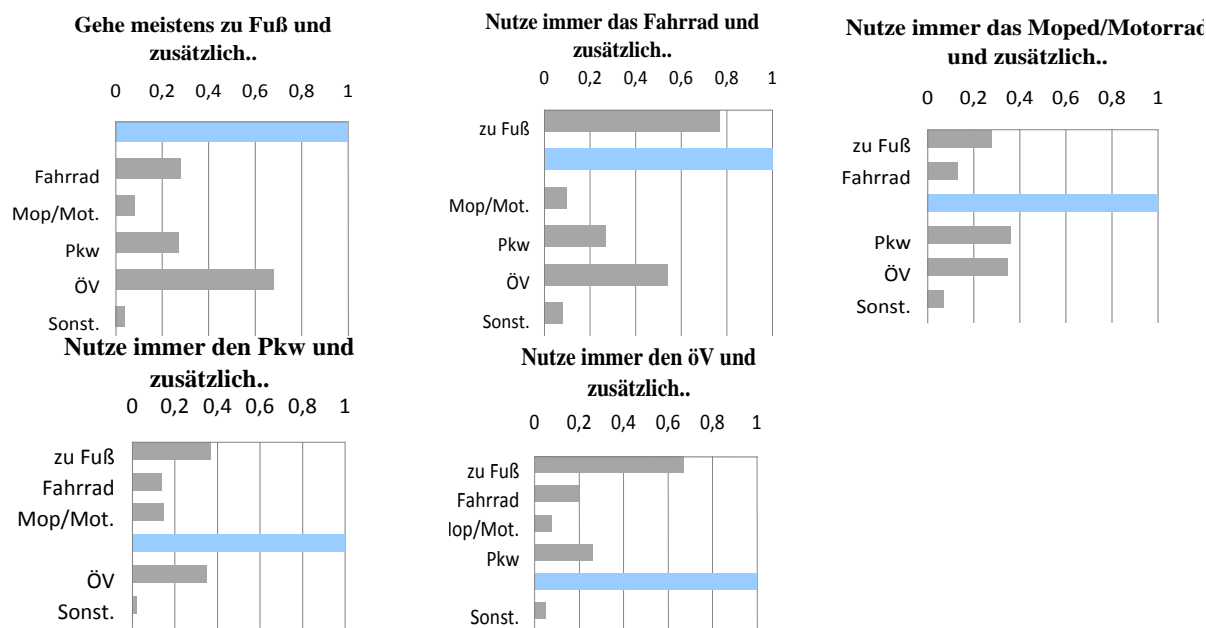
- Multimodalität: Jugendliches Mobilitätsverhalten ist meistens multimodales Mobilitätsverhalten. Aus den Daten wird ersichtlich, dass sich bestimmte Verkehrsmittel gut ergänzen: die Jugendlichen, die viel in ihrer Freizeit zu Fuß gehen, nutzen auch häufig das Fahrrad oder den öV. Das Auto ist nicht förderlich für die multimodale Fortbewegung. Jugendliche, die hauptsächlich mit dem Auto unterwegs sind, nutzen deutlich seltener andere Verkehrsmittel.


Fig.1: „Alle Verkehrsmittel, die von den Auskunft gebenden Personen in der Freizeit „immer" benützt werden (n=620), häufigst gewähltes VM =1, Werte zwischen 0 und 1: zeigen wie oft das betreffende zusätzliche Verkehrsmittel gewählt wurde.

- Unabhängigkeit: Knapp 80 % der Jugendlichen stimmen der Aussage zu, in ihrer Freizeit unabhängig von den Eltern unterwegs sein zu wollen. Erwartungsgemäß verfestigt sich diese Tendenz mit zunehmendem Alter. Bei Jugendlichen mit Migrationshintergrund ist der Wunsch nach Unabhängigkeit von den Eltern etwas weniger ausgeprägt.

- Umweltschutz/Nachhaltigkeit: Der Aussage, „damit die Umwelt geschützt wird, wäre es wichtig, dass man, so gut es geht, auf Fahrten mit dem Auto/Moped/Motorrad verzichtet und stattdessen öV oder Rad nutzt/zu Fuß geht" wurde von 67 % der Jugendlichen zugestimmt. Die Auswertung zeigte außerdem, dass den Jugendlichen der Zusammenhang zwischen intakter Umwelt und hoher Lebensqualität bewusst ist.

- Führerscheinbesitz: Für die Jugendlichen sind Führerscheinbesitz bzw. Führerscheinerwerb wichtig. Alle Befragten wollen als Erwachsene mit dem Auto unterwegs sein bzw. sind bereits Autofahrerinnen und Autofahrer. Die Autonutzung wurde aber durchaus kritisch reflektiert, z.B. dort wo Alternativangebote bestehen oder wo nur kurze Wege zurück gelegt werden.

- Lebenszufriedenheit und Verkehrsmittelwahl: Die meisten „sehr zufriedenen" Jugendlichen waren jene, die angaben, am häufigsten das Fahrrad als Verkehrsmittel zu benützen, gefolgt von jenen, die bereits selbst mit dem Auto fahren.
Fig. 2: „Wie zufrieden bist du mit deinem Leben?", nach Verkehrsmittelart, n=800

5 CONCLUSION

Jugendliche sind grundsätzlich bereit, sich nachhaltig fortzubewegen. Allerdings bringen sie auch deutlich zum Ausdruck, dass sich junge Menschen, die zu Fuß gehen, den öV nutzen und Rad fahren, als „Verkehrsteilnehmerinnen und Verkehrsteilnehmer zweiter Klasse" fühlen. Um sie darin zu bestärken, ihr „autofreies" Mobilitätsverhalten aufrecht zu erhalten, sollte diesem Umstand, der zweifellos die Lebensqualität beeinträchtigt, entgegen gewirkt werden. Unter anderem sollte es zu entscheidenden Verbesserungen seitens der Erwachsenen im Umgang mit ihnen als Verkehrsteilnehmerinnen und Verkehrsteilnehmer kommen. Dies betrifft, im weiteren Sinn, einerseits die Kommunikation mit Jugendlichen im Straßenraum und den öffentlichen Verkehrsmitteln, andererseits aber auch die Infrastruktur, die ihnen geboten wird.

Viele der Kritikpunkte, die Jugendliche äußern, sind hinlänglich bekannt. Sie werden aber nicht nur von ihnen, sondern auch von Erwachsenen, vor allem den Seniorinnen und Senioren, geäußert. Dazu zählen etwa die mangelhafte Infrastruktur für die Teilnehmerinnen und Teilnehmer im nicht-motorisierten Individualverkehr (nIV), Probleme mangelnder Sauberkeit oder die Beeinträchtigung des subjektiven Sicherheitsgefühls in den öffentlichen Verkehrsmitteln (vgl. z.B. Seisser & Wolf-Eberl, 2010, Ausserer et al., 2009, Risser, 2002).

Schwierigkeiten im Straßenverkehr, die besonders Jugendliche betreffen, sind neben dem bereits erwähnten Gefühl, nicht ernst genommen zu werden bzw. nicht als vollwertiges Mitglied der Gesellschaft zu gelten, die als kompliziert wahrgenommenen Fahrpläne oder zeitlich schlecht an die Bedürfnisse der Jugendlichen angepassten Angebote an öV.

Die Jugendlichen fühlen sich mitunter zur Verwendung bestimmter Verkehrsmittel gezwungen. Dieser Eindruck kann noch dadurch verstärkt werden, wenn die erwachsene Bevölkerung dieses Verkehrsmittel nicht oder kaum verwendet bzw. abschätzig beurteilt (zu Fuß gehen, Schülerbus etc). Haben sie im Rahmen dieser Verwendung Kommunikationssituationen zu bewältigen, die ihre schwächere Position verdeutlichen

(asymmetrische Kommunikation, wie unfreundlich behandelt werden durch Erwachsene, "Anmache" durch andere Fahrgäste etc.), so ist mit sinkender Akzeptanz zu rechnen.

In diesem Zusammenhang muss die Vorbildwirkung von Eltern und anderen Bezugspersonen erwähnt werden. Dies wurde von den Jugendlichen in den Interviews zwar nicht explizit thematisiert, muss jedoch aus sozialwissenschaftlicher Sicht ergänzt werden: Wenn Erwachsene bestimmte Fortbewegungsarten meiden, könnte das signalisieren, dass sie nur wenig attraktive Optionen darstellen. Das Mobilitätsverhalten der Erwachsenen prägt das Verhalten der jüngeren Generationen. Auch wenn sich gegenwärtig Tendenzen gezeigt haben (bislang vor allem im städtischen Raum), die in Richtung nachhaltiges Mobilitätsverhalten weisen, wie etwa ein steigender Fahrradanteil (vgl. Stadt Wien, 2012) oder zusätzliche Angebote wie Leihfahrräder oder Carsharing, so ermöglicht nur die Kombination sinnvoller und vor allem gleichgerichteter Maßnahmen ein dauerhaftes Umdenken. Im ländlichen Raum weisen etwa die Reduzierung des öV-Angebots in einigen Regionen und der zunehmende Zwang zu motorisiertem Individualverkehr (mIV) in die entgegengesetzte Richtung. Von den Jugendlichen zu erwarten, unter diesen Voraussetzungen nachhaltige Mobilitätsgewohnheiten zu entwickeln, ist nahezu illusorisch.

Auto- und Führerscheinerwerb werden von den Jugendlichen angestrebt, was vor dem Hintergrund mangelnder Kommunikation negativer Konsequenzen des Autoverkehrs nachvollziehbar erscheint. Gleichzeitig zeigen die Resultate dieser Erhebung, dass sich die Jugendlichen sehr wohl kritisch mit der Autoverwendung auseinander setzen. Das bedeutet, dass ein nicht zu unterschätzendes Potential hinsichtlich der Beibehaltung nachhaltigen Mobilitätsverhaltens vorhanden ist. Es gilt daher die entsprechenden Voraussetzungen zu schaffen. Das Vorhaben, die Jugendlichen im Umweltverbund zu halten, ist jedoch nur dann realisierbar, wenn die Rahmenbedingungen nicht weiterhin dem Autoverkehr dienlich sind, was vor allem in ländlichen Gebieten der Fall ist.

Es ist für die (jugendliche) Bevölkerung klar ersichtlich zu machen, dass sie als Fußgeherinnen, Fußgeher, Radfahrerinnen, Radfahrer, ÖV-Nutzerinnen und ÖV-Nutzer mindestens genauso gute Voraussetzungen, sei es was gesetzliche Regelungen, die Aufwendung von Finanzmittel oder eben die Infrastruktur betrifft, vorfinden bzw. in den nächsten Jahren vorfinden werden, wie es für den motorisierten Verkehr bereits Standard ist. Jugendliche ernst zu nehmen, beinhaltet auch ihre Mobilitätsbedürfnisse ernst zu nehmen. Gute Vorraussetzungen für nachhaltige Mobilität sicher zu stellen, bedeutet nicht nur einen zeitlich andauernden Gewinn für die Lebensqualität der Jugendlichen, sondern auch für die Gesellschaft als Ganzes.

1 ABSTRACT

Since the beginning of the 21st century, more than half of the global human population is living in urban environments and the dynamic trend of urbanization is expected to grow incredibly fast, with the number of urban dwellers currently increasing by about 180.000 people every day. In this framework, an effective monitoring of urban sprawl represents a key issue to analyse and understand the complexity, cross-linking and increasing dynamics of urban environments in order to ensure a sustainable development of urban and peri-urban areas. To this purpose, in the last decades satellite Earth observation (EO) has proved to be a promising tool in combination with widely automated methods of data processing and image analysis for providing up-to date geo-information on urban settlements at global scale; nevertheless, the geometric resolution of the current EO-based geo-information products is limited to 300-500 m, thus often resulting in poor accuracy to support decision makers and urban planners.

TanDEM-X (TerraSAR-X add-on for Digital Elevation Measurement) is a German radar satellite mission aiming at the provision of a global digital elevation model (DEM) at 12 m spatial resolution. Besides this primary goal, the global coverage with very high resolution (VHR) TerraSAR-X (TSX) and TanDEM-X (TDX) imagery collected in 2011 and 2012 can be used to characterize settlement patterns worldwide in a so far unique spatial detail. Accordingly, the German Remote Sensing Data Center (DFD) of the German Aerospace Center (DLR) has implemented a fully-automated processing system that detects and extracts built-up areas from the global TSX/TDX imagery acquired in the context of the TDM. The output of this approach is a global binary settlement mask that outlines urban and non-urban areas at the unprecedented spatial resolution of ~0.4 arc sec (i.e., ~12 m). The intended, world-wide data set is called Global Urban Footprint (GUF) and a public domain version of it will be made available at ~3 arcsec (i.e., ~50-75m) spatial resolution. With its global coverage and the enormous spatial detail, this initiative represents a promising contribution to global analyses of urban and peri-urban areas.

2 INTRODUCTION

Urbanization is one of the most pressing global challenges; indeed, according to the United Nations Development Program (UN 2011), almost two-thirds of the world's population will live in cities by the year 2030 (as an example, in China and India the number of new cities with more than one million inhabitants will come up to 30 and 26, respectively, just within the next 20 years). It is approximated that urban areas cover about 2 % to 3 % of the Earth's surface. However, despite this rather marginal significance in terms of spatial coverage, metropolitan areas represent the focal points of human activity. Therefore, the impacts of urbanization on the natural and human environment are much more far-reaching at all geographic and socioeconomic scales than the purely area-related perspective might imply. In this framework, regional to global analyses of urban growth patterns and the interrelation between urban areas and natural or anthropogenic processes have only just begun. Hence, there is much work remaining to provide spatially detailed, accurate and up-to-date geo-information on the patterns and processes within the urban and peri-urban environment. A key technology to provide the required data and information is satellite Earth Observation (EO), which in the last few years has proved being an effective tool for providing global geo-information on the location, spatial extent and distribution of urban areas. A comprehensive review of the available state-of-the-art EO-based and EO-supported global human settlements layers (GHSL) is given in (Gamba & Herold 2009, Potere & Schneider 2009). In particular, both papers highlights that the currently existing GHSL are mainly derived from medium resolution (MR) optical EO data, hence exhibiting a comparably coarse spatial resolution (i.e., at least a few hundred meters). Nowadays, the MODIS 500 (Schneider et al. 2009) and GlobCover (Bontemps et al. 2011) layers are considered to be the most accurate urban data sets provided on a global level; nevertheless, their limited spatial resolution (i.e., 463 m for MODIS 500 and 309 m for GlobCover) do not allow a precise characterization of urban settlements, especially in rural and peri-urban areas (which are characterized by small and scattered villages and towns).

Accordingly, some recent initiatives aimed at improving the current GHSL by developing efficient processing techniques for delineating settlement extents based on high resolution (HR) and VHR EO data. In this context, most promising approaches are based on: the analysis of a new global nighttime lights product derived from imagery of the Visible Infrared Imaging Radiometer Suite (VIIRS) (NASA 2012), the use of HR/VHR optical imagery (Pesaresi et al. 2011), and the employment of HR/VHR SAR data collected by the latest generation of radar satellite sensors (i.e., Envisat-ASAR, ALOS-PALSAR, Radarsat-1/2, TerraSAR-X, TanDEM-X, COSMO-Skymed).

The latter type of approaches looks particularly promising as, with respect to optical sensors, the weather-independent, day-and-night data acquisition capability and the low sensitivity towards atmospheric effects of SAR systems make them particularly suitable to provide temporally and radiometrically consistent global data coverages. In this framework, the authors yet explored and assessed the capabilities of the German TanDEM-X mission (TDM) (Krieger et al. 2007) to monitor built-up areas at very high resolution (Esch et al. 2012). With two global coverages of VHR SAR data acquired at 3m spatial resolution and collected within a period of about one year, the German TDM is predestined to be included to the new initiatives aiming at the provision of innovative GHSLs. Accordingly, the German Remote Sensing Data Center (DFD) of the German Aerospace Center (DLR) has developed and implemented the Urban Footprint Processor (UFP), i.e. a fully-automated, operational image processing and analysis procedure that detects and delineates built-up areas from the global TDM data. The outputs of the UFP are binary settlement masks – the Urban Footprint (UF) masks – indicating built-up and non-built-up areas at a spatial resolution of 0.4 arcsec (~12 m). The global coverage of UF data sets will then be used to generate a world-wide inventory of human settlements – the Global Urban Footprint (GUF) layer – that is also intended to be publicly provided at a spatial resolution of ~3.0 arcsec (i.e., ~50-75m).

3 URBAN FOOTPRINT PROCESSOR

The basic methodological components for detecting built-up areas from TSX/TDX data have been already introduced by the authors in (Esch et al. 2012). However, to effectively process the huge TDM mass data set of about 300 TB (one coverage comprises ~180,000 complex SAR images with each image having an average size of ~50,000 × 40,000 pixels), the abovementioned approach has systematically been enhanced and transformed into a fully-automatic processing chain with several additional modules and functionalities (Esch et al. 2013), namely the UFP. This processing chain takes single look slant range complex (SSC) Stripmap data of one TDM coverage (2011/2012) as input. The image analysis and classification module consists of three main components, namely feature extraction, classification stage, and mosaicking and post-editing. Each of them is described into details in the following.

3.1 Feature Extraction

The aim of the first module of the UFP is to extract the "speckle divergence" (Esch et al. 2010), an effective texture feature capable of highlighting areas characterized by heterogeneous and highly structured built-up. In particular, due to the strong scattering from double bounce effects in urban areas typical of SAR data, the attention is focused on the analysis of the local speckle and its development is estimated accounting for the local image heterogeneity (Esch et al. 2012) defined as:

$$H = \sigma_A / \mu_A \quad (1)$$

where, σ_A and μ_A represent the standard deviation and mean, respectively, of the original backscattering amplitude image A (stored inside a Single Look Slant Range Complex image product, SSC) computed in a local neighborhood. The image heterogeneity H, the fading texture F (which represents the heterogeneity caused by speckle) and the true image texture T are related as follows (Potere et al. 2009):

$$H^2 = T^2 F^2 + T^2 + F^2 \quad (2)$$

Accordingly, it is then possible to demonstrate (Esch et al. 2010) that (when considering radiometrically unenhanced SSC products as in our case) a reliable estimate $\hat{T}$ (i.e., the speckle divergence S) of the local true image texture is given by:

$$\hat{T} = S = \left(H - 0.5 \right) / 1.5 \quad (3)$$

To reduce the amount of data (due to technical restrictions) the multi-looking described in (Eineder et al. 2004) is finally performed for rescaling both A and S to a spatial resolution of ~0.4 arcsec (~12 m).

3.2 Classification

The second module of the UFP is dedicated to the production of a binary settlement layer (built-up, non-built-up) for the investigated scene once provided as input with the backscattering image A and the corresponding speckle divergence S and implements the technique described in (Marconcini et. al 2013). Generally, pixels associated with high values of S correspond to urbanized areas, while those exhibiting lower values correspond to non-built-up structures. Accordingly, for each investigated scene the objective is to determine a specific optimal threshold for S capable of effectively discriminating between built-up and non-built-up areas. Initially, all the pixels showing a backscattering amplitude lower than the prefixed threshold $Th^A = 100$ are marked as non-urban, since they always correspond to information classes not belonging to built-up areas (e.g., water bodies, surfaces with a smooth meso-scale roughness). A set of M candidate thresholds for S, $Th_1^S > \ldots > Th_M^S$, is then determined based on the specific image dynamics. For each of them, pixels are categorized into urban (U_m) or non-urban (L_m) candidates depending on whether the corresponding speckle divergence value is greater or lower than Th_m^S, respectively. Afterwards, we compute the Jensen-Shannon divergence $D_{JS}[U_m \| L_m]$ (Lin 1991) accounting for both A and S, which allows to estimate the "distance" between U_m and L_m (i.e., the probability distributions of U_m and L_m, respectively). The higher the divergence, the higher is the distance between the two distributions and vice-versa. $D_{JS}[U_m \| L_m]$ assumes high values for higher values of , while it decreases as the threshold gets lower. As soon as the two distributions U_m and L_m start to significantly overlap, then there always occurs a consistent fall in $D_{JS}[U_m \| L_m]$. When this happens, the corresponding threshold Th_{m*}^S is selected as optimal for the specific image under analysis and the subset U_{m*} is employed for training a one-class classifier based on support vector data description – SVDD (Tax and Duin, 2004). This approach allows increasing generalization and obtaining a more consistent and reliable final UF map G_{m*}.

3.3 Mosaicking and Post-editing

The last module of the UFP implements automated mosaicking and post-editing operations to further improve the quality of the generated UF products. The criterion adopted for selecting the optimal threshold for generally proved effective and robust. Nonetheless, it might happen that one or few UFs exhibit slight under- or over-estimation of urban areas with respect to corresponding neighboring UFs when mosaicking multiple images. To solve this problem we implemented a simple but effective technique, which accounts for the partial overlap occurring between neigbouring TDX/TDM scenes. In particular, by comparing the amount of samples categorized as urban falling in the intersections we can identify which UFs need to be improved and whether under- or over-estimation occurs and we then modify the threshold accordingly (i.e., we select the one resulting in the the lowest difference with respect to the neighboring UFs in terms of number of urban samples). It is worth noting that, sometimes highly mountainous areas could be wrongly categorized as built-up regions as they exhibit high values for both and as an effect of the particular topography. In order to solve this problem a dedicated mask has been implemented by taking into consideration the ASTER Global DEM (NASA 2013) and marking all those pixels showing a slope (i.e., the maximum rate of height change between each pixel and its closest eight neighbors) higher than 20 in the neighborhood of a local peak as non-urban. This approach allowed minimizing this type of error and to preserve urban settlements on the side of the mountains.

4   URBAN FOOTPRINT SETTLEMENT MASK

So far, the UFP has yet produced both A and S for a total of 140,000 scenes acquired in the context of the first TDM coverage (2011/2012) with each scene covering an area of ~50 × 30 km. Moreover, a number of globally distributed test runs for the final GUF generation have been performed investigating either single scenes or extensive mosaics consisting of several hundred images. An accuracy assessment of the corresponding results showed that the overall accuracies mostly lie in a range of 70 − 90 %. These results are in line with the outcomes of earlier studies investigating the methodological precursors of the UFP technique

Fig. 1 – Optical data (from Google Earth), TDM backscattering amplitude □, speckle divergence □, urban footprint and corresponding GlobCover 2009 urban class map for the cities of Accra (GH), Dar es Salaam (TZ), Baghdad (IQ), Amsterdam (NL).

(Esch et al. 2010, 2012). Figure 1 reports optical data from Google Earth, TDM backscattering amplitude □, speckle divergence □, urban footprint and corresponding GlobCover 2009 urban class map for four representative cases, namely the cities of Accra (Ghana), Dar es Salaam (Tanzania), Baghdad (Iraq), and Amsterdam (The Netherlands). The different scales of the given examples allow to assess the capabilities of

the GUF to see the large area settlement patterns in their spatial configurations with e.g. Accra or Dar es Salaam

as dominating urban centers and a hierarchical system of smaller urban centers or low density rural settlements. At the same time, structural details of cities are captured as the examples of Baghdad and Amsterdam. The capability of the algorithm to even ignore open spaces without any vertical structures such as buildings etc. or green belts within the urban centers becomes obvious. The examples stress that the settlement patterns can be extracted and characterized for diverse geographical regions and landscape types by means of TDM imagery and the UFP system.

5 CONCLUSION

In this paper we presented DLR's Global Urban Footprint (GUF) initiative along with its technical implementation, i.e. the fully-automatic processing and image analysis system of the Urban Footprint Processor (UFP). Using the already acquired TDM data of the first coverage (~140.000 images over ~180.000), we could yet test the performance of the processing chain and assessed the resulting built-up mask on the basis of several thousand globally distributed images. The results of these tests demonstrate the high potential of the GUF approach to provide a spatially detailed map of global settlement patterns for urbanized areas as well as for rural regions. With the described characteristics, the GUF (whose first completion is envisaged for 2014) will provide a unique data set that is to some extent complementary to the existing GHSLs derived from medium (MR) or high resolution (HR) optical imagery. Moreover, in addition to the full-resolution 12 m product also a public domain version downscaled at ~3 arcsec (i.e., ~50-75 m) will be generated.

Considering the challenges of the GUF production, we still investigate in the potential to improve the classification stage of the UFP. In particular, we intend to identify potentially existing, systematic weaknesses of the UFP that might not have been discovered so far and at the same time we gain more precise knowledge on the performance and optimal tuning of the algorithms for the classification and mosaicking stage. Regarding follow-on research and development, it is planned to adapt the UFP to all TSX/TDX imaging modes (ScanSAR, SpotLight) as well as to other SAR satellites such as Sentinel-1 or Radarsat-2. Moreover, the calculation and consideration of long-term coherences will be investigated. First studies have also shown the potential to characterize building structures and estimate building densities based on texture measures or the modeling of building volume on building block level using the VHR DEM data generated on the basis of TDM imagery.

1 ABSTRACT

The EU project HLanData aims to demonstrate the feasible European level harmonization of the Land Use and Land Cover datasets taking into account both the data categorization and the data models, for any of their possible uses and users through the development of user-oriented value-added services. This contribution presents the results of the project. These are harmonised land use and land cover data according to INSPIRE in European regions, and the development and implementeation of several geoportals that give access to the data and provide different viewing and analysis functions. For the demonstration of the results a video was created.

2 PROJECT DESCRIPTION

Digital information on Land Use and Land Cover has been managed on national, regional and/or local level which results in a suite of datasets that are not always compatible to each other. Anyway, in a context where environmental threats such as climate change, biodiversity loss, and food security become more and more global, there is a need for integration of various sources of information at different scales. This is why planning has great hopes in the past year's development of Spatial Data Infrastructures (SDI). SDI gives access to geographic data that is stored and maintained by different data providers in different sources on international, national, regional and local level, harmonised according to common standards, and shared across administrative and thematic borders. The past decade has been influenced by a change of paradigm regarding accessibility of geodata. Traditionally geographic data and information management has been characterised by semantic and structural heterogeneity, multiple storage, and lack of coordination which results in incompatible datasets. Today there are numerous European, national, regional and local initiatives that support the development from "information islands" to "information systems". INSPIRE – the European Directive for a Spatial Data Infrastructure – provides a robust framework.

The EU project HLANDATA contributed to the harmonisation process focusing on land use and land cover data across Europe and addressing several application areas such as the management of waste, and land monitoring through the implementation of various value-added services in European regions. The HLANDATA geoportal provides one central access to decentralised data using web service technology so that users can visualise data from different sources together in one map with one common legend.

Geographers, planners, GIS analysts, public administration, decision makers, researchers, the public and other stakeholders require access to adequate and comprehensive data to achieve interdisciplinary and holistic approaches, transparency and participation in decision-making, efficient integrated data management, comparison of data, and monitoring of changes for a sustainable development. SDI can be a supportive element for spatial planning processes as it provides more harmonised data input than ever and helps to better understand and steer urban and regional dynamics.

HLANDATA is a European project supported by the ICT Policy Support Programme (ICT PSP) between March 2010 and February 2013. ICT PSP aims at stimulating innovation and competitiveness through the wider uptake and best use of information and communication technologies by citizens, governments and businesses (ICT PSPS website). Involved are nine partners, i.e. public authorities, private companies and research institutes from six different European Union countries as well as one international planning organization. The partners are the Government of Navarre as lead partner, Tracasa, National Geographic Institute (all Spain), UAB "Aerogeodezijos institutas" (AGI) (Lithuania), GISAT (Czech Republic), Latvian society "Technology Development Forum" – TDF, Slovak Environmental Agency (SEA), CEIT ALANOVA (Austria), and ISOCARP.

3 PROMOTIONAL VIDEO

The results of the project are presented the HLanData promotional video. It was uploaded to YouTube (http://www.youtube.com/watch?v=XoCgNdN8XMY&feature=youtu.be). Links have been made already

from the HLanData website (http://www.hlandata.eu/). The promotional video was unveiled at the HLanData Habitats final conference on 14th February 2013 in Madrid.

"In the last years geographical information systems have developed at a great speed, supported by new technologies, but different organisms have worked independently. A large number of databases have been created but without taking into account their interoperability. We talk about the same thing, but in different languages.

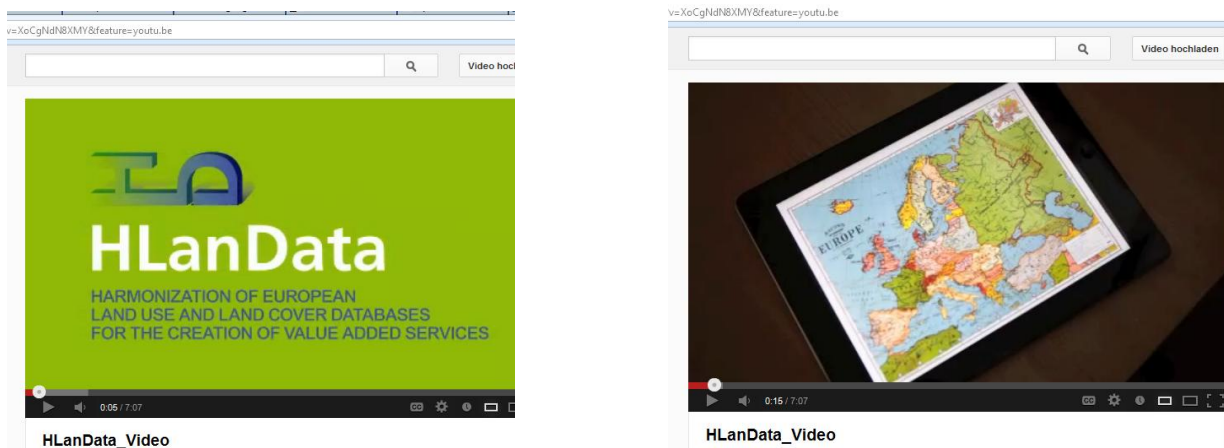
The HLanData project was born in this context with the main objective to demonstrate the feasible European level harmonization of the Land Use and Land Cover datasets taking into account both the data categorization and the data models, for any of their possible uses and users, through the development of user-oriented value-added services, and fully aligned with the INSPIRE directive.


Fig. 1: Hlandata Promotion Video – Introduction (Source: URL 1)

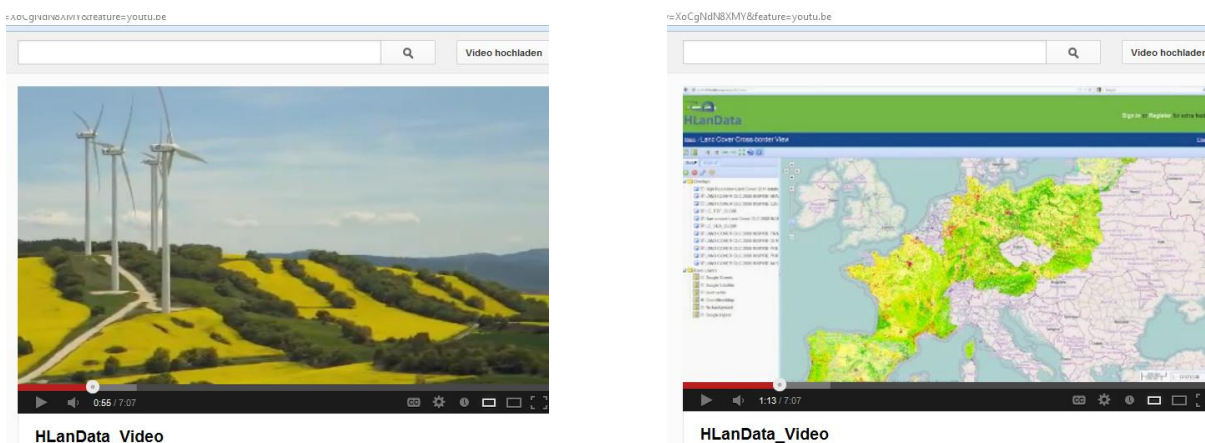
The HLanData geoportal is the gateway to harmonized land use and land cover data stored and maintained in different sources across Europe. It provides a map viewer to overlay and compare spatial data, and a metadata catalogue that allows to search and to find available data. The HLanData geoportal follows the principle: one centralized access to decentralized data. Your benefit is that there is one common legend. Due to the harmonization of the data according to common standards on the HLanData geoportal you can easily view different land use or land cover data from Europe together in one map. Moreover, you can have a cross-border view. Harmonized data is a key input for integrated and holistic analysis for example in regard to environmental, mobility, economic, and social issues.


Fig. 2: HLanData Promotion Video – HlanData Geoportal (Source: URL 1)

Besides a geoportal, four pilots have been developed, offering guidance that will be of great help when searching for different type of information about the territory. The pilot developed in Spain and Latvia provides, amongst other things, information of what can be found in a point or an area and on where you can find a given type of land use or land cover. It also allows seeing the variations in each part of the territory as well as in which points it has varied similarly. The other pilots provide information on stock and flows land accounts, socio-economic data, development of spatial indicators, and detection of illegal waste dumps. In fact, the pilot implemented in Slovakia is an interactive specialized web-based map application focused on

waste management sector allowing selected operations as visualization, overlay and integration of different information from different sources. It integrates harmonized European datasets, national waste management data and national sources of spatial data intended for the additional functionalities and analyses as protected areas, geological maps, urban atlas and vector maps of Slovakia.

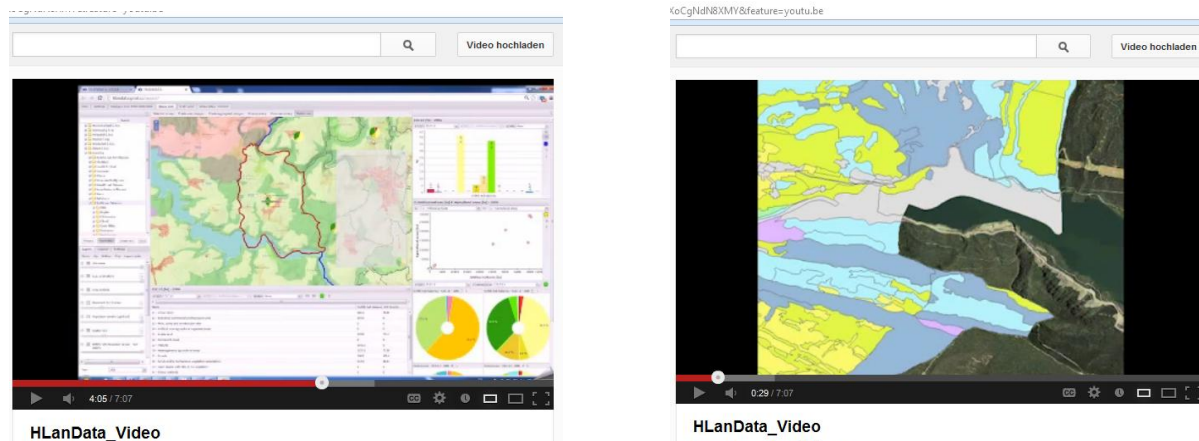
This work will be of great help to study and assess the territory. Thus, solutions are offered in different application fields taking into account the final users. The most important fields of action are territorial management and spatial planning on which dedicated pilots have been developed in the Czech Republic and in Lithuania, and the strategic environmental impact assessment for numerous emerging themes e. g. studies of the species, habitats and ecosystems and their potential to provide services including changes in their connectivity in relation to green infrastructure, calculations of CO_2 emissions, evolution of irrigated lands, preliminary calculations of soil erosion, study and assessment of the models of urban growth, waste management, but there can be many more.


Fig. 3: HLanData Promotion Video – HlanData Pilots providing advances analysis functions (Source: URL 1)

All these applications will profit from sharing harmonised data and advanced, but easy to use tools for data exploration. The services that HLanData offers are addressed to any user of this type of information, particularly technicians of the public authorities; decision makers; private companies; researchers; NGOs; planners; GIS analysts; consultants; architects and engineers but also the general public. That is why we go for free and open technology via web, providing decision makers with information about land use and land cover.

We gathered the momentum of INSPIRE, which will oblige the member states to harmonize their geographic information data and we have closely cooperated with its thematic working groups of Land Use and Land Cover. We have also taken into account the directive related to the reuse of the public sector information. That is why the European Commission supports us and the European Environmental Agency and our tools are in line with Copernicus and GEO initiatives. Besides providing information to the users in the moment they require, this project also intends to increase participation and exchange of information.

HLanData has been possible thanks to the fruitful cooperation between nine partners from seven European countries, but our efforts would have been in vain without the active participation of the final users in testing the tools. Moreover, the different project phases have been supervised by a group of experts in an advisory board and by independent technical reviewers. HLanData has also involved other relevant experts in the several forums organized by the project. To all of them THANK YOU!"

1 ABSTRACT

Metropolitan Lima is one of the the world's largest megacities located in an arid climate. Water-related problems and opportunities vary greatly from place to place due to diverse natural and urban contexts. They require different solutions to integrate the urban water cycle and the (green) open space system. An integrated planning approach called "Lima Ecological Infrastructure Strategy" (LEIS) was developed within the LiWa-research project to address the specific challenges. Its aim is to provide guiding principles for a water sensitive urban and open space development, in order to contribute to the improvement and protection of the urban water cycle. A GIS-based planning tool assists in analizing the city and in localizing the various potentials and threats for Lima´s sustainable urban development. In order to reflect the diverse conditions in Metropolitan Lima, considering the natural and man-made forces, the city is analyzed with a meso scale approach through hydro-urban units.

The unit's geometry is based on sectors for water provison and further characteristics of the built and natural environment including open space and the availability of divergent water sources were assigned. Several aspects were considered and information such as topography, natural and man-made water sources, population density and growth rates, state of water infrastructure, structure of urban pattern and open space and environmental functions were aggregated or disaggregated and transfered to the approx. 450 hydro-urban units of similar size that are linked to the water supply. The meso scale units allow to show the city like a mosaic, with enough information to differentiate them according to the characteristics but not too detailed information that distract from the overall comparison.

This approach allows urban planning as well as water management institutions – which are both partners of the LiWa research project – to recognize the relationship between water sources and the urban structure and as a consequence, planning activities can be harmonized in a better way and development scenarios can be evaluated. For areas with specific hydro-urban characteristics, site-specific water sensitive design solutions for the integration of the urban water cycle and open space are developed in the next stage, which if applied in a larger scale create the ecological infrastructure of the city.

2 INTRODUCTION

The Peruvian capital Lima, situated on a desert coast along the Pacific Ocean, is considered one of the most vulnerable cities in the world due to the effects of climate change. With an average precipitation of 9 mm per year, it depends solely on its three rivers, Rio Rimac, Rio Lurin and Rio Chillon, which are fed from water transfers, rain and glaciers in the Andes that are melting rapidly because of climate change. Lima was initially founded in the Rimac River valley, but today the metropolitan area of Lima and Callao with its more than 9,45 million inhabitants extends over extensive desert areas, dry hills and surrounding valleys.

Although there is almost no rain, Lima´s climate is very humid due to the effects caused by the interface of the Humboldt cold current and the Equatorial hot current over the Pacific Ocean in the West and the high Andes mountains on the East. Average annual humidity along the coast is between 80 and 88 % and in the higher altitudes still has more than 70 % as an average, with almost 100 % from June through December (Atlas Ambiental 2011). As a result the whole metropolitan area is coated with fog, that hangs constantly over the city and turns some of the desert hills into temporary, herb-rich meadow biotops called loma.

The fast population growth, lack of implementation of urban or regional planning instruments, economic crisis and other factors have led to a vast expansion of informal settlements. These settlements lack many basic urban services such as water supply, waste disposal and wastewater infrastructure, which has caused environmental degradation. In the last 70 years the urban development has been characterized by informal occupation. The non-implementation of planning instruments due to prioritization of open markets has brought to the city urban speculation and urban sprawl that has guided urban development. Productive and agricultural land as well as some parks were replaced by new urbanizations. In addition to that, the agencies

in charge of water management and urban planning were neither sharing a joint vision nor coordinating their actions due to belonging to different management bodies. For these reasons urban planning is very weak and the last metropolitan urban development plan already expired in 2010 – however a first regional plan for the city has been developed and approved in 2012, preparing as the next step the development of the metropolitan urban development plan that should guide the city towards a new urban development model.

City structure, open space and the urban water cycle

Water management in Lima is led by a state owned enterprise called Servicio de Agua Potable y Alcantarillado de Lima (SEDAPAL), which is in charge of providing potable water and wastewater services. Many settlements in the peri-urban areas lack basic urban services such as water supply, waste disposal and wastewater infrastructure, which has caused environmental degradation. About one million people, mainly living in the hilly and peri-urban areas, are not connected to the public water supply networks. They receive drinking water, often of very bad quality, from private water vendors at high prices. SEDAPAL invests in large infrastructural projects to increase the water supply by bringing the water from the Atlantic water basin by tunnels through the Andes to the Pacific water basin.

Although there is a limited amount of water resources and many people lack access to safe water and sanitation, most parks and road greenery of Lima and Callao are irrigated with potable water. Due to a change in pricing potable water for irrigation, the pressure is continuously shifting towards utilization of treated wastewater for irrigation. Moscoso (2011) states in his study that only 15 % of the wastewater is treated and only 10 % of that which has been treated is reused for irrigation of green areas in Lima. The existing wastewater treatment system often cannot meet the quality demand of treated wastewater suitable for irrigation, leading to calls for modernization and investments into improvement of treatment systems to provide water of sufficient quality. Many municipalities and administrative bodies are building small wastewater treatment plants to cover their needs for water for irrigation without a coordinated plan with SEDAPAL. These facilities often fail in function due to lack of knowledge for maintenance and management capacity. Polluted rivers are concreted and channelized and irrigation channels are covered due to pollution without considering them an integral part of the open space system, as a potential source of water and a drainage system needed during rainy events in the upper parts of the watershed.

There have been attempts to utilize different sources of water for greening the city than just potable water. The discussion about reuse of wastewater has focused so far mainly on suitable technologies of the treatment facilities to provide sufficient amount of water for irrigation. However, the question of how to make use of the treated outflow of the existing, large-scale plants and where to allocate new, decentralized facilities is also high on the agenda. But little has been discussed about the actual design of the open space and its water demand. The current design practice fails to exploit the potentials of open space design to decrease the over-absorption of water resources, improve water quality of the degraded and polluted seasonal rivers, irrigation channels and groundwater. Lima's hydrological conditions and water infrastructure as well as the design of open space and green areas need radical rethinking to make urban and natural systems perform in concert with one another and keep up with the increasing water demand for a growing, more liveable and green city.

3 LIMA ECOLOGICAL INFRASTRUCTURE STRATEGY

A planning approach called "Lima Ecological Infrastructure Strategy" (LEIS) was developed within the BMBF[1] megacity project "Sustainable Water and Wastewater Management in Urban Growth Centres coping with Climate Change – Concepts for Metropolitan Lima (Perú)" (LiWa) to address the specific challenges.[2] The approach follows the question of how to integrate water management and open space planning.

The ecological infrastructure is based on the green infrastructure concept and it can be described as a multifunctional system of open spaces that, due to its multiple functions, serves as integral urban structure providing essential infrastructural services (Benedict & Mahon 2004; Ahern 2007; Mell 2010). A further methodological and conceptual background derives from water-sensitive urban design (Feyen et al. 2009; Hoyer et al. 2011). It is assumed that the coordinated designation of multifunctional open spaces, as proposed in the ecological infrastructure strategy, tackles the urban development challenges in a more

---

[1] German Federal Ministry of Education and Research

[2] The web page of the project gives an overview of the whole project www.lima-water.de. For an overview of the challenges see also Schütze & Robletto (2010).

efficient way than conventional land use planning approaches. Therefore it can guide the urban development in a more sustainable way.

LEIS-Principles

The aim of formulating guiding principles for future open space design is to proactively contribute to the improvement and protection of the urban water cycle. The principles integrate multiple scales. On the metropolitan level, principles for a ecological infrastructure have been defined and harmonized with the Regional Concerted Development Plan 2012-2025. Those principles are translated into policies that will integrate the future urban planning and water management at macro, meso and micro scale.

They argue to

-        protect, develop and implement ecological infrastructure, considering availability and integral management of water resources;

-        protect and consolidate agricultural land and add value to improve ecosystem performance;

-        transform high risk areas as part of the ecological infrastructure;

-        promote water sensitive urban development that considers water catchment, saving, treatment and reuse of water in the city and develop water sensitive urban design according to water sources.

LEIS-Manual

On the site level, recommendations for prototypical water-sensitive solutions for different urban areas of Lima are developed. They are based on an a survey of several existing open spaces and new design projects to show how water sources and vegetation are dealt with in the open space design and management. Based on this survey, prototypical water-sensitive design solutions for different water sources in different spatial situations (=> hydro urban characteristics) are presented, which if applied in a larger scale create together the ecological infrastructure of the city.

LEIS-Tool

In order to localize for instance the areas with high irrigation demand and the various potentials for water saving, re-use of treated wastewater and multifunctional open space design, a GIS-based meso scale analyses of the metropolitan area is conducted. The objectives for the LEIS-Tool analyses are defined by both the LEIS manual and the LEIS principles alike – e.g. identification and quantification of all water sources – linking the overarching principles with programmes and prototypical projects on the ground.

With this approach integrated planning is not only applied in the sense that there is an integration of water management and urban planning, but also with regard to the integration of scales and most importantly through the interlink between the three components of the Lima Ecological Infrastructure Strategy.

4 MESO SCALE APPROACH – THE CITY AS A MOSAIC

4.1 Methodology

How to integrate water management and open space planning and why?

The lack of a unified view of the city that is shared by urban and open space planners and water management a like is one obstacle to integrated planning. The methodology developed in the research project and outlined in this paper leads to the creation of meso scale spatial units that define different typologies of urban spaces in relationship with the urban water cycle and provide guidance for the planning processes of both disciplines.

What information is available?

Due to the availability of satellite imagery with a resolution of up to 50 cm every level of detail that is needed for spatial planning can be captured. Furthermore extensive data about the socioeconomic situation is available (COOPI 2011), Google Earth communities contribute to specialised fields of interest and a new municipal administration updates important planning information.

Why is there a need for a less detailed meso scale approach and what means meso-scale in this context?

Despite the partially very detailed information, the problem of divergent spatial information depending on the field of interest, multiple scales, changing resolution and the incompletness of information remains. This

issue has been addressed by the planning institutions as challenges for integrated spatial analyses and there are recent examples that have developed solutions to overcome this problem – for large scale / country wide socioeconomic evaluation (Huyssteen et al 2009), and for geospatial analysis across scales, borders, sectors and disciplines (Naude et al., 2008).[3]

In the case of Lima, this common problematic is coupled with weak metropolitan planning institutions, historically fairly independent district municipalities and a strong sectoral organisation of spatial, social and infrastructure issues. Basic cadastral information of divergent sources are compeeting and a unified view on the city is lacking. The administrative districts of Lima and Callao are too diverse in terms of different urban conditions to be useful for any city wide comparison. On top of this, the provincial division between Lima and Callao force administrative borders onto the city that are hardly recognizable on the ground but have a strong influence for the availability and the harmonisation of information. At the same time, watershed outlines are in the case of Lima – a city without rain – not sufficient for spatial differentiation.

Meso scale as it is understood in this paper means the intermediate scale between the urban planner's block scale and the regional planners city scale.[4] For the people of Lima this intermediate scale is usually represented by the districts, even though they are by nature too heterogenous to be equally compared, with population ranging from 20.000 in the smallest district of La Punta to almost 1 million in the district of San Juan de Lurigancho.

The GIS-procedures of overlaying information, clustering, disaggregating and aggregating could be performed related to any homogenous spatial unit. The extensive SIRAD study (COOPI 2011) has shown the potential for a fine sclae block based analyses of risks and vulnerability. For raster based analyses the formerly known contrains with regard to fine scale resolution diminish. Processing power of standard computers would already allow for high resolution analyses (2 – 10 meters) of a raster based model and could facilitate suitability analyses with regard to the urban water cycle and open space planning. However the problem is not the level of detail of certain information but the divergence of information with regard to accuracy and timeliness and the lack of a unified perception.
Figure 1: Combination of relevant characteristics in hydro urban unit.

Furthermore the key information in this case is the water, the consumption and the potential supply, and one of the key actors is the water company, which led to the decision to choose as a meso scale unit the water management sectors that are used by the water company SEDAPAL for managing the distribution of potable water. SEDAPAL is responsible for the water and wastewater services throughout the largest part of the metropolitan area, it is therefore in the situation of also holding partially more detailed and farther stretching spatial information than the actual planning institutions. There are 450 sectors with an average population of 20.000 and an average size of 95.500 m². They are covering the SEDAPAL service area which extends over

---

[3] Avelar et al. (2009) have applied remote sensing analyses in order to pre assess the distribution of socio-economic classes in Lima on a meso scale level.

[4] Within the LiWa-Project, that actually covers all three Lima watersheds from the Ocean to the Andes in order to model climate change effects, macro, meso and micro scale are again used slightly different, with the whole metropolitan area of Lima and Callao being described as meso scale.

almost the whole built up area of Lima and Callao. A few sectors had to be added in order to cover the whole area of investigation with similar sized descrete spatial units.

Altogehter these units describe the city according to the water sources and the characteristics of the built and natural environments including open spaces. The hydro urban units consist of aggregated and disaggregated information, derived from topography, natural and man-made water sources, population statistics, the state of water infrastructure and structure of urban pattern and open space and environmental functions. They can be ordered into the spheres of "Water Demand", "Water Supply" and "Natural and urban environment" including population and society (fig.1). The combination of certain information results in specific hydro urban characteristics, the combination of all relevant aspects eventually leads to a set of distinct hydro urban typologies that are understood by urban planners and water management as a basis for their analyses, programms and projects.

Figure 2 shows an example for two sets of information that are assigned to the the mediating spatial unit, the HUU, through processes of aggregation and disaggregation. While in the one example the information about the level of connectedness of households to the sewage system is available in a fine scale (block), population growth trends as the other example are only estimated on the district level and therefore rather coarse. After processing the information can be combined in one spatial entity which is neither the block nor the district but the hydro urban unit.

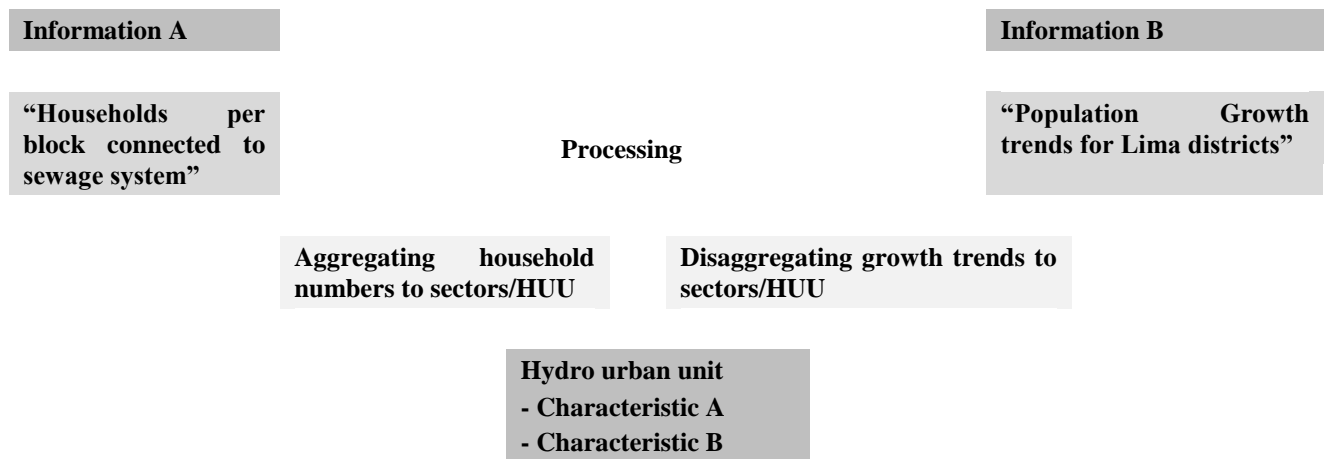
Information A		Information B
"Households per block connected to sewage system"	Processing	"Population Growth trends for Lima districts"
	Aggregating household numbers to sectors/HUU Disaggregating growth trends to sectors/HUU	
	Hydro urban unit - Characteristic A - Characteristic B	


Figure 2: Processing information for hydro urban units.

4.2 Application

The usability of this approach will be shown with the following planning task that is derived from the principles of the Lima Ecological Infrastructure Strategy. One of the principles states: Protect, develop and implement ecological infrastructure considering availability and integral management of water resources. This results e.g. in a need to quantify the demand for the irrigation of green open spaces in Lima areas and the estimation of the potential supply for the irrigation of green areas.

Water demand

In a first step the water demand for irrigating green areas is quantified. Although there is detailed information about the irrigation of crops and the specific water demand for certain species, general numbers for the actual water consumption for green areas are not available. Within the LiWa-project divergent numbers for the demand of water were estimated. In a general survey Mosoco (2011) estimated 1,95 m³/m²/year. Based on an analyses of actual water supply information from SEDAPAL for 800 green areas, an average consumption of 1,49 m³/m²/year was identified by the author.[5] The district of Villa El Salvador in the sandy south of Lima estimates a demand between 2,5 and 2,7 m³/m²/year as an average for the district parks and 3,1 m³/m²/year for grass surfaces (Municipalidad de Villa el Salvador 2012).

Estimations for the demand based on real needs of intensive lawn vegetation result in only about 1 m³/m²/year which leads – depending on the type of irrigation – to 1,25 (pressurized irrigation) to 2

---

[5] The sample consists of monthly consumption rates between May 2011 and May 2012 and the dataset includes the size of the actual serviced area. It is therefore assumed that it mirrors quite well the "normal" demand for irrigation including the standard management.

m³/m²/year (gravity irrigation). This leads to the assumption that besides the real need for the vegetation and the demand depending on the irrigation regime a third component that may be called "other losses" has to be considered. However for the estimation of the water demand the figure 1,5 m³/m²/year that is based on actual consumption data is taken, without speculating on the amount of "other losses".

Green open spaces

The main source of information for the green open spaces in Lima and Callao that are collected in the green catalogue[6] has been adopted from a dataset provided by SEDAPAL (12/2012). It quantifies the total green area that is serviced by SEDAPAL stretching over the whole area of Lima and Callao. The second source is the first draft of the green inventory which was put together by SERPAR and IMP and was supported by the LiWa project (9/2012). The green inventory was updated with Google Earth (visual comparison) and attributed according to coverage with vegetation, hard surface or bare soil. Other sources of informationen with less detail had to be taken for Callao and two Lima districts, because of availability reasons. Altogether a heterogeneous situation with regard to legal zoning status, ownership, real shape, vegetation coverage and categorization. Therefore the only comparable information was a rather crude differentiation in linear green areas, parks of all sizes and functions and the larger zonal and metropolitan parks (incl. Zoo) summing up to altogether 3.500 ha.[7]

Type	Area m²	Area ha
Linear green areas (mainly along streets)	8.216.672	822
Parks and other green areas	22.969.977	2.297
Zonal /Metropolitan Parks & Zoo	3.917.340	392
Total	**35.103.989**	**3.510**

Table 1: Green areas in Lima and Callao (ILPE 2013)

Considering a demand of 1,5 m³/m²/year and a total area of 35.100.000 m² a total water demand of 52.650.000 m³ or 1,67 m³/sec for the irrigation of green open spaces – without agricultural land – can be assumed. In comparison the total amount of potable water distributed through the water pipes was 18,22 m³/sec in 2011.

The future demand for irrigation is calculated depending on three factors:

a)   Enhancement of irrigation regime and adaptation of water sensitive design schemes for open spaces

The water management in parks is presently not very efficient. To estimate a potential for a reduction, the two irrigation systems that are presently most often used in Lima can be compared. The by far most often used gravity irrigation is only 50 % efficient the pressurized irrigation has an efficiency of 85 % .

Theoretically a complete compensation of gravity irrigation with pressurized irrigation would lead to a reduction of the water demand of roughly 40 %. However this situation can hardly be achieved and a realistic reduction of water consumption through a better irrigation regime and the adaptation of water sensitive design schemes for open spaces as proposed in the LEIS-Manual, lies rather with 10-15 % in a time span of 10 years. Therefore for any future water demand 1,35 m³/m²/year is taken for further calculations.

a)   Population growth

The last census for Lima by the Instituto Nacional de Estadística e Informática (INEI) was in 2007. There is no more recent census data available, but there are estimations by INEI about the future development of the whole country and its departments. INEI's estimated number for population growth until the year 2021 for the whole metropolitan region of Lima and Callao were broken down to growth rates for districts by IMP based primarily on district growth trends of the past (IMP 2011).

From 8.470.000 inhabitants in 2007 to 9.450.000 in 2012 to estimated 10.850.000 inhabitants in 2021 the city's population is expected to grow by more than a fourth within 15 years.

---

[6] Within the project a collection of various information with regard to green areas is compiled in the green catalogue. It is not the green inventory that is presently being updated for the Municipality of Lima.

[7] Other studies, like the recently published survey by Ludena summarize about 2.550 ha for Lima alone (Ludena 2013) which is, considering the approx. 460 ha that are in Callao, 500 ha less than in this study.

But the growth is heterogeneously distributed over the city with a population that remains constant in consolidated districts to areas with an increase of 50 % up to 240 %. Within this project a further disaggregation from districts to sectors (hydro urban units) took place in order to show the process spatially distributed in a better resolution.[8]

b)   Ratio m² green area per inhabitant

The current ratio of m² of green public spaces per inhabitant in Metropolitan Lima and Callao ranges from 2,4 – 3,7 m²/inhabitant depending on the data source and the selection of the areas that account for "public green". Within the LiWa-project the higher numbers were chosen because they include all the linear green areas along streets with mostly decorative functions but nevertheless a considerable water demand.

In the public debate in Lima much higher ratios are considered, such as the 8 m² per inhabitant as proposed by the World Health Organisation is often used as the target indicator (Ludena 2013). In the Regional Concerted Plan for Lima an intermediate ratio of 5 m²/inhabitant is envisaged (IMP 2012, 361), this figure is therefore used in this study. Table 2 shows first the calculations for the whole city based on a status quo extrapolation with 4 m²/inh. also for the future population and than the calculations based on the intermediate goal of 5 m²/inh . In the lower part of the table the ratios are calculated for each hydro urban unit in order include the local conditions that vary greatly within the city.[9] This lead ultimately to higher numbers because in this case the green areas in HUU with more than the 4 or respectively 5 m²/inh. do not compensate for a deficit in another HUU.

4.3 Analyses

According to population growth until 2021, and a ratio of 5m² green area/ inhabitant, the quantification of the future demand for green areas results in 6.130 ha of green open spaces and 5,65 m²/inh. for the whole city and would have a water demand of approximately. 2,62 m³/sec (table 2). The map of the hydro urban units (fig. 3a) shows a very diverse image of the city with a great demand for an increase in the South of Lima and the North East but large areas which lie in the centre and the consolidated districts with only little demand.

According to Moscoso (2011), presently only a 10th of the treated waste water is used for irrigation of green areas and agricultural land, which amounts to roughly 0,3 m³/sec. It is widely acknowledged that there needs to be an increase in the use of treated waste water, but the question is how and where. An increase of the re-use of treated waste water could in theory compensate for instance the demand that results from the population growth. But is the water available where it is needed most?

Year/ irrigation regime	Water demand m³/m²/year	Population	Ratio green area m²/inh. whole city	Green area total	Water dem. m³/second
2012 – present	1,5	9.450.000	3,7 m²/inh.	35.100.000	1,67
2021 – no change		10.850.000	4,0 m²/inh.	43.400.000	2,06
2021 – water saving	1,35				1,86
2021 – no change	1,5		5,0 m²/inh.	54.250.000	2,58
2021 – water saving	1,35				2,32
			Ratio green area m²/inh. each HUU		
2021 – water saving	1,35		4,0 m²/inh.	54.800.000	2,34
2021 – water saving			5,0 m²/inh.	61.300.000	2,62

Table 2: Water demand changes according to irrigation regime and green ratio. Note the difference in total area, which is depending on the application of the ratio for the whole city or the more local hydro urban units.

---

[8] Further adjustment of the distribution of the growth trends within a district is needed, in order to identifiy the most likely expansion area.

[9] Ludena also points out the existing contrast related to the unequal distribution of green-open space in the city. For instance some districts reach over 15 m²/inhabitant of green open space. However other districts located over desert or hilly areas reach an average of 0,2 to 2 m²/inhabitant of green public space, confirming the lack of coherence and unsustainability of the current urban development (Ludena 2013).

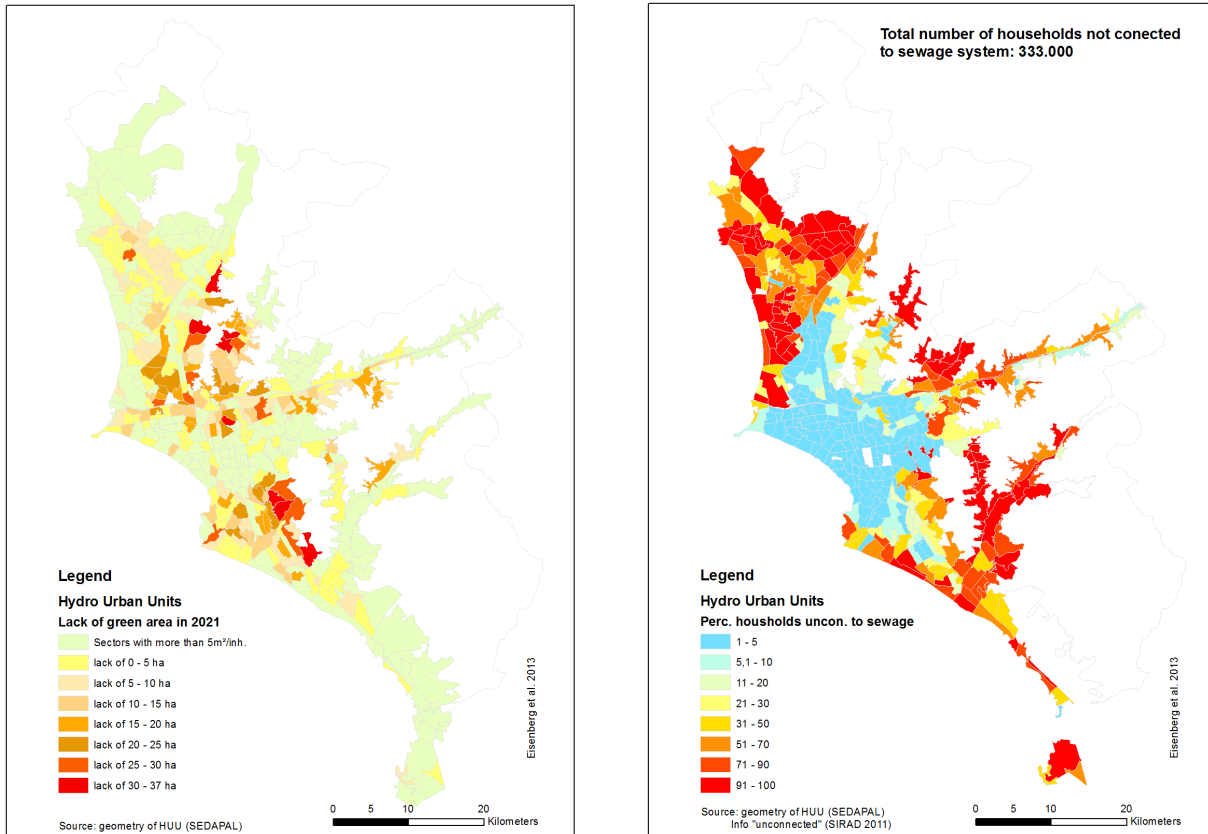
To answer that question the second step of the analyses identifies the HUU with a high percentage of households that are not connected to the sewage system (fig. 3b). Therefore these areas are potential areas for the connection to new, decentralized treatment plants that first of all clean the waste water but also provide irrigation water. With follow up analyses specific areas can be outlined and the respective design prototypes for "wastewater treatment parks" and other proposals and designs that are adequate for these areas and which are developed within the LEIS-Manual, can be implemented.


Fig. 3a: Lack of green areas in 2021 based on a ratio of 5m²/inh. in each sector/HUU. b) Percentage of households that are unconnected to the sewage system.

5 CONCLUSION

The Lima Ecological Infrastructure Strategy tries to bridge the sphere of general planning guidelines and principles for an integrated urban planning and water management to site-specific water sensitive design solutions. The question of what to aim for in order to integrate urban planning and water management is connected to the questions where to implement and how to do implement. This integrated approach is seen by the authors as an alternative route to tackle the fragmented planning that Lima's suffers from today.

The meso – scale analyses is adequate to localize specific demands for water consumption as well as the divergent potentials for water soruces. In a situation without updated population data, the disaggregation of general population growth trends is the only way to quantify future demand for green open spaces and localize it. The example presented in this paper shows only one of many possible solution to overcome the shortage of public green areas and and to identify potential water sources for irrigation at the same time. In this case the areas that are today unconnected to the sewage system are in the future potential catchment areas for waste water that can be treated and used for irrigation. More complex combinations of hydro urban characteristics will eventually be useful to identify distinct typologies that are understood by urban planners and water management alike and that may lead to a common vision of the metropolitan area of Lima and Callao.

1 ABSTRACT

The i-SCOPE project is based on interoperable 3D Urban Information Models (UIM) and delivers an open platform on top of which it develops, within different domains, three 'smart city' services. These will be piloted and validated, within a number of EU cities that will be actively engaged throughout the project lifecycle. The services will address:

(1) Improved inclusion and personal mobility of aging and diversely able citizens through an accurate city-level disable-friendly personal routing service that accounts for detailed urban layout, features and barriers.

(2) Optimization of energy consumption through a service for accurate assessment of solar energy potential at building level.

(3) Environmental monitoring through a real-time environmental noise mapping service, by leveraging citizen's involvement will who act as distributed sensors city-wide measuring noise levels through their mobile phones.

All smart services will be based on already available technologies which will be integrated, deployed and made publicly available from a "3D smart EU cities" portal.

The paper explores how the different pilots are being implemented in the various cities and what is the relationship between the public administration and the end users.

2 INTRODUCTION

"Smart City" is part of the current terminology that is strictly related to the way ourdays cities perform as for livability, efficiency and sustainability, reason why it has become to goal also at EU level, such as with the Digital Agenda (2013).

The fields of application are therefore very wide and address a development of 'smarter infrastructure' on the one side and a 'smarter usage' by citizens on the other (Caragliu et al. 2011).

Among the various scopes of smart cities are the introduction of advanced mobility management solutions, dealing with both transport infrastructures and information/monitoring systems, but also services are being developed to address environmental monitoring and energy efficiency issues. This is affecting not only the energy retail market, where utilities can benefit from smart grid technologies, but also the building construction sector, where the design of low-environmental impact buildings can significantly benefit from more efficient services optimising heating, air-conditioning or power consumption.

The European Commission, within the Digital Agenda, is paying significant attention to smart cities, as technologies associated to smart cities can bring to an improved knowledge-based economy, to better social inclusion and, in more general term, to a more livable environment.

The i-SCOPE project is therefore an example of how technological solutions are being tackled, including aspects dealing with social and environmental issues. Indeed in i-SCOPE each technological solution is not considered as an achievement "per se", but it engineered following an open-innovation, user-driven approach, with the ultimate goal of promoting a so-called "humane city".

In fact the approach within the i-SCOPE can be seen as a bottom-up research process based on open innovation systems, being promoted within three key research domains: 1) inclusive routing, to facilitate personal mobility of diversely-abled citizens; 2) solar impact analysis, to promote energy savvy planning policies; 3) crowdsourced environmental monitoring, to be able to use citizens and mobile IT technologies (i.e. smartphones) as distributed sensors of environmental information.

3 TECHNOLOGY

i-SCOPE integrates open source technologies and previously developed partner projects within a comprehensive toolkit promoting interoperability through the use of OGC and other open standards for data exchange and services. This allows for independent development and functionality deployment provided by different web-services. In i-SCOPE pre-existing technologies, wherever not available as services, will be wrapped by a service layer in order to ensure compliancy with the overall schema The following diagram provides an overview of the project architecture.

i-SCOPE will significantly rely on CityGML. This is the open standard for interoperable encoding of 3D Urban Information Models. Since i-SCOPE refers to Smart Cities CityGML and its extension according to the requirements of the project is the most prominent solution. The standard is being developed by the Open Source community under coordination of OGC. As previously mentioned, i-SCOPE requires extension of the core standard as well as the creation of two Application Domain Extension (ADEs) and the extension of a third one (on noise) of the current CityGML. This will extend modelling capabilities making CityGML compliant to the requirements of the three scenarios tackled by the project:

- Sun Potential Mapping
- Noise Mapping
- Differently-abled-friendly routing

The latest generation of 3D Urban Information Models (UIM), created from accurate urban-scale geospatial information, can be used as basis to create smart web services based on geomet-ric, semantic, morphological and structural information at urban scale level. CityGML (Open-GIS 2008) represents a very attractive solution that combines 3D information and semantic in-formation in a single data model.

The aim of i-SCOPE is to deliver an open platform, based on interoperable 3D CityGML UIMs, on top of which it possible to deploy various 'smart city' services. The main challenge of the work is to develop into the i-SCOPE framework an effective way to exploit the CityGML potentiality to provide Smart Cities services.

CityGML is a common information model for the representation of 3D urban objects. It is realised as an open data model and XML-based format for the storage and exchange of virtual 3D city models. As an OGC standard, CityGML plays a leading role in the modularisation of urban geospatial information.

Visualisation is a complex and important issue in 3D city model applications. Efficient visualisation of 3D city models in different levels of detail (LODs) is one of the pivotal technologies to support these applications and it is fundamental to visualise the urban environment in different scales, e.g. from overview scale like a region down to detailed scale like a building or even a room. Furthermore Internet has become a basic information infrastructure all over the world even for the deployment of new smart cities technologies. Therefore, it is necessary to develop methods to visualise 3D city models through the Internet (fig.1).
Image 1: LoD1 model of Trento visualized into i_SCOPE 3D environment

I-SCOPE project implements the possible services to stream the data to the client considering two different features: a) obtain optimum performance and very short response time avoiding the complex queries that can

be made with the WFS; b) transmit to the client the geometries plus the semantic information in a single stream. The way to obtain this kind of results is to stream data directly in the CityGML format. The method consists in a downloading service, which provides to the client the CityGML data fol-lowing a classic tile-based approach fig 2. Within the iSCOPE project the client has been developed on top of Nasa World Wind java SDK. Thanks to this approach many useful features can be implemented in parallel: different services like the WMS, WFS and the proposed approach can run concurrently allowing a great flexibility of the entire system.
Image 2: System architecture of the proposed approach

i-SCOPE will also rely on integration of existing technologies. Specifically i-SCOPE will integrate a tool to generate 3D city models based on existing geodata data such as terrain models and floor plans to produce a realistic 3D city as CityGML. The technology will be customized and adapted to i-SCOPE's requirements in order to operate as a web service The service is asynchronous and realized with novaFACTORY software solution, the user once finished the generation can validate, both downloading and visualizing the final result, both through a summary report the quality of the model. After validation, CityGML data will be stored in 3DCityDB (2011), a free and Open Source 3D geo database to store, represent, and manage virtual 3D city models on top of the Oracle 10G R2 spatial (or 11G), developed by Institute for Geodesy and Geoinformation Science of the Berlin University of Technology.

4 THE PILOT SCENARIOS

The smart services proposed address the following three scenarios:

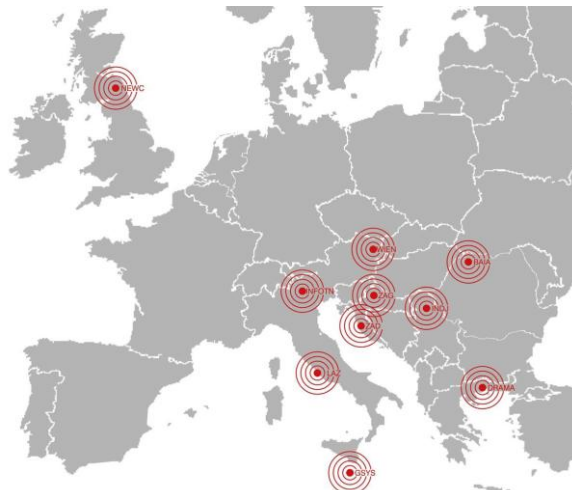
- Improved inclusion and personal mobility of aging people and diversely able citizens;
- Energy dispersion & solar energy potential assessment;
- Noise mapping & simulation.


Image 3: Map of pilot cities within the i-SCOPE project

4.1 The solar energy potential assessment

Current solar assessment GIS (e.g. ESRI Solar Analysis) calculate solar potential based on raster data that need to be created separately from existing terrain and, if available, merging building information. Other online services are simply based on the position and through manual specification of the roof layout (orientation, slope etc.).

i-SCOPE solar assessment is based on accurate 3D georeferenced models of urban environment and therefore accounts for:

- Real layout of roofs and other structures (e.g. walls, slabs etc.).

- Correct positioning.

- Shadowing effects induced by adjoining buildings as well as vegetation, infrastructures (e.g. power line posts).

Unlike other solution all the aforementioned information is automatically calculated from a high precision UIM available in the interoperable standard CityGML. In turn as output the services delivers:

- Interoperable provision of solar maps through Web Coverage Service (WCS) or Web Map Service Time (WMS-T).

- Solar simulations can be calculated through a remote service, based on interoperable standard WPS.

This way any client (including commercial or open source GIS software) can perform simulations by invoking a smart service based on an interoperable protocol.

The solar energy potential assessment involves two services:

- Irradiation calculation: computes solar irradiation raster maps for given day, latitude, surface and atmospheric conditions

- Solar energy potential calculation: requires the irradiation calculation and delivers assessment settings for the buildings

Finally we propose an innovative scenario to support the update of data on heat dispersion from community of citizens and professionals. This information can be later accessed by city administration for planning or taxation purposes. City administrations can easily create maps to show how policies have contributed to improving energy efficiency in areas of the city.

4.2 Noise mapping scenario

The second scenario that i- SCOPE focuses on is that of mapping noise in urban areas, both through a novel participatory approach involving citizens and their mobile phones, as well as through the more standard approach of simulating the most important traffic-related sources of noise in a city.

Noise pollution is a substantial problem in societies of today: a recent report of the WHO calculates that in Western-Europe only every year 1 million healthy life years are lost due to traffic-related noise exposure (WHO, 2011). As a result there is high benefit in assessing noise in urban areas, as apparent from the Environmental Noise Directive (END) imposed by the European Union (European Parliament and Council, 2002). These dictate that urban areas above a certain size – applicable to all of the pilot partners involved in i-Scope – are to produce strategic noise maps, created through computer simulations based on general statistics, such as the average number of cars in the city. These maps are backed up only by limited amounts of sound measurements, because current measuring methods are expensive and thus not very scalable. The resulting maps give an average but not at all a complete view on the situation, entirely missing local variations due to street works, neighbourhood noise etc. The NoiseTube platform proposes a solution to these issues, by facilitating sound measuring at any place and time through a mobile app that exploits basic smartphone functionalities, namely microphone, wireless connectivity and localisation through GPS. Through these three components, NoiseTube transforms already ubiquitous smartphones into highly portable, accessible sound measurement devices, thus enabling all citizens to measure ambient sound levels whenever and wherever they please. The NoiseTube website collects all user measurements and visualises them on maps. Recent research (D'Hondt & al, 2012) showed that given calibrated phones and enough measurements for a particular area, we can construct noise maps of comparable quality to those produced by

governments today, thus providing a complementary view on the noise situation of urban areas. The i-Scope project is innovative in that it covers both mapping techniques within one framework, together with several pilot actions involving city administrations.

NoiseTube is a user-friendly, free and open source tool with which citizens can estimate the quality of their daily environment and how it is affected by their behavior, providing support for awareness-building as well as for undertaking citizen- as well as city-steered actions to solve local issues. It has been used by citizens all over the world, for individual use as well as for measuring campaigns by citizen action groups.[1] With i-Scope project came the first application of NoiseTube as a top-down noise mapping campaign method steered by city administrations, with pilot activities for Zagreb (HR), Baia Mare (RO) and Trento (IT).

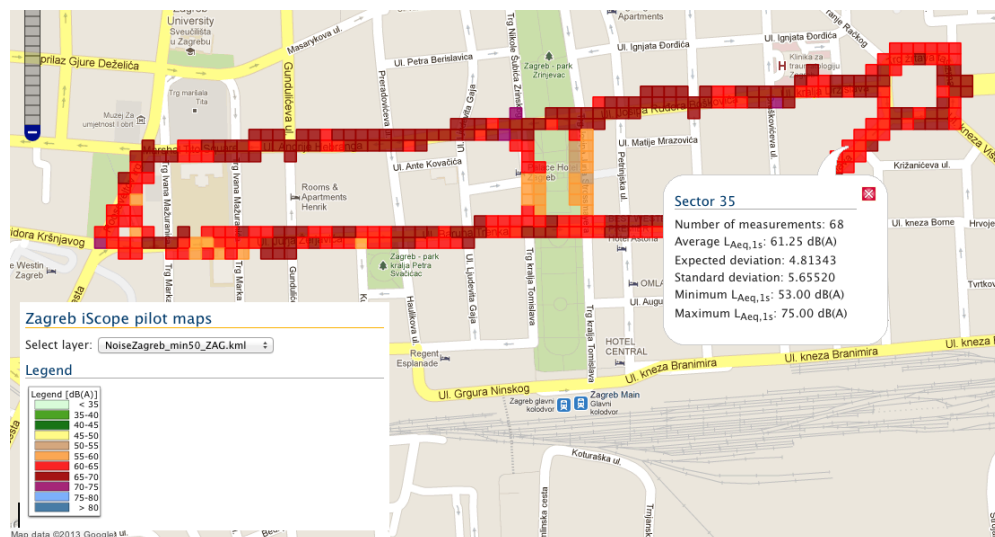
A noise mapping campaign is different from individual use of the NoiseTube platform in that a campaign unites a group of people in an orchestrated measurement action, typically focussing on a specific concern. Concerns can be geographical (i.e. noise issues in a neighbourhood), temporal (how do peak hours in different cities compare?) or task-oriented (your boss at city hall asks you to evaluate how street works affect the commune, or a combination of the former. In a campaign it is important that measurements are gathered in a focused way so as to increase accuracy as well as representability of maps. Concretely, the campaign in Zagreb focused on a particularly busy city trajectory during peak hours (weekdays at 8 am). Five volunteers walked this 3,5 km trajectory daily for 5 days in June 2012, jointly amassing enough measurements so that a statistically relevant dataset was obtained. The map shown below was obtained by distributing measurements over a grid and computing averages for each 20mx20m cell. Volunteers used HTC Desire C (uncalibrated) phones, while the map's colour coding adhers to the colour codes used by Croatia. Pilot activities in Trento and Baia Mare have so far been focused on individual noise trajectories rather than on aggregated campaign maps.


Image 4: Noise Map from the Zagreb Pilot

Our experience with city-based campaigns has been quite different from citizen-based ones. Most importantly city-based campaigns are much more centralised than grassroots ones. Indeed, the latter are more collaborative in terms of defining campaign specifications (area, time, material used). A second, related issue, is to do with communication with volunteers. Grassroots actions typically rely on a group of people already cohesive, both at the level of motivations as of concerns shared. This facilitates dissemination of NoiseTube essentials as well as communication of campaign requirements. Typically, one meeting involving a NoiseTube expert is enough to ensure a succesful campaign. In a city-based context it is often a city administrator who acts as the interface with volunteers in a hierarchical structure. Communication with the NoiseTube expert always occurred through this administrator, and never directly with the volunteers. This has led to issues with understanding campaign basics (in particular the importance of gathering enough measurements at the same tim), with motivating users to keep on measuring (by not giving them live feedback on what they had measured), and with organisation in itself. In our opinion, a well-maintained

---

[1] See http://www.brussense.be/experiments for interactive, aggregated maps of our noise mapping campaigns so far.
Colour codes for noise maps under the END may be chosen freely by each member state.

(ideally face2face) communication chain, either directly between an expert and the whole group of volunteers, or between expert-administrator-volunteers, is essential in delivering a succesful campaign. Since, especially in an international context, it is not always to achieve this, we are currently working towards better support for campaign definition, management and analysis within the NoiseTube framework itself.

4.3 Accessible routing scenario

The i-SCOPE project will develop inclusive routing that will be targeted for visually impaired and wheelchair users. The results of route planning can be made available for blind people as spoken instructions. Unlike route planners, the innovativeness of the application lies in the fact that the blind are guided in and at the same time have the possibility to experience and understand city spaces, streets, places, parks, etc. as spatial constructs.

The aim is to provide a holistic description of the urban space which means that the user should be able to discover as many attributes of a street section as possible to get a better image of the city. The description includes information about streets, intersections, blocks, points of interest, possible causes of risk, etc. and their spatial relation to each other. The elements of the map need to be described in a semantic way that is adapted to the requirements of pedestrians, especially blind and visually impaired ones.

How does it work?

The City portal will have the option to choose the type of user requirements needed which will be:

- Wheel chair user
- Visually impaired:
    - Blind
    - Partially sighted
    - Colour blind

In this way the user will be able to identify from where to where they need to go and receive the best path for their needs.

Additional information will be provided to the user such as Points Of Inteterest (POIs) and dangers, that var according to the need. For example wheel chair users will receive information such as the quality of the pavement or the lack of ramps, whilst visually impaired users will know what shape a crossing has, if there is a zebra crossing or if there are interesting places nearby.

The service will have the option to be used on a personal computer at home, so to prepare the route in advance, or to be used in real time via the use of a Smart Phone (Android).

The added value of a mobile service is that in case of any unforeseen changes due to road works or changes in plans, the user will still be able to receive an ad hoc route. It must be said though that most users still will be preparing their route at home as this makes them often feel more secure.

The i-SCOPE accessible routing service will not be an alternative to other devices such as a guide dog or a cane, but it will be an additional aid that can provide great benefit.

4.4 The experience of the City of Vienna

In occasion of the Wiener Charta talks, a series of events held within the Local Agenda 21 activities of the city of Vienna where citizens define issues that the City Adminstration should tackle, a discussion on urban accessibility was held and the i-SCOPE project was discussed with the various user groups.

The half day workshop had representatives from the City of Vienna, Companies and research institutions involved in the development of accessible technologies and the user groups, respectively the visually impaired associations and the wheel chair users.

There was a presentation of the i-SCOPE project and then an interactive and lively debate where many issues were tackled, from broader comments such as the fact that accessibility is related to an overall societal attitude to more specific issues such as the affordability of accessible technologies.

What was interesting was that various stakeholders sitting round the table had the possibility to express needs and requirements yet at the same time provide comments and possible solutions to the other.

The event was considered very useful and it was agreed that other events like this will take place again, also out of the Wiener Charta context, also in view of the upcoming testing phase of the i-SCOPE prototype.

In this sense all the participants decided that the idea of starting up an ongoin platform to discuss about innovations within the city would be very useful, reason why the idea of becoming a Living Lab was received with great interest.

In fact the city of Vienna in the coming years will get more and more involved in the Living Lab network in order to bring together public administration, companies and citizens on a regular basis.

5   CONSIDERATIONS ON THE RELATIONSHIP BETWEEN CITIES AND CITIZENS

Citizens' involvement in the i-SCOPE project is an essential strategic element that allows demonstration of the use of the smart services that will be developed during the project implementation and thus to give assurance to the stakeholders of the investment's value . The citizens are one of the most important final users of the services that are going to be developed. Part of the project's sustainability is connected to the capability of local administrations (pilot partner cities/regions) to convey citizens' interest towards the platform/smart toolkit services and to involve them firstly as users but even as co-designer of/for smart solutions that are to be developed. Not only that the main results are directed to them, but also they are involved in the entire process of creating and achieving the necessary data for the project. Moreover, they are involved in the testing of the smart services that are to be created.

Also when thinking about citizens' involvement, it is important to consider that addressing citizens means not only addressing specific categories of stakeholders (e.g. cultural, environmental, economic grassroots organizations), but also to address citizenship in its various expressions (e.g. citizen as politicians, civil servants, city users, teachers and apprentices…). In fully experiencing citizenship rights, people (inhabitants) change roles different times. It is for these reasons that i-SCOPE is increasing citizens' awareness using direct (seminars, workshops, lectures…), semi-indirect (web communication, social networking…), and indirect (press releases, brochures, scientific articles…) means. Indeed, i-SCOPE partners are proceeding using all these communication possibilities.

Finally, it can be stated that the citizen's involvement takes place in 3 key phases:

(1) General information and publicity of the project to the citizens and relevant actors.

(2) General presentation of the stage of the project (evolution), initiated actions, finalized action, first results, and permanent dialog with the citizens and feedback selection from the citizens. Involvement of the citizens in the improving of the prototypes (using a careful predefined methodology). Periodic testing of the prototypes and products.

(3) General presentation of the implemented project (all actions implemented). Dissemination of the final results. Implementation of the prototypes. Future ideas for the improvement of the products

6   CONCLUSIONS

The many i-SCOPE outputs, from the more technological ones to the definition of indicators and frames for policies, will fall on different categories (from meta data modelling, definition of platform to the design of services and urban/territorial policies) that cannot bring to a synthesis if not faced in the context of a pluralistic and multi-faced governance based on the directive and directions given by the EU. The questions connected to inter-regional/cross border use of data, those connected to the indications for the design of trans-national services (the market is definitively global), the other linked with the indication to provide for the design of policies and strategies (the EU should provide a soft creation of coherence among all national and local policies in order to avoid unbalances in use of funds and in the definition of policy principles) are just few examples that demonstrate how the i-SCOPE purposes cannot be solved at local or at national level, but required to be set up, experimented and implemented at EU scale through the implementation of a partnership including, public administration (cities and regions) SMEs and research centres.

1 ABSTRACT

Wise decisions regarding land use transformation should consider potential impact of human activity and assessment to measure those changes. Indicator-based assessment should be established in a way which can be implemented in a given area on time. One of main issues which should be measured is environmental group. This paper presents the use of geoinformation system – CommunityViz for impact assesment of local polices and local development plans for communes around City of Wroclaw (Large Urban Zone). Simple but very useful impact model include demographical, environmental and vehicle-journey factors. Research has shown that CommunityViz can support environmental impact assessment very well.

Keywords: environmental changes, indicator-based assessment, GIS, CommunityViz

2 INDICATOR-BASED ASSESSMENT

The need of monitoring changes in the environment, as a complementary component of a comprehensive assessment of local development, has been discussed for many years. However local governments are not always able to forecast or monitor impacts of their policies effectively. The lack of consistent and comprehensive system of monitoring the investment processes and space transformation at the local level was found. It is a serious obstacle in the assessment of actual risks arising from land development. Moreover, one of the main conclusions defined in the scientific discussion on the phenomenon of urbanization, is urgent necessity to develop techniques which allow precise and clear as possible assess the scale of the phenomenon of urban sprawl. This is considered by the experts of the European Union as a "priority task of the Member States of the Union" (Kozlowski 2006).

In order to investigate the possibility of measuring indicators with the use of geoinformation systems, analysis focused on the current state of knowledge and reliable indicators were selected. As noted Czochanski (2010) indicators used in monitoring, should be simple (one-dimensional), relational and synthesizing (showing wider background of phenomena and relationships with other elements) and context (showing the relationships between different areas or variants of phenomena).

System used for assessment of the environmental effects is CommunityViz. It is an extension of ArcGIS Desktop. The two main components of CommunityViz are Scenario360 and Scenario3D. It's designed to assist process of decision-making by stakeholders in the planning process. It helps to evaluate the future traits that define the area and the factors that affect the local community. It can be used to carry out experiments with hypothetical scenarios, perform parametric evaluations, modify spatial calculation assumptions, present visual effects of the proposed action, make decisions based on comprehensive information and connect your work with three-dimensional visualization variants.

U.S. experience shows that CommunityViz with skilful use and cooperative society can be an effective tool to support decision-making (Walker and Daniels 2011). Case studies have shown that complexity of this software is really low. It can be successfully used for helping social participation even during work with laymen, people who are not specialists (http://placeways.com/communityviz/gallery/casestudies/pdf/). We used CommunityViz for assessing influence of spatial planning policy of City of Wroclaw and sourrounding communites. The essential thing was proper interpretation of principles for the formulation of indicators.

3 METHODOLOGY AND RESEARCH AREA

The research area includes Wroclaw and rural communes which are located around the city. Wrocław is the historical capital of Silesia and the largest city in western Poland. The city originated as a Bohemian stronghold at the intersection of trade routes, the Via Regia and the Amber Road. At various times it was a part of the Kingdom of Poland, Bohemia, the Austrian Empire, Prussia, and Germany. The city, as well as almost all of Lower Silesia became again part of Poland under the terms of the Potsdam Conference. In

August 1945 the city had a German population of 189,500, and a Polish population of 17,000. Almost all of the German inhabitants fled between 1945 and 1949 and were settled in Allied Occupation Zones in Germany. The Polish population increased by the postwar resettlement of Poles as well as forced deportations from Polish lands annexed by the Soviet Union in the east, especially from city of Lwów.

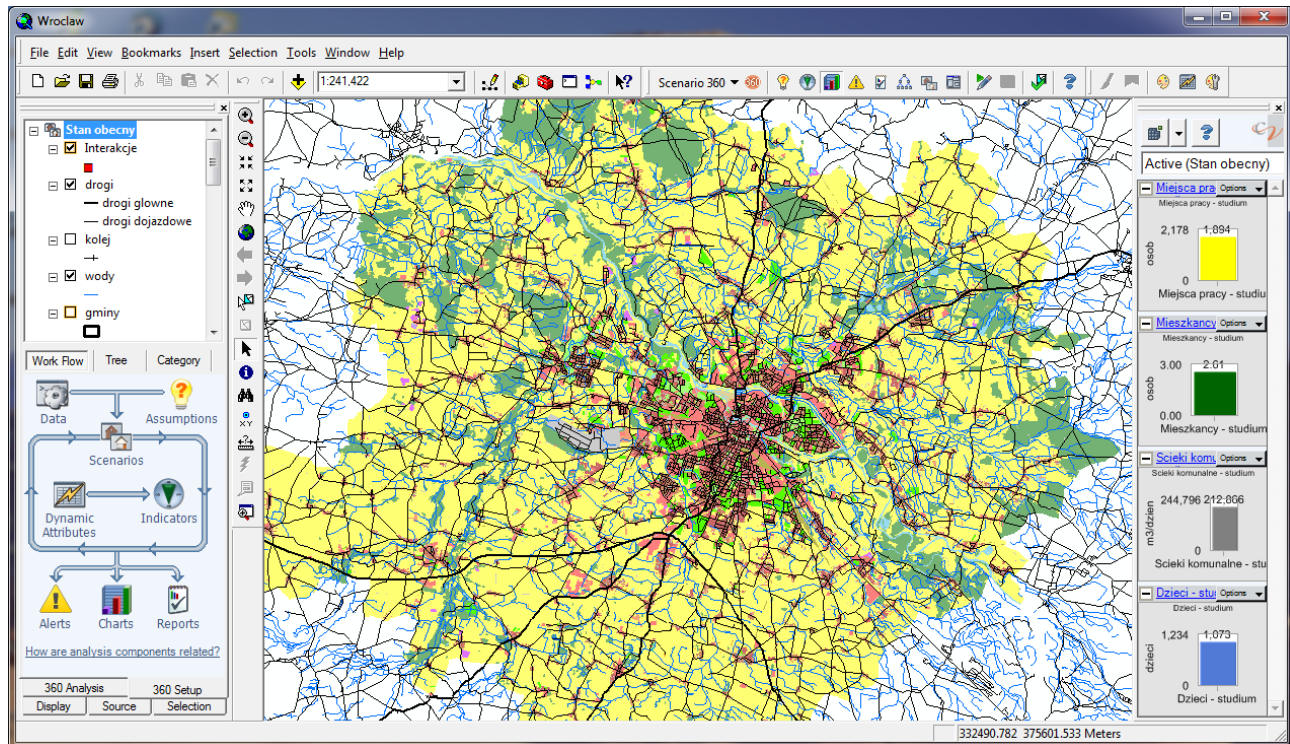
With over 650000 inhabitants Wroclaw is now the second city after Warsaw in terms of revenue (3.814 billion zł in 2012) and expenses (3.804 billion zł in 2012) budget in Poland. Income per capita is also second only to Warsaw. Wrocław manufactures buses, trams, railroad cars, home appliance, chemicals and electronics.


Fig. 1: Landuse of Wroclaw Region (2012)

Research was taken on local development plans for City of Wroclaw and communes located in the suburbia of Wroclaw: Miekinia, Oborniki Slaskie, Wisznia Mala, Czernica, Dlugoleka, Katy Wroclawskie, Kobierzyce, Siechnice, Zorawina and Kostomloty.

4 RESEARCH

Wanting to discuss desirable strategies for development of Wroclaw Region we started with evaluation of impact of current plans. Variety of spatial and non-spatial data including cadastral land-use, environment, changes in population, consumption of natural resources, energy and waste production was integrated. Additionally information about the approximate load of the road network by setting an indicative number of cars and daily trips as well as latest census results from National Statistical Office.

The core dataset prepared for the project was the unified landuse zoning plan for whole region. It was preapared on a base of 11 different landuse plans of communes and the city. Those plans are different in terms of abstraction level (from general to more concrete) as well meaning of definitions of landuse designation (the same designation have different meaning as well as different designation have similar meanings). The horizontaly integrated dataset includes 5748 planned landuse polygons. Polygons were interpreted to common landuse model developed with CommunityViz 4.1 and ArcInfo 9.3.1.

CommunityViz is not operating on integrated urban model like powerful predictive tools in kind of UrbanSim and TRANUS, that can run dynamic analysis of complex urban systems. CommunityViz is rather suitable for "what if", interactive sketch planning. Yet the models planners can develop with it's open modeling framework can be very sophisticated thanks to dynamic attributes, the unique capability of CommunityViz features. A dynamic attribute is based of formula that specifies how the attribute is calculated. It's value is automatically updated as any changes are made in the analysis. For example every

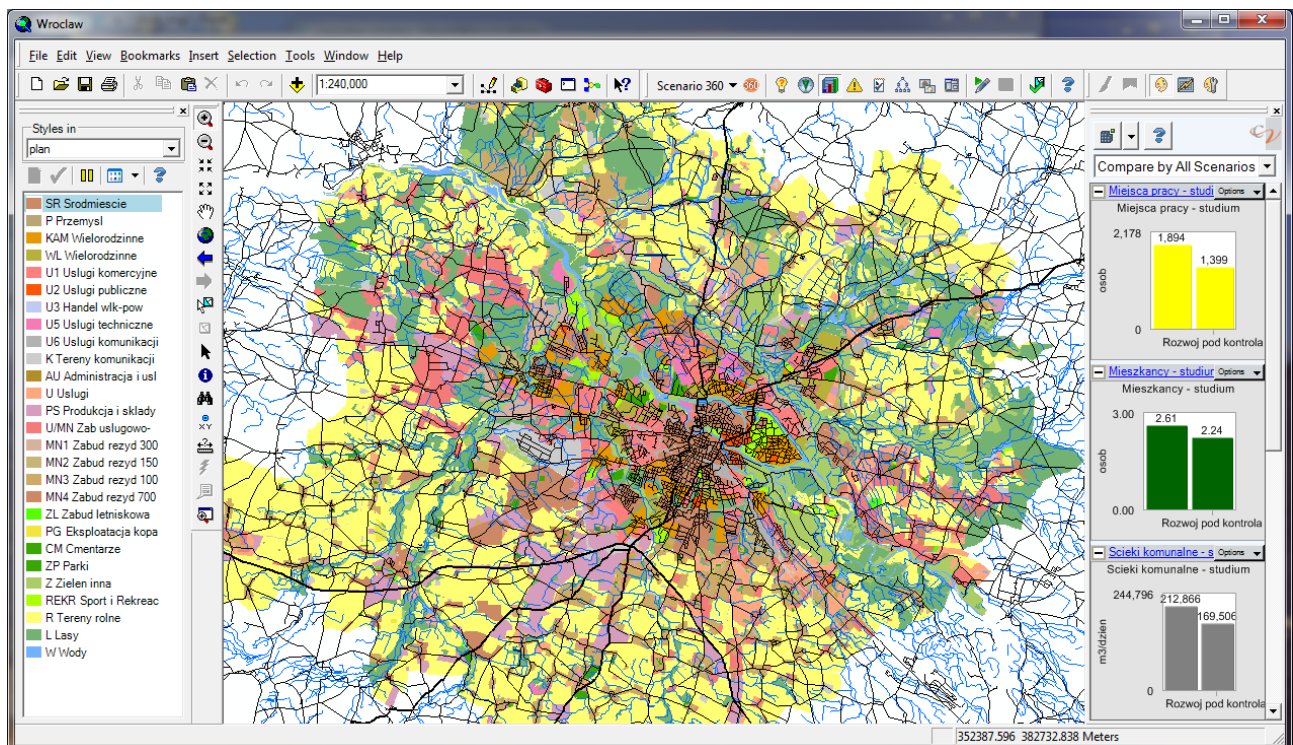
separate landuse plan unit is reevaluated :on the fly'' as it's area, mix of use or distance to nearest infrastructure changes for any scenario. We suggest that such, relatively simple in use planning tool may very relevant to community planning.


Fig. 2: Landuse models and planned landuse for Wroclaw Region (2012)

Indicator name	Description
Dzieci – studium	Children up to 19 years old
Emisja CO przez samochody	Total carbon monoxide emissions generated by vehicles associated with residential buildings in landuse plan layer.
Emisja CO2 przez samochody	Total carbon dioxide emissions generated by vehicles associated with residential buildings in landuse plan layer.
Emisja Hydrocarbon przez samochody	Total hydrocarbon emissions generated by vehicles associated with residential buildings in landuse plan layer.
Emisja NOx przez samochody	Total emissions of oxides of nitrogen generated by vehicles associated with residential buildings in landuse plan layer.
Gospodarstwa domowe – studium	Total number of dwelling units
Komercyjne zuzycie energii	Total annual energy used by commercial buildings in landuse plan layer for all applications, including electricity and heating.
Miejsca pracy – studium	Total number of commercial jobs
Mieszkancy – studium	Total number of inhabitants
Podatki PIT – studium	Tax (PIT income tax) revenues for local commune budget
Powierzchnie komercyjne – studium	Total commercial floor area
Scieki komunalne – studium	Waste water associated with residential buildings in landuse plan layer.
Wyjazdy samochodem	Total number of motorized trips taken each day, on average, by residential households (dwelling units).
Zuzycie energii przez GD	Total annual energy used by residential buildings for all applications, including electricity and heating.
Zuzycie wody – studium	Total water use associated with residential buildings in landuse plan layer.

Table 1: List of indicators defined to measure scenarios impact

Illustration presents application window with unified landuse plan and a list of 27 land-use models predefined for Wroclaw area. Each model (panel of the left) is given a name, symbolics and detailed characteristics (set of attributes, many of them dynamic) representing building density, mix of use, resources utilization rates etc. Using Scenario Sketch tools of CommunityViz, a land use can be applied to a feature by simply clicking on it on a map or by querying data. The planned landuse polygon takes on all the specified characteristics, and corresponding impacts are calculated automatically. Landuse models reference several regional changable, user-defined assumptions.

The set of indicators was defined within CommunityViz framework for Wroclaw region. Indicators measure accumulated impact of all plans, referencing datasets anywhere in the scenario. They provide an overall measurement opposed to landuse model attributes, which are an individual characteristic of polygons on a map. The list of indicators describing the demographic changes, build-out capacity under different zoning regulations, natural resources and energy consumption, waste production and increase the indicative amount of cars and the number of their daily trips is presented in tabular form below.

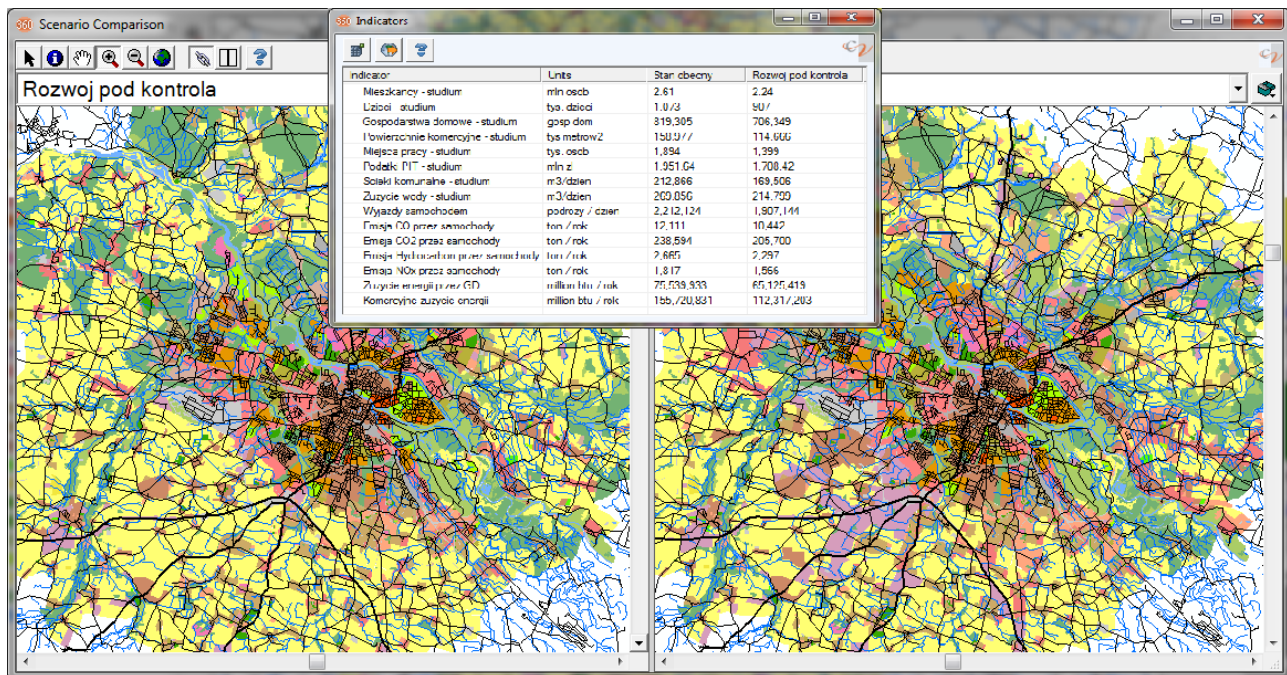
To demonstrate the technical feasibility of CmmunityViz alternative growth scenario was also defined. Concurrent to continuation reflecting development under the current growth plan, the second, more conservative scenario substantially concentrating development was proposed. It's increasing density of development in some areas by transferring growth from others reducing possible, undesirable effects of urban sprawl. Two variants are presented below side-by-side. A more sustainable scenario on the left and current growth on the right. The values of indicators are also shown.


Fig. 3: Current growth plan (right) vs more conservative plan (left)

The analysis of current growth scenario provided the citizens and leaders of the Region with an understanding of the implications of their planning decisions. Big picture of land management policy conducted by independent communities not suprisingly makes negative impression. Incredible amount of land that was planed for development does not reflect any demographic trends. Plan that can make sense from the point of view of separated community is totally unrealistic for the region. It's hard to find any fit of infrastructure and landuse development. Landuse planning system does not seem to be linked with budget (planninng) capabilities of communes. It promotes rather than constraines urban sprawl.

We present here just preliminary results of the project. In comming months we are going to to determine the suitability of locations for accommodating future land use demands for residential, comercial and other land uses. Next stage is to define assumptions like population, employment and use it to project possible future land use of Wroclaw region.

5   CONCLUSION

Assessment the impact of local polices and local development plans can be carried out by using multiple techniques and tools. One of these instruments is GIS environment with CommunityViz. This system enables the assessment of the effects in parametric values, based on statistical assumptions. On the basis of the availability of local variables, the system can reliably and efficiently support the forecast, assessment and monitoring spatial transformations. CommunityViz is an understandable tool for participants, clearly outlining the results of the planned activities. The scenarios can illustrate alternative to current spatial polices and plans and their impact on the eco-capacity of the space before making a final decision on changes to the functional areas. The system allows to estimate the future potential media consumption, waste production, estimated load of the road network and many other features of the freely-defined demographic trends.

 A major advantage of the system is possibility to dynamically construct and analyze impacts of many scenarios with indicators based on any combination of available geoinformation and user-defined assumptions. Very important fact is that all calculations and resulting visualizations react „on the fly", nearly at the same time when assumptions are modified. That is why CommunityViz can be useful not only during time-consuming research but also in discussion with society.

Authors recommend CommunityViz as powerful educational tool for the decision-makers, planners and the citizens giving a better understanding of the complexities and impacts of land-use decisions. We recommended especially for those that want to use geoinformation creatively adding value on growing spatial data infrastructure.

(Dr. Wolfgang Loibl, AIT – Austrian Institute of Technology, wolfgang.loibl@ait.ac.at)

1 ABSTRACT

For a research initiative, such as JPI Urban Europe (http://www.jpi-urbaneurope.eu), analysing the long term trends for urban development is crucial for the strategic focus of the programme. An Urban Megatrend study aims at providing the basis for the integrated, multidisciplinary urban research with a time horizon of 2050+ of JPI Urban Europe.

Global megatrends can be observed in cities in distinct ways depending on the characteristics of urban areas. Therefore, a multi-scale analysis of these trends has been conducted. The megatrend categories to be identified are: demographic evolution, climate change and environmental state, science and technology, economic dynamics, built environment and infrastructure and last but not least social-cultural issues. From these categories, a wide set of challenges for urban areas has been derived.

Beside a detailed data-based study, an intensive consultation and workprocess with experts and national representatives in workshops aimed and will aim at generating a differentiated picture of the urban development across Europe.

The Urban Megatrend Project will be completed in May 2013. Thus, final conclusions can be presented at the conference. This paper summarises our preliminary findings after two workshops and aims at giving an outlook on further research which is going to be conducted.

2 INTRODUCTION

2.1 What is the Joint Programming Initiative (JPI) Urban Europe?

The Joint Programming Initiatives (JPIs) are transnational research and innovation initiative introduced by the European Commission. The aim is to pool national resources in creating transnational R&D programmes with focus on grand challenges which cannot be solved on level of individual countries. With increasing urbanisation, cities are more and more put in the focus for a variety of reasons and by diverse disciplines. Therefore, JPI Urban Europe is striving to establish a large scale, long term, multidisciplinary and transnational research and development programme dedicated to urban development. JPI Urban Europe has been accepted as one of ten Joint Programming Initiatives.

2.2 Relevance of Urban Megatrends in JPI Urban Europe

Urban Areas across Europe are going to be faced with a number of challenges in the decades to come. As JPI Urban Europe is currently in its pilot phase, analysing urban megatrends is a central building stone for the strategic direction. The aim of this study has been to identify the trends, to analyse the interdependencies, to create a differentiated picture of the expected development path of cities across Europe and to identify the challenges resulting from the developments. Therefore, a multi-scale analysis, from global to local, has been undertaken.

Although the a majority of urban challenges result from global megatrends, the occurrence and effects on the local scale are very diverse depending on the geographical properties, the governance system with respect to urban planning and development, historical trends and economic performance. Thus, for a multinational long term initiative such as JPI Urban Europe it is essential to analyse the prospects and foreseeing possible trends and challenges on various scales to get a differentiated picture of the urban areas across Europe. The findings of this study are significantly influencing the Strategic Research Agenda of the JPI Urban Europe. Furthermore, in the short term, this study contributes to concrete call topics and to identify the immediate research needs. A comprehensive and differentiated study on urban megatrends and on the resulting challenges is a central building stone for the future strategic orientation of the Joint Programming Initiative.

3 METHODOLOGY

The methodology of the study is based on a multi-tire process. Desk research of available literature and exploration of existing foresight documents relevant assessing on urban megatrends provide the basis for further research. Therefore, scientific papers and national planning and development related documents with various thematic views, geographical scopes and time horizons were analysed. Cross linkages between and the integrative view upon the documents is ensuring a holistic analyses.

Representatives and experts from several countries participated in the in-depth research and analyses on national perspectives: Austria, Belgium, Denmark, Finland, France, Italy and the Netherlands. Thus, countries participating in the investigation are geographically distributed throughout Europe which aims at generating an all-inclusive view on the situation in 2050.

A quantitative analysis has been conducted for countries across Europe looking upon developments in demography, climate, social structure and economy. On basis of NUTS 3 regions, regionalised data on European urban regions regarding long-term trends of climate exposure, demographic and socio-economic development have been explored as a European wide data-driven backbone on the major trends.

4 MEGATRENDS AND CHALLENGES AT DIFFERENT SCALES

The study analyses urban megatrends at different scales: the global, the European and the national scale. Although global trends and geopolitical shifts are affecting countries across Europe, the occurrence, and thus the challenges stemming from the trends are diverse and depending on the circumstances in the countries and cities.

The data analysis illustrates a European wide image of trends and challenges influencing urban areas in the coming decades. Therefore, all urban regions with an urban population above 250,000 inhabitants within the functional urban areas have been taken into account. In total, 148 city regions were integrated into the analyses according to megatrends in demography, social structure and economy and climate. Data from EUROSTAT, as a baseline data, and projection data from IIASA (demography), the University Paris 1 (economy), the University of Edinburgh (land use) and from AIT (intraregional distribution in the urban regions) carried out within the PLUREL project (dealing with periurban land use relationships – www.plurel.net) and further ESPON projects (particularly ESPON climate as well as ESPON FOCI) have been applied for these analyses. The results clearly show that the megatrends manifest differently in space. In the study, two scenarios based on the PLUREL framework, which have been adapted from IPCC, were considered. Due to the limitation of this paper, only the highlights of the findings can be mentioned here.

4.1 Demography

Most urban areas are going to face a significant change in the demographic composition in the decades to come. Until 2025, while the majority of western European cities are expected to gain in population, especially the Central-Eastern parts of Europe are going to lose population which results in diverse challenges. While an aging society is going to influence urban areas across Europe, Central-Eastern and Eastern Europe are going to suffer even more by continuous out-migration driven by local economic decline. Therefore, this trend is amplified in the region.

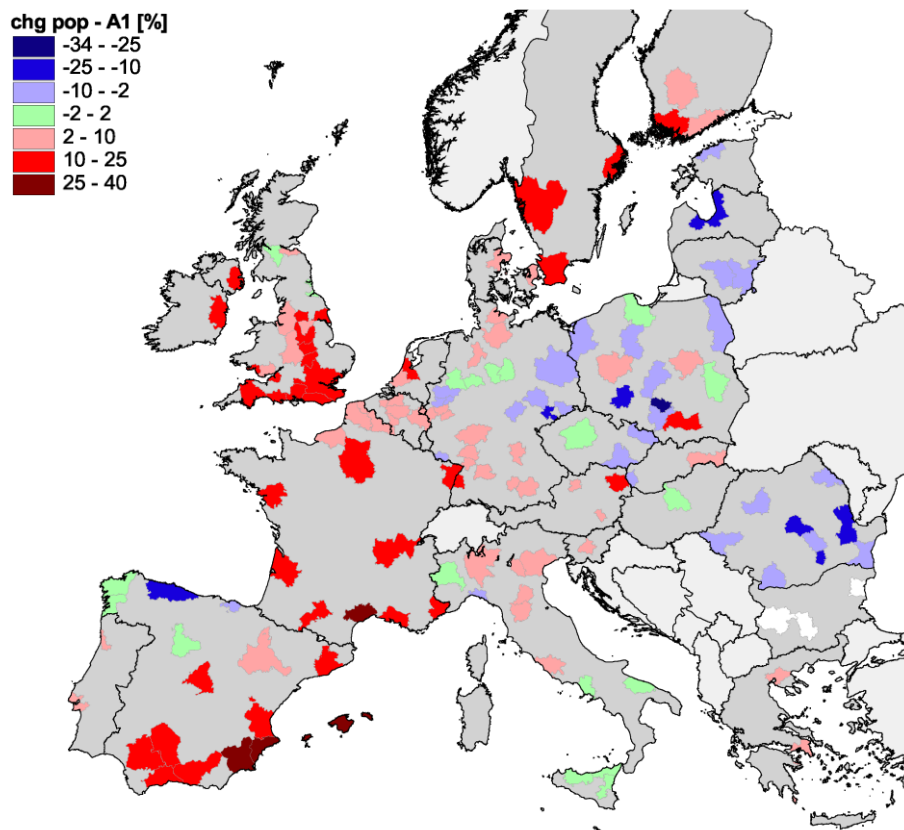
In the contrary, urban areas with growing population are less prone from massive aging since the majority of people moving to urban areas are younger ones. Figure 1 shows the detailed expected population change in urban areas until 2025. The graphic is based on the scenario for moderate economic development. The demographic development of European cities is expected to influence the appearance and structure of urban areas significantly. Urban design, urban infrastructure and service provision have to be adapted to the needs of an aging society. Shrinking cities are going to be faced with a wide range of challenges. At the same time growing cities, especially in the European Pentagon (as suggested by ESPON), are challenged by demographic developments influencing the social composition in space as well as the built environment.


Figure 1: expected population change 2025. Data source: PLUREL project 2007-2010, scenarios A1. Population projections: IIASA, GDP projections: Univ. Paris, Nuts2 to NUTS3 disaggregation: AIT

4.2 Social-Cultural Issues

Due to the roll back of the welfare state and increased polarisation, social cohesion is expected remain under pressure. Thus, the willingness for solidarity and the further distribution of wealth are endangered. Especially, under the circumstances of an aging society with more retired and thus low income people, this issue is of high relevance. Within the urban regions, as well within entire Europe, the increasing economic polarisation results in higher spatial segregation at the local – as well as the supra-regional scale.

4.3 Economic Dynamics, and the Role of Science and Technology

Throughout Europe, a lack of qualified labour is expected. Due to the demographic dynamics, like the aging society, the workforce is decreasing. In 2050, due to global competition and the uprising BRIC and other Asian countries, the role European cities play in global competition is expected to be changed significantly. Service, high tech and innovative industries are expected to be of great importance for continuous growth in Europe.

Innovation, science and technology are seen as future opportunity for Europe. On the one hand it could significantly increase the sustainable development of cities, and thus contribute to the liveability of urban areas; on the other hand urban technologies bear great opportunities for economic growth. What is needed for a sufficient and successful implementation is the acceptance by the citizens. Furthermore, science and technology has to act and react to the social needs of the people. In the decades to come, the economic situation of and the quality of life in European cities are going to be highly dependent on developments in innovation, science and technology.

4.4 Natural Environment and Climate Change

Climate change is going to influence urban development in differentiated ways until 2050. Coastal urban areas will be affected by storm surges and have to adapt their infrastructure and built environments accordingly. Furthermore, extreme rainfall events with higher frequency and magnitude will be more likely causing river flooding affecting smaller cities by local events more frequently than larger ones by big events. Cities in the Mediterranean region and on the Balkans are going to face significant changes in the number heat days (Tmax >25°C) and tropical nights (Tmin >20°C) which can be severe if longer heat episodes will

occur. It is expected that the climate exposure in these regions is going to shift substantially and will affect more the older and ill population. Cities in Central-Eastern Europe observing a continental climate will suffer from more frequent and longer heat day episodes – the climate properties will change to those in near and far South-Eastern Europe Cities in Southern Europe are expected to suffer from temperatures currently observed along the African and Middle-East Mediterranean Coast. Urban Heat Island effects (lack of nocturnal cooling, lack of open space climate comfort, lack of cooling and ventilation in street canyons and apartments) will turn out to be growing issues. Cities in the Alpine areas will be less, Scandinavian and Baltic cities will be far less exposed by these trends.

5 FIRST CONCLUSIONS AND OUTLOOK

In the first part prospection exercise , the urban megatrends and stemming challenges have been identified by experts and committed by representatives of the participating countries. Based on data analyses, and the review of local studies a distinguished picture of the trends of urban space could developed for the European scale. The multi-scale analsyses depicts heterogeneous challenges for urban areas until 2050 across Europe regarding the megatrends in demography, social-cultural issues, economic dynamics, built environment and infrastructure, science and technology and natural environment and climate change.

The study is expected to be finalised in April/May 2013. The findings and storylines are going to be discussed with experts, stakeholders and city practicioners in order to draw robust conclusions how to proceed. By challenging the results with experts from various fields the scope of the study will be ensured and underlined. At the conference we will present the final storylines for urban development upon 2050 regarding the identified megatrends and challenges and draw conclusions for JPI Urban Europe.

This integrated and multidisciplinary study is providing essential input for the strategic research agenda of JPI Urban Europe is gaining in profile for a long term research and innovation initiative. Furthermore, in the short run, topics for research calls and for immediate actions are identified.

LIMES – From Beacons to Facebook

Rainer Zementz

(Rainer Zementz, Projektentwicklungsgesellschaft des Landes Rheinland-Pfalz (PER) GmbH, Mainz, Germany, rainer.zeimentz@per-rlp.de)

1 ABSTRACT

Communication is the basis for trans-border control of networks. With Project LIMES, the central element is the Limes, the ancient frontier region of the Roman Empire. The region is developing as a European cultural heritage site in 10 countries and parts of it have been recognized as a UNESCO world heritage site. The inhabitants of the European regions, the employees of the LIMES prototype project, representatives from the European Commission as well as actors and concerned people with their various interests and cultural backgrounds all have to be incorporated into communications networks. Facebook, Twitter, Google-Translator, Drop Box and blogs also present practical, simple and free (which is important for volunteers) possibilities.

2 LIMES ACTION

2.1 The Historical Region

The ancient Roman eastern frontier, about 3.500 kilometers long, passes through Europe. Even today, from Hadrian's Wall in the north to the Black Sea, its visible trail runs through forests, over hills and along rivers. Until about 1500 years ago, this is where beacons were burning all along the watchtowers. This frontier was also a rapid news chain between military stations (all north of the Alps, all are cities now). The beacons along the Limes were a very early precursor of the military ARPA net which was the predecessor of today's internet.

Today, the Limes passed through10 countries, 8 of them in the European Union. They all more or less use the cultural heritage of the Romans in today's tourism development.

2.2 The Interests of the European Commission

Commissioned by the European Commission for the project "Cultural Tourism in Rural Areas", analysts see a potential for an annual economic growth of 6 percent. Even two thousand years later, ancient Roman foundations, ruins of watchtowers or the depiction of historical situations in theaters and museum, guided tours on e-bikes or hiking paths can contribute to modern-day European economic growth. – When we talk about sustainability, we should take this 2000 year old economic history into focus.

In the first and second decade of the 21st century the mobile internet with access via smartphones and tablets plays an ever growing role in the life of the consumer. Local based information is an important driver for trade and tourism.

5 partners from three European countries were given 2 years to bring the Limes into the smartphone age. The most important goal is to initiate economic services via the smartphone and to encourage movement into the new economic age. Project LIMES is financed by the European Commission with approximately 500,000 Euro. Project LIMES is one of three large scale demonstrators. These three prototype programs are directly supervised and evaluated by the Commission.

About 1700 years ago, the Roman beacons burned for the last time. It wasn't until the 19th century that the historical significance of the Limes was rediscovered. In the 20th century a comprehensive touristic utilization of this cultural heritage began, initially with Hadrian's Wall in Great Britain. In the meantime, the Limes in Great Britain and Germany is recognized as a UNESCO world heritage site; the Netherlands are preparing a request for recognition of the "wet Limes" (the Rhine).The UNESCO seal and the care it requires are always a guarantee for increasing numbers of tourists. But despite all this, in many regions the Limes is often marketed as locally or regionally and not as an international world heritage site. The internationality of the Roman Limes troops and the monumentality of the construction do not find any comparable network in the millions of people along the 3.500 kilometer route.

From the very beginning, Project LIMES was able to rely upon a sound archeological network along the Limes. For tourism specialists, regional developers, tourism service providers or local politicians, many

Limes kilometers are merely a local historic location. Of course, we must also recognize the down-side of this Roman monument: seen purely from a local standpoint, the pre-industrial construction method of pile walls, watchtowers and castles frequently reduces the monument to "a few foundation rocks".

3 NETWORKS ALONG THE 3.500 KM MONUMENT

Setting aside all technological joys in the everyday life of a project member, the regular face-to-face meetings with Limes country representatives are the backbone of the project. Proposals and coordination on the business model can be developed much better if everybody works together.

3.1 Europäisches Advisory Board

LIMES-Action started at the beginning of 2012. Even in the European Commission application stage, partners were sought in all 10 Limes countries. All 10 Limes countries should be represented in a project-specific advisory board. But it wasn't until the second year of the project (2013) until this became a reality. The origins and the Limes-related interests of the advisory board members are heterogeneous: maintaining the monument is always the first priority of our archeological colleagues. Tourism and economy representatives do not questions this, but they have other priorities. The Advisory Board is a forum for scientific exchange as well as practical advice from the real economy. While, in Great Britain, millions of people visit Hadrian's Wall, parts of the Limes in Croatia are still located in the minefields of the 1991-1995 war. In Germany, Limes-related efforts are concentrated on building reconstructions, while in Lower Austria economic initiatives, like wine growing, are added to the reconstruction efforts.

The Advisory Board meets every 3 to 4 months.

3.2 Partners

The five partners of Project LIMES are now cooperating for the first time. The PER GmbH in Rheinland-Pfalz is a regional development agency of the state. The technological start-up business MARVIS hails from this region. It is the core of all technical tasks: developing and testing a smartphone app. In Lower Austria, CEIT (Central European Institute of Technology) is a partner whose specialty is public relations and dissemination. In Bulgaria, our partner is the German-Bulgarian enterprise INI-Novation. INI is an international business consulting company with a focus on innovation management and technology commercialization. The company has been providing tailored services to local governments, universities and R&D institutes. The Bulgarian city of Ruse is also a member of the partner team. The industrial city of Ruse develops cultural tourism on the historic foundation of the Roman fleet harbor. Every partner is responsible for individual work packages which are compiled separately or in cooperation with others.

The focal point for partnership cooperation is the weekly telephone conferences. Experienced partners were initially critical of the weekly coordination and regarded it as time-consuming. Nevertheless, the Friday morning conference has proven helpful. There are hardly any more time delays, the coordination is without problems, and even regular changes of personnel can be accommodated effortlessly. In the three partner countries, there is a total of about 12 people working on the LIMES project.

3.3 Stakeholders

In the three test countries Bulgaria, Austria and Germany, several steps the partners want to take need to be discussed with regional stakeholders. The tourism structure in Rheinland-Pfalz is compartmentalized and must often be addressed at the local decision-making level. In contrast, there is the simple city model in Ruse which is responsible for tourism development. Small working groups meet regularly in the text regions to coordinate ideas on economic initiatives and Smartphone app service offers. One of the essential questions continues to be which project-relevant data can be used and networked for the LIMES project. The partners communicate on a regular basis, often in weekly e-mail newsletter (in the local language plus English), with the stakeholders.

A total of about 1,500 actors are involved in the LIMES Project in the three countries.

4 SOCIAL NETWORKS, NEW MEDIA AND DIGITAL TOOLS

There are dramatic changes in the opportunities for international projects by social network systems (SNS), micro-blogs and blogs.

At the moment, the LIMES Project operates 6 blogs, micro-blogs and websites in three languages (German, Bulgarian, English): information is passed in a timely and cost-effective manner to a large number of people. Smartphone messages or photos on Project LIMES provide a positive impression of a very abstract project. The first photo of the app prototype was published via digital media.

Fig. 1: The common LIMES Blog

With the LIMES App as the project's core element, a lot of rural area actors are initially left out. Awakening an interest or understanding for a European network and a mobile phone service for tourists regarding the entire Limes in the over-40 population is slow. Even by eliminating postal deliveries almost completely we found that the communicative backbone in the non-commercial area tends to be e-mail versus Facebook or Twitter.

In addition to the LIMES App, the activities in the Rheinland-Pfalz Limes region are focused on regional services in the 2013 tourist season.

Fig. 2: The Facebook page of Creative Tourism Limes

Creative Tourism Limes offers digital (and thus inexpensive) services with around 30 programs presented by 90 providers. In partnership with professionals, market newcomers are given the opportunity to enter the market without financial risk. A central editorial staff and common market-related, standardized modules (web building blocks, Facebook page) provide assistance.

Fig. 3: The common Creative Tourism Limes Homepage.

For its internal work Project LIMES does not employ a joint server but uses private, free-of-charge cloud services for document administration.

5 CONCLUSION

For internal administration as well as telephone and mail services, the helpful services provided by Facebook, Twitter and blogs are the most important tools for the European prototype project LIMES. When it comes to "office-to-office" communications, however, social network systems do not play any role. With external contacts and for information and communication purposes within the project environment, social network systems (SNS) are becoming increasingly important today. At the moment, the role played by social networks when designing and offering regional tourist services remains to be seen. An answer will be found in the 2013 season.

LIMES – Older than the Way of St. James

Franz Schafranksi

(Dr.-Ing. Franz Schafranski, Projektentwicklungsgesellschaft des Landes Rheinland-Pfalz mbH, Adolf-Kolping Straße 4, Franz.Schafranski@per-rlp.de)

1 ABSTRACT

Like the ancient Limes, the Way of St. James connects various countries and regions in Europe. For many years, the Way of St. James has been a success in the tourism market. However, the Limes – which is considerably older than the Way of St. James and certainly has the same potential – is much less developed and known as far as tourism is concerned. Only some regions in Europe make use of the Limes as a location factor to promote economic development and to keep up with social challenges. They demonstrate multiple opportunities how the Limes can be valued creatively and how these values (i.e. guided tours, events, exhibits, authentic replicas, illuminations, interactive museums, creativity offers) can be communicated. All regions can profit from these experiences.

The LIMES project strives to interconnect the regions along the Limes and promote sustainable tourism in the regions by innovative services and technologies. Creativity will play a central role in the strategic approach to this project.

2 PRELIMINARY REMARKS

This presentation deals with tourism development of the Roman Limes in Europe. It is based on the assumption that, with the Limes, similar tourism development is possible as was experienced with the Way of St. James in the last decades. My views are based on the experiences and results which have, so far, been achieved by the Limes project which is sponsored by the European Commission. Aspects on sustainability, competitiveness and territorial cohesion will also be discussed.

3 THE WAY OF ST. JAMES – AN EXAMPLE FOR THE DEVELOPMENT OF A CULTURAL ROUTE

The Way of St. James is one of the most well-known long-distance hiking paths in Europe. For more than 1000 years, pilgrims have walked this path to the tomb of the Apostle St. James in the Spanish City of Santiago de Compostela. Mostly, the Way of St. James is considered to be the main route through Northern Spain, the so-called "Camino Frances". This route goes from Saint Jean Pied de Port through the Pyrenees, then traverses the north of Spain near Pamplona, Burgos, Leon and Astorga all the way to Santiago. However, it is not only this main route which is referred to as the Way of St. James; also all pilgrims' paths whose destination is the tomb of the Apostle James in Santiago de Compostela are also referred to by that name. There are Ways of St. James in Germany, Poland, the Czech Republic, Hungary, Italy, Austria, Switzerland, France, Spain and Portugal. Together, they form a Europe-wide network of main and side routes which connect throughout Europe (ref. figure 1).

It is not just the European dimension which makes the Way of St. James so interesting in the touristic development of the Limes; it is also the successful activities carried out in the past decades in the revitalization of the Way of St. James. The following facts are cited as examples:

- In 1962 the main route, Camino Frances, was officially declared as a historic-artistic ensemble.

- In 1984 the European Council pronounced the Way of St. Frances as a European Cultural Route and declared its protection as a major goal of European cultural policy.

- In 1993 the Camino Frances in Spain and, in 1998, the four main Ways of St. James in France were incorporated into the list of UNESCO world heritage sites.

- In 2005 the transnational cooperation project "European Ways of St. James" was begun. The reactivation of the Way of St. James network was thus expanded to other countries. An internet homepage (www.jakobsweg.net) was established as a central platform in order to facilitate the exchange of communication and information.

These and other activities have resulted in a considerable increase in the number of pilgrims. In the last 10 years, more than 2 million pilgrims (possibly many more) from all continents hiked the Way of St. James

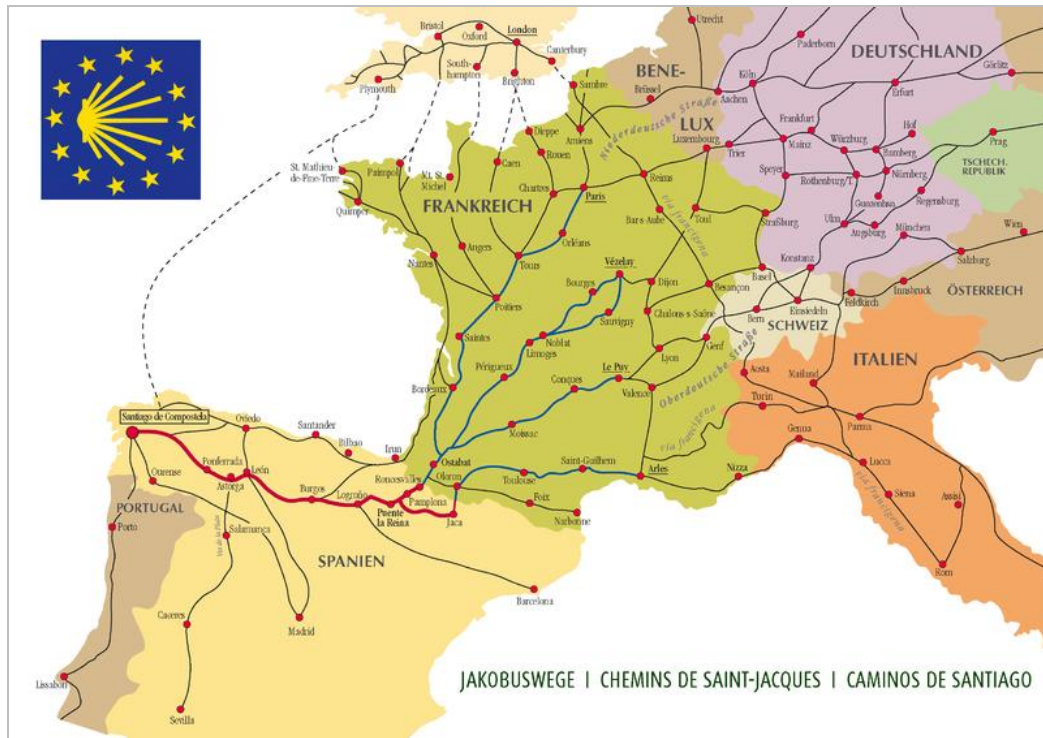
and made use of the multiple services and products along the way, thereby contributing to the economic development of cities and regions.


Fig. 1: Ways of St. James in Europe (Source Wikipedia)

4 THE LIMES IN EUROPE

4.1 The Limes Route

Unlike the net-like formation of the Way of St. James, the Limes has a linear shape. At the time of the largest expansion of the Roman Empire under Emperor Trajan (99 till 117 A.D.) the Limes ran from the Atlantic coast in the north of England through Central Europe to the Black Sea, from there to the Red Sea and through Northern Africa to the Atlantic coast. In Europe alone, the Limes was more than 3,500 kilometers long. It was secured in its entirety by a chain of watchtowers as well as small and large castles. Rivers like the Rhine and the Danube as well as mountains formed natural borders. In places where there were no such natural barriers, the Romans secured the borders of their empire with palisades and walls. The Roman border facilities served as a military "early warning system" and were supposed to ensure control of the daily traffic of people and goods with neighboring tribes. The economy was booming along the Limes. The land was cultivated. Roads and cities were built.

Today, the Limes passes through 10 European countries (Great Britain, the Netherlands, Germany, Austria, Slovakia, Hungary, Croatia, Serbia, Romania, Bulgaria) – see figure 2.

4.2 Requirements for the Touristic Development of the Limes

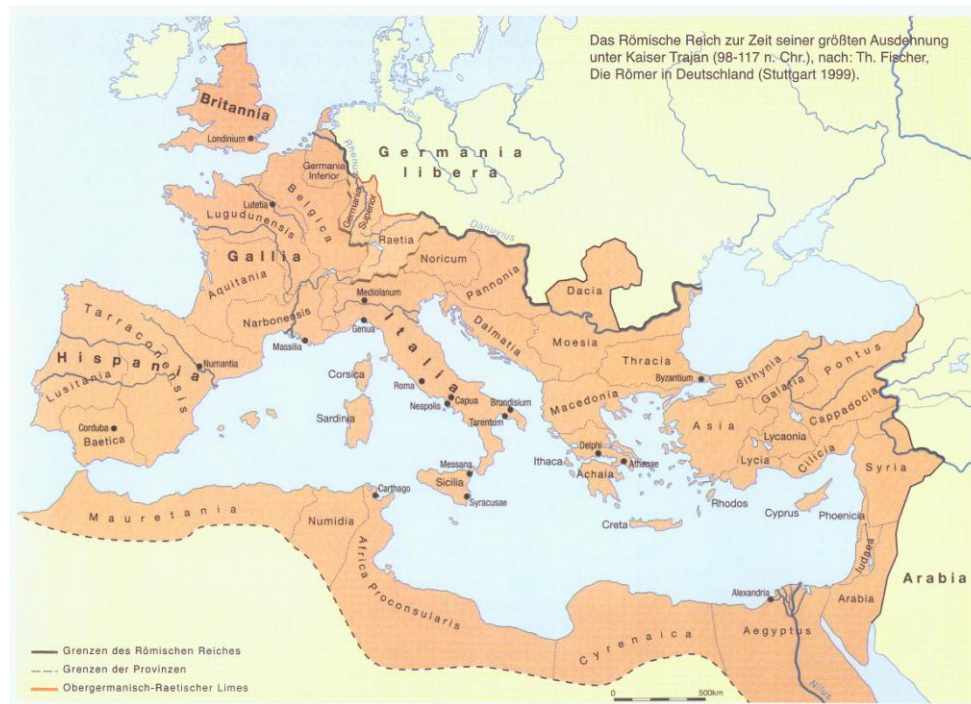
Compared to the Way of St. James, tourism development of the Roman Limes is in its infancy. There are, however, some countries which have initiated regional selective attempts at development. But there are also countries where there are no attempts whatsoever to utilize the Limes for tourism development. In the past years, cooperation at European level was essentially limited to the specialized area of archeology and tourism was not considered.

Why is it that the Roman Limes, which is 1000 years older, could experience the same successful touristic development as the Way of St. James?

Let me first describe the natural and cultural potentials.

In many places, original structures of the Limes (walls and trenches, ruins of watchtowers or castles) still exist and can be experienced as such (Schafranski 2010, www.vici.org, Vujovic 2008). Measures have been

taken to utilize some sections for tourism. The spectrum of measures taken is so large, that only a few examples are cited here:

- Reconstruction of Limes-related facilities, e.g. castles (The minor castle in Pohl, Saalburg), watchtowers, hot springs and building.
- Performance of Limes-related events (Roman markets, game and sports competitions, illuminations, theater performances, etc.)
- Expansion of gastronomic services along the Limes by including Roman food and drink.
- Improvement of information services, e.g. by building museums and information centers, training tour guides/Limes Cicerones, erecting information boards.
-


- Fig. 2: The route of the Roman Limes at the time of its greatest expansion around 117 A.D. (Source: LVermGeo Rheinland-Pfalz. GDKE)

Development of hiking and bicycling paths along the Limes.

The Limes sections or locations which experienced tourism development (e.g. Hadrian's Wall in Great Britain, Xanten, the Limes Castles in Pohl and Saalburg in Germany, Carnuntum in Austria) demonstrate that tourism development along the Limes can be promoted significantly by these measures. The deciding factors for success are creativity, cooperation and the focus on a target audience.

Along the Limes in Europe there are many more natural and cultural sights which have not been cohesively compiled and evaluated. It is especially notable that along the Limes there are 20 UNESCO world heritage sites which make the Limes a special cultural route.

Further aspects for initializing opportunities for tourism development are as follows:

- The increasing importance of culture tourism even in rural areas (Drda-Kuehn 2010).
- The inclusion or intended inclusion of the Limes in the UNESCO world heritage site list (so far, the following sections of the Limes in Europe have been included in the world heritage list: Hadrian's Wall and the Antonine Walls in Great Britain, the Upper Germanic-Rhaetian Limes in Germany).
- The successful beginnings of touristic marketing of the Limes in several sections of the Limes.
- Eastern and Western Europe are growing together.

For the successful utilization of these development opportunities it is vital that the regions along the Limes cooperate more comprehensively in the future.

5 PROMOTING SUSTAINABLE TOURISM ALONG THE LIMES WITH THE EUROPEAN "LIMES" PROJECT

It is a central goal of LIMES (abbreviation for: Large Scale Innovative and Mobile European Services for Culture Tourism in Rural Areas) to promote culture tourism in the rural regions along the Roman Limes. The major points are as follows

- Economic development of the test regions in Bulgaria, Austria and Germany with innovative services and mobile technologies as a pilot project.
- Promote cooperation at various levels.
- Develop a prototype LIMES App for the 3 partner countries, thus creating the technical basis for the expansion of the information system to all 10 countries along the Limes.

The project includes our partners from Bulgaria, Austria and Germany. The other 7 European countries, which are located along the Limes, are represented in an Advisory Board.

Promoting sustainable tourism is an ambitious goal of the LIMES project. Sustainable development certainly is the key for the competitiveness of tourist destinations. This means that economic, social, cultural and ecological goals must be coordinated. It is emphasized as EU policy by the Commission's 2010 communication "Agenda for sustainable and competitive European tourism". It proposes various principles to achieve the goal of competitive and sustainable tourism (e.g. development with a suitable rhythm, i.e. by considering the specific character of the destination – including all interest groups – utilization and Europe-wide dissemination of available knowledge).

Not all these principles can be considered and implemented in the promotion of sustainable tourism along the Limes in this European LIMES project, which is limited to two years. The focal point of LIMES is the impetus for a joint and coordinated touristic utilization of the Limes by the countries along the Limes. This is expressed in the activities which have, so far, been initiated and which are described as follows.

5.1 Awareness Development

Awareness of the opportunities to promote tourism development by smart phone and tablet mobile services hardly exists, even in tourist organizations and enterprises. That is why it became necessary to develop awareness. In addition, it was our goal to make people aware that a Europe-wide touristic development of the Limes presents opportunities which do not occur in regional development and which should be utilized accordingly.

At the same time, the goal of these activities was to energize development forces at regional level, to mobilize potential and to promote cooperation.

Various events were hosted in the test regions along the Limes. In our own LIMES newsletters, newsletters and journals of other organizations as well as media releases information was provided about the LIMES Project and the development opportunities it provided.

In summary, it can be said that, based on our activities, the interest to use new technologies for the promotion of tourism, to cooperate on a European level and to learn from each other has obviously grown significantly.

5.2 Cooperation on Various Levels

Measures to promote cooperation were used for the entire European level, the regional level as well as for the cooperation between regional actors, organizations and enterprises.

In order to improve cooperation at European level, the LIMES Project partners participated in and contributed to a series of international events in Europe. The cooperation between the partners from Bulgaria, Austria and Germany is close. The Advisory Board, which contains representatives from the other 7 countries along the Limes, is regularly informed about the progress and results of the project. The European cooperation has made LIMES known internationally and has provided many impulses for tourism development in the regions.

At the regional level, measures were taken to improve cooperation between regional community administrations, tourism organizations, economic development agencies, chambers of commerce and

industry, as well as other organizations with a view towards tourism development of the Limes region. In Rheinland-Pfalz these activities were geared toward concrete projects, e.g. developing a market strategy for the Limes region, improving the sign-posting of the Limes hiking path and implementing an organization for the development of the Limes region. The willingness for cooperation in this rural area is very high. It is the basis for improving competitiveness and cohesion in the Limes region.

A high value was put on the cooperation between regional actors, organizations and enterprises. In Rheinland-Pfalz, information events and workshops were held in cooperation with the chamber of industry and commerce. In addition, the actors were directly approached via a so-called Limes tour. This resulted in co-operations within established projects.

5.3 Development of Innovative Services

It is well-known that the life cycle of offers and the change in tourism expectations, which are a factor of societal changes, make it necessary for the competing destinations to continually develop innovative services. This is a challenge for all regions along the Limes. Competition between the regions along the Limes can be favorable for development.

In Rheinland-Pfalz we were successful in developing innovative services in cooperation with businesses, tourist organizations and citizens. In 2013, 90 private hosts will offer 26 new tourist services with 70 events within the "Kreativreisen Limes" program. This will result in revenue of approximately 50,000 Euro for the service providers. The events are aggressively marketed, to include Facebook and internet home pages.

In addition, E-bike tours along the Limes are offered for the first time in the 2013 season. We were able to get 4 service providers to offer a total of 12 interesting E-bike tours.

5.4 Developing a LIMES App

The LIMES App, which is intended as a prototype within the framework of the LIMES project, is very important for tourism development and competitiveness of the regions along the Limes. For the first time, the entire Limes in Europe is the focus of tourist development. In addition to information about the Limes, the App will contain important information on tourist services along the Limes, to include the innovative services which were developed jointly by the regions. Initially, the App will only apply to the test regions, but all regions and countries along the Limes will be included in the future.

6 CONCLUSION

Europe is one of the most attractive tourist destinations in the world. Accordingly, tourism is an important economic factor in Europe. It contributes significantly to economic growth and job creation.

Like the Way of St. James, the Limes can become an outstanding European destination. The conditions for the development of sustainable and competitive cultural tourism along the Limes exist. We must now use and combine the potentials. Tourism trends have to be acted upon in a creative and anticipatory manner.

In all European countries along the Limes there is a willingness for tourism development of the Limes and to utilize new technologies in the process. The development of the LIMES App within the framework of the European LIMES Project makes an important contribution to develop and market the European Limes as a whole. The formation of a Limes Alliance is sought for the development of the Limes as a European cultural route.

1 ABSTRACT

LIMES [1] is an EU project which examines whether new, innovative, mobile services can strengthen the economy in areas outside the big cities. Test areas are rural regions along the Roman Limes in Europe. There are multiple challenges in the project: low infrastructure (regarding technology, mobility, supply, etc.), constrained thinking of the population, low employment, outdated industry, etc.

The rural regions, however, have an enormous unused potential which should be developed. By creating a "bottom-up" cooperation, a "we-feeling" will exceed borders. The pitfalls of low network coverage are avoided by a large open Wi-Fi initiative. Studies have shown that the rigid sector mentality must be eliminated in order to create new, cross-sector approaches which will strengthen the region from within. With all this, innovative mobile services play an enormous role – to lead rural regions into the present and to turn on a common light switch.

2 INTRODUCTION

The challenges citizens and planners face in rural areas are widely known. Demographic change and a declining infrastructure have left their footprints. This not only applies to closing post offices, banks, supermarkets, etc., but it is also a mobility factor. A possible sector, which defies the decline of the regions outside the big city lights, is tourism. But how can it survive when public transportation is decreased and hikers have no place to eat or spend the night? How can rural regions be economically supported under these conditions? This question is the purpose of the European LIMES project. Its goal is the promotion of economic development in the regions along the Roman Limes in Europe by culture tourism and the application of innovative mobile services.

Limes is the name of the ancient Roman frontier that represented the border of the Roman Empire at its greatest extent until the beginning of the 3rd century AD. The influence of the Roman Empire, which was one of the greatest states the world has even seen, survived for over 2000 years. Successive generations have built on that heritage and modified it, thus helping to create our modern world. Parts of the Limes became a UNESCO world heritage site: Hadrian's Wall, the Antonine Wall and the Germanic Limes were added to the world heritage list (JILEK; KUTTNER; SCHWARCZ, 2011, p. 8ff; ALTHOFF et al.). The potential of the cultural heritage has not been exploited as far as cultural history is concerned.

3 THE OPPORTUNITIES OF CULTURE TOURISM AND MOBILE SERVICES

Tourism has always been an important economic factor for rural areas. According to OECD, culture tourism is that sector of tourism which is predicted to experience a dynamic development in the next years. Culture is an important factor for the attractiveness of most destinations, for international as well as for domestic tourists. More and more people put culture into the focus of their vacation planning. Destinations, cities as well as regions, increasingly use the opportunity to point out cultural offers in order to establish a better market position (ref. OECD 2009).

A big potential for tourism is provided by new, innovative mobile services (ref. European Union, 2012, p: 11ff). They are designed to make travelling easier. With their mobile phones, travelers have all the information they need at all times at all locations world-wide. This is the reason the European Commission created the European Mobile and Mobility Industries Alliance (EMMIA). EMMIA's goal is to bring together representatives from politics and industry to ensure joint sustainable solution approaches in the development of mobile services (ref. EMMIA, 2013). To test these solution approaches in real life, there are three Large Scale Demonstrators. The three demonstrators develop and test transferrable concepts for the provision of

---

[1] Stands for Large Scale Innovative and Mobile European Services for Culture Tourism in Rural Areas

mobile services for tourists. This is done in close cooperation with tourism agencies, public administrations and businesses in rural areas with valuable but under-used cultural heritage sites (MAYO 2012, p. 18).

4   THE LIMES TEST REGION IN RHEINLAND-PFALZ

In addition to Austria (Lower Austria) and Bulgaria (the region around the city of Ruse), another test region is the rural region along the Roman Limes in Rheinland-Pfalz (Germany) . A different partner is responsible for each region so that diverse objectives can be realized in the individual region.

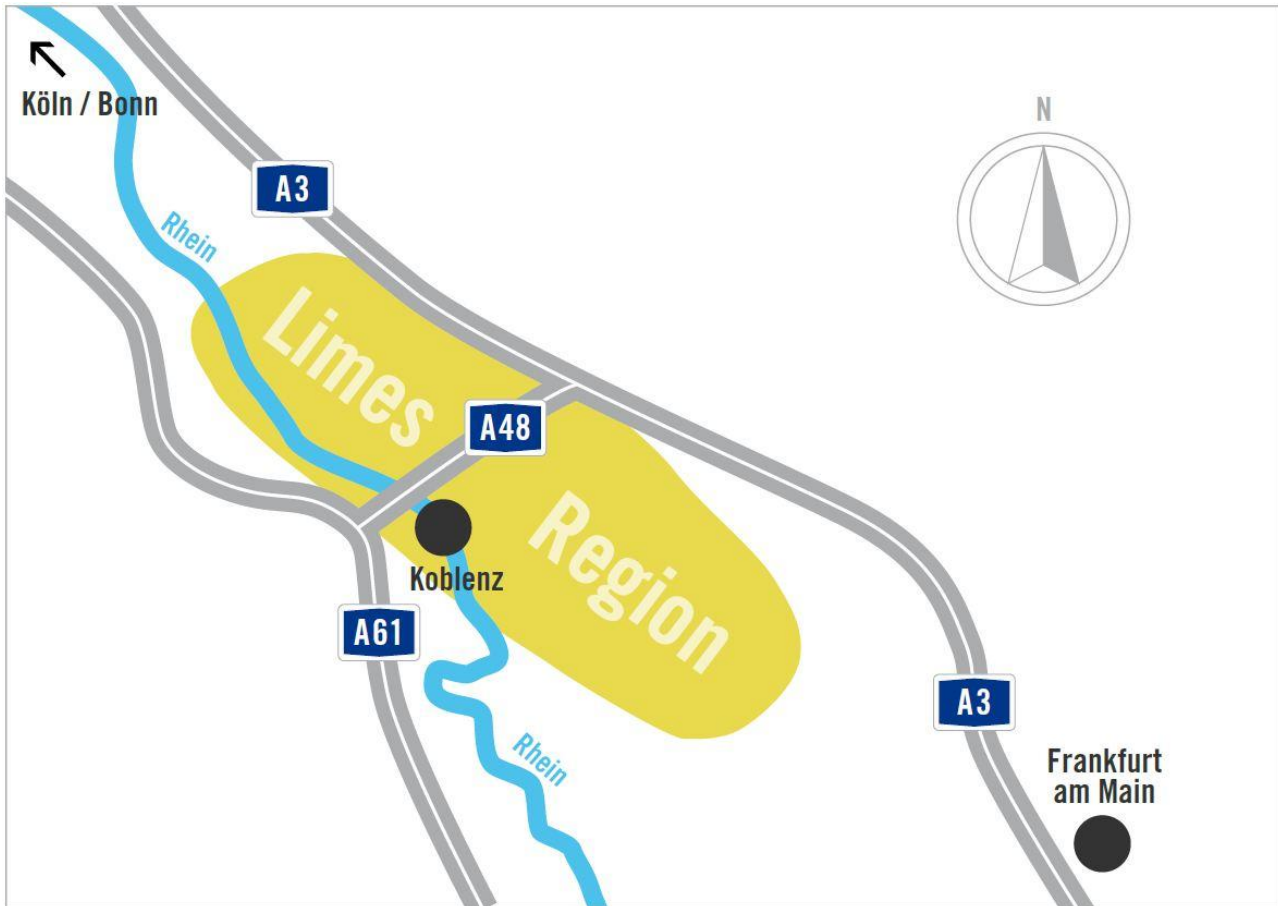
The State Project Development Agency (PER) is responsible for the region in Rheinland-Pfalz. Geographically, the Limes region is located in a triangle between Cologne/Bonn, Koblenz and Frankfurt/Main (ref. figure 1).


Fig.. 1: The Limes Region in Rheinland-Pfalz is located in a triangle between Cologne/Bonn, Koblenz and Frankfurt/Main.

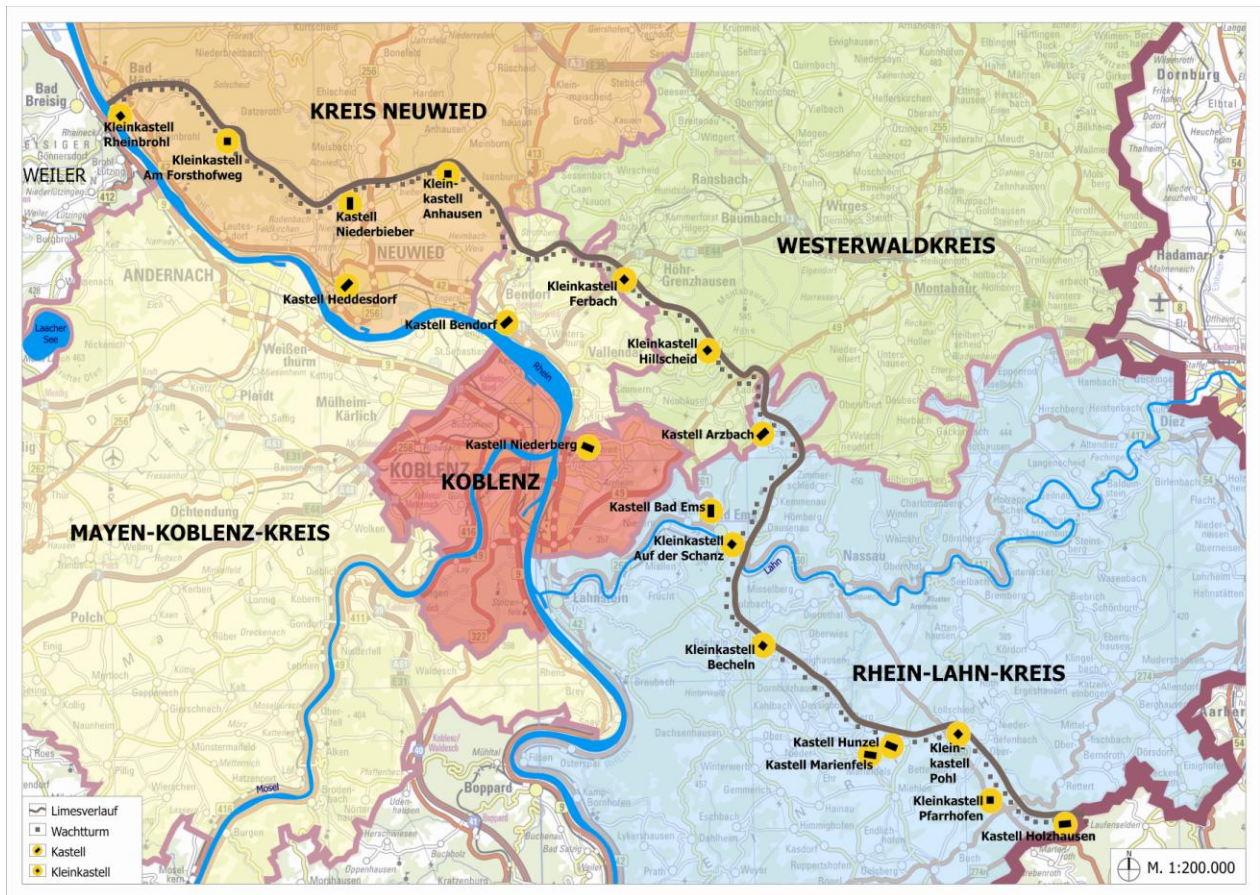
The area of 750 square kilometers has 250,000 people in 4 counties, 12 associated communities and non-associated cities as well as 42 villages and suburbs (ref. figure 2). During the past years, various visualization and maintenance measures were implemented (SCHAFRANSKI; THOMAS, 2010, p. 158 ff). One of the obstacles for an expansion of the tourist infrastructure is the narrow-focused thinking of many actors in the region. The idea that visitors are not interested in political borders and that they want to experience the region as a whole has not yet been realized. There currently is no central organization which deals with the touristic development of the Limes region as a whole.


Fig. 2: The Limes passes through rural areas and has a few spots which are interesting for tourists.

5 THREE INITIATIVES TO INITIATE INNOVATIVE SERVICES

The pronounced narrow-focused thinking is only one challenge faced by project LIMES in accomplishing its goal to promote culture tourism in Rheinland-Pfalz.

As a first step of the project, the situation was analyzed with a view toward tourism and technology. This resulted in two interesting facts: Firstly, there are relatively few touristic offers in the region. In order to market the region successfully, however, a minimum of tourism-related infrastructure is recommended. Secondly, it was found that the 3G network coverage in Bulgaria and Austria is very good, but in the German test region it was very limited and spotty. If mobile services are to function, all visitors must have internet access – at least at certain locations.

Developing potentials in rural areas requires an intensive exchange with stakeholders from the region. Solution proposals must be developed together with the stakeholders, otherwise they cannot be realized practically later (ref. HOEFER, 2010, p. 328). Promotion attempts often fail because, after the on-site promotion is terminated, no-one from a local level stands behind the project. In order to achieve a "bottom up" cooperation, several on-site workshops and events with various subjects were organized. Actors from the local political scene, tourism, business as well as volunteers from the region were invited. The feedback from these events was used to develop various concepts to make the region along the Limes attractive for tourists.

5.1 Creative Tourism Limes as a Cross-Sector Approach

One approach which created new tourism services in the region is Creative Tourism Limes. This initiative came about in cooperation with Creativ Tourism Austria. It is supported by regional economic developing agencies, community associations, local tourism organizations and the Koblenz Chamber of Industry and Commerce. It is, therefore, a good example for trans-community and international cooperation.

Creative Tourism Limes promotes the idea that creative courses (like distilling one's own single-malt whisky or a professional painting course) are offered as a package combined with a culinary experience program and overnight stays in a hotel (ref. figure 3). Tourists are offered an experience which is perfectly attuned, and tourist specialists profit from the synergy effect.

Fig. 3: Creative Tourism Limes – Something for Everyone

More than 70 enterprises or private persons are involved in Creative Tourism Limes; with almost 30 offers and more than 70 events in the year 2013 they generate an additional economic value of at least 50.000 Euro. The investment costs are relatively low, with approximately 20.000 Euro for personnel, costs for a joint home page, a marketing cooperation with the Big Brother Creative Tourism Austria, plus print and design costs for flyers and PDF brochures. With the marketing cooperation program, Creative Tourism Limes was introduced to the general public at the International Tourism Fair in Berlin.

As a cross-sector approach, the creative economy together with tourism specialists put the program on the joint home page www.kreativreisen-limes.de and on Facebook www.facebook.com/kreativreiseamlimes. The partners are challenged to actively participate in the promotion and communication via Facebook. This will strengthen their understanding of mobile services and the opportunities of this potential which was, up to know, unused.

So far, results demonstrate that a big budget or sponsoring opportunities are not always needed in every case for the stimulation of the economy in rural regions. It requires courage, time and a view beyond state borders. It's worth talking to neighbors, to learn from others and to become active one's self.

In the 2013 season, Creative Tourism Limes will be tested under real-life conditions to investigate how tourism in the rural regions can be better developed. Whether the Limes regional concept works and what the future will bring will be determined at a joint meeting in October. One thing is sure right now: other Limes countries like The Netherlands have great interest in expanding the concept to their Limes regions.

5.2 E-Bike Tours along the Limes

Another approach which created new program for tourists in the region was the E-Bike Initiative along the Limes. E-bikes have become very trendy in the past few years. Supported by environmentally-friendly electric motors, e-bikes can be used to master steep hills and long distances. Joint bicycling tours no longer depend on how old or physically fit people are; e-bikes provide active recreation even for "silver agers". In view of the demographic change e-bikes will stay trendy even in the future.

The newly created e-bike tours take people to the special sites along the Roman Limes, the Roemerwelt museum, or the authentically reconstructed Limes castle in Pohl as well as to other unique cultural and scenic sites of the region. Examples are the castles and fortresses in the Middle Rhine Valley, a UNESCO cultural heritage site. Four providers have joined forces and are offering 12 interesting tours, most of which are guided.

As with Creative Tourism Limes, investment is comparatively low. A flyer was printed for 2.750 Euro; it provides information on tours, services, dates and booking methods. The service is also advertised on the Creative Tourism Limes homepage, thus creating a synergy effect between Creative Tourism and e-bike

tours. The partners who arrange e-bike tours along the Limes are challenged to actively participate in the marketing and communication via Facebook and their own home page. The end of the 2013 vacation season will show whether this program was successful.

5.3 Network Coverage via Free Wi-Fi

The "Free Wi-Fi and Loading Facilities for Visitors and Customers" program was created to face the challenges of low network coverage in the Rheinland-Pfalz Limes region. With the support of the Koblenz Chamber of Industry and Commerce, all businesses in the region were asked to make their Wi-Fi and electrical outlets available for customers and visitors to the region. This means that visitors can use mobile services despite the limited network coverage and international visitors avoid the high data roaming charges. As smart phone batteries are usually charged only for a limited time, offering visitors the opportunity to charge their smartphones in a restaurant, makes good sense. In this way, hikers can use mobile services like hiking apps without having to worry about discharged batteries.

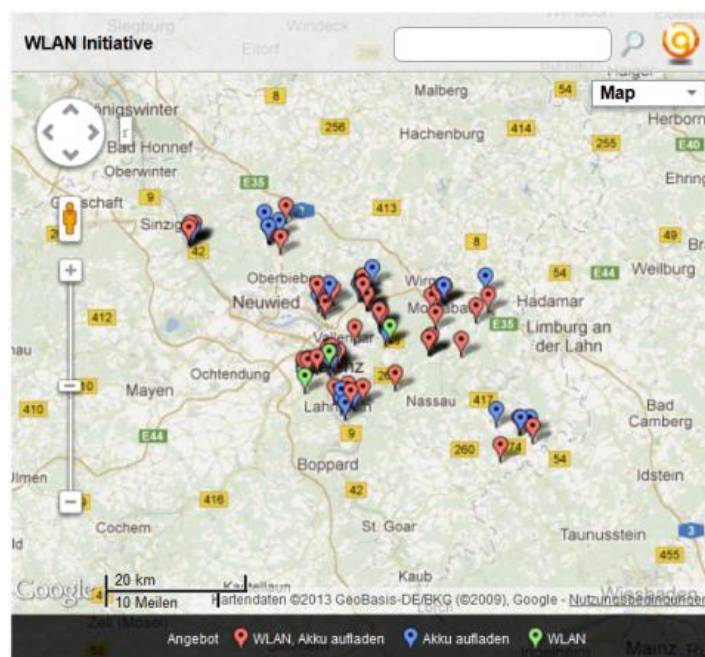
So far, more than 100 regional businesses are participating and are covering the gaps in network coverage (ref. figure 4). Visitors may recognize the participating businesses by a sticker which was distributed to these enterprises (ref. figure 5).


Fig. 4: The Wi-Fi program closes Network Coverage Gaps

Fig. 5: Stickers of the Wi-Fi Initiative that Fills Gaps in Network Coverage

6 CONCLUSION

As demonstrated by our results, the rural area has multiple economic potentials. The biggest challenge, however, is to acknowledge and utilize them. To do this, new paths must often be explored, as demonstrated

by the Creative Tourism Limes example. The creative economy is a significant economic factor in Germany and, by combining it with existing sectors or industries, can be used to promote the areas (ref. HERING, 2010, p. 31 ff). The Wi-Fi initiative along the Limes demonstrates how a regional disadvantage can be turned into a business advantage. Visitors, who charge their smartphones or tablets or surf on the internet, will automatically stay longer in a business and consume more of its products.

It is obvious that a low financial budget can also be regarded as an opportunity, i.e. to use one's own dedication and the assistance of unconventional ideas to achieve one's economic goals. A very important factor is to make use of the synergy effects. Goals can be achieved by acting in concert and to promote each other. It is easier to inspire visitors for other program in the region if these visitors were satisfied by their initial visit to the Limes. And thus one profits from the other.

The negative trend in the development of rural areas can only be combatted by a joint, borderless presence of the region. To put it graphically: only if we stick together can we explore new paths and turn on the lights in the rural area.

1 ABSTRACT

In 2011 Green City Lab e. V. and an interdisciplinary project team conducted the project „Green Network Leoben" funded by the Climate and Energy Fond Austria in the Smart Energy Demo – fit4set research program. The aim of the project was to address climate change and preserve and improve the quality of life in Leoben through a stakeholder process. This process was based on initial surveys on the CO2-status of the town, on mobility and on open and built space typologies as well as on a demographic analysis. This paper mainly focuses on the nexus between demographic change, urban structure and climate change.

Leoben, the second largest city in the federal state of Styria, is characterised by heavy industry, as well as by the Montanuniversität and research and technology companies. Leoben has about 25.000 inhabitants. One of the current challenges the city council is facing, is a demographic shift – a population decline of 4 % in the last decade. One of the key questions in this project was how everyday life in 2025/2050 can be environmentally friendly, energy-efficient and with the highest quality of life for every age group living in Leoben.

This paper outlines in particularly the challenges arising from a demographic shift in the context of climate change adaptation and demands on open spaces and housing. The authors present results from an analyis of demographic data on polling station level and an urban and open space typology on the spatial scale of parcels. The demographic and spatial data were overlapped to gain social-space specific results. The results provide a more specific insight in possibilities and capacities of each age group and building and open space type in terms of setting climate protection measures and the quality of the housing environment. The gained data can consequently inform a stakeholder process in a more accurate and efficient way by linking social with environmental data.

2 THE URBAN AND THE DEMOGRAPHIC STRUCTURE AS 'KEY PLAYERS' IN CLIMATE PROTECTION ACTIVITIES

The urban structure and the open spaces of a town are the physical setting for measures adressing energy efficiency and climate protection. The role of buildings and the open spaces framing them, e.g. gardens, parks and streets, is often underestimated. The organisation and design of open spaces influences the quality of life of urban citiziens significantly.

Besides the urban structure, the demographic situation in a town, a block or a building play an important role in the success of climate protection activities since it informs planners and the community administration about the prospensity to invest in climate protection, acceptabilty of new policies and designs and about the sensitivity to climate change. In particular the latter depends on the age group and on the urban structure (e.g. heat island effect). (EPSON & IRPUD 2011)

The authors of this study investigate the thesis that climate protection measures can only be implemented successfully – that means with a high citizens' acceptance and improvent of the quality of life – if data on the urban structure are overlapped with data on the socio-demographic situation of a town. Interlinking the urban structure with the demographic data provides stakeholders involved in climate protection projects with valuable knowledge about the needs and demands of different age groups in different housing types.

2.1 Methodical approach

Within the project several surveys were conducted and interlinked: an analyis of demographic data on polling station level, an urban and open space typology on the spatial scale of parcels including a townwide mapping of the urban and open space types, an assessment of the potential of buildings for installation of photovoltaic panels (short PV-potential). A CO2-status-analysis carried out by the project partner Voigt &

Wipp Engineering GmbH and Energieagentur Obersteiermark provided essential information on CO_2 emission sources. A mobility survey and CO2-emmission estimation conducted by the project partner verkehrplus GmbH gave a detailed picture of the mobility data and behaviour of the inhabitants of Leoben.x[1]

Through overlapping the data in a map, correlations between the urban structure and the demographic situation get visible and together with the map of PV-potential and the CO2-status-analysis the results provide a specific insight in possibilities and capacities of each age group and building and open space type in terms of setting climate protection measures and the quality of the housing environment. Furthermore, the results can consequently inform a stakeholder process in a more accurate and efficient way by linking social with environmental data.

3 THE CASE OF LEOBEN/AUT

Leoben is the second biggest town of the Austrian federal state of Styria with a population of approx. 25.000 inhabitants. Leoben is situated in the the Mur-Mürz-valley, a lateral valley, in a region characterized by heavy industry and timber industry. The Montanuniversität Leoben and technlogy companies are also an important economic motor for the area. Since the 1970ties the region has to face a profound change in the demographic and economic development which manfests itself not only in a shrinking and aging population but also in new demands on the urban structure, open spaces and land use.

In 2011, the project „Green Network Leoben" included a feasibilty study to identify, initiate and implement falgship projects for Leoben to transform the town into a Smart City. A city can be defined as smart, when investments in human and social capital, traditional and modern communication infrastructure fuel sustainable economic growth and a high quality of life, with a wise management of natural resources, through participatory governance. (CARAGULIU et al 2009). A project conducted by the Centre of Regional Science at the Vienna University of Technology identified six main 'axes' (dimensions) by which cities can be characterised as „smart": a smart economy, smart mobility, a smart environment, smart people, smart living and smart governance. (Centre of Regional Science, Vienna UT, 2011)

The following case study of Leoben focussing on the (built) environment and on the people of Leoben was part of the „Green Network Leoben" project and aims at exploring the social captial and its spatial link of the town. It also aims at identifying potentials – in regards to the tranformation of the town into a smart city – which are very much interwoven with the hitherto unused and overlooked knowledge, experience, capabilities and possibilities of the people living in the town. Results of the analyis of spatial and demographic data were discussed in several meetings with a group of stakeholders in Leoben.

3.1 The urban structure of Leoben

The map „Urban Structures" (Fig.1) illustrates the different types of housing and open spaces in the districts of the town. In the old town, the town centre, pre-industriel and Gründerzeit (second half of the 19th century) buildings with mixed use dominate the townscape. The town centre is sourrounded by residential areas with single, detached and terraced houses, residential blocks as well as the occacional solitary high-rise buidling. Remnents of old peasant buildings and villages are also still recognaziable in the town's urban fabric.

The building types correlate with the open space structure: residential areas with houses (detached, terraced or duplex) their inhabitants and some of the pre-industriel and Gründerzeit buildings provide their residents with privat gardens or yards. However, residential blocks and in particular solitary high-rise buildings do not have private open spaces. The residents of these building types have to share the green spaces with all block's or building's residents.

The availabilty of and access to private open space decide on the opportunities and possibilities to set climate protection measures in a household: private gardens provide space for e.g. gardening and food production, leisure activities close to the house, for installing photovoltaic pannels, etc. All these activities carried out in private open spaces adjacent to the house can contribute to the reduction of CO2-Emission since they reduce transport distances or encourage the implementation of alternative energy source. In buildings with shared green spaces, these activities are harder to organize because any change in the use of the shared green spaces

---

needs to be discussed with and agreed by all residents of the block and the building management and owner. However, vegetation of open spaces – no matter if private, public or semi-public – contributes to CO2-storage. Though the amount of CO2 stored depends on the type of vegetation: deciduous trees store more than conifers, trees in general more than hedges, lawn or herbaceous planting. (DAVIES et al. 2011)

On a bigger scale, public open spaces and green spaces accessible by the public also play an important role in a town's vulnerability and adaptability to climate change. A townwide survey on Leoben's land use shows that 78 % of the municipality area are covered with forest. The forest are an excellent CO2-storage, a local recreation area, source of fresh and cool air and supports a sustainable timber economy. 14 % of the area are built areas which are located along the rivers. Urban sprawl which could threaten the forest and could cause more traffic and cost for the maintenance of the infrastructure is currently only a marginal issue in the municipality of Leoben.

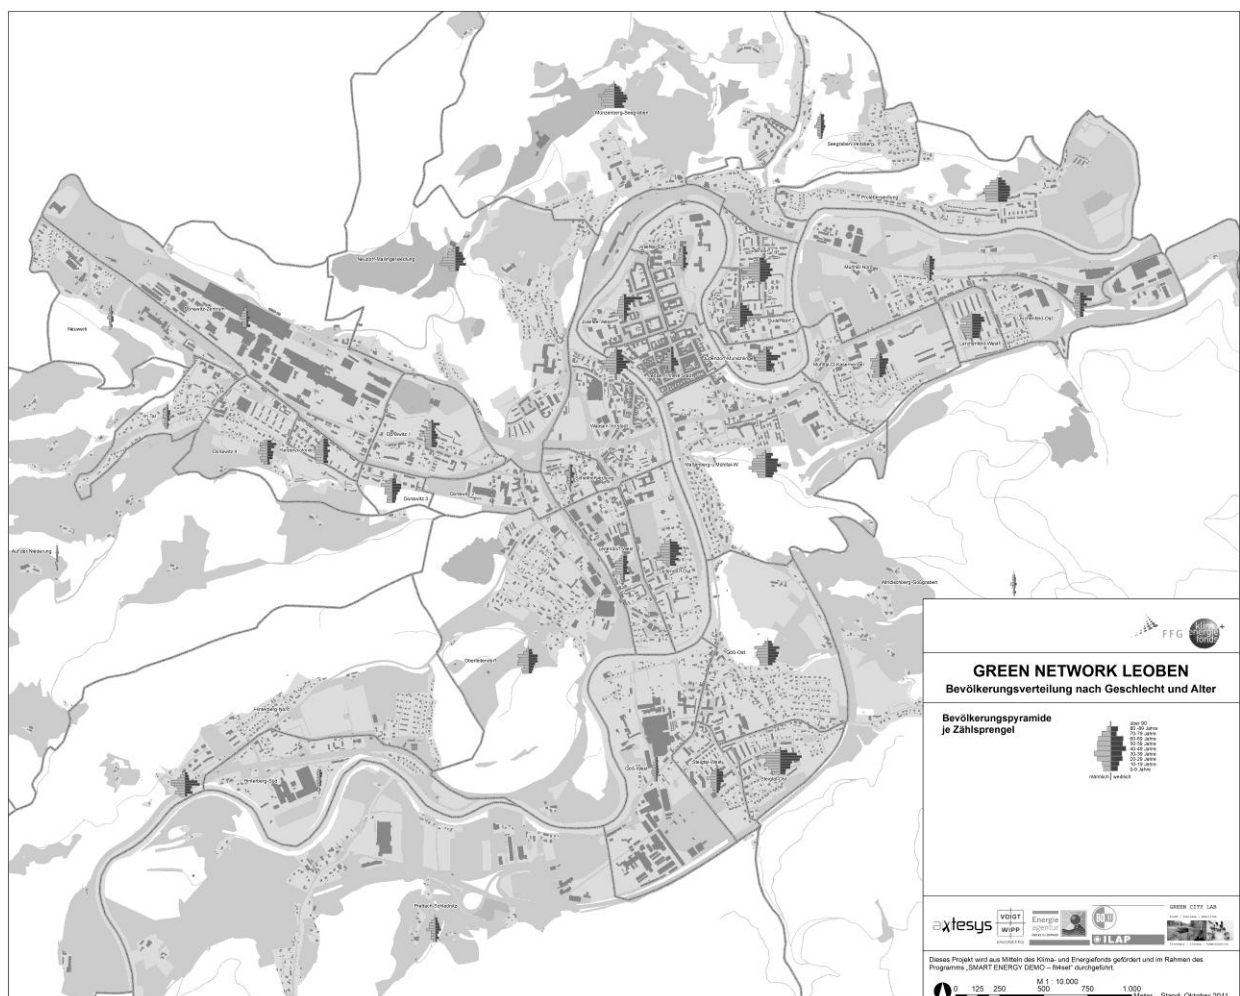
In addition, public open spaces in the town and along the rivers, bicycle routes and trails along the rivers as well as natural riparian areas provide high quality open spaces close to the town centre and help avoid heat islands in the densely built areas. They can also help promote walking and cycling (eg pedelecs) as an alternative to using a car.


Fig. 1: The urban structure, buidling and open space types in Leoben

Typical for Leoben are big industrial areas of different dates of origin and different trades (heavy industry, technology, research, crafts). They hold great potential for measures in terms of environmental protection and renewable energy. Furthermore, they provide 4500 work places in the sector of material goods (JAUSCHNEG et al. 2012). From the perspective of the employees and workers there are additional challenges in terms of climate change which need to be focussed on more than used to be the case. The working environment can be improved climate friendly in more than one sense. For example, open/green spaces for employees and workers for healthy and regenerative breaks can also contribute to reduce soil

sealing and create new habitats, climate friendly cooling of offices and workshops can be realized through using PV-panels to procude the necessary energy.

3.2 The socio-demographic characteristics and prognosis of Leoben – Getting older and less

The current population prognosis predicts a continuing decline of the population down to approximately 24.000 inhabitants in 2030. (Regionale Bevölkerungsprognose Steiermark 2009/2010 – Bundesland, Bezirke und Gemeinden Bevölkerungsprognosen) The population pyramid age structure indicates an ageing population. The total decline of the population through the last decade was 4 % (Quelle: Statistik Austria). The general demographic data for Leoben gives an overview of the main demographic trends in the municipality but cannot describe the situation on a smaller spatial scale like in the districts and blocks of specific neighbourhoods in the town. To gain this specific insight, the project team analyzed the demographic data on polling station level (data of 1.1.2008, Statistik Austria) by age and gender. (Fig. 2)

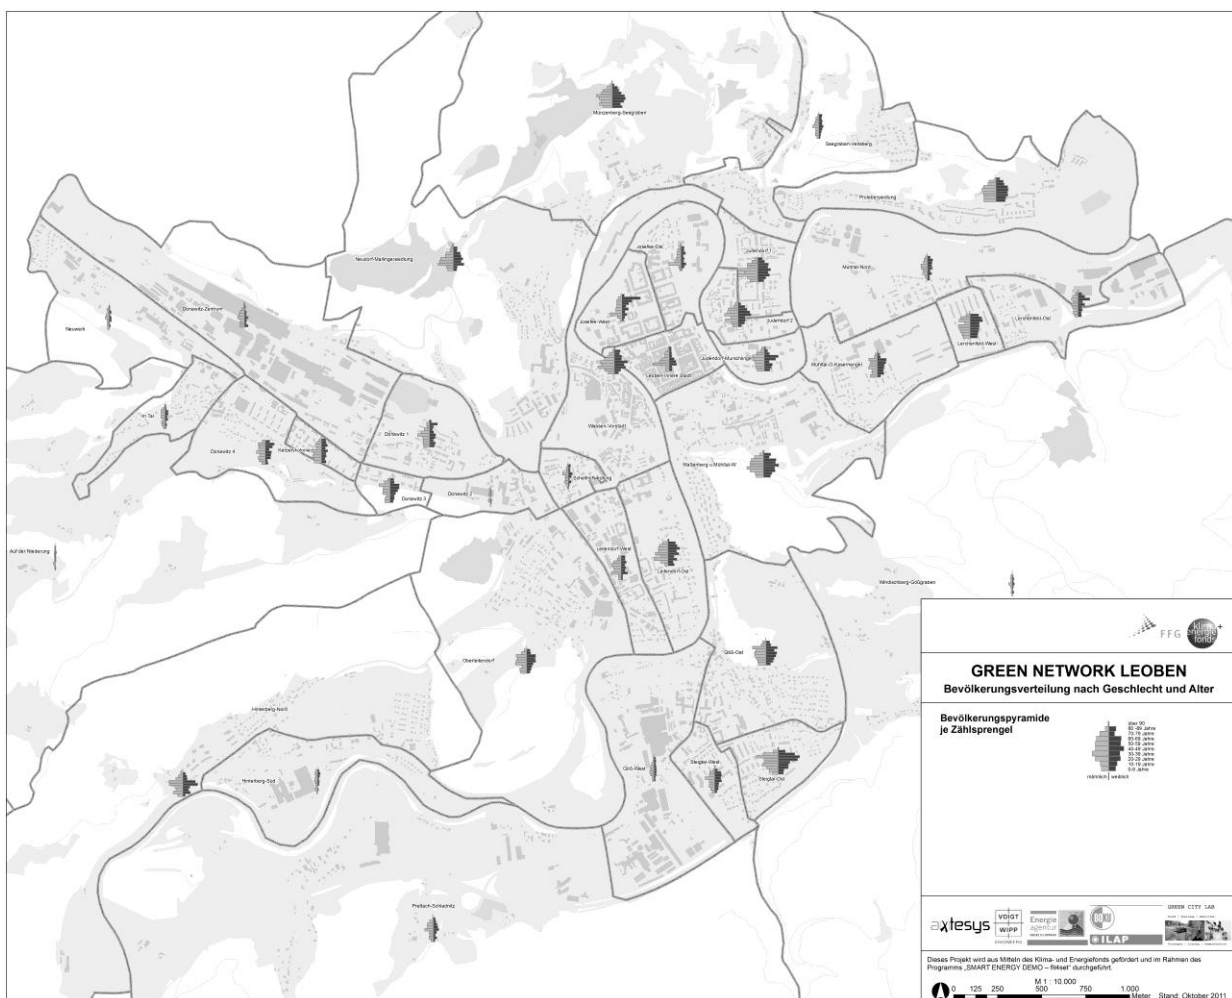
In general, the age cohort of the 40 – 49 year-olds is the biggest age group in the municipality of Leoben. A closer look on the polling station level reveals a more differentiated picture of the age pattern.[2] For example, in Hinterberg-Nord, a residential, suburban area of Leoben, not only the the age cohort of the 40 – 49 year-olds but also the the age cohort of the 50 – 59 year-olds is over-represented. In Steigtal-Ost and Göß-Ost the age group of 60+ is relatively big.


Fig. 2: Demographic data on polling station level by age and gender (data of 1.1.2008, Statistik Austria)

---

[2] Some noticeable deviations from the general trend: In the town center (Innere Stadt, Josefsee West and East) the age cohort of 20 -29 year-old males is dominant. That phenomenon is linked to the Montanuniversität which is located in the town center. The above average size of the age cohort of the 80 – 89 year-olds in Donawitz 1 can be explained by the the retirement home which is located in this area.

By overlapping demographic data with the urban structure of the town, „younger" and „older" urban districts can be identified. Depending on the „demographic age" of an urban district, the needs, demands and desires of their inhabitants concerning the built environment and the open spaces diversify. (DAMYANOVIC 2007) Also, the inhabitants' capability and potential in participating in climate protection activities as well as the vulnerability to climate change vary.

4 CONCLUSIONS: THE BUILDING TYPE AND AGE MIRROR THE DEMOGRAPHIC CHANGE

Overlapping the demographic and urban structure map revealed that in the areas built in the 1970/80ties and in the areas at the fringes of the town, where detached houses are the pre-dominant building type, the age group of 40+ is the biggest population group. Especially in the residential areas with detached houses built in the 1950ties to the 1970ties, the average age of the inhabitants is even higher and a significant increase of the age group of 50+ and 60+ can be observed. Furthermore, the maps revealed an increase in the percentage of old people in the solitary high-rise buildings of the 1960ties and 1970ties. This phenomenon corresponds with the increase of population due the economic boom of this era.

4.1 Potentials, obstacles, motivation for setting climate protection messures depending on the age group and building type

Detached and terraced houses offer the possibility to set various climate protection measures since they provide private open spaces like gardens etc. They offer a high quality of live. In addition, they are often in private ownership. An improvement of e.g. the insulation or investment in alternative energy sources can be made on the basis of the individual decision of the house owners. But, the residential areas with detached and terraced houses in Leoben show an aging population whose willingness to invest in e.g. energy saving measures is diminishing in comparison with a younger age group. The amortization of photovoltaic pannels takes at least 14 years but can also take up to 50 years depending on the efficiency and the individual demand. (KAUFMANN et. al 2011) The age group of 60+ is therefore hesitant to invest in this kind of climate change protection measures unless other subsidies shorten the amortization. On the other hand, the houses built between 1950ties and 1970ties have bad thermal characteristics. Taylor-made incentives for the age group of 60+ to encourage investments in thermal renovation and installation of alternative energy sources would contribute to climate protection.

Compared to terraced or detached houses, the quality of open spaces and the built enviroment of residential blocks and solitary high-rise buildings is lacking in some points. The absence of private open spaces with direct access to and from the house reduces the quality of life and the options concerning setting climate protection measures on the buildings and in the green spaces. All activities and decisions involving the building and/or the open spaces must be discussed and agreed by the building owners, buidling asscociation and management and the owners. These aspects could hamper climate protection measures. On the other hand, these buildings often have huge roof tops with excellent PV-potential and space for example roof top gardens, which would reduce the grade of soil sealing and provide additional green space. Activities set in the green space, e.g. community gardens, planting of trees and facade greening would not only contribute to climate protection and the prevention of heat islands, they would also improve the quality of living conditions especially for the elderly. In contrast to detached and terraced houses in private owner ships, not only financial resources for the technical realization of climate portection measures are required, but also a budget to enable a partizipation process involving all stakeholders concerned with the building (including the inhabitants). This ensures a sustainble implementation of climate protection measures and high acceptance of these activities as well as equal access for all inhabitants of a residential block.

Linking the demographic data on polling station level and data on the urban structure not only revealed a more differentiated picture of the town's and ist inhabitants' situation and options but also highlighted the need for a more differentiated approach in stakeholder processes concerned with climate protection. Furthermore, it points out the need for a more differentiated budgeting which not only takes the technical implementation of e.g. energy saving activities into account but also the social aspects of climate protection measures like stakeholder processes.

(Student of Administrative Sciences Tiia Tanskanen, Finnish Environment Institute, Finland, tiia.tanskanen@ymparisto.fi)

1 ABSTRACT

The environmental planning is shifting towards a more open and collaborative direction. Nowadays it is widely recognized that citizens ought to have not only the right but also genuine possibilities to influence the planning and the decision making concerning their living environment (e.g. Puustinen 2004; Healey 1997, Fischer 2000). In Finland, the renewed Land Use and Building Act came into force in 2000, announcing that in a planning process it is obligatory to offer opportunities for the citizens to take part in. However, despite the change in law and attitudes, there have been difficulties in integrating the citizens' knowledge and views into the planning processes (Bäcklund 2007, Leino 2006, Puustinen 2006). Hence, the knowledge should be incorporated into the planning more efficiently, so that the citizens' views can have a genuine impact on the decisions made. (Bäcklund 2007, Staffans 2004).

Electronic services, such as public participation GIS applications, are suggested to help bridge the gap between authorities and the citizens. It is said that gathering citizens' knowledge attached to its geographical whereabouts enhances the integration of the knowledge into decision-making practices (Kahila & Kyttä 2009). Fagerholm (2012) also stresses the importance of locating knowledge when gathering citizens' opinions. By developing new tools for planning, the Living Environment Information Services, participation will be made easier for the citizens and the authorities to utilize. But how will these three internet applications enhance openness and collaboration between authorities and citizens?

Firstly, with the help of Alert service Tarkkailija (Observer), citizens will be integrated more efficiently into the decision making at the very early stage of the planning process. As the Finnish name of the service suggests, it serves as an observer, alerting the citizens on the planning concerning their environment. Secondly, with Enquiry Service Harava (Rake), citizens will be able to express their opinions and views on a map so that the planning can be directed to the geographical whereabouts. The name of the service stems from the metaphor that information can be gathered widely and efficiently as if raking leaves. What is more, this experiental knowledge gathered with Harava can be taken to Liiteri, the Information service, where it can be analyzed and examined freely. The name of Liiteri (Shed) represents its role as an information storage or a shed, where a wide range of data can be collected and stored. By opening the data used in the planning process, the decisions made will be better justified. These three services are part of SADe, the Action Programme on eServices and eDemocracy which aims at making public administration more efficient and customer friendly.

2 LIVING ENVIRONMENT ESERVICES AS A PART OF THE SADE PROGRAMME

The national development project Action Programme on eServices and eDemocracy (SADe) is currently underway in Finland. SADe programme runs until the end of 2015 and it is among the Government's key projects. SADe is coordinated by the Ministry of Finance in Finland, and Living Environment Information Services are a part of the programme. The objective of the programme is to create eService packages that enhance the cost-efficiency and quality of the public sector and are used by citizens, companies and the authorities alike. The services in the SADe programme are created to provide citizens, companies and organisations with smooth and efficient eServices (The Ministry of Finance 2013). The premise is also to make services more readily available, regardless of time or place. These new services will enable the creation of new means of participation and interaction, of which the services presented in this article are only one example.

According to Steinmann, Krek & Blaschke (2004) there are only few truly interactive GIS-based applications for web based public participation. They say that web based Public Participatory Geographical Information Systems (PPGIS) applications have developed at the same pace as the theoretical analysis concerning the theme. Also Hawthorne (2004) points out that participation in web based systems is difficult to maintain over an extended period of time. Academics, who in many instances develop and uphold these systems are often

overworked and they lack funding and time. Now ten years have passed and we see clearly that the situation has changed. Development around PPGIS applications and services has been progressive and in Finland the Environmental Administration is taking the consciousness into national level.

Harava, Tarkkailija and Liiteri are a part of the Ministry of the Environment's eServices for Housing and Building package. It provides electronic services related to housing and the built environment. They can be used when applying for various permits and subsidies, and for information and analysis purposes. The goal with electronic services is to improve citizens' participation opportunities and to improve the information flow between citizens, the authorities and companies. Another goal is to make it easier to collect and utilize the information required for land use planning.

Both national and international examples of the services selected for the SADe programme were sought during the initial investigation phase in 2010. There are various kinds of map-based query services in Finland, while the UK is home to such services as Mappiness. There are local planning observation services similar to Tarkkailija in Australia, under the name Planning Alerts, and in the UK, under the name TwitterPlan, among other places. Services resembling the Liiteri information service include Helsinki Region Infoshare in Finland and Mapumental in the UK.

The Harava, Tarkkailija and Liiteri services are produced in co-operation with IT providers. Bidding contests have been held to determine the parties implementing the Harava and Tarkkailija services. Dimenteq Oy and its partners will implement Harava, while Solita Oy with its subcontractors are responsible for implementing Tarkkailija. The bidding contest for Liiteri will be held in the autumn of 2013. The implementation projects were preceded by a preliminary investigation in 2010 and requirement specifications in 2011.

2.1 Alert service Tarkkailija

Most of us are likely to have encountered a situation in which we have had to search numerous sources and services for information regarding issues related to planning and building in our immediate environment, a recreational environment located in a neighbouring municipality, or the municipality in which our summer house is located. We may not have been able to resolve this issue online, having to call a municipal official. Next summer, the Tarkkailija service will be adopted in Finland. This service is developed to assist for example in situations mentioned above, providing access to online information content regarding the built environment that the user finds interesting. The service will be available throughout Finland, free of charge for all citizens.

Tarkkailija keeps citizens, companies and authorities informed on the changes happening in their environment. The service understands the meaning of information content by comparing it to an extensive concept model. It also determines the location based on the information content. Users may determine the topics, areas and projects they wish to monitor, or, alternatively, locate their area in the service and search for events related to their local surroundings.

Information content related to the built environment serves as the basis for Tarkkailija. Tarkkailija has been set to process the information content on more than 400 websites. The service "scrapes" websites for content related to the relevant subject matter on a regular basis. Screen scraping means that the service reads the content on pages, comparing it to an extensive concept model, an ontology. In the first phase, websites subjected to screen scraping and analysis will include the websites of all Finnish municipalities and other public-administration operators and public-sector projects related to the built environment. The search may also be extended to cover such things as news websites, online magazines and social media services.

Therefore, the contents of Tarkkailija exist before the service is available. This information will simply be further processed through analyses and GIS. Attempts will be made to determine locations for website content significant to the service, using coordinates, addresses and other local names. This will enable the provision of information on the basis of location and regional limits.

The service will provide end users with an alert service that will keep them abreast of news in the areas that interest them. Users must select which topics they are interested in and which areas they wish to monitor. When the alert service detects new information in the user-determined area that may interest the user, the service will send prompts to the user by email, for instance. Tarkkailija enables its users to gain a comprehensive understanding of their surrounding area, along with its services and changes. Tarkkailija is

primarily aimed at citizens, but other actors such as companies may also use it to monitor changes impacting company operations, while the authorities may use it as a communications channel.

2.2 Enquiry service Harava

It is widely known that public participation has an important role in community planning process especially at the local level. According to Graig, Harris, Weiner (2002) and Milovanovic (2003) participation is commonly considered to be positive and the new applications and technologies are welcome.

Enquiry service Harava represents one form of a PPGIS application: a map-based feedback system for collecting citizens' experiences. With Harava, organizations are able to conduct structured surveys to gain a wider perspective in decision-making. In addition to data captures, Harava can be used for nature inventories. It also functions as a question & answer platform, allowing inhabitants to ask questions from the authorities. Through the SADe programme Harava is planned to be a valuable application particularly for authorities and municipalities. The service will be easy to adopt in different kinds of organizations, for example associations and companies.

Harava enquiries' basic idea is to draw points, lines and areas on a map and specify for example why the object is a meaningful place for the respondent. A single line or a marked area informs the cityplanner very quickly where the place is and what the existing structures of the area are. Moreover, when there are more marked places, routesand interesting points, the gathered objects can be called spatial data. Every single object has coordinates and attributes and together the objects can be analysed further with the GIS software. Harava is not an analysis tool, but it enables data collection explicitly to the right formula. The information collected with Harava can easily be processed into thematic maps or other visual representations. As "a picture is worth a thousand words", the citizens' views, opinions or observations can be displayed so that the findings of the enquiries are easy to grasp for everyone. Visualisation of the GIS data is a different field of science, but one can assume that it generates more discussion than plain tables and figures. Bamberg and Lehtonen (2011) argue that visualisation of information is the key factor in creating interaction between the planners and the public.

In the Harava case, the user's point of view is two-sided. The first group of users of Harava, or other PPGIS applications, is the general public. It is often a very heterogeneous group of users who have a diverse range of world views, cultural backgrounds and knowledge. These aspects require that the systems are accessible and easy to use. For normal users Harava appears in the form of enquiries and a question & answer platform, and the user interface for the respondent is quite simple.

On the other hand, the administration aspect of the PPGIS applications is used by professionals from the different municipal sectors and organisations. All of them are not GIS experts and the level of computer knowledge is variable. Administration interface enables the construction of enquiries, maintaining online forum or nature inventories. The most important purpose is to create enquiries and it includes dozens of functionalities. To name a few: selection of backround maps, determining the scale, maintaining the user access inside the organization, writing the questions and determining the response options. What is more, the service contains former enquiries, which the admin can use as they are or develop further. The user interface also enables downloading data from the database while the enquiry is still on, so that the results can be evaluated in the middle of the process and not only after the enquiry has been turned off. Harava gives statistics easily on the number of respondents relative to time. Harava application has been tested and evaluated also from the administration perspective so that enquiries are easy to construct and maintaining the system is adoptable.

Pilot organizations have a very important role in building the contents of Harava. The group of pilots consists of 35 different organizations: municipalities, regional councils, companies, universities etc. Each organization creates an enquiry for an existing project, simultaneously creating question series available for further use. The focus of the existing enquiries is on land use planning, but there are also different themes like findings of invasive species, noise abatement, resident survey and many more. The service aims to transform citizens' location-based knowledge, opinions and ideas into an environmental planning tool for the authorities. When working together with a large scale of organizations, the goal is achievable.

2.3 Information service Liiteri

The information service Liiteri is an information and analysis service, where one can not only search for information on the built environment, but also analyze and make visualisations of it. In Finland, the GIS-based information on the built environment has been dispersed in various different registers. As the information is gathered to the Liiteri service, the information can be found and utilized more easily. Liiteri consists of a map section and a statistical section, which are dynamically interactive. Therefore, a lot is expected of the new service: usability, combining different kinds of information and new information contents.

The information content consists of data concerning urban structure, population, buildings and housing, jobs and commuting, mobility and transport, services, recreation, natural resources, cultural environment and land use, for example. The information is mainly produced by Finland's environmental administration, Statistics Finland and Population Register Centre.

Liiteri is mainly targeted at authorities in municipalities for implementing their regulatory assignments. Until now, a major part of the information has mainly been easily available only for the authorities. However, with the help of Liiteri, also inhabitants will be able to obtain information on their living environment. The interesting contents for the citizens are related to the quality and planning of their surroundings. The service provides users with ready-made thematic maps and statistics on for example accessibility of services, which also helps the inexperienced user to make use of the data. Furthermore, the service serves for both companies and research and study purposes. Using the service is free for everyone concerning the data owned by the Finnish environmental administration and ready calculated statistics.

One new and important theme for the information content of Liiteri is the perceived quality of the environment. Therefore the citizens have a significant role as producers of the data as well. As Harava offers a way of gathering uniform data all over the country, Liiteri brings the information all together providing an analysis platform. Hence, with similar enqueries made in municipal level the observation can be expanded to nationwide scale. The development of Liiteri has commenced and the service will be completed by the end of 2014.

3 CONCLUSIONS

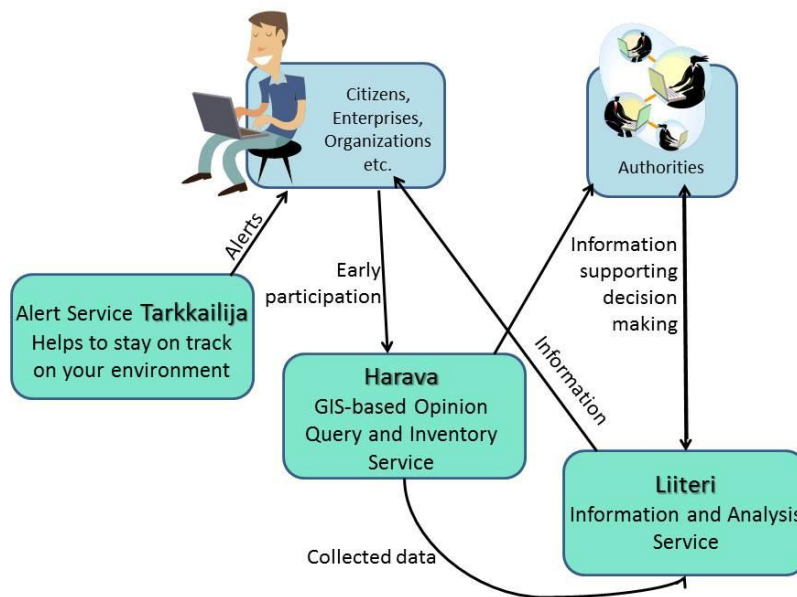
The main purpose of developing Living Environment Information services is to bring planners' desktop closer to the citizens and on the other hand the services give numerous possibilities for planners to gather information, ask opinions and get perspectives from the inhabitants. The aim is also to construct applications that are quickly adobtable in any demographic range. The idea is that these services will support one another (see figure 1).


Figure. 1: Synergy from the interaction between eServices

As Harava launches an enquiry, the inhabitants of the area are notified via Tarkkailija service. By examining the citizens' views at an early stage of the planning process the risk of conflicts will be reduced (Leino 2006; Laine & Peltonen 2003). After the enquiry is completed, the results will be transferred to Liiteri, the information service, where the information can be analysed by anyone.

More transparent governance and deliberative democracy are the main objectives. We believe that these objectives will be accomplished with the enhanced information flow due to the Living Environment Information Services. It is also interesting to see what kinds of innovations and new ideas emerge due to easier access to large amounts of information. Developing the services is a significant step concerning not only Finnish Government's open data policy but also enhancing openness and equality in Finnish planning. The thought of more thoroughly justified decisions, better planning, smoother planning processes and satisfied citizens inspires everyone working in the developing of the service package to thrive for creating functional services.

However, a change is needed concerning attitudes and ways of incorporating the citizens' knowledge into planning. The real challenge is to improve the way the knowledge produced by citizens is taken into consideration by the public administration. Therefore, there is a growing need to study the impacts of these services in planning and decision making more profoundly. By learning the defects, the services can be developed further to match the needs. Special attention should be given to the question on how the knowledge produced by citizens can be integrated into the decision making more efficiently.

The Living Environment Information Services Harava and Tarkkailija will be launched in 2013 and the expectations are high!

Meeting the Needs of Different User Groups in Mobility as Key to Ensure Social Inclusion

Tina Uhlmann, Wiebke Unbehaun

(Dipl.-Geogr. Tina Uhlmann, Institute for Transport Studies BOKU Vienna, Tina.Uhlmann@boku.ac.at)
(Dipl.-Ing. Wiebke Unbehaun, Institute for Transport Studies BOKU Vienna, Wiebke.Unbehaun@boku.ac.at)

1 ABSTRACT

An accessible public space and self-determined mobility are important preconditions for most activities in daily life and social inclusion. The design of outdoor environment, e.g. streets and facilities, as well as the supply of different transport modes have major impact on the opportunities of people for participation in everyday life. There is a variety of user groups with special requirements concerning the public space and transport modes, such as persons with reduced mobility or sensorial impairments. But beside the attributes of these well known groups, also other characteristics exist that can cause mobility impairments, like missing knowledge of the national language, poverty, learning disability etc. All these user groups indicate a different picture concerning their mobility pattern in comparison to average values.Therefore their needs in public space and mobility offers vary substantially. Sustainable community planning has to take into account those facts in the present as well as in the future and therefore requires an inclusive design that allows people of all ages, backgrounds and abilities the use of open spaces and transport means. In Austria a survey with 450 persons was conducted to analyse and compare mobility pattern of different groups of persons, which have different potentially mobility impairing characteristics. Besides the mobility pattern, the survey focussed on the experiences in the outdoor environment, the subjective perceived degree of impairment, problems and ideas of solutions. The paper presents the results of the study showing that the mobility pattern of the persons in focus vary significantly from average values in Austria. Based on the study results fields of action could be identified which authorities should consider when developing sustainable short- and long-term strategies for inclusive design of public spaces and supply of transport modes.

2 OBJECTIVES

In Austria a survey with 450 persons was conducted to analyse the mobility pattern of different groups of persons, which have different potentially mobility impairing characteristics. Aim of the survey was to show differences in mobility pattern of certain groups, identify obstacles and coping strategies of persons in focus and to analyse the subjective perception of the individual mobility options. This paper will present the methodology of the survey as well as its resuslts. It will deal with measureable facts on mobility, which will be compared with average values from Austria. Furthermore, it gives examples of individually reported barriers as well as assessments of the accessibility of transport modes and outdoor environment. Based on the survey results of the survey fields of action were identified, in which local authorities should plan, develop and implement measures in order to enhance the accessibility and therewith the social inclusion for different groups of persons. The results of the project emphasise the linkage between inclusive design and sustainable community planning and provide recommendations for spatial and transport planners and communities.

3 MOBILITY SURVEY

3.1 Methodology of the survey

One possibility to analyse mobility behaviour and detect mobility barriers and needs of persons with possible mobility impairing characteristics is to calculate mobility indicators for the persons in focus and to compare them with average values of the country. For Austria nationwide data is available for the year 1995 (Herry, Sammer 1996). To collect data of mobility behaviour of persons with possible mobility imapiring characteristics, a mobility survey was conducted in the framework of the study. In 450 personal interviews persons with at least one of the following characteristics were surveyed:

- Physical or sensory impairment,

- Difficulties in reading and/or writing and in understanding the national language,

- Risk of poverty,

- Single parents and families with 3 or more children,

- Aged over 74 years,

Most participants of this survey can be allocated to the groups of hard-to-reach persons (Brackertz, 2007); on the one hand, they are difficult to identify because their characteristics are not mentioned in official records; on the other hand, the willingness to participate actively in a survey is comparatively low (Riandey & Quaglia, 2008). In literature one can find a number of publications addressing the specific problems of sampling and conducting surveys with hard-to-reach persons (Banister & Bowling, 2004; Chlond & Ottmann, 2007; Schwanen, 2010). For the survey potential interview participants were contacted via their social environment, at work, family, neighbours, associations or specific organisations (Cowham et al., 2008). Within the interviews the persons reported about trips they made on two reference days using trip diaries. For each trip origin and destination, means of transport used, reported length and trip duration, trip purpose, accompanying person(s), aids used to overcome mobility barriers as well as problems encountered on the trip and their solution were reported. Furthermore, they were interviewed on availability and use of means of transport, frequently encountered problems affecting everyday mobility, subjective perception of their mobility impairment and socio-demographic issues. The participants were also asked about barriers with which they are confronted in their mobility. There were no categories provided for answering this question in order not to influence the direction of the responses. After all interviews were conducted the answers were summarised in categories.

3.2 Comparison of mobility pattern

It was assumed that by comparing mobility indicators one can deduce differences in the mobility behaviour between the persons in focus and the Austrian population. In spite of some methodological limitations the descriptive analysis of the mobility data shows typical and well interpretable differences between most of the groups investigated and the average of the Austrian population.

In the year 1995 on average about 3.7 trips per person were accomplished on a working day in Austria. The trip rate per day of the persons surveyed is lower for almost all groups (see fig. 1). The trip rate is significantly lower for persons with learning disabilities, wheelchair users, deaf and elderly persons (between 2.4 and 2.7 trips per day). For the elderly it can be assumed that the trip rate is lower because they are not employed anymore and the missing daily trips to work and back home are reasons for the differences. For the other groups mentioned this can't be the explanation, because participants were interviewed in workshops and training facilities, which they frequent each day. If a high or low trip rate has to be assessed positively or negatively depends on the number of trips and the activities connected are desired or enforced. Nevertheless, in different sources it is assumed that lower trip rates are related to social exclusion and disadvantages (e.g. BMVBS 2012, Stanley et al. 2011).
Fig. 1: Trip rate of mobile persons per working day (*= significantly different from Austrian population)

Singel parents have a higher trip rate per day compared to the average in Austria. This disparity is not significant but can be explained clearly. Also in other studies implemented in Germany this phenomenon was observed (e.g. Stiewe & Krause 2012). The higher trip rates can be interpreted as forced mobility, because daily trips like bringing and picking up children have to be accomplished by one person only.

Shorter average trip lengths indicate that persons have a smaller range of action to accomplish their daily activities (fig. 2). Especially trip lengths of wheelchair users (5.5 km/trip), persons with an impaired ability to walk (6.4 km/trip), visually impaired persons and persons with immigrant backgrounds (both 7.7 km/trip) are below the average value of the Austrian population with 9.5 km/trip. Combining these numbers with the lower trip rates it is obvious that the range of action is smaller. A conscious choice of the residential location of the persons in focus with all important infrastructures around can be one reason for this phenomenon, but Schoenfelder & Axhausen (2003) interpret these numbers as an indicator for a possible social exclusion. Negative deviations are interpreted as not-realised trips (Duvarci & Mizokami 2009).

The comparison of average trip lengths and trip durations delivers insight into the average velocity, with which the trips are accomplished. The average trip lengths of many groups are below the average value of Austria and also trip durations vary significantly from 23 minutes, which is the mean in the country. Although trips are shorter the persons interviewed need more time for accomplishing them, which shows that the average velocity of the persons is much lower. The combination of all three mobility indicators points out that the effort to accomplish trips and to fulfil activities seems to be much higher than for the average population.
Fig. 2: Average trip length in km and average trip duration in minutes on working days (*= significantly different from Austrian population)

Partly the lower velocities can be explained by the availability and choice of transport means. The modal split varies significantly for almost all groups investigated compared to the average in Austria. Most of the groups use public transport significantly more often. Especially deaf persons and persons with learning disabilities have to be mentioned here: more than 50 % of their trips are accomplished by public transport. Also for the other groups – excepted wheelchair users, families with 3 or more children and single parents – the part of the trips made with public transport means is higher than for the average population. Families with 3 or more children and single parents use the car as much as often as the Austrian population in average. Because of the high number of trips per day, their restricted time budget and required transport capacities they seems to be bound to the car use. All other groups – excepted hearing impaired persons – use the car for for not more than 20 % of their trips, which is significantly lower than the value of the average population with 40 %.

The comparison of these mobility indicators as well as other figures from the study show that the mobility behaviour from the persons interviewed differ significantly from the Austrian average. Taking into account only these quantitative values it can be assumed for the groups investigated are less mobile and therewith they are at risk of being excluded from the society (Dodson et al. 2010). If the differences in the mobility indicators really cause restrictions in the activities and social inclusion for the persons in focus of the study can't be proven with these indicators. Persons can use different organisational strategies, support offers and devices in order to accomplish their activities without or with less restrictions.

4 BARRIERES IN THE PUBLIC SPACE

4.1 What people hinders to be mobile

The follwing groups of barriers mentioned in the interviews are related to the public space and have to be taken into account by urban and transport planners.

Barriers in the build environment form main obstacles for persons with potentially mobility impairing characteristics. Especially high kerbstones, stairs, steep ramps and missing or broken lifts in public space and buildings were mentioned by elderly, persons using wheelchairs or having mobility impairments as well as parents with children. Also uneven pavemantes were mentioned by wheelchair users, elderly and visually impaired persons. Further on, it is peceived as a barrier if space for pedestrians is limited and if crushes begin to develop. A problem which was mentioned basically by persons with visually impairments is the incorrect installation of traffic signs or other fixed equipment (e.g. letter boxes), which constitute high risks of injuries.

Missing boundaries between areas of different usage can be barriers for the persons in focus. Persons with visually imparments and elderly, whose ability to see is decreased, information reception became slower and reaction is delayed (Rytz, 2006), have problems in such environments due to an increasing feeling of insecruity and a higher risks for collisions. In contrast, for mobility impaired persons and people, who are mobile with prams or baggages, the absence of kerbstones and boundaries between different areas is an advantage. Planners have to find a compromise to meet the needs of both groups. Especially with regard to the upcoming discussions on shared space this problem has to be resolved.

Street crossings are perceived as obstacle by persons with visually impairments, elderly and persons with children. Barriers are constituted by highly frequented streets without traffic signals, traffic lights without accustic signals and short green phases. Crossings and the corresponding flattened kerbstones should be marked to show visually impaired persons where to change to the other side of the street.

Not only in the built environment barriers are hidden, also mobile or unexpected obstacles in public space limit the mobility of different groups. For example, building sites comprising shutoffs, signboards and building material hamper persons with mobility reducing characteristics. As barriers also decorations and advertisments in front of shops or other objects on the sidewalk (waste containers, carriage of postmen, etc.) were mentioned, which in some cases even obstruct the guiding system for visually impaired persons.

Almost all groups in focus of the study perceive long distances to different locations as reason for their mobility impairments. Particularly if the persons have to carry goods problems occure. Poor persons are effected by this problem remarkably because they often live in areas that are not connected sufficiently to city infrastructures. Due to a lack of mobility options they are not able to reach service facilities and therewith they are in risk of social exclusion.

A problem, which is not related to urban or regional planning directly, but which has to be taken into account by decision makers in overall strategies, is the feeling of the interviewees that other traffic participants are not aware of the problems of different person groups. This often has negative consequences on the mobitliy options of the persons analysed in the study. For example, car drivers who ignore crosswalks, heedless pedestrians or cyclists as well as bus drivers who disregard the special needs of public transport users were mentioned by the interview participants.

4.2 Fields of action

On the base of the barriers and problems mentioned by the interviewees some main fields of action could be identified, which should be considered by urban, regional and transport planners in their decision making processes.

Planning processes

People with mobility impairing characteristics accomplish their trips more often by foot or public transport. This means that the distances covered are shorter and the ranges of action are limited. Therefore, the idea of "short distances" should be promoted more intensively and the configuration of the residential environments has to be adapted to the needs of potentially impaired persons – especially in rural and suburban areas. In all planning processes the convenient and barrier free accessibility of public space and buildings has to be taken into account. The best way to consider all issues that concern persons with potentially mobility impairing characteristics is to include the groups affected in decision making from the beginning on. Participation processes should be integrated as a firm component of each planning process.

Information provision

One main field of action for improving mobility options of the persons in focus of the study is the information provision. Here, information on public transport (e.g. barrier free vehicles, interruptions) and unexpected obstacles in public space (e.g. building sites) should be offered. New information and communication technologies and channels have to be developed to inform impaired persons. These technologies have a high potential to help persons with impairments, but one should never forget that there are always persons who can't use technological devices. These are not only elderly but also persons who cannot afford to buy new technologies or persons who are not able to use it. Therefore also "traditional" services, like call centres or on-site support personnel should always be available.

Awareness raising

Awareness raising has also high potentials to improve the situation of persons with mobility impairing characteristics. Training courses and campaigns should be offered to educate and inform service personnel (e.g. of public transport services) on the one side and the broader public on the other side. It has to be elucidated how problems can be avoided and how everyone can help persons with reduced mobility.

The differences between mobility indicators of the persons investigated and the average population show a significant disparity in the behaviour and therewith in the chances to participate in everyday life. Problems and needs of most of the groups which were mentioned in the survey are well known and many measures to overcome obstacles are developed. But still the implementation of measures is not satisfying and has to be further supported and promoted. It also has to be considered that there exist further groups of persons having considerable mobility problems which are not in focus of planners and authorities until now.

1 ABSTRACT

Smart meters are one of the pillars of the smart grids and since few years are attracting much attention. They will help in the transition towards "active networks evolution" to massively integrate renewable energy sources into the grid and they will enable the full exploitation of technologies like electro-mobility and active demand programs with great benefits in terms of the overall sustainability of the energy system, positively impacting both the society and the environment. The massive introduction of intelligent metering systems will assist the active participation of consumers in the energy market, promoting transparency and competition and favouring the emergence of a well-functioning and non-discriminatory retail market in the whole Union. The paper presents initial results regarding consumers' involvement of the European project Meter-ON, a coordination and support action which aims to steer the implementation of smart metering solutions throughout Europe by effectively collecting the most successful experiences in the field and highlighting the conditions that enabled their development.

Meter-ON Consortium is led by the European Distribution System Operators for Smart-Grids, including 32 leading DSOs and associations throughout the European Union. The Consortium comprises university-linked foundations (EnergyLab), technological institutions (RSE and CEIT Alanova) and communication experts (ZABALA).

2 INTRODUCTION

In most cases smart metering involves the installation of an intelligent meter at residential customers and the regular reading, processing and feedback of consumption data to the customers. Smart metering is often referred to as automated meter reading (AMR), or in the case of real-time, two-way communications, as advanced metering infrastructure (AMI) (Van Gerwen et all, 2006).

The evolution of power grids into smart active networks is key in enabling the transition towards more sustainable and environmental friendly energy systems, and smart metering is a core tool to develop smart grids in the future. In this field, Distribution System Operators (DSOs) from all over the world are designing, developing and implementing different smart metering systems, and testing them in pilot projects before proceeding with large scale roll-outs. Different transmission technologies and protocols are used. Although the first objective of smart metering infrastructures is the "metering and billing", it emerged they are also key to enable other advanced services related to smart grid features and to make consumers more active players in the energy market (Bavarian et all, 2012).

The intelligent meters will enable the massive penetration of distributed energy resources by supporting the bi-directional flow of communication and energy needed to effectively integrate electricity produced from green energy sources. Smart meters will also allow the introduction of electro-mobility and the deployment of related charging infrastructures. According to the feedbacks, Meter-ON has observed from its first collection of data that even if supportive smart metering regulation is not already in place throughout Europe, DSOs are exploring smart metering deployment possibilities and, leveraging on this infrastructure, they are developing other advanced services that can support the development of smart grids at large.

The successfull deployment of smart metering infrastructures relyes on different interlinked aspects: technical, economic, regulatory and consumer involvement issues. This paper aims to take a deeper look on the consumers' side, as they represent the end-user but also (in many cases) the less experienced actors when it comes to smart metering.

3 METHODOLOGY AND OBJECTIVES OF THE METER-ON PROJECT

The Meter-ON project is a coordination and support action financed by the Seventh European Framework Program (FP7) which aims to steer the implementation of smart metering solutions in Europe by effectively

collecting the most successful experiences in the field and highlighting the conditions that enabled their development. On the basis of the lessons learned, the goal of Meter-ON is to provide to any stakeholder an open information platform with clear recommendations on how to tackle the technical barriers and the regulatory obstacles endangering the uptake of smart metering solutions in Europe. Meter-ON will address completed, on-going and planned smart-metering projects and is consisting of a three-step approach performing the following activities (as shown in Figure 1):

(1) collection of information related to smart metering projects;

(2) analysis of each project according to the identified set of information domains (see below);

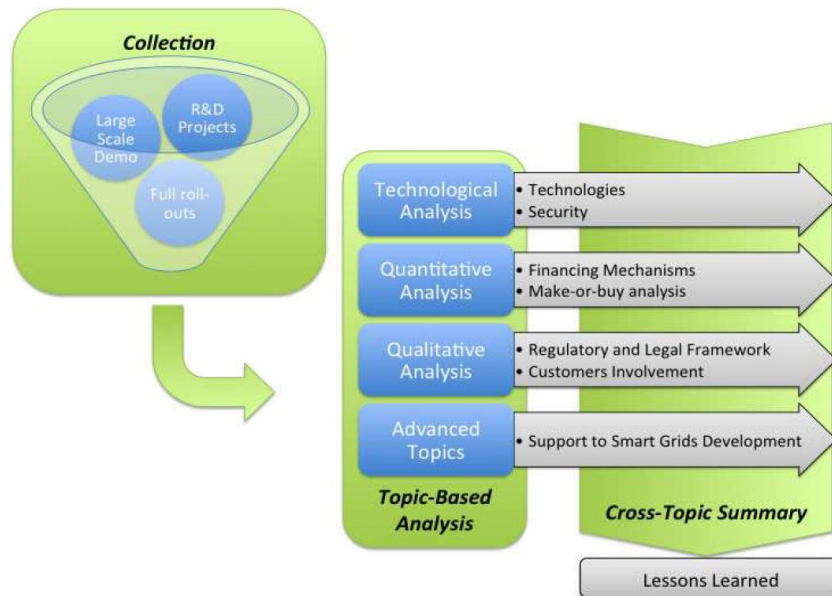
(3) drawing conclusions and recommendations on the way forward based on the lessons learned from the most successful smart metering experiences.


Figure 1 Meter-ON Approach

During the Topic-Based Analysis, each project goes through the following analysis:

- Technological analysis of the grid characteristics of the company running the smart metering project, of the overarching smart metering architecture, of the smart meter devices installed, of the cyber security and privacy policies applied by each smart metering solution presented.

- Quantitative analysis, comprising cost and benefit originating from the project and information on the supply chain development process related to each project.

- Qualitative analysis on the regulatory and legal framework in place in each country where the project is running and on user acceptance and customer involvement assessment, to evaluate consumers perceptions and attitudes towards smart meters.

- Advanced topics, comprising information on the impact of electricity smart meters on distribution network operations, information on smart metering solutions as supportive of electric vehicle infrastructure, demand response programs and the existence/plans of smart metering solution for other energy carriers (heat, gas and water), when applicable identifying also multi-utility approaches.

4 QUESTIONNAIRES AND FEEDBACK

Aside from the available literature, the consortium has developed a questionnaire having four main information domains, as decribed above. This has been distributed to the utilities involved in the project in order to receive direct input but also to make sure that sharing experiences ensure a win-win situation for all parties involved. In the first collection phase of the project, 15 project information questionnaires have been gathered. Projects collected take place in 10 European countries (Figure 2) and according to the information available in total it is foreseen that by 2020 about 100 million meters will be installed. The project information sample comprises 1 project in the R&D phase, 5 projects in the pilot phase, 1 project in the

demonstration phase and 8 projects in the roll-out phase (on-going or completed), in the countries outlined below:

Figure 2 Meter-ON coverage

5 CONSUMER FOCUS

The involvement of the customer is noted to be a complex point linked to the regulation in place in each Member State, where customers are expected to be engaged in these changes, but as some evidence show the information needs to be shared in a more accessible and understandable manner for them to do not see smart meters as a danger and to experience real benefits from their usage.

Three matters are recurrent in the acceptance and involvement of customers' vis-à-vis smart metering solutions: security and privacy related issues, cost related issues and energy efficiency. Even if the latter is used as a tool to convince the user of the importance of the smart meter, there is evidence showing that energy savings are reached not only by installing the device, but by having a combination of advice, precise billing and smart meter (Klopfert & Wallenborn, 2011).

The concerns related to data collected from smart meters range from how is this information handled to what might happen in case of unauthorized accesses. Along with this issue, trivially, consumers might fear they are charged the costs related to the infrastructure without receiving back the corresponding benefits.

As a general rule it is observed that effective information campaign promoting consumer awareness and knowledge should be performed by the company running the smart metering project, not only to mitigate their resistance to the technology but to promote at an early stage the interaction with the meter, to support those advanced smart metering uses, such as demand response programs, where the involvement of the customer is crucial.

Information collected by Meter-ON shows that in some cases companies running the smart metering projects adopted a clear strategy targeting the engagement of the end-users, but in other cases it is clear how the focus was more on the technological side and how the customer was not involved at the early stage of implementation. The initiatives to engage the consumers in the smart metering implementation range from basic informative letters on the matter with updates throughout the process, to round-table meetings with the stakeholders and to large-scale surveys and Customer Service platforms to attract customers in providing their opinions and to enhance their interaction with the smart meter. In the next phases Meter-ON will try to identify the most successful strategies to involve consumers in the smart metering field.

6 CONCLUSION

This paper highlighted that the customer should be put at the core of smart metering developments, as he/she is the first actor concerned by the deployment of this technology. It is observed that effective information campaign promoting consumer awareness and knowledge should be performed by the responsible company, to promote at an early stage the interaction with the meter and thus supporting those advanced smart metering uses, such as demand response programs, which are expected to bring energy savings.

Meter-ON project has gathered already information from 15 projects that are going to involve about 100 million customers in the next few years. Considering the high number of households affected by the deployment in various cases, the consumer needs to be a priority at all levels. Creating a transparent environment around smart metering will facilitate understanding about the topic among consumers and consensus at the higher decision levels.

Motorways in Agglomerations – Changing Concepts for Changing Needs

Thomas Steiner

(Dipl.-Ing. Thomas Steiner, Autobahnen- und Schnellstraßen-Finanzierungs-AG, 1010 Wien, Rotenturmstraße 5-9, thomas.steiner@asfinag.at)

1 ABSTRACT

Limited financial resources, environmental regulations, new mobility trends and outdated planning concepts call for a rethinking – not only in politics, society and spatial planning, but also in infrastructure development.

The past thrieve for constantly expanding capacities of motorways through new routes or enlarging existing infrastructure is becoming outdated. Intelligent expansion and new technologies displace "conventional"

(= increase-driven) strategies. Austrian motorway provider ASFINAG is already extending his future policies to new topics of strategic network planning: effects of motorways on space- and regional development, opportunities for intermodal crosslinking, enhance of information services, etc.

Also the demands of customers have changed. Linked traffic information in real time like Traffic Message Channel (TMC) is already an integral part of traffic-information and will in future be increasingly offered in a package with various mobility services. The discrete one-dimensional traffic information is already past. Future services will provide a cross-modal integrative mobility information, which means, that customers get reliable support in multimodal routing and mobility any time he needs.

Further, ASFINAG defines itself not only as a provider for road-infrastructure and high-quality technical services, but also committes itself to a builing culture in the sense of environment responsibility. The ambitious objective in the long term is to improve the appearance of motorways and expressways in terms of architectural quality and their integration in landscape. In cases of construction of new routes, ASFINAG early began to pay considerable attention to design aspects. Now, these activities will be extended to the existing network. From noise barriers up to motorway maintenance buildings, all design-related constructions will be architecturally revised, so that the appearance of our entire network – from bridge to rest areas – will be refurbished for our customers and residents nearby motorways.

2 MOTORWAYS IN COMPETITION OF SITES

2.1 Motorways affect Spatial Development

Spatial development in Austria is strongly influenced by highcapacity-infrastructure and has generated certain principles: industrial parks settle mainly in the catchment area of existing motorway junctions. It is considered as a precondition by local authorities and investors to build new junctions for the purpose to establish commercial real estates. It is even politically demanded. Common task in spatial und infrstructure-planning is it therefore, to develop an integrative view, ie. to anticipate possible effects of infrastructure on regions and communities followed by deriving regional and balanced transport policy objectives. Positive and negative effects are to be faced in terms of balancing interests!

2.2 EU Research project "TIILUP"

In 2012 a noteworthy EU research project named "TIILUP" (Transport Infrastructure Integrated Land Use Planning) was started. As a member of the coregroup team, ASFINAG assists to develop innovative instruments and methods, which can integrate land-use-planning more efficient into the process of multimodal infrastructure planning. Existing cases in the Netherlands, Germany and Austria have shown how such an integrated approach can lead to significant increases in cost efficiency in terms of investment costs, improved planning and investment processes and social/economic benefits as well as better reliability of the transport system and liveability for citizens in the regions involved. The TIILUP approach will analyse these and other relevant best practices to determine the key elements of the various approaches and consolidate them in a suite of generic approaches: the TIILUP toolbox.

The outcome will be a practical toolbox which enables organisations (such as local, regional and road authorities) to plan infrastructure more efficiently and meet policy objectives. The solutions in the toolbox

will be proven in practice and be accompanied with common standards, guidelines and specifications. This product will be disseminated through a sound knowledge transfer process.

2.3 Paying for benefits initiated by motorway connections

Fulfilling her duties, ASFINAG is increasingly confronted with projects and measures in the interests of other (third) parties. Especially interchanges often prove as a "magnet" for extensive business relocations. Usually the provision of infrastructure generated by ASFINAG implicates a significant rise of values in land use creation, but there are no adequate benefits (eg. road toll income) in return. As a customer-financed motorway operator it is therefore legitimate interest, to share costs with other parties according to the calculated moneticed benefits. In these cases of cost sharing, the funding is usually aliquot to the achieved benefits.

Since a few years this approach was established as common practice in ASFINAG. Further appropiate cost-sharing models are applied successfully for: the provision of noise barriers, protection of torrents and avalanches, Park & Drive facilities etc.

3 MOTORWAY OF THE FUTURE: INTELLIGENT AND CROSS-LINKED

3.1 Intelligent solutions replace expansion measures

The strategic focus getting motorways more efficient, is – by implication – focused on urban areas. Changed transport policy perspectives, changing mobility needs and rigorous cost reduction targets have distinct consequences: capacity constraints on the primary road network will in future be faced not only through expansion projects, but will be compensated by intelligent inventory-orientated solutions.

ASFINAG is developing sustainable solutions as follows:

- Emergency Lane Release: on critical routes a temporary realease of emergency lanes shall compensate high traffic volumes during morning and evening peaks. The objective is it, to keep traffic fluent and avoid accidents and traffic jams. To make this concept work, appropriate dynamic overhead displays and a video control system have to be installed. After implementation of all traffic safety-related requirements, the emergency lane can be released temporarily.

- Ramp metering: ramp meters could be installed to restrict the total flow entering the motorway, temporarily storing it on the ramps – a process called "access rate reduction." In this way, the traffic flow does not exceed the motorway's capacity.

3.2 Cross-modal network

ASFINAG has developed a strategy- and action plan for linking road networks with other modes of transport – concerning both – passenger and freight traffic. Appropriate locations connecting motorway with other carriers are examined regulary in order to find and develop multimodal nodes. First measures on motorways as signposting of Park & Ride (P&R) facilities were already implemented on ASFINAG network.

To optimise collaboration and information generally, regular meetings with delegates of other infrastructure operators are taking place. Besides P&R supply ASFINAG also thinks ahead how existing Park&Drive (P&D) facilities and service stations or rest areas can be developed as intermodal nodes for bus line operators in future. New "features" can be implemented in those locations, such as "Ride&Drive" (a combination of public transport and carpooling), as well as e-mobility devices in Park&Drive locations.

Concerning P&R facilities, information management in Austrian motoway-network will be continously expanded. The information provided includes the current connection status, the availability and utilization of public-transport, which can provide incentives for customers to change modes efficiently.

ASFINAG telematic network shall play a key role in intermodal information management. The development and implementation of "Cooperative Systems", based on an exchange of information and communication between vehicles and road infrastructure, is progressing rapidly. As part of the recent ITS World Congress 2012 in Vienna, achievements in cooperative services were demonstrated live in a "Showcase" in and around the city Vienna. Through a wireless communications network, a cooperative vehicle system can enable cars, buses, trucks to communicate not only with each other, but also to intermodal nodes. Major goal is to

integrate different modes of transport and to provide efficient interchanges between private and public transport.

Fig. 1: "Car-to-Infrastructure" – communication

Increasing cross-linking of vehicles through the area-wide availability of mobile, wide band, communication solutions offers numerous opportunities for communication with infrastructure networks. Thus, traffic information will be an indispensable part of future mobility.

3.3 Incident management, traffic control, Level of Service

Another strategic approach to improve quality of transport in urban areas are „soft" skills like intelligent network monitoring and data analysis. These traffic control measures also help to increase capacity of motorways without constantly enlarging capacities by additional lanes. Associated with comprehensive congestion causal-research activities, alternative solutions (for example release of emergency lanes) can displace expensive expansion measures. Intelligent traffic-monitoring can result in quite ordinary optimization measures which increase road safety substantially and thus a better route availability. Since today ASFINAG has already installed numerous of intelligent analysis- and control systems. The objective of all activities is it, to offer customers a safe and efficient traffic-network and make use of the existing data-infrastructure as much as possible. Since a few years, traffic problems on Austrian motorway-networks are actively managed and motorists are informed immediately about hazards or obstacles. To be able to communicate with drivers, road-side facilities, known as Traffic Control Systems – supported through different traffic information services – are already provided.

Basis for all Real-time informations are 2150 sensors along the Austrian motorway network, as well as Real-time data from partner organizations (eg executive or radio Ö3). Skillful coupling these different data sources significantly improves the quality of single informations.

Figure 2: webbased ASFINAG Traffic Control and Level Of Service Information

Further, as truck parking facilities are increasingly demanded, ASFINAG, for example, has installed a truck parking information systems for metropolitan areas of Vienna and Linz.

Another successful information-service are, for instance, ITS-supported recommendations of alternative routes in case of line blocking and congestions situations.

4 INFORMATION / COMMUNICATION: MORE IMPORTANT THAN EVER

4.1 Telematic services

Successfull Transport systems in urban areas are today a matter of information. Future traffic information services of transport operators will be a highly specialized, quality-assured, data-management that provides reliable, timely, high-available and multi-modal informations for the linked up customers. The usefulness of mobility information is elementary for the customers and has to be offered easy and simple to understand. Especially traffic information has to be integrated to those platforms which are utilized by customers for their daily information. Not to forget additional „key-innovations" like e-Mobilty, e-Safety, as the latest progressions in urban mobility.

Standalone-Informationtechnologies of today will continuously be replaced by integrated centralized services. Multimedia service for traffic information is provided on uniform, standardized platforms and available for customers by mobile devices and digital broadcast services.

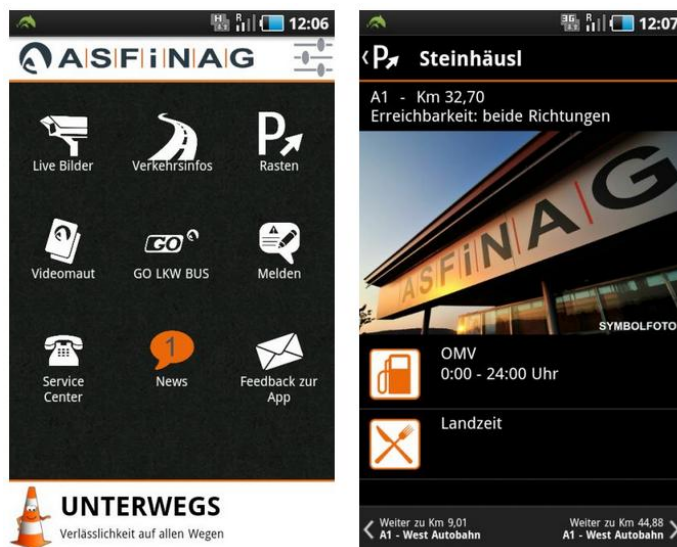
Figure 3: Traffic information services ASFINAG


Figure 4: Mobile Internet ASFINAG

From ASFINAG point of view sustainable mobility can only be achieved by measures along all three intervention-axes: vehicle – man – infrastructure. In multimodal transport networks of the future, users choose from the most comfortable and best suitable transport-facility for the particular route, travel purpose and the current traffic situation (eg unavailable route because of roadworks). Successful application of multimodality in daily life requires integrated route planning, reliable knowledge of the current traffic situation and well directed alternative options. For those pursoses powerful communication and information solutions are necessary. A variety of different traffic information services are currently available to road users in Austria. One oft he most efficient services will be the „Traffic Information Austria (VAO)", a

plattform developed under guidance of ASFINAG. The mission was to create a collaborative information service covering all Austrian traffic means and all traffic-states (for cyclists, pedestrians, public transport, motor vehicles, Park&Ride) in realtime and in consistently high quality. Highlighting alternatives and options enable customers to switch to more environmental-oriented means of transport and ensure more attractiveness and greater awareness. According to the results of the research project „ITSworks", the potential for shifting traffic from the car to more environmentally friendly modes ranges up to six percentage points.

Particular requirements in data quality and comprehensive information have to be implemented:

- the offering has to become coherent and not only cover small sections of the mobility range, as is currently often the case

- the quality of all services should be equally high; they should thus have access to a collaborative database in order to prevent inconsistent recommendations

- the digital maps currently employed should also be standardised to reduce inconsistencies in routing and localisation to a minimum

- a common coordinated strategy would ensure traffic control more flexible, ecological and efficient in terms of mobility

5 MOTORWAYS AND BUILDING CULTURE

The perfect motorway meets several aspects: it must be planned safe and functional – and simultaneously must fit in the landscape as much as possible. Motorway routes, noise barriers, bridges, tunnels, rest areas, toll cabins and other buildings leave – because of their size and feature – distinctive marks in landscape and are therefore not only a technical but also an architectural challenge for Highway authorities.

As part of the ASFINAG – design initiative, launched in 2010, was the founding of a „design advisory board" of internal and external experts in the fields of architecture, landscape architecture and planning as well as representatives of the Austrian Chamber of Architects. As a strategic approach, the company has focused not on ordinary design proposals or catalogs but on sustained strategic and organizational regulations, in order to allow plenty of room for creative minds to realize innovative (design) ideas in the project execution.

Austria's 2175 km long road network consists of over 1,250 kilometers of noise barriers and 4745 bridges, both with renewal cycles starting from 15 to 20 years up to 70 years. Purpose of the design initiative ASFINAG is to guarantee, that our construction projects are not reduced on safety and functionality, but should also fit aesthetically into the landscape.

In cases of construction of new routes, ASFINAG early began to pay considerable attention to design aspects by undertaking architecture competitions. Very positive customer feedback confirmed the chosen path. Now, these activities are already extended to the existing network, which is a far more complex exercise. Just in the year 2012 eleven different design contests for renewal measures in the existing network were settled.

An important aspect of the design initiative was, already from the beginning, the subject of economics. To ensure efficient and cost effective solutions, one of the most decisive requirement is to implement design aspects early and coordinated in the planning process. This must be guaranteed by all involved disciplines.

Objectives of the ASFINAG design initiative:

- Continuity and long-term effectiveness

- Standardization instead of sprawl

- Innovation as an element of design

- Basic principle of economics

- Defined and achievable quality criteria

- Employee training on "Architecture"

- Top-quality renovations – particularly bridges and noise barriers

Fig 5:. Construction of Motorways has to deal with building culture

6 CONCLUSION

Already for several years ASFINAG faces increasing traffic challenges in urban areas, which only can be solved in an overall context. Common target of all measures is it, to run the road-network to the lowest possible costs and related to highest efficiency and innovation. Thus under precondition of largest possible customer satisfaction on high level of quality. To ensure furthermore, that customers travel safely and unhinderd on ASFINAG network, it requires increasing intelligent and innovative solutions – with a reinforced focus on optimizing the existing infrastructure as well as deepen intermodal strategies and information services.

Opportunities for Sustainable Development of Suburban Rural Areas on Example of Karabiha Rural Settlement

Anastasia Dubova

(Anastasia Dubova, Civil engeneering department of Yaroslavl region, 42, ul. Chaikovskogo, Yaroslavl, Russia, dubova88@mail.ru)

1 ABSTRACT

Thinking about planing cities we also should not forget about improving living condition in rural areas and their potentials for sustainable development.

Karabiha rural settlement located to the south of Yaroslavl – major town of Yaroslavl region, it is extended rural area, that occupy about 217 square kilometers and contain 63 villages with overall population about 13.350 residents. Some processes, that going on here today can be also recognized in rural territories, that surround another cities and towns in Russia like increasing of building detached one-family houses and dachas, appearance of huge retail and logistic centers, but there are some features, that can help to distinguish Karabiha from another rural areas. Although Karabiha's residents dependent from center of region in labor, culture, education, health care and another needs, territory has potentials not to be only a kind of remote "bedroom community" of Yaroslavl. During the last few years in Karabiha were opened several new factories of food and construction equipment industry, ski and recreation centers, and even dolphinarium. Karabiha often associated with famous Russian poet Nikolai Nekrasov, who wrote here poems "Russian women" and "Who lives well in Russia?", today his estate transformed into a museum.

Recent years Karabiha survived dramatical growth of building, that was provoked by allocation of land, mainly for individual housing. Increasing of building detached one-family houses explained not only by appearance of "newcomers" from Yaroslavl and another regions, but about a half of new homes were constructed by Karabiha's inhabitants. While Yaroslavl and Yaroslavl region demonstrate population decline, Karabiha shows grow of residents, that was ensured, on the one hand, by natality, on the other hand, by migration inflow. Population can increase more as a result of realization low-rise housing projects, that launched by government of Yaroslavl region and private sector. But in this case very important not only to rise quantity of residential real estate, but also expand quality of life in new and established residential areas, improving accessibility of education, health care, culture and sport facilities.

This paper focused on determination, problems and potentials for sustainable development and smart grow of Karabiha, taking into account of local administration's responsibility.

2 INTRODUCTION

Rural areas are often mentioned as home for almost a half of overall world population and their development is vitally important. Although in Russia according to statistic data 74,03 % of residents concentrated in cities, many of the rural areas now face significant challenges and survive dramatic changes. Influence of urban sprawl on the countryside especially visibly in vicinities of cities, where it is seen as widening of urbanized space.

Yaroslavl region is a part of Central Federal okrug, and situated to the north from Moscow region. It has passed through urban sprawl process, despite of negative demographical trend, in the recent 10-15 years. Increasing number of housing as well as industries and logistics on the territories that surround major cities of the region, like Yaroslavl, Rybinsk and Pereslavl-Zalessky dramatically accelerates. Negative impact of this process can be recognized in consuming of agriculture land, spreading the recourses and environmental degradation. But at the same time appearance of investment and newcomers can be considered as a potentials for improving living conditions for rural inhabitants and development of territories in a sustainable way. Rural areas influenced by planning policy implemented by different levels of public authority and, at the same time, in the last 10-15 years with the emergence of private land ownership affect of private sector has also increased significantly.

For rural areas Russian legislation provides a two-tier system of municipal management, including division into municipal districts and settlements . Sharing of responsibility between districts and settlements can be flexible, and depends from ranges that is called " issues of local importance " that contain maintenance of common infrastructure, roads, repair of municipal housing, provision of education, healthcare, cultural and public services, protection of nature and cultural heritage sites and landscaping.

If realization of planning policy is concern, local councils responsible for development planning documentation, that according to legislation named " Territorial planning scheme of municipal district" or "General plan of settlement", that show dislocation of social objects, streets, infrastructure and border of the villages, with components of strategic vision of development for 20-25 years. Another document, "Land use and development plan", that establishes variety of permitted uses of land according to zoning and regulation for each zone. In this case importance of planning policy, pursued by local councils became crucial.

Another thing, that affects on development of rural areas is allocation and privatization of land. New private land owners often tend to sale or develop their allotments for housing, or logistic and industry, that have cause increasing of urbanized space.

3   KARABIHA RURAL SETTLEMENT

Karabiha rural settlement located to the south of Yaroslavl – major town of Yaroslavl region, it is extended rural area, that occupy about 217 square kilometers and contain 62 villages and township with overall population about 13.350 residents. Territory of settlement populated unevenly, majority of population concentrated in villages Karabiha, Dubki, Kormilitsino, Ananyino, Shchedrino, Nagorny, and township Krasnye Tkachi, that have good connection to the center of region by public transport. Another villages inhabited by much less number of permanent residents, but at the same time, in summer population doubles because seasonal migrations out of Yaroslavl for vacation or holydays.

Since Soviet times Karabikha have had a huge number of dachas and horticultural associations, which territories consist of 600 square meters pieces of land with small huts, but today it is more common to build big houses with all amenities, although this second dwelling, not used for permanent living, mainly for rest.

Karabikha, Krasnye Tkachi and Kormilitsino compactly located along the road Yaroslavl – Shopsha, closely related to each other economically, socially and culturally, and form a kind of rural agglomeration.

Village Karabiha is administrative center of the settlement that often associated with famous Russian poet Nikolai Nekrasov, who wrote poems "Russian women" and "Who lives well in Russia?" at the time being here. Today his estate with poet's house and English park transformed into a museum and attract tourist, especially for celebration of poetry Day . There is also a school founded by poet 's brother Feodor Nekrasov, administration and hospital.

Krasnye Tkachi – township was formed around the textile factory, founded by Sakin's family in the end of XIX century. Despite significant advances in the Soviet era, the company experienced a difficult restructuring, reduction of production and number of employees. Currently, the factory employs only about 70 people, but at the same time its territory located on the banks of the river, and includes several historic buildings can be converted into a museum or creative spase. In structure of township we can trace the stages of its development: the factory buildings and owner's house, dormitories and barracks preserved somewhere in the central part of the township, then, there are five-storey blocs of flat along the road built in the 70-80 years of the 20th century, surrounded by detached one-family houses, some of them were built recently. After the referendum in 2009 Krasnye Tkachi became a part of Karabiha rural settlement.

The settlement Dubki was founded for families, resettled from neighbor villages for construction of the oil plant and families living in Karabiha estate after its transformation into a museum. Houses were built at the same time with poultry farm and greenhouse complex. Over the past few years the greenhouse complex was renovated and expanded, opened hatchery and meat processing plant.

Shchedrino, Ananyino, Kormilitsino and Nagorni – central manor of agriculture enterprises, were built under the influence of idea of "agriculture towns", that was popular in 60-80 years of the 20th century. Agriculture towns – settlements, that surround large enterprises or farms, built mostly of blocs of flat with full range of services, like culture, retail, education and health care. All these villages were equipped by facilities, but it's condition highly depended on situation with local industry.

Shchedrino and Nagorni , that located just in 5 minutes by bus from the core of Yaroslavl, tend to became a kind of remote "sleeping quarters", after realization of low-rise residential micro-region in Shchedrino, it's population is going to triple.

Currently actions of regional government have a huge impact on development of Karabiha. On the territory, that adjacent to Yaroslavl in the northern part of the settlement was founded industrial park, wgere were

opened production of construction machinery, pharmaceutical plant and a number of other industries. In 2010, most part territory of industrial park was included in the boundaries of Yaroslavl. But its creation has played a major role in the development of adjacent areas, related to logistics, trade and service for vehicles.

Nowadays regional government launched the program of constructing affordable housing and one of pilot project of low-rise micro-region with social infrastructure was started on the territories annexed to the Krasnye Tkachi. At the time of this paper was written about 200 hectares have been allocated for the integrated development for the construction of low-rise affordable housing, it is assumed that these areas will be provided to contractors on preferential terms.

4 TRENDS AND PROSPECTS

While Yaroslavl and Yaroslavl region demonstrate population decline Karabiha shows grow of residents, that was ensured, on the one hand, by natality, on the other hand, by migration inflow. Growth of building, that was provoked by allocation of land, mainly for individual housing, increasing of building detached one-family houses explained not only by appearance of "newcomers" from Yaroslavl and another regions, but about a half of new homes were constructed by Karabiha's inhabitants. The birth rate is accompanied by increased demand for both in nursery schools, sport facilities and public spaces attractive for young people. The last year, administration of the settlement started program of creation athletic fields in Krasnye Tkachi, Dubki, Ananyino and Shchedrino.

Despite the availability of jobs in the settlement, according to various estimates, up to 50 percent of the working population prefer to work in Yaroslavl, residents of Karabiha settlements also depend on the city in culture, education, health care and another needs. At the same time, area contain many tourist attractions like Nekrasov's estate, picturesque landscapes and churches, historical factory buildings, dolphinarium, ski and recreation centers that may considered as s good base for development local tourism and creation of new jobs.

Karabiha demonstrates positive trends, not only in population, but also on indicators such as fiscal capacity, resettlement of dilapidated housing, construction new real estate and industrial buildings, development of infrastructure, retail, culture and recreation facilities, and it may seems that everything "goes well" by itself without planning or clear strategy. However Karabiha rural settlement have a good position for further development and smart grow, but this way needs to be planned in collaboration with residents and neighbor municipalities.

5 FUTURE VISION

for Karabiha it is possible to choose between a number of potential strategies including the industrial or tourist-oriented development. Both directions could be successful, but for provide better quality of life for inhabitants it is essential to take measures to improve the ecological situation, especially in Nagorny, Dubki and Shchedrino, that located near the southern industrial hub. Their need to accelerate the implementation of sanitary protection zone.

In case of increasing in birth rate creating of space for childhood may be a good challenge for Karabiha to attract young families who wish to raise children closer to nature and protect them from the harmful effects of the city. Under the circumstances it means invest more in social services, education and sport infrastructure.

Karabiha rural Implementation of planning policy and the allocation of land in accordance with the developed in 2009 planning documentation, that sets rules for interaction between municipality and developers.

6 CONCLUSION

Whether experience of Karabikha can be useful to other rural areas, taking into account all the possible differences? For the region with overall negative population trend, like Yaroslavl region more detailed study of the experience of its parts, that demonstrate increasing of natality could help to improve demographical trend.

Orijentir – Interactive City Guide for All

Ljubica Gajević, Vidan Danković, Miloš Milovanović

(MSc Ljubica Gajević, Centre for Society Orientation (COD) Milutina Milankovića 68b, 11090 Belgrade, Serbia, ljubica.gajevic@cod.rs)
(Vidan Danković, Audit Association in Serbia (URP), Zaplanjska 78, 11000 Belgrade, Serbia, vidan.dankovic@pristupacnost.org)
(Dipl. -Man. Miloš Milovanović, Centre for Society Orientation (COD), milos.milovanovic@cod.rs)

1 ABSTRACT

"Orijentir" is conceived as an accessible city map that pretends to provide solutions for better accessibility for people with visual, cognitive, mobility and hearing limitations in Belgrade, capital of Serbia and Novi Sad, the second biggest city, through an accessible application for mobile devices with Android, iOS and Windows OS. The application will be used as an assistive technology to guide from a point of origin to a destination by using of metropolitan transport and/or pedestrian routing. By providing optimal and accessible routing and orientation by GIS and GPS it will try to improve freedom of movement of persons with disabilities as one of the key human rights and to help their independent living.

The project presents the extension on just developed application called Accessibility Map designed by Vidan Danković that provides information about the accessibility of facilities. The application is intended for all those who have a need for this information, persons with disabilities, pregnant women, parents with young children, the elderly, etc.

Orijentir will be a coalition project of Centre for Society Orientation (COD) as a project leader, Accessibility Audit Association of Serbia, Ecumenical Humanitarian Organization (EHO) and different participants from public sector such as government and administration of Serbia, Belgrade and Novi Sad and University of Belgrade as well as different private companies and European funds and US development funds for disability issues.

The project development started in January 2013 and our team of 3 NGO's from Belgrade and Novi Sad is at the moment on the first stage, working on important cadastral data collection. Estimated project duration is two years.

2 INTRADUCTION

There is an increasing awareness of social responsibility in every community to make an inclusive society, society accessible for. This accessibility applies to both the outside environment and to the interior environments. In many countries this awareness is reinforced by anti-discrimination legislation advisory and regulatory guidelines. The collaboration of all important stakeholders in the process of making decisions during the definition of laws and standards, design of urban plans, construction works is crucial for understanding of necessities of every individual and providing environment without barriers. However, in many cases such as Serbia crucial stakeholder are not included in these processes which lead to creation of inaccessible environments.

Accessibility is a general term used to describe the degree to which a product, device, service, or environment is available to as many people as possible. Accessibility can be viewed as the "ability to access" and possible benefit of some system or entity. Accessibility is often used to focus on people with disabilities and their right of access to entities, often through use of assistive technology.

The term "accessibility" is also used in the Convention on the Rights of Persons with Disabilities as well as the term "universal design". Accessibility is strongly related to universal design when the approach involves "direct access". This is about making things accessible to all people (whether they have a disability or not).

Disability according to ADA standards is a generic term that includes all the components about the person: impairments, activity limitations and participation restrictions. It expresses aspects of negative interaction between the individual with health problems and physical and social environment.

The disability rights movement advocates equal access to social, political, and economic life which includes not only physical access but access to the same tools, services, organizations and facilities.

While it is often used to describe facilities or amenities to assist people with disabilities, as in "wheelchair accessible", the term can extend to Braille signage, wheelchair ramps, elevators, audio signals at pedestrian crossings, walkway contours, website design, reading accessibility, and so on.

Consider redefinition of laws and standards as long and complicate process which includes changes on all levels, therefore through this project it would be tried to provide solutions for better accessibility for people with visual, cognitive, mobility and hearing limitations in Belgrade, capital of Serbia and Novi Sad, the second biggest city by using ICT (Information and Communication Technology), or more specific: GPS (Global Positioning System) and GIS (Geographic Information System).

3 OBJECTIVES

"Orijetir" is conceived as an accessible city map that pretends to provide solutions for better accessibility for people with disabilities in Belgrade and Novi Sad through an accessible application for mobile devices with Android, iOS and Windows OS. The application will be used as an assistive technology to guide from a point of origin to a destination by using of metropolitan transport and/or pedestrian routing. By providing optimal and accessible routing and orientation by GIS and GPS it will try to improve freedom of movement of persons with disabilities as one of the key human rights and to help their independent living.

It is easy to see how in the urban or natural environment the same message is presented on many different ways. The analogy of presenting the same message on different ways in the same urban environment is essential for providing equal opportunities to all and Centre for Society Orientation (COD) as a project leader dealing with this issue from the human rights perceptive. This application will provide specific guiding to persons with visual, cognitive, mobility and hearing limitations trough voice, text and imaging inputs on different languages.

The project presents the extension on just developed application called Accessibility Map designed by Vidan Danković (Accessibility Audit Association of Serbia) through the program Social Change Hackathon presented on the 48 hours competition for the development of 15 social responsible applications for mobile devices. Accessibility Map provides information about the accessibility of facilities. The application is intended for all those who have a need for this information, persons with disabilities, pregnant women, parents with young children, the elderly, etc. Objects are mapped for users with a few simple questions followed by illustration. There is the option of adding additional images and descriptions, and all objects are passing through the administrator verification. Furthermore, data provided by users can be useful tool for city administrators about inaccessible places in town. The project is supported by SEE ICT organizations from Belgrade, with the support of the Institute for Sustainable Communities (ISC) and USAID.

There is an increasing awareness of social responsibility in every community to make a society accessible for all. In many countries this awareness is reinforced by anti-discrimination legislation advisory and regulatory guidelines. However, in many cases such as Serbia, people with disabilities are classified as persons that need protection or care, outside of mainstream society in the medical model of disability.

This project pretends to make one step forward by providing solutions for better accessibility of people with disabilities in Serbia by using ICT. We strongly believe that this project as one of the first step in accessibility improvement in Serbia will raise awareness about the needs of people with disabilities and initiate changes on all levels.

4 PROJECT SETTING

"Orijentir" project will be developed in the following phases:

- Cadastral data collection as a preparatory stage for the creation of digital map for Belgrade and Novi Sad [1]

- Cadastral data processing as a preparatory stage for the development of applications

- Focus groups sessions- gathering information about the needs of future application users

- Software development [2]

- Software testing

---

[1] Since Serbia is not covered with sufficient data on Google Maps and OSM servers the first stage of the project will be data collection for the creation of interactive map. It will include cadastral information about buildings and streets as well as information about public transport and pedestrian crossings. The information will be collected from our cadastre and public companies in charge for maintaining public transportation and pedestrian crossings.
[2] The application will be first developed for Android since it is the most widely used in Serbia.

- Volunteers training on accessibility standards for special data collection [3]
- Special data collection by usage of Accessibility Map [4]
- Training for future users
- Software operation
- Maintaining application stability and update
- Visual identity

Since the project development started in January 2013 our team of 3 NGO's from Belgrade and Novi Sad is at the moment on the first stage. Estimated project duration is two years.

5 PARTICIPANTS

This project will be a coalition project of COD as a project leader, Accessibility Audit Association of Serbia, Ecumenical Humanitarian Organization (EHO) and different participants from public sector such as government and administration of Serbia, Belgrade and Novi Sad and University of Belgrade as well as different private companies and European and US development funds funds for disability issues.

COD is Serbian NGO working since 2008 on providing support to local coalitions of disabled people organizations. Through the development of Local Action Plans in field of disability they focus on the inclusion of disability issues in the process of creating a local policy. Out of consultancy process, coaching and mentoring of local DPO coalitions COD works on outlining specific measures that need to be taken to ensure the full participation of people with disabilities in all fields. For the moment COD is working with 9 local coalitions of disabled people organizations, representing 60 DPO's from 13 municipalities, from all 6 regions in Serbia. Projects are supported by Handicap International, European Commission, USAID y Swedish International Development Cooperation Agency.

Accessibility Audit Association in Serbia (URP) is a non-profit organization, established in 2009 to gather recognized individuals and organizations advocating for the development and implementation of accessibility standards in order to create an environment that benefits for all people. They are committed for implementation of the concept "Design for All" (DfA), which is the professional support for designers and architects with the aim that public space, buildings, services, products and services are planned in a way so that they can use them all the people, regardless of their physical, sensory, intellectual, social characteristics or age.

EHO is a humanitarian, non-factional, non-governmental and non-profit association of citizens from Novi Sad, Serbia. They are actively involved in the building of a cohesive civil society in Serbia by working in the following areas: poverty reduction, development of inter-church cooperation and promotion of human rights. Their work and activities are entirely project-based and resources for project are provided through calls for proposals from national and international donors who support social development and support, inter-church cooperation and health-educative program.

6 INNOVATION

From the late 1980s when GPS was introduced there have been huge number of projects trying to provide better accessibility for visual impaired trough smart city concept which implies usage of ICT. These projects are usually specialised only for visual impaired and provide maps for West countries and are not multi-lingual. Also, it is important to mention that because of the high costs these applications are not accessible to users form developing countries. In order to provide lower development costs new applications are usually based on free sources such as Google Maps or Open Street Map. That is a good platform, but unfortunately without sufficient information for our country, so in the first step we are working on development of maps for Serbia.

---

[3] Educative short move that provides volunteers with basic information about accessibility standards will be made.
[4] Students of architecture from University of Belgrade and Novi Sad will be included in data collection trough university seminar as well as 20 volunteers with disability who are cooperating with one of the partner organization. The source for the mapping will be existing Accessible Map application. It will be amended with information about bus stops location and pedestrian crossings which accessibility should be evaluated.

Consider a local context and knowledge more adequate in resolving problems of disabled in Serbia, because global applications didn't bring adequate solution, this project will pretend to provide solutions for better accessibility for people with disabilities in general in two biggest cities in Serbia. The application will be developed on three relevant OS's and supported by latest technologies available on mobile devices such as GPS, compass and accelerometer, as well as 3G or Wi-Fi connection to provide maps and a guidance system. The application will be developed to achieve full accessibility following principles of universal design. It will be multi-modal and multi-language project.

7 OUTCOMES

The direct result of this project reflects in improvement of mobility and accessibility of persons with disability in order to raise their quality of life and independent living and that is his major benefit. For now, trough the Accessible Map project we have recorded over 5000 accessible and inaccessible public buildings in Serbia. However through the data collection phase it will give a further step in creating a greater data base relating to the accessibility: accessible facilities, pedestrian crossings with lowered curbs, sound semaphore, etc.

Through the process of mapping, in order to improve this database, volunteer training will be done. By this training our volunteers will learn about the principles of accessibility, which will increase public awareness of the needs of people with disabilities in our society. It is important to mention that since the first phase of the project will include basic cadastral database collection required for the formation of an interactive map of Belgrade and Novi Sad this project is not only useful for people with disabilities in Serbia but for the benefit of all citizens as well as tourists who come to visit Serbia.

It is important to emphasize that in this project people with disabilities are actively included. Regardless of the existing principles of universal design and accessibility, we believe that every context is different and that through active work with interest group we all begin to get a clearer picture of their actual needs in our society.

8 CONCLUSION

Implementation of the project will ensure free movement of persons with disabilities by giving them opportunity to participate in ordinary life activities. Through the citizen participation on mapping accessible and inaccessible spots in our cities we will try to motivate people to start their own small actions to help their neighbours with disability. Indication of inaccessible environments in Serbia will force authorities to initiate some changes as well.

Since the application will be based on pedestrian and public transport routing it will be able to indicate most common routs for people with disabilities in Belgrade and Novi Sad and provide companies responsible for implementation of accessible standards on street and in public transport with information which routs and spots are their priorities in future accessibility improvement.

The application will bring more people with disabilities to public and change generally accepted attitude about medical model of disability in our society and that after the successful development the application could be extensible to other Serbian cities and cities dealing with the same problems in this region.

It is not possible to eliminate all barriers at once, but the right information is halfway. If you pointed the finger on barriers people will know what kind of different problems exist and it will raise awareness of this important issue.

Prato: Organizzazione e Tecnologie per un nuovo Modello di Sviluppo urbano consapevole

Davide Puccianti

(Dott. Davide Puccianti, Responsabile dell'Unità Operativa "Trasporti" Comune di Prato, d.puccianti@comune.prato.it)

1 INTRODUZIONE

La città di Prato ha circa 188.000 abitanti, capoluogo di una Provincia di 7 comuni all'interno dell'area metropolitana di Firenze, Prato e Pistoia. Ha subito una fortissima immigrazione cinese (60.000 abitanti), ed è una città dove sono diventati complicati i rapporti tra le varie etnie. Inoltre, con la crisi del settore manifatturiero tessile, la città attraversa un periodo di grande ristrutturazione industriale.

Dispone di una rete urbana di 600 km di strade, 45 km di piste ciclabili di cui 3 varcano i confini comunali, verso Campi Bisenzio, Montemurlo e Vaiano, e un rete bus urbana di 240 km. Ha sviluppato progetti innovativi sulla mobilità puntando a realizzare un sistema di drenaggio del traffico esterno sfruttando l'asse est ovest dato dall'autostrada declassata Firenze Pistoia e dalla tangenziale Ovest. Ha, inoltre, creduto sul trasporto pubblico realizzando tre linee di forza della rete bus (Linee ad Alta Mobilità) e progettato a livello esecutivo la prima linea tramviaria urbana che prevede estensioni in area metropolitana e l'interoperabilità con la rete ferroviaria.

La città affronta notevoli problemi di traffico e di inquinamento per cui la mobilità deve essere coinvolta in qualsiasi processo di sviluppo urbanistico.

Ha, quindi, deciso all'interno del progetto GIOCO di dotarsi di nuovi strumenti di pianificazione e di gestione del territorio che permettano di gestire in modo integrato la mobilità e di poter intervenire per tempo nelle decisioni che possono impattare sul territorio e, più in generale, sul traffico urbano.

1.1 Obiettivi del progetto

- Evitare ingorghi e blocchi di traffico (mancato coordinamento degli interventi)
- Migliorare la qualità delle strade (controllo dei cantieri)
- Ridurre il numero di buche e aumentare la sicurezza stradale
- Ridurre la burocrazia
- Evitare lo scambio di carta tra i settori
- Eliminare le asfaltature inutili (tagli su strade appena asfaltate)
- Tenere costantemente informati i servizi di emergenza sulla viabilità alternativa.

1.2 Sistemi informativi

Il Comune è sempre stato all'avanguardia per tutto ciò che è connesso ai sistemi informativi. Già da tempo si è dotato di un sistema informativo territoriale che raccoglie una gran mole di dati, informazioni legate al territorio che sono di valido aiuto per le decisioni da prendere quotidianamente.

Inoltre, si è dotato da tempo di un sistema di gestione delle ordinanze che permette di tenere sotto costante controllo lo stato della viabilità e soprattutto tutte le modifiche attuate temporaneamente o con ordinanze permanenti.

1.3 Nuovi metodi organizzativi e nuove tecnologie applicate: il progetto Prato City Works

All'interno del progetto finanziato dalla Regione Toscana assieme al Comune di Firenze e alle Province di Firenze, Prato e Pistoia, è stato deciso di realizzare una cabina di regia che permette di governare le trasformazioni del territorio, riducendo l'impatto generato dai lavori stradali sulla vita quotidiana dei cittadini.

Con questo nuovo modello è possibile finalmente gestire la quotidianità e programmare in modo appropriato anche gli interventi a lungo termine.

Inoltre, mettendo in dialogo più uffici dell'amministrazione si possono prendere decisioni più responsabili e si evitano gli errori commessi in passato.

1.4 Prato e Firenze: l'area metropolitana

Questa esperienza pone in rilievo il tema della gestione trasversale dei territori contigui: in una logica di area metropolitana, è necessario avere una piattaforma comune per capire cosa succede anche a 50 km di distanza, mettere in dialogo una grande realtà. I vari enti possono finalmente adottare delle regole comuni, agevolare gli attori esterni, rendendo il territorio più appetibile e interessante per i nuovi investimenti.

Si sta, infatti, attivando un processo di standardizzazione delle procedure amministrative: precedentemente i Comuni della Regione Toscana non avevano uno scambio di informazioni e si era adottata una modulistica differente per ognuno degli stessi. L'obiettivo, invece, di Regione Toscana è di riuscire a standardizzare le procedure, agevolando di conseguenza anche tutti gli operatori del territorio.

1.5 Il procedimento amministrativo integrato: coordinamento, alterazioni e ordinanze in un processo omogeneo e congiunto

Il Comune rilascia circa 3000 ordinanze all'anno e 2000 alterazioni: dal 2012 ha a disposizione una banca dati geografica per le attività di progettazione e per tutta la gestione quotidiana degli interventi. In Prato City Works sono contenuti i diversi interventi per poter comprendere meglio le dinamiche di sviluppo del territorio e le necessità degli operatori economici. Al processo complessivo partecipa anche la SO.RI, agenzia di gestione della riscossione che funge anche da sportello unico per professionisti e privati che devono presentare una richiesta di occupazione nel territorio del Comune di Prato.

1.6 Caso d'uso

Caso d'uso attuale

Il sistema Prato City Works è attualmente utilizzato dal settore strade e dal settore mobilità. Vengono inclusi i lavori del Comune e quelli delle società che gestiscono i sotto servizi.

Di seguito possiamo riassumere come vengono attualmente gestiti questi procedimenti:

- Le società convenzionate (ad es. Telecom Italia e Publiacqua) inviano le richieste di alterazione con il sistema on line. Devono allegare in formato PDF Planimetrie, Sezioni, Relazioni tecniche e indicare con precisione gli spazi occupati per il calcolo COSAP
- Attendono dal coordinamento l'approvazione per spazi e periodi proposti
- Il settore strade verifica la congruità dei progetti presentati, i tempi e le superfici. Richiede all'ambiente eventuali prescrizioni
- Se l'istruttoria va a buon fine, è possibile richiedere l'ordinanza di traffico
- La società consegna a sportello le istanze ufficiali e ritira la concessione. L'ordinanza viene scaricata direttamente dal sito del Comune.

1.7 Qualiutenti lo utilizzano

Prato City Works viene utilizzato da tutte le società dei sottoservizi (Publiacqua, Telecom Italia, Estragas, cc.) per le richieste di concessione di alterazione suolo pubblico ed in particolare per la comunicazione entro 24 ore dall'evento di tutti gli interventi di urgenza (fughe/guasti, ecc.) e per gli interventi che rientrano nella concessione unica (inferiori a 20 metri quadri).

1.8 Quanti utenti lo utilizzano

Ci lavorano 2 persone a tempo pieno, oltre agli istruttori degli altri settori coinvolti quotidianamente o su richiesta specifica, circa altri 50 utenti comunali.

1.9 Quali informazioni gestiamo

Il sistema include tutte le informazioni legate all'occupazione del territorio (scavi, ponteggi, occupazioni in genere), oltre alla gestione dei provvedimenti di mobilità. È l'archivio storico di tutto ciò che è accade sul territorio per permetterci di controllare se un lavoro viene eseguito a regola d'arte.

La gran parte dei problemi incontrati sulle strade non sono causati dal deterioramento naturale ma dai "tagli" eseguiti per la gestione delle infrastrutture. Nel caso i ripristini non vengano eseguiti correttamente, questi porteranno all'accelerazione del deterioramento del piano orizzontale.

É, quindi, necessario migliorare la qualità dei ripristini stradali per ridurre le buche, gli avvallamenti, le fessure, perché solo così è possibile usare meglio le risorse dedicate alle manutenzioni stradali e ridurre il numero dei contenziosi ricevuti dai cittadini.

L'obiettivo del progetto è migliorare la sicurezza delle persone e delle cose e utilizzare meglio le ridotte finanze comunali facendo aumentare la vita naturale delle strade.

1.10 Lo stato di attuazione del progetto

Dopo oltre un anno di esercizio, abbiamo finalmente una banca dati significativa che ci mostra come le società stanno operando sulla città di Prato. Solo grazie a Prato City Works siamo riusciti a controllare le società e abbiamo intenzione di estenderne l'uso per riuscire ad avere un controllo completo sulla manutenzione e sulle occupazioni delle strade stesse. Stiamo, infatti, studiando delle nuove metodologie operative che costringano i gestori di sottoservizi ad aggregare gli interventi tra loro. Questa esigenza è maturata, in particolar modo, con il progetto che coinvolge l'estensione della rete in fibra ottica. É obiettivo dell'amministrazione richiedere agli operatori telefonici di utilizzare un'unica servitù nella quale collocare tutte le dorsali delle compagnie telefoniche interessate a cablare Prato in fibra ottica.

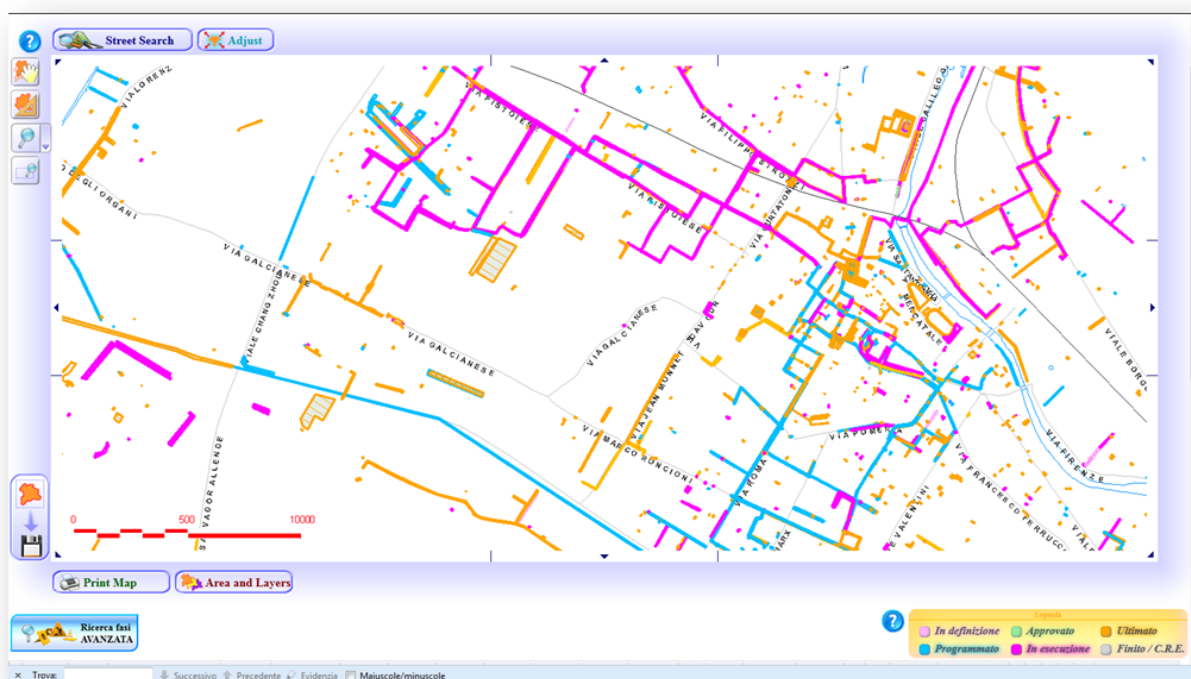
Abbiamo, di fatto, impostato un controllo del territorio, fino a ora mai applicato in Italia, che ci permetterà nel tempo di avere strade migliori, che dureranno più a lungo.


Figura 1: come è attualmente in trasformazione il tettorio

1.11 Ricadute sull'organizzazione dell'ente

Il progetto ha portato a dover cambiare il modo di ragionare di tutto il personale dell'ente. Avendo a disposizione una quantità enorme di informazioni e mettendole a disposizione di tutti, utenti del comune e delle aziende esterne, è oggi necessario fare delle scelte che hanno un impatto trasversale su tutto l'ente. Non si può più ragionare in modo ultra settoriale e verticale, ma è necessario comprendere che qualsiasi decisione ha un impatto sugli altri settori e anche sulle aree territoriali confinanti.

In futuro sarà, infatti, sempre più necessario prevedere di integrare i sistemi dei vari comuni dell'area metropolitana tra loro, per riuscire a prendere decisioni che riducano il disagio sulla cittadinanza anche quando il punto decisionale non è all'interno dell'ente stesso.

2 ESTENSIONE E NUOVI SVILUPPI DEL PROGETTO

Avendo già avuto dei ritorni positivi dall'utilizzo del sistema, è obiettivo del settore estenderne le funzionalità. In particolare, verranno realizzate delle nuove funzionalità che coinvolgono il miglioramento della pianificazione territoriale.

Inoltre, è prevista la possibilità di completare lo sportello unico per il suolo pubblico, permettendo agli utenti di presentare le pratiche on line firmate digitalmente. Questo processo prevede la necessità di integrare, quindi, anche il sistema di Protocollo Informatico del Comune, oltre ai processi legati ai pagamenti: marche da bollo, diritti di sopralluogo e canone di occupazione del suolo pubblico.

Inoltre, a breve, verrà data la possibilità agli utenti di presentare anche le richieste di ordinanza in una forma più avanzata, cioè con un'interfaccia che guiderà l'utente nella richiesta e nella compilazione, rendendo gli utenti più consapevoli e responsabili nella gestione delle modifiche che coinvolgono il traffico e la viabilità.

3 CONCLUSIONE

Questo nuovo modello gestionale dimostra che è possibile utilizzare la conoscenza e la consapevolezza unita alla tecnologia per fare un salto di qualità e aiutare gli amministratori a fare delle scelte innovative e coraggiose.

Proseguendo nell'applicazione del progetto e continuando a raccogliere informazioni di giorno in giorno sarà anche possibile eseguire una pianificazione di sviluppo del territorio che abbia a disposizione tutte le trasformazioni già eseguite e di ottimizzare le attuali poche risors economiche del Comune.

Regional Effects of Urban Planning – an Informal GIS Tool to Support Sustainable Strategic Planning

Anja Brauckmann, Alexander Mayr

(Dipl.-Ing. Anja Brauckmann, Research Institute for Regional and Urban Development, Brüderweg 22-24, 44135 Dortmund/Germany, anja.brauckmann@ils-forschung.de)
(Dipl.-Ing. Alexander Mayr, Research Institute for Regional and Urban Development, Brüderweg 22-24, 44135 Dortmund/Germany, alexander.mayr@ils-forschung.de)

1 ABSTRACT

Nowadays the demand for a more sustainable urban development rises. At the same time demographic, climatic and structural economic changes are new overall conditions that require new concepts in spatial planning. The article describes a new tool for Geographic Information Systems that supports strategic planning with objective values about the local, municipal and regional effects of planned urban development projects. The tool models different economic, ecological and social effects of residential areas and areas for industry, commerce and retail. For example costs for infrastructures, financial benefits, ecological, climatic and traffic effects as well as accessability to important infrastructures are considered. For a new residential area in Germany the article presents the results of the modules "municipal revenues" and "land use change and ecological value" and reports on first reactions of partners working in planning practice.

2 INTRODUCTION

The european population and economic development cause land use change for new areas for housing, industry and commerce or retail. Although the population in Europe is growing in total, there is a coexistence of growth and shrinkage in several countries on all spatial levels. In shrinking areas the infrastructure costs per inhabitant rise and schools and other infrastructures are threatened to be closed. This enhances the competition for inhabitants and firms between regions and municipalities with the aim to maintain these infrastructures. In Germany the situation is intensified because the financial equipment of municipalities mainly depends on the amount of inhabitants and located firms. This system is an incentive for an extensive settlement development as a basis for new inhabitants and firms.

But at the same time, the demand for a sustainable development rises. Not only fiscal effects, but also ecological and social consequences of settlement development should be taken into cosideration in planning and negotiation processes. The knowledge about fiscal, ecological and social effects is often very limited. This especially applies in an early stage of planning, when important decisions about the locations and main characteristics of the projects are made. As a consequence, discussions about new projects in spatial planning are often more dominated by general statements than by science-based analyses. Furthermore, spatial planning and decision-making processes are characterised by isolated considerations and fragmented responsibilities. Sustainable urban development needs tools, instruments and methods to consider effects of planned projects.

3 STATE OF THE ART – EXISTING TOOLS IN GERMANY

In the german discussion about the effects of new residential areas – especially for single family houses – the aspects of infrastructure costs and fiscal impacts are very important. Especially municipal revenues are an essential factor for the competition between municipalities for new inhabitants. But decision-making processes are often dominated by general statements: It is a common opinion that new residential areas will have positive fiscal effects for a municipality.

The fiscal impacts of urban sprawl is discussed since several years – especially in the USA, but also in Germany since the 1970s (Danielzyk et al. 2010). In the last few years a lot of tools have been developed in Germay with the aim of giving objective and science-based information about the costs and benefits of new residential areas (an overview gives Dittrich-Wesbuer/Osterhage 2010 or the website of "Allianz für die Fläche"[1]). In spite of their similar aims they are based on different concepts, referring to the technical realization, the level of details and the precision of results. The existing tools are web- or MS Excel-based or have been developed as independend software. Furthermore, municipalities can purchase reports for a cost-benefit-calculation. Further differences result from the technical realization and vice versa. Some tools focus on the calculation of costs for investment and maintenance as well as operating costs. Technical

---

[1] http://www.allianz-fuer-die-flaeche.de/Kosten-Nutzen-Modelle-273.html

infrastructures like streets or (waste) water infrastructures are considered in all mentioned tools. Some of them also include social infrastructures (for example kindergarten, schools), public transport and fiscal revenues. But the level of detail and the precision of results are connected to the expenditure to compile and enter the necessary data. Web-based tools can often be used to create results in a few minutes if all required information is available. They are more suitable to give an impression of general relationships and make decision-makers and spatial planners aware of the consequences of their decisions. More complex tools produce very detailed analyses that can be used in different stages of spatial planning or the political discussion. There are different tools that can be used in all imaginable spatial applications.

These new tools are already in use and support local spatial planning processes with objective and science-based information about costs and fiscal impacts resulting from new residential areas. The experience is that not all new residential areas have positive fiscal impacts for municipalities, even though general statements are not possible. Impacts depend on the individual local situation. Infrastructure costs decrease with an increasing density, but they also depend on the specific location. This has an influence on the effort of building additional and the utilization of existing technical and social infrastructure.

Against often expressed fears, these tools did not lead to dominating economic aspects in spatial planning. Instead infrastructure costs and fiscal impacts can be one aspect in the consideration of interests. Additionally, there is a rising awareness for the long-term follow up costs of infrastructures as an important aspect for sustainable settlement development.

But in addition to these tools, a more expansive view on impacts of urban development projects is necessary. This concerns different aspects: Sustainability requires the consideration of economic, ecological and social aspects. The tools are limited to housing areas, but settlement development also includes new areas for retail or industry and commerce. In addition to that, the impacts of analysed projects are mostly not restricted on single municipalities, but the projects can cause effects on the regional structure and the development of interdependent municipalities. There is a need for additional decision-support-systems (DSS), that expand the view by more information about the impacts of urban development projects in all dimensions of sustainability.

4 A NEW APPROACH: REGIO PROJEKT CHECK

4.1 Overview

Based on these experiences the project team – consisting of institutions that have developed some of the mentioned cost-calculators – has worked on a follow-on project called RegioProjektCheck. The new instrument expands the existing decision-support-systems in three different aspects. Firstly, it illustrates the effects for both the affected neighbouring municipalities and the region. Secondly, in addition to housing, models for companies and retail become involved. Thirdly, it models additional topics of impacts (Fig. 1).

Fiscal impacts remain an important topic. Production and follow-up costs for the public sector as well as changed municipal revenues resulting from taxes and other payments are modelled. The effects are replenished by a regional model for multiplier effects, containing effects on jobs or consumption. Besides the fiscal topics the tool also covers ecological and social effects to expand the existing instruments. The ecological topic contains models for soil sealing, landscape fragmentation, energy consumption and emissions. The social effects deal with accessibility of infrastructures and therefore give evidence for inhabitants with limited mobility (for example children, handicapped, persons without a car). Every effect is visualized in a different way because the effects might occur in monetary dimensions, points, distances, minutes or CO_2-emissions.

Therefore the tool can be used in a wider context, for instance in strategic regional planning processes. Because of this complexity it aims at experts who interpret the results and use them to advise municipalities and regions concerning multidimensional effects of projects. These experts can be external personal working as consultants or internal employees working in the public administration of the affected region itself. Single values as well as joint evaluations are available depending on the topic of effects. The aim of the tool is to visualize effects of decisions and to objectify discussions by offering a joint basis for decisions. It has to be underlined that the new tool should not replace existing formal processes but expand and support them in an early consideration.

Technically it is realized via a set of toolboxes in a Geographic Information System (GIS). According to the local context and problems, the tool offers different toolboxes which can be used optionally in a modular system. The users are able to modify single parameters to test variations of projects and different basic conditions, so the regional discussion becomes enriched.
Fig. 1: Overview RegioProjektCheck

4.2 Test calculations

To illustrate possible results of the tool, we use it for the case study of a housing area and juxtapose the fiscal effects on the one hand with the effects on land use change and ecological value on the other hand. These topics of effects are very different with regard to their methodologies and evaluations. Our case study is a new housing area in the municipality of Kürten (19,500 inhabitants; district: Rheinisch-Bergischer Kreis) consisting of 70 single-family houses on 2.9 ha.

4.2.1   Municipal Revenues

The municipal revenues contain tax revenues and effects on the municipal revenue sharing system as direct effects. The regional value added, job effects and effects on regional consumer spending are modelled as indirect effects in an economic point of view (Kronenberg 2010). The model does not deal with the whole municipal budget but it visualizes the project-depending absolute change in revenues in order to simplify a comparison between projects and municipalities. While the direct effects are modelled for every affected municipality, the indirect effects are modelled for a wider region.

Fig. 2 shows that the municipality of Kürten gains additional yearly revenues concerning property tax, income tax and equalization payments but also has to pay additional county rates. The neighbouring municipality of Bergisch Gladbach looses income tax and equalization payments but has to pay less county rates. This effect is caused by the inhabitants moving from Bergisch Gladbach to Kürten. The new housing area also has effects on the district Rheinisch-Bergischer Kreis. It receives additional county rates caused by additional inhabitants in the district. These shifts in inhabitants are calculated in a complex population model which operates in the background and offers the project-related effects on migration in different municipalities.
Fig. 2: direct effects on two neighbouring municipalities

In addition to these direct effects, the housing area evokes temporary indirect effects. The construction of the housing area stimulates additional demand in the construction industry. The regional value added amounts to yearly 1.1 million EUR, at maximum 5,300 EUR additional income tax and 29,000 EUR less social subsidies for the region during the construction phase. This brings along 6,000 EUR additional consumer spending in the region devided into different product groups.

An evaluation of the direct effects is possible, when we compare them with the production and follow-up costs. Our experiences show that the additional revenues can become considerably reduced, sometimes the yearly costs even exceed the yearly revenues. Both direct and indirect effects can be evaluated if they are compared to other similar projects on the regional level.

4.2.2   Land use change and ecological value

The topic of land use change and ecological value models and evaluates the ecological effects resulting by the shift of the built environment. The effects of human use (energy consumption, greenhouse gases and transport emissions) are covered in other topics of effects. This topic falls into three parts: the effects on the project area, the effects on the regional area and a regional evaluation of the rarity of the ecological conditions as well as the quantity and quality of land use change.

Local effects on the project area itself are evaluated by the model of an ecological area performance (Arlt/Lehmann 2005). It evaluates the contribution of different types of land use referring to the maximum ecological potential, for example concerning percolation or thermal storing. Regional effects are at first evaluated by the model of undissected lowtraffic areas (UBA 2003: 283) which regards the dissection of the biotopes in a regional context. As a second step, it is examined if the location affects regional cold air flows. The regional evaluation of rarity compares the existence of nature reserves on the one hand as an indicator for regional rarity and evaluates on the other hand. In addition, the quality of land use change is evaluated by the location to existing settlements (demand for integrated locations) and the density, that is to say the efficiency of land use. More integrated projects minimize the requirement for additional infrastructures and have positive links to other ecological effects. Table 1 shows the results for the case study. The different effects are evaluated either in a scale (1 = very poor to 5 = very good) or via a qualitative description.

	Evaluation	Explanation
1. Local Effects	1	
2. Regional Effects		
Undissected Lowtraffic Areas	2	
Regional Cold Air Flow	No effects expected	
3. Regional evaluation		
Existence of nature reserves	!	Conservation area "Mittlere Suelz" Fertile soil to be protected
Integration	1	
Density	5	

Table 1: Evaluation of land use change and egological value

4.3 Evaluation of the results

The test calculations indicate the great variety of effects additional projects might have on the municipal and the regional level. Considering the municipal revenues we can say that the quantity of new inhabitants and their previous place of residence form very influential issues. These keyfactors mainly influence the revenues with regard to the income tax or the fiscal equalization system.

For land use change and ecological value the exact location and the former use of the area are more important. Soil sealing before and after realizing the project are crucial for the local level, the location in relation to biotopes and cold air flows might concern neighbouring municipalities and existing nature reserves might be affected. Considering the degree of integration and the density results are very different. While in the presented project the density is higher than the mean of the district, other results in this module are worse because of the chosen location.

Because of the variety it is not easy to summarize the results in terms of single values over all types of effects. The experiences with the partners working in planning practice have shown that this complex point of view is very helpful for the experts. But additionally, for political discussions an easier way of showing the results would be useful, for example as "traffic-light-systems". But an automatically generated overall evaluation neither is possible nor makes it sense. A possible result for local effects might be that one municipality makes a profit regarding one topic while neighbouring municipalities lose compared to the status without the project. Concerning another topic the result might even switch into opposite. Furthermore, for the regional level results are of a different nature. On the one hand a region can be understood as a summation of single municipalities, on the other hand some joint effects cannot be located exactly within the region (like CO_2 emissions). In this case, the region as a whole is considered.

5 CONCLUSIONS

With an isolated way of looking at the situation the revenues of single municipalities increase with a higher immigration rate. New housing areas seem to be the solution for every municipality. But especially in times of demographic changes the amount of population is limited in a regional context. Additional revenues in one municipality cause less revenues in others. Because of strong interconnections concerning migration and commuting within regions as well as regional social and ecological effects of settlement development we need regional cooperation – and DSS with a spatially and thematically expanded point of view.

The models are predominantly developed and partly already programed as GIS-toolboxes. First urban projects have been calculated, but further tests are necessary to verify the models. RegioProjektCheck illustrates the effects for different topics on different spatial levels. The consideration of the different effects should be integrated in planning and political processes. By using that kind of instrument, knowledge about the decisions´consequences can be increased and cooperation concerning regional development can be encouraged. First experiences show great interest from different administrative institutions of spatial planning, that comprise municipalities, regions and a federal state. They all need a DSS with a spatially and thematically expanded view to push on sustainable urban settlement development.

Rete Ecologica Locale, aree verdi al limite tra città e campagna

Giacomo Cozzolino, Alessandro Piazzi

(SETIN Servizi Tecnici Infrastrutture srl, giacomo.cozzolino@setinsrl.eu)
(SETIN Servizi Tecnici Infrastrutture srl, alessandro.piazzi@setinsrl.eu)

1 ABSTRACT

Nell'ambito dei Piani di Recupero (PdR) di nuclei abusivi nel Comune di Anzio (Provincia di Roma, Italia), è stato sviluppato uno Studio di Rete Ecologica Locale (REL), con l'obiettivo di definire gli obiettivi di conservazione della biodiversità a scala di paesaggio locale e di inserire nei documenti di piano indirizzi e misure volte alla tutela degli ecosistemi agro-forestali.

L'area in esame si trova ai margini di agglomerati urbani consolidati, in una condizione definibile rur-urbana (rurale-urbana), laddove 13 frammenti principali (i nuclei abusivi) sono immersi in un mosaico paesaggistico rurale, a sua volta ulteriormente frammentato da edifici sparsi.

Pertanto l'azione principale dello Studio è l'individuazione REL, nell'ambito interessato dai PdR e nelle aree limitrofe, attraverso una analisi finalizzata a capitalizzare ed integrare le conoscenze naturalistiche disponibili, in un ottica conservazionistica e di sviluppo sostenibile. I risultati del disegno di rete ecologica a scala locale sono stati utilizzati a supporto dei PdR.

Lo Studio è stato articolato in diverse fasi ed attività: 1) Raccolta e catalogazione di tutti i dati e le informazioni inerenti la biodiversità e, secondariamente, le componenti ed i fattori ambientali ad essa correlati (copertura e consumo di suolo, aspetti abiotici, aspetti urbanistico-territoriali, aspetti infrastrutturali, etc); inserimento di tutte le informazioni raccolte ed i dati originali in un geodatabase, rendendo quindi disponibile l'informazione geografica nell'ambito di un Sistema Informativo Territoriale Ambientale; 2) applicazione di 2 sistemi di classificazione del paesaggio (induttivo e deduttivo), e confronto dei risultati; 3) individuazione un set di indicatori di qualità e stato di conservazione; 4) analisi, attraverso gli indicatori, del contesto ambientale (con particolare riferimento alla biodiversità), al fine di valutare la qualità ambientale e lo stato di conservazione; 5) individuazione, attraverso l'applicazione di modelli e l'approccio esperto, degli elementi della REL (aree core, stepping stones, etc); redazione di indicazioni per la zonizzazione e le Norme Tecniche di Attuazione dei PdR.

I risultati sono stati rappresentati in una relazione tecnica ed in cartografie tematiche.

Reuse of Abandoned Churches in the Netherlands

Albert Reinstra

(drs. Albert Reinstra, Cultural Heritage Agency of the Netherlands, Smallepad 5, 3811 MG Amersfoort,
a.reinstra@cultureelerfgoed.nl)

1   ABSTRACT

Churches for sale, quite unthinkable only fifty years ago, but nowadays a harsh reality. Plenty of choice, as you can see on websites like www.redres.nl or www.reliplan.nl, the leading real estate agencies that specialize in selling churches. Important medieval city churches, landmarks in the countryside or postwar buildings in the suburbs, if you want one, you can buy it in the Netherlands. Every type of building is available, but mostly with a lot of different restrictive conditions attached. Finding new forms of use therefore is a difficult and time-consuming affair.

From 'Domus Dei' to real estate. How did it get this far en how do we deal with the problem of abandoned churches and the reuse of this type of building in the Netherlands? In this paper I will try to answer these questions. I want to outline the different policies, tell about the Dutch approach and show some interesting solutions. But before I do, let me first give a global impression of the situation and some facts and figures.

2   SOCIETY IS CHANGING

In the last twenty-five years Dutch society has changed dramatically. The population has grown from 15 to 17 million inhabitants, prosperity has increased, more people live on their own and more people leave the countryside because of unemployment and a lack of facilities. Traditional religious values are vanishing and the ongoing secularization is causing financial problems for the Protestant congregations and Catholic parishes. A shrinking group of (mostly elderly) people has to take care of the maintenance and conservation of about 6,500 churches, including the most important – and most expensive- 2,700 church buildings, listed as national, historical monuments.

In 2004 there was a merger of the three main Dutch Protestant Churches. This Protestant Church in the Netherlands is the country's leading denomination in the North and West, other than in the South, which is predominantly Catholic. The Catholic Church is also reorganizing, resulting in fewer parishes. For instance, in the archdiocese of Utrecht the number of parishes fell from 316 to 49. These processes have led to a large number of closures – usually of non-listed, often younger buildings as these have no grants for maintenance and are easier to sell.

3   CHURCH AND STATE

In the Netherlands there has been a strict and clear separation between Church and State since 1795. The government does not interfere in ecclesiastical matters and the Church takes care of its own personnel and buildings. Churches are owned by the local parishes or congregations. They have to take care of their property and only if a church is listed as a national monument there are State grants available for restoration and maintenance (for 6 years, up to 50 % of 3 % of the reconstruction costs). Demolishing listed churches is not allowed, so selling for reuse is often the only option once these churches have been abandoned.

4   ECCLESIASTICAL POLICY

Selling churches is a problem for Catholics, more than for Protestants. This difference results from their divergent views on the religious value of the building. For Protestants the building itself is mainly functional, the place to meet, the place for reflection and necessary for preaching God's Word. It is not a consecrated, sacred place and therefore does not have the religious importance that it has for Catholics.

Another important factor is the difference in the way the Protestants and Catholics are organized. Protestant congregations have a governing body for areas of common interest, the General Synod. The Synod, for instance, takes care of the education of the clergy or draws up church ordinances and regulations. But the local congregations are independent, have their own governing authority and can make their own decisions. So if a church cannot be used for worship anymore, the local congregation decides what will happen to the building, mostly in addition to the general, ecclesiastical rules. The Roman Catholic Church has another, more centralistic organizational structure. Even though the local parish owns the building, according to the

ecclesiastical rules the bishop eventually decides if a parish is viable and he decides on whether the building should be sold, reused, or demolished.
Fig. 1: Demolished churches in the Netherlands 1970-2008. (Source: N. Roeterdink e.a. Haarlem, 2008)

Their organizations, processes and responsibilities may differ, but what both denominations have in common is that they fear 'unworthy' new functions and 'improper' use after a church has been sold. Because of this the Dutch bishops and the General Synod declared their policy and visions on abandoned churches and formulated various conditions for churches on sale. In short: new community functions like health centers, libraries, schools, and day care centers for children are fine, but only if they respect the religious and historic values of the buildings. Preferably no commercial or profane functions. Likewise, non-Christian religions are not preferred by Protestants, and with regard to Catholic churches not even allowed. This last point of view is based on a few negative experiences in the past.
Fig. 2: Community functions, 'worthy' and 'unworthy'. Left, Brielle St. Jacobschurch, wonderful converted into a General Practitioners Practice. Right, church of St. John Baptist in Roosendaal, since 2007 partycentre and in cultural use.

5 2008, YEAR OF RELIGIOUS HERITAGE

These documents were written in 2008, the national Year of Religious Heritage. This public initiative had two main goals. First to make the authorities and the general public aware of the important social role and cultural, historical and religious values of churches. And second, to make them aware of the large quantity of (upcoming) abandoned churches – including their interiors and religious objects – and the need to do something on this societal problem. A lot of local and national events took place. The website www.reliwiki.nl, with information about all the churches in the Netherlands, was launched and the organizing committee published Geloof in de toekomst (Faith in the future), a strategic document with facts and figures, important issues, analyses and recommendations that was presented to the government. [1]

The Year of Religious Heritage had its positive effects. Many books and guidelines were published about processes, policy, regulations or best practices, etc. New funds and possibilities for grants appeared and new solutions and instruments were developed by the national government, provinces, local authorities or by

---

[1] http://www.religieuserfgoed.nl/doc/GelooftoekomstWEB.PDF

private initiative. The national government for instance raised their heritage budgets and invested in the restoration and maintenance of churches. As a result today up to 90 % of the listed churches is in a good state of maintenance.

5.1 Effects

5.1.1 Governmental

In our 'A Future For' series of guidelines, the Dutch Cultural Heritage Agency has published two church brochures. One is about how to deal with changing historic churches in religious use, the other is about new use in abandoned churches. The latter brochure contains all kinds of information about governmental and ecclesiastical policies, laws and regulations, heritage aspects, communication, the process of converting churches and the range of functions and design principles. [2]

A revolving fund was installed to stimulate shared use/multifunctional use in listed churches. The National Restoration Fund, the principal bank of the Cultural Heritage Agency, offers low-interest loans, up to € 50,000, especially for adjustments and facilities in churches to make them useful for more than just religious purposes. [3] The municipality of Utrecht has also possibilities for non-listed buildings. They encourage additional use and reuse and give grants for measures that contribute to a better exploitation. [4]

Commissioned by the Dutch Ministry of Education, Culture and Science, the Guidelines on Ways of Dealing with Religious Objects were developed in a joint project by the Churches, heritage institutions and the National Museum for Christian Art and Culture – Museum Catharijneconvent. This instrument helps to deal with the surplus of religious objects when churches have to be closed. [5]
Fig. 3: Left governmental brochures. Right, the church of Groede. Multifunctional use made possible by the low-interest loan of The National Restoration Fund.

5.1.2 Provincial and local authorities

Not only the national government, but also provincial and local authorities have taken their responsibility after 2008. Provinces like Noord-Brabant, Limburg, Zeeland, Gelderland and Friesland started extensive church inventories and used the results for their heritage policy. For example the predominantly Protestant province of Friesland in the North. This rural province has 647,000 inhabitants and about 770 churches, mostly in towns and small villages. A lot of them are threatened or already abandoned. A number of 240 churches are still converted and 45 of these are owned by a private trust that acquires historic churches, exploits and maintains them. To understand the extent of the existing and upcoming church problems the provincial government started an inventory. They gathered all kinds of information, from heritage value,

[5] http://www.hrre.nl/assets/Uploads/Guidelines-on-Ways-of-Dealing-with-Religious-Objects-1.1.pdf

maintenance costs, the financial situation up to the amount of church members. Some of the conclusions were shocking. For instance 25 % of the churches are owned by congregations who have less than 100 members. At least 85 congregations expect serious financial problems within 5 years and 219 within 10 years. Maintaining their church on the long run is not possible. Because of these outcomes the province has installed a 'Deltateam'. This team consists of four regional specialists; a heritage consultant, an architect, a financial advisor and a social community expert, who consult the small communities and help them to find solutions and new functions for churches under threat.

Interesting and successful initiatives are also found on a local level. In an increasing number of cities the civil and ecclesiastical authorities collaborate in so-called church visions. The church vision answers questions like: which parishes must be merged, which churches remain in religious use, which churches can be converted and which churches can be demolished. The document contains an inventory of all the churches, analyses (religious values, heritage values, spatial, functional, etc.) of the buildings, and an overview of needs and opportunities of the district or neighborhood. As soon as a church is threatened or abandoned, the vision helps to make more well-considered decisions on conservation, reuse or demolition. Church visions can be recorded in zoning regulations. Recently the city and deanery of Heerlen for example researched all their religious heritage. Data was collected about use, parish prognosis, monumental value and reuse opportunities (square meters, parking places, etc.). A number of 44 churches have been described and valued. In the next step Heerlen City Council and the Church authorities draw up their church and heritage policy together.

Similar projects are run in Bergen op Zoom, Amsterdam, Helmond and The Hague. In the last two cities the City Council decided to buy abandoned churches. In The Hague the Protestant Juliana church from 1926, situated in an economically disadvantaged neighborhood, was bought by stadsherstel. Converting the church into a social community center in 2006 had a positive effect on the immediate area. The same could be seen in Helmond where a Catholic postwar church, in 2003 converted into a theatre, is part of an upgrading process of the neighborhood. A vibrant health center in the same city, initiated by the municipality and developers, is found in the Leonardus church.

5.1.3 Private initiative

Some private initiatives are also important, successful or promising. Since 1981 we have the Vereniging van Beheerders van Monumentale Kerkgebouwen. This national association for owners and managers of historic church buildings is committed to the proper management and use of monumental church buildings. They facilitate professionalism and educate their members in the upkeep and exploitation of the churches used for congresses, concerts, exhibitions or other manifestations. Very successful is the Stichting Oude Groninger Kerken, a trust already 40 years old that acquires old churches in the province of Groningen and takes care of them. They own, protect and exploit 70 churches in the province of Groningen.

Fig. 3: The abandoned church of Oosterwijtwerd still has his its important interior thanks to Stichting Oude Groninger kerken.

They have a team of professional employees who educate volunteers, involve the local population, arrange activities or performances and are very keen on fundraising and getting legacies. Trusts of this kind, but a lot smaller, can also be found in five further provinces. Recently a new trust that operates on a national scale was founded. This 'Church and Cloisters' trust buys, converts and exploits churches and cloisters and has its roots in BOEI, a private non-profit organization for redeveloping industrial heritage. Their know-how in real estate, finance, exploitation and heritage helps them to find new functions and creative solutions. Like Stichting Oude Groninger Kerken they are very active in fundraising and one of their sponsors is the National Bank Lottery.

6 RELIGIOUS HERITAGE AND REDEVELOPMENT, NEW STEPS

Despite all these initiatives and trusts the problems keep growing. Due to the financial crisis, not only churches are abandoned, also other heritage such as town halls are at risk as well. This increases the competition for churches and makes it more difficult to find new functions. The national government has considered the huge task of redevelopment both in its Policy Document on Architecture and in its new policy on heritage management. Redevelopment has become one of the main pillars of policy. Because of this in 2010 the National Redevelopment Programme started and also a new subsidy system for stimulating the redevelopment of monuments was introduced. This system consist of two parts. First the 'wind- and watertight scheme', devised to prevent demolition or prolonged vacancy and to promote the sustainable use of valuable objects. And second, the possibility of granting redevelopment plan feasibility studies, for property owners to help them explore the options for redevelopment.

More governmental action in favor of Dutch religious heritage started last year. The director of the Cultural Heritage Agency, Cees van't Veen, noticed that central direction and coordination in addressing the problems failed, but is strongly needed. This point and the next step in the process were discussed in several meetings with national key players and stakeholders. Essential is commitment of all partners and the development of a national agenda for religious heritage. Specific themes like financing, heritage selection, regulations, policies, etc. must be part of that agenda.

7 CONCLUSION

In conclusion, the reuse of churches is not a new phenomenon, but more than ever it has become an urgent and very complex issue in which religious opinions, cultural awareness, emotional attachments, rational and economic arguments all play a part. Because of the large quantity of abandoned churches, the lack of money and the lack of worthy new functions, it will be difficult to convert them all. I think we have to choose, but in a well-considered and communicated way, based on mutual respect and trust.

Risk Management and Spatial Planning – Understanding Rapid Urbanization in Climate Change

Harry Storch, Nigel Downes

(Dr. Harry Storch, Brandenburg University of Technology Cottbus, Department of Environmental Planning, storch@tu-cottbus.de)
(Nigel Downes, Brandenburg University of Technology Cottbus, Department of Environmental Planning, downes@tu-cottbus.de)

1 ABSTRACT

In the emerging mega-urban regions of Southeast Asia, both planned and unplanned urbanisation into flood prone areas appears to be an unavoidable consequence of socio-economic development. These risks occur, often not due to a lack of risk awareness or weak planning instruments, but seem to be an accepted consequence of maintaining current economic success and social progress. Flood risk protection and implementation of costly mitigation measures are often shifted to a future development cycle, where implementation is not seen to constrain the economic goals. Asian cities located in deltaic settings such as Ho Chi Minh City (HCMC) in Vietnam, exhibit higher exposure levels to flood risk primary as a result of their location, their low elevation and if located in tropical regions, the significant annual variations in climatic and weather extremes they incur, so that a compelling need for dedicated site specific risk assessment and urban planning arises. Disasters like the recent flood in Bangkok in 2011 have shown that this development strategy cannot be justified any longer, especially in the times of a changing climate. Associated economic losses and social implications are simply too high.

Our results are an outcome of a 5 year research project in HCMC funded by the German Federal Ministry for Education and Research, focused on developing adaptation options to climate risks that could then be subsequently implemented into the existing land-use planning framework. Based on the development of core indicators describing future urban structural changes in relation to the changing patterns of risk exposures, spatially explicit planning recommendations were compiled in close cooperation with the responsible city authorities. Our contribution focuses on how to overcome the current limitations in implementing scientifically-founded and evidence-based adaptation planning to flood risks by communicating the importance in realising the present and plausible opportunities to influence future urban land-use.

2 STRATEGIC LAND-USE PLANNING UNDER A CHANGING CLIMATE

To support the potentials of urban land-use planning for adaptation in HCMC, the focus has to be on and towards the evaluation of land conditions and urban development potentials in a more spatially explicit manner than prevously undertaken. In the development of planning recommendations to assist master plan adjustments for both land-use and urban development, recommendations need to be both grounded in realistic land-use and urban development scenarios.

By Year	2003	2004	2005	2006	2007	2008	2009	2010	2011
Total Locations	64	63	64	67	125	126	96	58	31
Locations in the Center	62	62	61	61	107	86	69	31	14
Locations in the Periphery	2	1	3	6	18	40	27	27	17
Fig. 1: Number of flooding locations in the central and periphery districts of HCMC 2003-2011 (Source: Ho Chi Minh City Steering Centre for Flood Control, 2011)

These need to in turn consider both the underlying land conditions and site suitability for development and additionally are required to integrate the pressing climate-related issues into HCMC's existing urban planning framework. Following the recent heavy investments seen in storm-water drainage upgrading and expansion, the number of flood-prone areas within HCMC – while remaining fairly constant between 2007 and 2009 at around 100 localities per year – was seen to decrease significantly in the inner-city districts (Ho Chi Minh City Steering Centre for Flood Control 2011). In contrast, districts located in the periphery, which were subjected to the most rapid recent urbanisation, and are located in general in low-lying areas display the largest number of flood events over the same time frame. (Figure 1). This substantiates the need for urban planning and urban management to be more carefully assessed to ensure that both site and off-site flooding considerations have significantly been addressed in planning. Resultantly, there is a pressing need for a risk assessment methodology to integrate the physical aspect of exposure of new urban developments with the environmental impact-related information of built-up areas.

The main factors affecting urban development activities are natural factors, like naturally flood-prone area, topography and soil conditions (Figure 2), and artificial factors, like urban services (water supply, drainage, roads), accessibility to urban centres and land prices. The current urban development situation in HCMC is characterised by a high population density in the existing urban core area, mostly by low-rise housing structures. This has led to an extreme inherent urban compactness (Figure 2), which ensures due to location a good accessibility and short commuting times for the residents. At the same time, however, low-density sprawling into the peri-urban fringe – partly caused by illegal development is visible, resulting in an ineffective infrastructure provision. The current development trends – a continued concentration and densification within city centre and along the major transportation corridors – is highly impractical, yet is mainly driven by small private development projects on the level of the single building or street block. This trend is worrying from an environmental standpoint, as without planning interventions of some degree, such small scale yet high-density developments fail to provide adequately for open space provision and environmental services. The assessment of HCMC's urban development strategy highlights a lack of effective planning and plan enforcement mechanisms for guiding urban growth orientated to the basic underlying natural conditions, against a backdrop of strong market mechanisms that have recently dictated the current development activities.

3 DEVELOPMENT OF RECOMMENDATIONS FOR ADAPTATION PLANNING

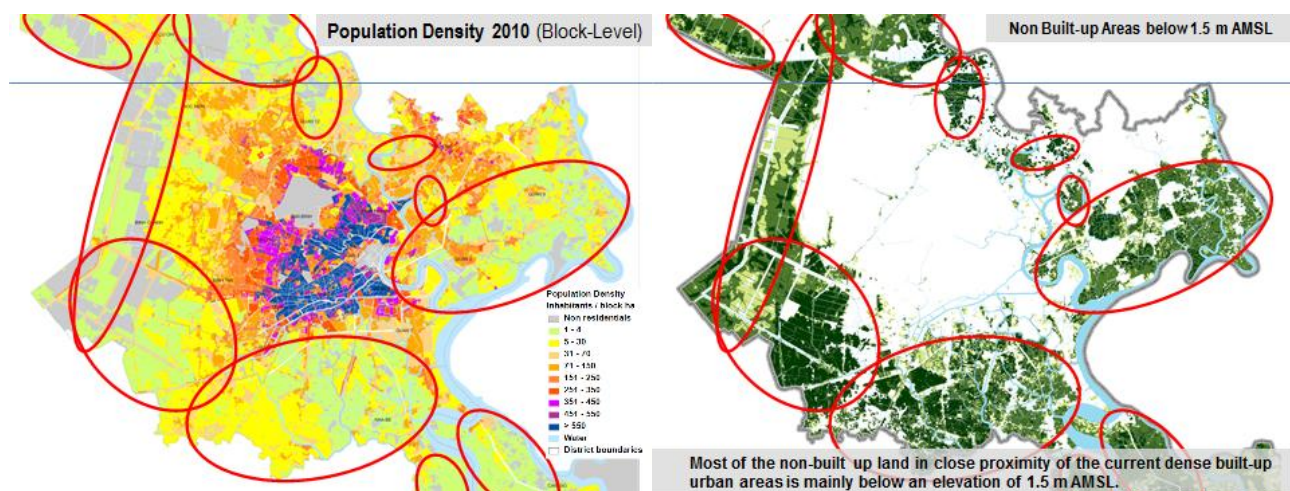
The rapid urban growth and expansion of cities into natural areas is not solely the problem of HCMC, but is a global phenomenon presenting an important challenge to both sustainability and adaptation planning. Effective planning policies are required to stem the tide of increasing land-consumptive development into the high-risk flood-prone areas of HCMC. Here, without delay urban containment policies should be considered as a promising adaptation approach to address the current and unfolding spatial risk-patterns of HCMC. Figure 2 highlights clearly that the current urban form and structure of HCMC is strongly influenced by and to some extent constrained by its underlying natural conditions.


Fig. 2: Non built-up areas at flood-risk (right map) surrounding the densely populated city-core (left map) – (Storch&Downes 2012)

The few remaining open spaces surrounding the extremely dense core –mainly agricultural land–have an elevation below the current high-tide level of 1.5 m AMSL.These spaces currently act as a natural blue and green belt–akin to flood risk zoning by nature–and strongly influence the ongoing inner-city re-densification. Hence only a genuine understanding the interrelationship between urban densification and adaptation processes to current flood risk can aid the guidance the spatial adaptation processes of HCMC in the uncertain times of rapid urban growth and climate change.

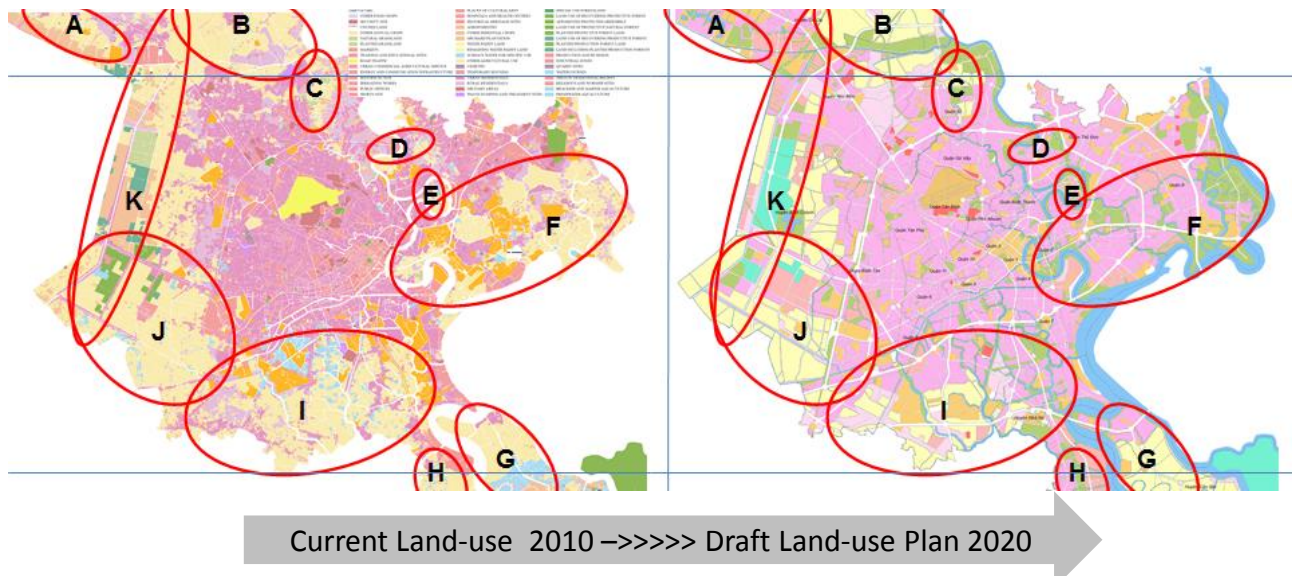
During the many meetings in HCMC, final discussions over the location of the main focus areas and the areas of interests with unique impact patterns and development pressures (Figure 3) were held with the Department of Natural Resources and Environment (DONRE) and their land-use planning consultants from the Sub-National Institute of Agricultural Planning and Projection, to aid and facilitate DONRE's consultation activities with the 24 districts of HCMC.


Fig. 3: The defined Focus Areas for Land-use Planning Recommendations (red circles areas A-K) marked on the current-use map derrived from our urban strcuture type approach and a draft verison of the land use plan 2020 (Storch&Downes 2012)

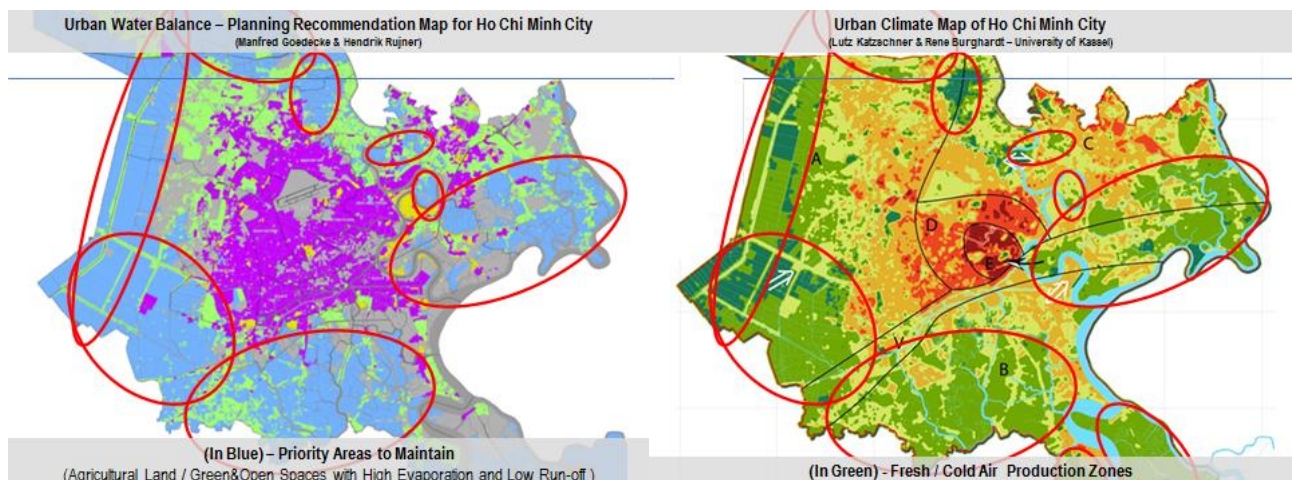
Our developed planning recommendations for climate change adaptation focus on supporting the designation of natural flood-prone greenbelts (Figure 2), the most restrictive form of urban containment policy. Utilising the existing flood-prone areas as greenbelts for current and future flood protection measures would additionally provide significant urban environmental benefits including recreational value, protection of open space, agricultural land, natural resources, all in additional to the highly important supporting ecosystem services for storm- and floodwater management and their important function as fresh and cold air production zones to mitigate the urban heat island effect (Figure 4).


Fig. 4: Urban water balance planning recommendation map (left) and urban climate map of HCMC (right) – (Storch&Downes 2012)

To be ultimately climate resilient, urban development planning need to reconcile and use the already the already existing ecological services at their disposal in adaptation planning. Supported by environmental planning methods and tools land-use planning can protect these environmental services in a systematic manner (Figure 5).

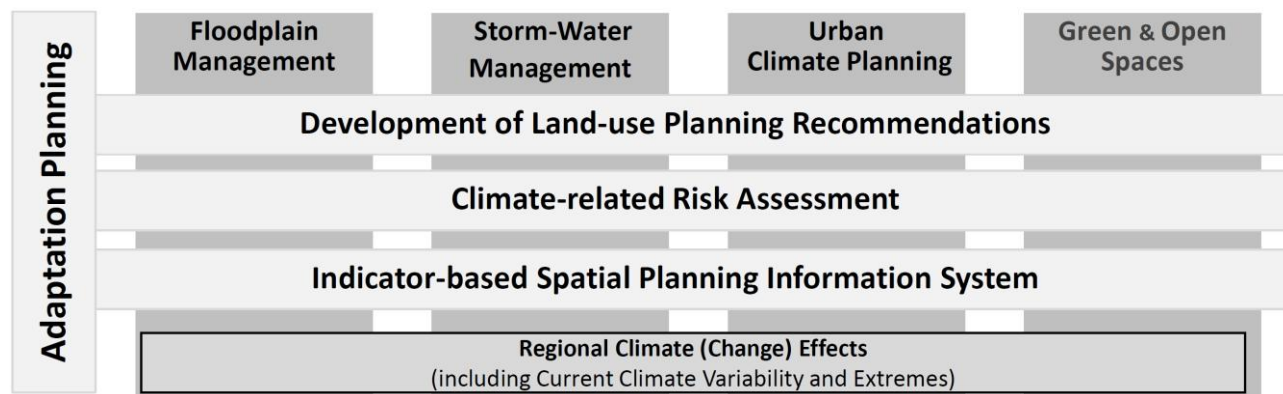
The basic incorporation of Strategic Environmental Assessment (SEA) methods for core climate-related environmental impacts in the thematic areas urban climate, urban floodin and storm water retention highlights the valuable ecological services of open spaces and agricultural land for climate-related risk mitigation. The consideration of multiple types of climate-related hazards can reduce the likelihood that adaptation planning and risk reduction efforts targeting one type of climate-related hazard will increase exposure and vulnerability to other climate impacts, in the present and future (Figure 5).


Fig. 5: The environmental planning tools and methods used for the integrated assessment of blue and green infrastructure for an adapted land-use planning in Ho Chi Minh City

For high-dense urban patterns, a larger share of blue and green infrastructure is in general beneficial for adaptation, as it provides space for urban agriculture, natural spaces for retention and detention of storm- and flood water management, and areas to generate and transit cool and fresh air, lowering and offsetting the energy demands for cooling in cities such as HCMC with tropical climates.

The developed planning recommendation maps can be used to assist the application of zoning guidelines for climate-adapted land-use planning (Storch et al. 2012, Storch&Downes 2012). In HCMC the need for adaptation will largely be associated with managing climate extremes – like urban flooding or urban heat waves (Figures 2 and 3). The spatial zoning of adaptation needs in land-use planning must therefore be associated with future urban growth and socio-economic development (Figure 4). By spatial-explicitly examining the rates of socio-economic change at the local level, the demand for adaptation can be assessed. These changes – represented by urban land-use changes – if compared with projected changes in climate extremes can highlight that the rates of socioeconomic change are likely to be greater than those for climate over the next decades (Storch&Downes 2011).

4 SUPPORTING ADMINISTRATIVE INTEGRATION AND IMPLEMENTATION

For high-dense Asian megacities, the inherent complexity of risks and vulnerabilities requires high resolution spatial information, in order to identify hazard patterns, vulnerabilities and risks at a scale that can provide guidance for urban land-use and development planning. Planning for risk and uncertainty for future urban growth will not just be a challenge for high flood prone areas; it will be a broader challenge impacting on the very nature and location of future urban development, particularly in planning for climate change (Labaeye et al. 2012). Here land-use planning that takes into account disaster risks is the single most important adaptation measure for minimising future losses (Storch&Downes 2011). The spatial planning framework and subsequent urban planning decisions, as currently applied, do not attach ample or sufficient importance to the physical exposure, the rate of urban growth and the risk of disaster losses. Generally, urban governments are responsible and have a moral obligation for regulating either construction or development in such a way that minimises risks. Urbanisation does not necessarily have to lead to an increasing hazard portfolio and can, if managed properly, contribute towards risk reduction. However, there are a number of key characteristics of the urbanisation process that do directly contribute to the formation of risk. Solely spatial and physical exposure alone does not explain nor directly lead to increased urban risk. If urban

growth in risk-prone locations is directed by adapted land-use zoning and at the same time guided by adequate building standards, ensuring risk patterns can be effectively managed and mitigated.

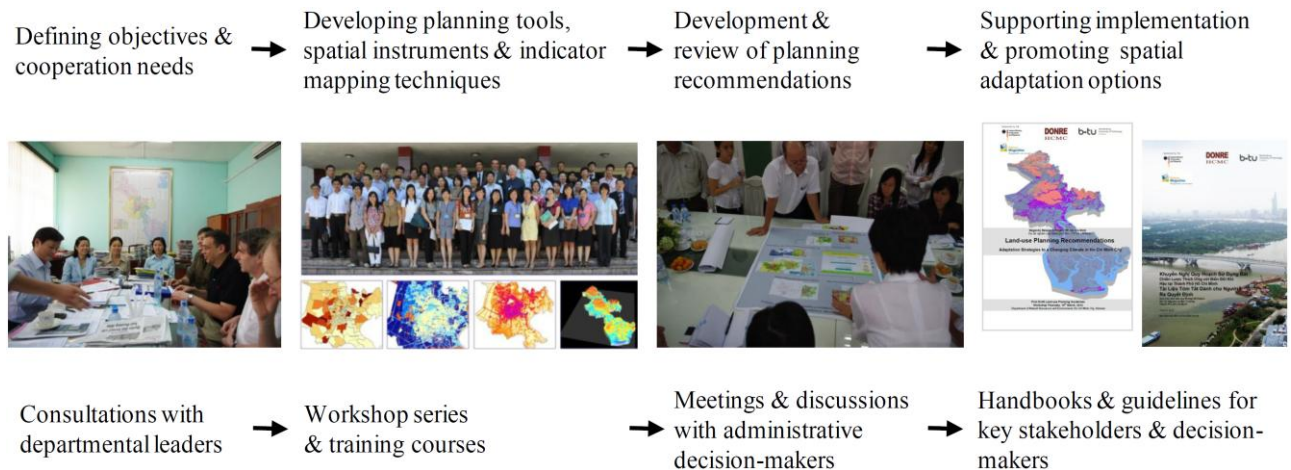
Land-use planning is seen as having a key role to play in developing efficient and tailored strategies to climate-proof HCMC (Storch&Downes 2011). As such, our research has not been carried out in isolation but from the outset was foremost intended to assist DONRE with administrative policy making (Figure 6) in making informed decisions underpinned by the latest assessment techniques (Figure 5). The results of our cooperation show the apparent gravity of the grave challenges faced by DONRE with respect to climate proofing past and future urban development.


Fig. 6: The cooperation and joint research activities with DONRE in the development and implementation of planning recommendations for adapting HCMC's land-use plan to climate change (2008 to 2013).

Ultimately, DONRE has the task to determine the overall land-use, spatial zoning and environmental quality of HCMC. As such, DONRE possesses executive powers over one of the most important instruments for the adaptation of HCMC to climate change, the steering and management of land-use. To their credit, DONRE has become very conscious of its responsibility in relation to climate change responses and the management of associated impacts. Externally, these matters have gained increasing acceptance and importance within the wider administrative structure of HCMC; while, internally they have reinforced the essential need to adapt their own planning. However integrating climate change considerations into land-use planning in HCMC is inherently a complex decision-making problem, which requires the careful assessment of the current decision situation, related to place and space.

Fig. 7: Meeting and discussion in October 2012 with DONRE and Sub-National Institute of Agricultural Planning and Projection over the unique characteristics and development challenges of each focus area.

Upon the request of the Planning Division of DONRE and with their close cooperation, a workshop entitled "Adaptation Strategies to a Changing Climate in HCMC – Development of Land-use Planning Recommendations" was organised to outline and more importantly discuss, the integration of the research results form the various work packages into consistent, transferable and usable planning recommendations for the revision of the Land-use Plan.

The need to disseminate the project results to the local districts of HCMC was highly stressed prior to the workshop by the Planning Division of DONRE, as a much needed and essential further step. As such, all key stakeholders from district-level were officially invited by Ms. Nguyen Thi Cam Van (DONRE) to the workshop. The workshop promoted the integration of our research results into the existing planning framework respectively to the needs of DONRE´s land-use planning.

At the workshop, the compiled Handbook "Land-use Planning Recommendations – Adaptation Strategies to a Changing Climate in Ho Chi Minh City" (Storch et al. 2012) was showcased and distributed to the administrative stakeholders of the 24 districts of HCMC. With the support of Vietnamese-German University students of the Urban Development Planning master programme, it was possible to translate the whole handbook into Vietnamese. The handbook summarises over 40 pages, the main findings and recommendations for the adaptation of the new Land-use plan (Figure 8). The Planning Guidelines are divided into five chapters, three chapters summarise the strategic environmental assessment of urban surface runoff, exposure to tidal flooding and future sea-level rise and the urban climate situation, while two chapters explain the applied methods for urban structure type mapping, urban growth monitoring and plan conformance assessment.

Fig. 8: Development of Handbooks: Land-use Planning Recommendations (Storch et al. 2012, Storch&Downes 2012)

The discussions with the administrative stakeholders on district-level highlighted the accepted and crucial need to integrate climate-related issues into planning and decision making processes. The workshop was chaired by Dr. Nguyen Van Phuoc, Vice-Director of DONRE and Head of Environmental Management and Director of the strategic program "Ho Chi Minh City Moving towards the Sea with Climate Change Adaptation". Valuable clues and insights were gained into the feasibility of science-based planning recommendations and the exact needs of our Vietnamese partners for future thought-out, sustainable and efficient planning strategies. Emphasis was placed on how to better integrate our gained project results into the land use planning framework in a transparent, usable and comprehensive manner for DONREs land-use planning tasks until end of 2012 and future capacity building needs.

The second handbook (Figure 8) was produced according the demands of DONRE and addresses the cooperation with DONRE in ensuring and facilitating the integration of our research results into the formal and official procedural steps for the development of the Land-use Plan 2020 (LUP 2020), upon request from the Planning Department of DONRE and the Land-use Plan consultants from Sub-National Institute of Agricultural Planning and Projection. Additionally a short summary of 15 central maps explain and support our science –based planning recommendations visually. Again, the whole handbook was translated into Vietnamese language and cross-checked by DONRE and its consultants, reproduced 400 times and distributed to administrative stakeholders and planning institutions by DONRE (Storch&Downes 2012).

5 CONCLUSION – VISIBLE IMPACT OF PROJECT RESULTS

The main visible impact of our intensive cooperation with DONRE to integrate our planning recommendations into the Land-use Plan 2020s administrative procedure, is seen in the integration of our assessment results and core planning recommendations maps for all selected 11 focus areas into DONREs official report for submission of the Land-use Plan 2020 to the Peoples Committee of HCMC entitled "Draft

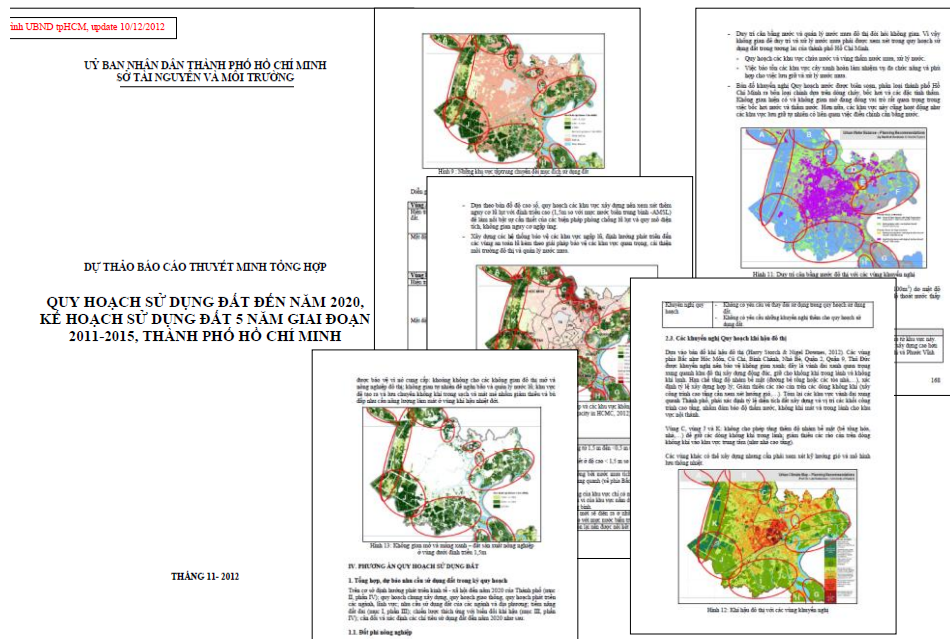
report of land-use planning toward 2020, land use plan for the 5 years (2011-2015) for Ho Chi Minh City" (DONRE-HCMC 2012).


Fig. 9: Impact of the Megacity-Project on Adapted Land-use Planning Integration of the jointly developed Planning Recommendations into the Official Report by DONRE for Submission to the Peoples Committee in December 2012 (DONRE-HCMC 2012)

The joint development and refinement of the planning recommendations for the climate-risk adapted Land-use Plan 2020 has resulted within DONREs Planning Division and the Consultant Institution providing a strong impression of co-ownership. In total our results are integrated within a 20 pages chapter of their official LUP2020 report (Figure 9). The content of our assessment results have been left unchanged, they have been only been shortened and re-edited to the formal administrative requirements.

(Chiara Caranti, Comune di Bologna, Bologna Italy, Chiara.Caranti@comune.bologna.it)

1   ABSTRACT

The urbanAPI project has been funded by the European Commission in the context of European initiatives to improve policy as a more transparent and understandable process: it is a three-year, €4 million, multi-partner collaborative project developing ICT tools to support urban governance and spatial planning in four cities across Europe.

Underpinning the project is the understanding that the delivery of more sustainable cities requires the application of enhanced intelligence in urban management, to produce an effective basis for assessment of urban complexity and decision-making.

Fraunhofer IGD (Project Coordinator), AIT (Austrian Institute of Technology) assisted by GeoVille are responsible of ICT tool design and implementation, UWE and AEW (Rome) with the contribution of ICLEI, are responsible for engagement with stakeholders in order to define their needs, organisation of workshops and assessment of the tools application in the partner cities. Vienna, Bologna, Vitoria-Gasteiz, and Ruse are the partner cities supporting the applications with practical experience, governance needs and data.

The urbanAPI tools provide advanced ICT based intelligence in different urban planning contexts:

- First, directly addressing the issue of stakeholder engagement in the planning process by the development of enhanced virtual reality visualisation of neighbourhood development proposals.

- Second, at the city-wide scale, developing mobile (GSM) based applications that permit the analysis and visual representation of socio-economic activity across the city.

- Third, the development of simulation tool applications in the city-region responding to the simultaneous demands of both expanding city populations for certain European cities, and declining and frequently ageing populations elsewhere.

Lessons derived from the urbanAPI experience will permit the development of generic ICT tools that can be used in the majority of the cities of Europe.

In this context, the enhanced ICT tools proposed by urbanAPI offer the potential to provide urban planners with the tools and intelligence needed to actively manage the urban environment. These tools will provide planners with precisely the information they need to fully expose the socio-economic and environmental impacts associated with alternative options for territorial development and thereby create conditions in which the political mandate and the basis for more effective management is secured.

In this paper will be analysed the project expected impact on urban governance and the results achieved with the 3D application in the city of Bologna during the first phase of the project implementation.

2   ICT-INTELLIGENCE FOR URBAN PLANNING CONTEXTS

Effective governance of the cities and city regions of Europe today is fundamentally undermined by urban complexity, whereby the high degree of interconnectedness and multiple interactions between socio-economic and environmental factors in a territorial context create major barriers to the effective implementation of sustainable urban development. The proactive governance of cities and the delivery of more sustainable compact cities require the application of enhanced intelligence in urban management, to produce an effective basis for assessment of urban complexity, and decision-making support.

The governance of cities is a collective effort requiring joint initiative between planning and management agencies from EU to local level, clear coordination between a variety of agencies at the local level, as well as critical inputs from all stakeholder groups including citizens.

In this context the urbanAPI applications -3D virtual reality visualisation, mobile phone based mobility dynamics, city region growth simulation – will be brought as common toolsets to the four cities serving as

---

test cases (Vienna, Bologna, Vitoria-Gasteiz, and Ruse) addressing different spatial scales in the multi-level governance setting of urban environments.

The proposed urbanAPI toolset and the applications will make use of the vast data resources – geospatial and statistical datasets – related to urban planning, by integrating smart ICT technologies to promote sustainable planning policies by engagement with the public through ideas and visions that address alternative urban planning perspectives and new city development proposals.

Local initiatives will be encouraged to participate within the planning process, to contribute to the appropriate solutions and understand and finally endorse the expected impacts on environment and citizens.

Each application developed in one city context will be paired with another similar application in another and different city and national context, where different socio-economic, environmental and territorial characteristics, as well is governance structures and practices will be evident. Lessons will be derived from the comparative assessment of the applications developed in these differing contexts that will form the basis for the future development of generic ICT tools that can be utilised in the majority of the 500 cities of Europe with populations over 100,000, as well as other smaller cities and towns throughout Europe.

• Vienna	• √	• √	•
• Bologna	• √	• √	•
• Vitoria-Gasteiz	• √	• √	•
• Ruse	•	• (√)	• √

Fig. 1: City wise urbanAPI applications at the three urban contexts: neighbourhood (3D), city (PME) and urban region (UGS)

The urbanAPI project will support both sides in the urban policy and governance system: the policymaking and practitioner side as well as the stakeholders and the public.

The generic ICT applications will be built from a set of common libraries for data integration, policy modelling, simulation and visualisation, to be easily adapted to changing requirements by integration of the relevant data sets, to inform the practitioners and gather feedback from the public. Public participants in urban governance processes usually are not always ready to observe simulations for hours, to orient themselves in relation to complex cartographic products or use special equipment to experience results. Making these applications available to the public requires on the one hand simplification in the simulation concept, and on the other hand enhancement of visualisation techniques.

3 THE USER PERSPECTIVE

Most European citizens embrace the "collaborative Internet" and expect to be able to interact with city governments using ICTs. ICTs are seen as enablers of more and better participation (e-Participation), and democracy (e-Democracy) and more inclusive societies (inclusive e-Governance and e-Inclusion), extending beyond enhanced service delivery, to facilitate and enhance interactions between actors, thus requiring change in regulatory and governance processes. However, especially at the city level there is as yet only limited evidence of the direct effects of ICT-enabled innovations on city governance systems.

The urbanAPI project provides ICT enabled innovations for city governance and adapted governance models to support new stakeholder engagement and citizen participation, in order to enhance sustainable urban policy development and delivery. The conceptual frame for the project is based upon the understanding that urban managers throughout Europe face common challenges in responding to the desire for a more participatory democracy, in order to define the basis for securing urban economic vitality, social inclusion and environmental sustainability.

The urbanAPI project ICT tools will be developed with the application cities of Vienna, Ruse, Vitoria-Gasteiz, and Bologna. Local initiatives in the four urban regions working in this project will be encouraged to participate within the planning process, to contribute to the final solutions and understand and finally accept the expected impacts on environment and habitants.

In order to gain relevance beyond the four cities implementing the ICT tools proposed by urbanAPI, to gather additional input from urban experts and to reach out to the many cities throughout Europe that could

potentially benefit from the project's results, various activities at different stages in the project foresee the involvement of one or more relevant stakeholder organisations:

- Stakeholder Board: This advisory group convened a number of (approx. 10) networks, associations and other organisations dealing with urban policies, urban planning and/or urban sustainability.

- Requirement Workshops, organised in each application city: In order to tailor the application of the ICT tools proposed by urbanAPI as much as possible to the needs and possibilities of the four cities participating in the project.

- Evaluation Workshops: In the evaluation phase, expert input will be organised through another series of workshops, setting the criteria for analysing the outcomes and reflecting on the experiences made during the application of the ICT tools.

4 3D VR APPLICATION

The 3D urbanAPI system is built on the basis of the City Server 3D, developed by Fraunhofer IGD, which has already been proven in use by various municipalities. A web-portal is set up for the integration of several reusable visual interaction components that will be accessible over the internet.

The applications in the three cities (Bologna, Vitoria Gasteiz and Vienna) will allow, through an interactive process, the implementation of a new 3D scenario creator.

These technical developments will permit the transfer of Virtual Reality from academic research to real world applications by developing a generic tool:

- to display live content, such as other users□ interactions, sensor data and simulation results;

- to render 3D content adapted to the requirements of the policy making support application;

- to add content and to modify 2D and 3D objects depicting alternative urban planning decisions, e.g. on the basis of parameters (such as eaves height) defined in the zoning plan;

- to create custom projections, e.g. in vertical and horizontal cross-sections across time, space and theme on the fly;

- to process large amounts of rich 3D models, but also little and coarse 3D information from standard CAD and GIS data bases and selected elevation views (photos, renderings) as texture information;

- to allow easy and widespread applications, by providing a simple and intuitive graphical user interface (GUI) to introduce alternative planning scenarios;

- to focus on data integration and harmonisation and to the delivery of seamless applications.

Figure 1: Preview of the 3D scenario creator (source: Fraunhofer)

Using the 3D VR (virtual reality) visualisations, the general effects and the visual impact of urban development plans can be realistically shown. The 3D scenarios support the negotiation process for urban development projects. Interactive control of planning interventions and presentation of the new visual effects, released through changes in zoning, help citizens to experience these changes.

In order to guarantee the best user experience possible high quality 3D geodata are used as well as rich interaction elements, especially to provide feedback on planning in various forms. This means that special emphasis is put on user-friendly client interfaces and an easy-to-understand simulation. Users will have the possibility to choose between the 3D web client and a mobile application.

5   BOLOGNA NEIGHBOURHOOD SCALE: 3D APPLICATION

Bologna is pursuing ICT solutions for both urban planning as well as environmental objectives. The aim is to communicate more effectively with citizens by visualising future development and potential impacts and enhance public engagement for a quick feedback on planning initiatives.

The development of the 3D scenario creator is conceived to enhance public and stakeholder engagement in the rehabilitation and mobility plan for the city centre ("Di nuovo in centro").

A pilot area of the city centre has been chosen for the application: this area is also involved in a project called „Ambiente Vitale", which aims to increase awareness and public participation in relation to green and public spaces provision, as well as sustainable lifestyles.

The 3D application will help planners to better visualize urban transformations in the district, improve interdepartmental collaboration and coordination in decision-making, and take account of citizens' opinions and suggestions, in line with the community participation processes already started with the many citizen committees and cultural associations.

Citizens will be able to interact with the Municipality through the 3D scenario creator, and chose their focus on including, for example, the rehabilitation and mobility plan, bike and car sharing points, public transportation and cycle track routes. They can also provide inputs concerning the management of pedestrians' route ways, the rubbish collection system and the use of public spaces.

The tool will help public and private planners to take easily in consideration citizens' suggestions and feeds, in order to better take care of interests and needs of the community, and come to an agreement with environmental sustainability issues.

- The application is started: the process of needs definition and requirements gathering has been completed, work on cartographic data is finished, it was time consuming work, because available data derived from different sources and have been collected for different purposes;
- after the selection and the final check, Geoville harmonized the data.

At present the visualisation of the district's routes has been realised and we are working on communication to public and private stakeholders: a specific urbanAPI 3D application link to add to the Bologna Municipality web page, is under development.

Fig.2- Bologna city centre

6 CONCLUSION

The urbanAPI 3D virtual reality visualisation toolset will allow the fast development and deployment of participative policy support applications for decision support, conflict management, analysis and visualisation, being developed and evaluated in collaboration with the cities partners.

The Bologna application will be assessed in comparison with the experiences going on in differing city contexts (Vitoria and Vienna) and will form the basis for future generic and reusable ICT tools. Setting this goal will ensure the sustainability of the approach, as the created solutions will be applicable beyond the application cases used for evaluation in this project.

Stadtentwicklungsfonds – ein innovatives europäisches Finanzierungsinstrument zur Entwicklung integrierter Immobilien

Michael Nadler

(Univ.-Prof. Dr. Michael Nadler, Lehrstuhl Immobilienentwicklung, Fakultät Raumplanung, TU Dortmund, August-Schmidt-Strasse 6; 44227 Dortmund, Michael.Nadler@TU-Dortmund.de)

1 ABSTRACT

Integrierte Stadt- und Immobilienentwicklungen weisen zwar hohe externe Effekte für die urbanen Stadtakteure auf. Gleichzeitig ist ihre Rentabilität oftmals unterhalb der Vorgaben privatwirtschaftlicher Immobilieninvestoren, weswegen es in vielen europäischen Mitgliedsstaaten bei derartig komplexen Projekten außerhalb von Wachstumsregionen zu einem Marktversagen. Genau hieran setzt seit 2007 die Europäische Kommission mit ihrer JESSICA-Initiative an, in deren Mittelpunkt das innovative revelovierende Finanzierungsinstrument, der Stadtentwicklungsfonds, steht. Die Idee, rechtlichen Rahmenbedingungen und Anwendungsgebiete zur Förderung integrierter Immobilienentwicklungen in Europa werden im Rahmen dieses Beitrages vorgestellt.

2 STADTENTWICKLUNGSFONDS

2.1 Rechtlicher Hintergrund

In der aktuellen EFRE-Förderperiode (2007-2013) wurde im Rahmen der sog. JESSICA (= Joint European Support for Sustainable Investment in City Areas)-Initiative den europäischen Mitgliedsstaaten die Möglichkeit eingeräumt einen Teil der Strukturfonds-Ressourcen im Rahmen ihrer Operationalen Programme zur Unterstützung von Finanzinstrumenten in der nachhaltigen Stadtentwicklung zu nutzen. Im Mittelpunkt der Initiative stehen dabei die Stadtentwicklungsfonds (sog. Urban development Funds, UDF), welche sich nachfolgend beschrieben werden.

2.2 Idealtypische Fondsstruktur

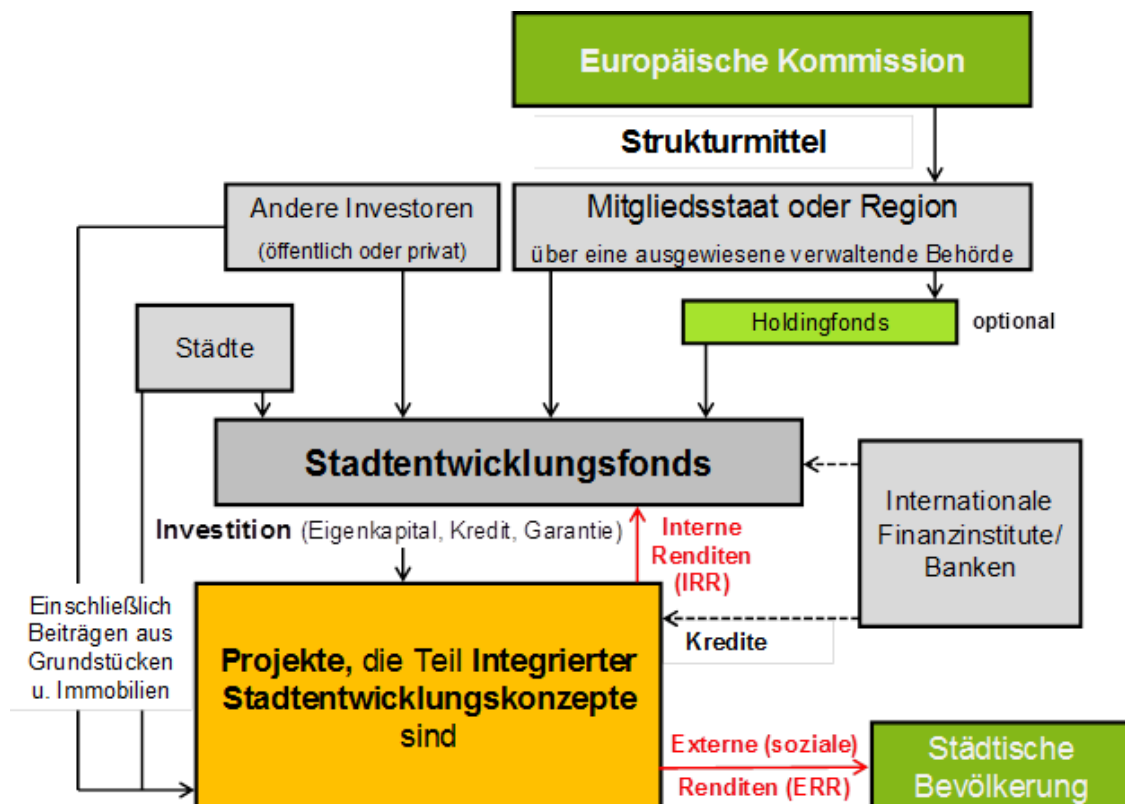
Immobilienentwicklungsprojekte, die Teil einer integrierten Stadtplanung sind, sollen im Rahmen von Stadtentwicklungsfonds über gün¬stige Fondfinanzierungen (Eigenkapitalbeteiligungen, Investitionskredite und/oder Garan¬tien) unter¬stützt werden:


Fig. 1: Struktur eines Stadtentwicklungsfonds.

Die Stadtentwicklungsfonds selbst werden hierbei durch Mittel aus dem Euro¬¬päischen Strukturfonds für regionale Entwicklung (EFRE), die durch die mittel¬ver¬wal¬ten¬de Be¬hörde ggf. unter Einschaltung eines nationalen oder regionalen Holdingsfonds einge¬speist wird, sowie möglicher kommunaler und/oder privater Finanzmittel refinanziert. Die Rück¬flüsse aus den Projektfinanzie¬run¬gen sollen in der Folge wiederum in nachhaltige Stadt¬entwick¬lungsprojekte eingesetzt werden und so einen Finanzie¬rungskreislauf erzeugen. In diesem Sinne bilden Stadt¬entwicklungsfonds ein neues Förderinstrumentarium, welches ange¬sichts öffentlicher Kassen, die immer stärker in ihrem finanziellen Handlungsspielraum einge¬schränkt werden, die nötigen nach¬haltigen Förderwirkungen im Bereich der Stadtentwicklung sichern kann.

2.3 Umsetzung in der aktuellen EU-Förderperiode 2007-2013

Die JESSICA-Initiative ist in dieser Förderperiode ein experimentaler, innovativer Ansatz, weshalb die EU Kommission (DG Regio) und die Europäische Investitionsbank (EIB) diese Pilotphase durch technische Hilfen unterstützen, um einen Informationsaustausch der erforderlichen Akteure auf allen räumlichen Ebenen zu bewirken.

In Deutschland erfolgte die Diskussion und Einführung von Stadtentwicklungsfonds im Rahmen zweier Forschungsprojekte (u.a. eines ExWost-Forschungsprojektes für fünf Modellvorhaben), welche vom Lehr-stuhl Immobilienentwicklung federführend für das Bundesministerium für Verkehr, Bau und Stadtentwicklung in Zusammenarbeit mit dem Bundesinstitut für Bau-, Stadt- und Raumforschung betreut wurden. Parallel dazu wurden durch den Lehrstuhl Immobilienentwicklung für die EU Kommission und die EIB fünf mögliche Geschäftsmodelle („Prototypen") für Stadtentwicklungsfonds in Europa entwickelt, welche zwischenzeitlich in 51 Fonds (mit einem Gesamtdotierung von 1,8 Mrd. Euro, Stand Januar 2012) auch bereits umgesetzt wurden:

Fig. 2: Umsetzung der Stadtentwicklungsfonds in der aktuellen EU-Förderperiode 2007-2013

3 CONCLUSION

In der kommenden EFRE-Förderperiode (ab 2014) sollen Stadtentwicklungsfonds zu einem Standardin¬strument in der Förderung nachhaltiger Stadt- und Regionalentwicklungen von den Mitgliedsstaaten genutzt werden. Die Erkenntnisse aus den aktuellen Pilotfonds in Europa aber auch die neuen rechtlichen Rah¬menbedingungen für die kommende Förderperiode stehen im Mittelpunkt eines aktuellen europäischen Forschungsprogramms des Lehrstuhls Immobilienentwicklung der TU Dortmund, welches unter WWW.IMMO.TU-DORTMUND.DE/EIBURS eingesehen werden kann. Sie zeigen recht deutlich, dass Stadtentwicklungsfonds keine Konkurrenz zu nationalen rein zuschussorientierten Förderprogrammen zur nachhaltigen Stadtentwicklung, wie sie in Deutschland die Städtebauförderung zum Inhalt hat, sind, sondern ein komplementäres Finanzierungsinstrument mit abweichenden Voraussetzungen und Anwendungsgebie¬ten.

Stadtklimakomfortzonen – von übergeordneten Planungen zu lokalen Interventionen

Bernd Eisenberg

(Dr.-Ing. Bernd Eisenberg, Institute of Landscape Planning and Ecology, bernd.eisenberg@ilpoe.uni-stuttgart.de)

1 ABSTRACT

Global Climate Change has a major impact on cities and their inhabitants. The ordinary Central European city with an average of 2°C temperature increase will therefore face significant impacts on the usability of open spaces and needs the attention of urban planners, the civil society and decision makers. The number of heat days in the region of Stuttgart for instance is predicted to double until the end of the century. With the urban climate comfort zone approach – that is proposed and investigated within the EU-funded TURAS-project (www.turas-cities.org) – an integrated set of measures is introduced that aim to maintain and to improve the usability of open spaces with regard to the increase of bioclimatic stress. This will be reached by urban planning guidelines that focus on green infrastructure and local interventions. One of these local measures is a green wall that serves as a cooling and shading facility as well as a potential noise barrier and water storage. It will be built and tested in order to feed back the results into an integrated transition strategy that serves as a role model for the TURAS partner cities.

2 EINLEITUNG

Im Fokus der Berichterstattung zu den Auswirkungen des globalen Klimawandels stehen häufig die drastischen Folgen, wie zum Beispiel der Meeresspiegelanstieg, der die Metropolen an den Küsten bedroht, oder die Zunahme von Extremwetterereignissen mit vermehrten Hochwassern und Überschwemmungen auf der einen und Hitzewellen und Dürren auf der anderen Seite. Aber bereits für die „normale" Stadt mit durchschnittlichen Temperaturanstiegen von 2° C werden die Folgen signifikant sein und stellen eine Herausforderung für die Stadt- und Landschaftsplanung und die beteiligten Akteure dar. Im Rahmen des von der EU geförderten Projektes „TURAS – Transitioning towards Urban Resilience and Sustainability" (www.turas-cities.org) stellen sich nun 28 Institutionen aus 16 Städten und Regionen dieser und weiterer Aufgaben „auf dem Weg zu mehr Nachhaltigkeit und Resilienz in Städten". In den kommenden vier Jahren entwickeln und testen sie Maßnahmen, die am Ende in einer auf andere europäische Städte übertragbaren „integrierten Übergangsstrategie" zusammengeführt werden sollen.

Die TURAS-Projektpartner in der Region Stuttgart – Verband Region Stuttgart, Helix-Pflanzensystem, Universität Stuttgart – sind an unterschiedlichen Arbeitspaketen beteiligt. Eins davon beschäftigt sich mit dem Konzept der Stadtklimakomfortzonen, um den Auswirkungen des Klimawandels auf das lokale Stadtklima mit einem abgestimmten Maßnahmenpaket zu begegnen.

3 DER ANSATZ: STÄDTISCHE KLIMAKOMFORTZONEN

Das Problem ist einfach umrissen: Für die Region Stuttgart wird eine Verdoppelung der Anzahl der heißen Tage (> 30° C) bis zum Ende des Jahrhunderts prognostiziert. Die im Rahmen des Klimaatlas der Region Stuttgart erstellten Bioklimaanalysen (vgl. Abb. 1) identifizieren die räumliche Verteilung der belasteten Gebiete und setzen sie mit Bevölkerungszahlen in Beziehung. Über 50 % der Verbandsfläche und 45 % der Bevölkerung werden bei einer Verdoppelung der Hitzetage bis zum Ende diesen Jahrhunderts von Hitzestress an mehr als 30 Tagen im Jahr betroffen sein (VRS 2008, 130 ff), was ganz erhebliche Auswirkungen auf die Nutzbarkeit des öffentlichen Raums zur Folge haben wird.

Das Konzept für städtische Klimakomfortzonen setzt an diesem Punkt an. Die Stadtklimakomfortzonen sind Bereiche des öffentlichen Raums, die trotz eines hohen bioklimatischen Belastungspotenzials aufgrund ihrer Ausstattung bzw. stadträumlichen Einbindung einen erträglichen, wenn nicht sogar angenehmen, Aufenthalt im öffentlichen Raum auch an Hitzetagen ermöglichen.

Die Errichtung der städtischen Komfortzonen zielt darauf ab, die Aufenthaltsqualität des öffentlichen Raums in Bezug auf die Umgebungstemperatur zu erhalten und zu erhöhen. Dies geschieht durch den Ausbau der Grünen Infrastruktur, durch konkrete Empfehlungen zur Erhöhung des Durchgrünungsanteils und weitere etablierte Maßnahmen der Stadt- und Landschaftsplanung (BMVBS 2011, Landeshauptstadt Stuttgart 2010, VRS 2008), aber auch durch lokal begrenzte Interventionen.

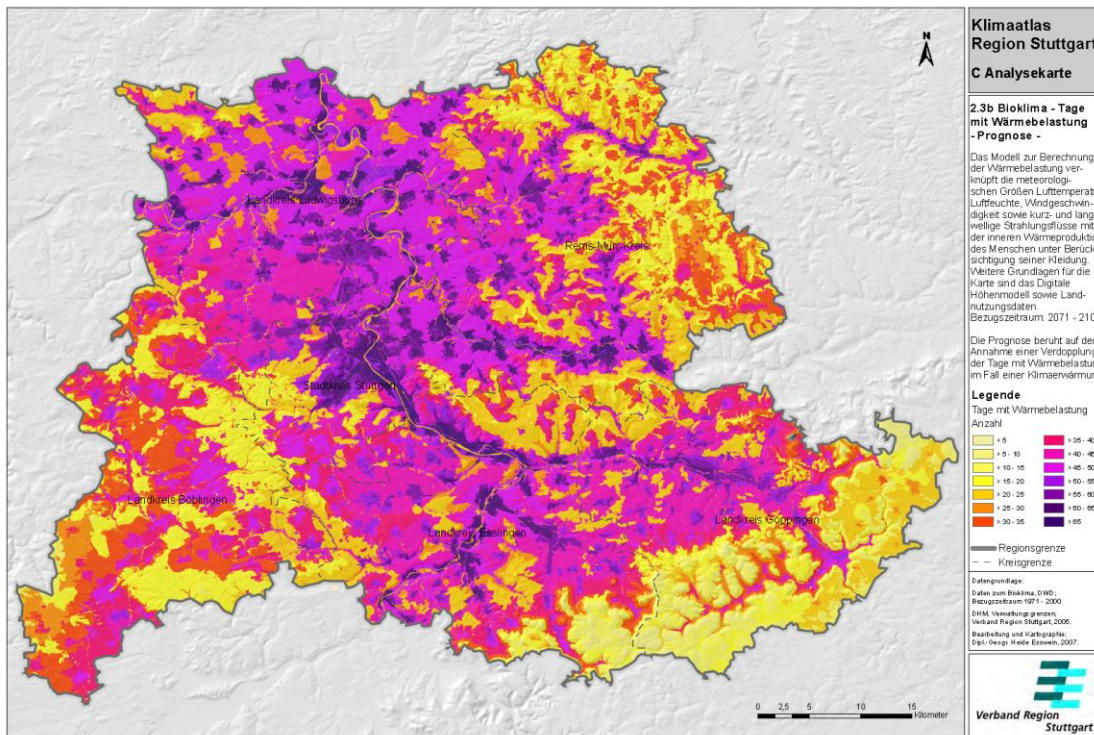
Aufbauend auf den Daten und Analysen des Klimaatlasses der Region Stuttgart werden prioritäre Gebiete definiert, in denen Anpassungsmaßnahmen vorrangig in Angriff genommen werden sollten. In Kombination mit Analysen zum Nutzungspotenzial der Grünflächen (Eisenberg 2009), zur „Fußläufigkeit" (walkability) und zur Nutzungsfrequenz des öffentlichen Raums lassen sich Bereiche identifizieren, in denen mit lokalen, begrenzten Interventionen ein möglichst großer Effekt hinsichtlich der Aufenthaltsqualität und Nutzbarkeit erzielt werden kann.


Abbildung 1: Bioklima – Tage mit Wärmebelastung (Quelle: VRS 2008, 134)

Der Verband Region Stuttgart, die Firma Helix-Pflanzensystheme aus Kornwestheim, das Institut für Landschaftsplanung und Ökologie der Universität Stuttgart sowie die Stadt Ludwigsburg als assoziierter Partner arbeiten zusammen, um exemplarisch eine städtische Klimakomfortzone auszuweisen, zu testen und zu evaluieren. Die „Stadtklimakomfortzonen" werden als ein abgestimmtes Paket von Anpassungs-maßnahmen an den Klimawandel entwickelt, dessen Übertragbarkeit auf andere TURAS-Partnerstädte ebenfalls Gegenstand der Untersuchungen ist.

4 LOKALE INTERVENTIONEN

Eine lokale Maßnahme der Klimakomfortzonen wird näher auf ihre Wirksamkeit und Alltagstauglichkeit hin untersucht: die Grüne Wand, die sowohl stadtklimatische, lufthygienische, wie auch ästhetische, stadträumliche und Lärmschutzfunktionen aufweisen wird.

Der Standort für die Grüne Wand ist so gewählt, dass diese punktuelle Maßnahme als Bindeglied zwischen bestehenden Grünverbindungen fungiert und daher nicht nur im unmittelbaren Umfeld ihre Wirkung entfaltet, sondern auch die Ergänzung einer bestehenden klimatischen Komfortzone ermöglicht.

Die Wirkung der Wand auf das Mikroklima und bezogen auf die Funktion als Bindeglied in der städtischen Komfortzone wird im Rahmen des Projektes untersucht. Die Erfahrungen mit der Grünen Wand werden anschließend in die übergeordnete integrierte Übergangsstrategie des TURAS-Projektes, wie auch in die Empfehlungen zur Anpassung an den Klimawandel für die Region Stuttgart einfließen.

5   DIE GRÜNE WAND

Die Grüne Wand wird an einem Standort erbaut, der die oben skizzierten Anforderungen erfüllt. Es ist vorgesehen in der Summe bis zu 30 m lange und ca. 2-3 m hohe, flächig mit Vegetation bewachsene Wandelemente zu erstellen, die von einer baubotanischen Baumkrone auf dem Wandkopf überragt wird.

Bei einer Wandhöhe von 3 m und einer Länge von 30 m würde eine vertikale Nettogrünfläche von etwa 200 m² entstehen. Um möglichst schnell ein mikroklimawirksames Kronendach zu erhalten, wird in die Wand eine baubotanische Konstruktion eingefügt, die das Grünvolumen innerhalb kurzer Zeit signifikant erhöht. Mithilfe der baubotanischen Methode der Pflanzenaddition (Ludwig 2012, 219 ff) werden Pflanzenstrukturen erschaffen, die sich nach einer kurzen Anwuchsphase, in der sie auf eine Versorgung aus der Grünen Wand angewiesen sind, autark aus dem Boden versorgen (Ludwig 2012, 257). Die folgende Abbildung veranschaulicht diese baubotanische Konstruktion (vgl. Abb. 2).
Abbildung 2: Grüne Wand mit baubotanischer Konstruktion (Quelle: F. Ludwig, unveröffentlicht)

6   ENTWURFSPROZESS UND BEGLEITENDE MESSUNGEN

Die Ausgestaltung der Grünen Wand und ihres Umfeld erfolgt in der ersten Jahreshälfte 2013 in enger Abstimmung zwischen der Kommune, der Universität Stuttgart und den Konstrukteuren der Wand. Dabei werden Effekte der Wand auf das Kleinklima mithilfe von Analyse- und Simulationssoftware untersucht und Entwurfsvarianten verglichen. Soweit es an dem innerstädtischen Standort möglich ist, wird auch ein integriertes Regenwassermanagement, das die Bewässerung der Wand sicherstellen soll, einbezogen. Um die Akzeptanz sowohl für die Maßnahme an sich, wie auch die dahinterstehende Konzeption der städtischen Klimakomfortzonen zu steigern, werden lokale Akteure frühzeitig eingebunden .

Vor und nach Fertigstellung der Grünen Wand sind umfangreiche Messungen zu bioklimatischen Parametern an der Wand und in ihrem Umfeld vorgesehen . An der Wand selber werden umfangreiche Untersuchungen zur optimalen Pflanzenauswahl und den Auswirkungen auf die Biodiversität durchgeführt. Ergänzt werden die technischen Messreihen durch ein Nutzermonitoring, das Frequenzzählungen, Beobachtungen und Befragungen beinhaltet.

7 ERWARTETE ERGEBNISSE UND AUSBLICK

Das Konzept der Klimakomfortzonen verbindet etablierte Anpassungsstrategien mit Analysen zum Nutzungspotenzial des öffentlichen Raums. Durch die Konzentration der Maßnahmen zur Verbesserung der Aufenthaltsqualität entstehen Zonen, die auch bei höherem bioklimatischem Belastungspotenzial die Nutzbarkeit des öffentlichen Raums gewährleisten sollen. Dies ist auch im Hinblick auf die demographische Entwicklung von Bedeutung, wird doch eine alternde Gesellschaft umso stärker auf funktionierende öffentliche Räume im Wohnumfeld und den städtischen Zentren angewiesen sein.

Die Einzelmaßnahme „Grüne Wand" entfaltet sicherlich nur sehr begrenzt eine stadtklimatische ausgleichende Wirkung. Der Wert der Grünen Wand liegt vielmehr darin, vor Ort konkret eine Lücke in der Abfolge von Grünflächen zu schließen. Somit kann eine Klimakomfortzone geschaffen und an einem innerstädtischen Standort das Thema „Klimawandel und Anpassungsstrategien" platziert werden.

Durch die wissenschaftliche Begleitung wird sichergestellt, dass verlässliche Aussagen zu Stärken und Schwächen der Maßnahme gemacht werden können und darauf aufbauend die Übertragbarkeit auf andere Standorte in der Region Stuttgart, aber auch in den TURAS-Partnerstädten, beurteilt werden kann.

1 ABSTRACT

SUNSHINE – "Smart UrbaN ServIces for Higher eNergy Efficiency" delivers innovative digital services, interoperable with existing geographic web-service infrastructures, supporting improved energy efficiency at the urban and building level. Specifically, SUNSHINE delivers a smart service platform accessible from both a web-based client and from an App for smartphones and tablets. In parallel to technical integration a key standardisation activity will also result in the definition of the extension of existing data model (CityGML) through the definition of a specific Application Domain Extension (ADE) on building energy behaviour, something very important for the pilots within SUNSHINE and its large-scale uptake beyond current locations.

SUNSHINE is a European funded project in the competiveness and innovation framework program for the duration of three years with 16 partners from ten countries and it started in February 2013.

2 INTRODUCTION

Energy consumption in urban areas is increasingly recognized as an important source of global greenhouse gas emissions. Cities account for approximately two-thirds of global primary energy consumption and 71 % of energy-related greenhouse gas emissions (IEA 2010). Energy demand patterns vary widely from city to city and across countries. Today, energy use in residential, commercial and public buildings accounts for 40 % of total global final energy consumption (UNEP 2007). There is a huge energy saving potential in this sector and significant scope for adopting more efficient technologies and services in buildings (IEA 2010).

Energy certification of buildings is a key policy instrument for reducing the energy consumption and improving the energy performance of new and existing buildings. It should provide information that may increase demand for more efficient buildings, thereby helping to improve the energy efficiency of the building stock in the country (ARKESTEIJN, K., VAN DIJK, D. 2010).

SUNSHINE – "Smart UrbaN ServIces for Higher eNergy Efficiency" is a step towards this policy and is a tool to improve the energy efficiency of buildings and urban areas. This paper presents the young European funded project SUNSHINE, which will develop a smart service platform for planners and public administration to extract analytical indicators necessary for the definition of energy saving policies for the existing public buildings asset and to define energy pre-certification mechanisms. Further, building managers can use SUNSHINE to optimize energy use of large-scale optimization of public illumination network. SUNSHINE uses three scenarios which lead into a smart service platform that will be accessible from web-based client and from an App for smartphones and tablets. An important aspect of the SUNSHINE project is the use of a scalable approach, based on CityGML standard format, which makes a simultaneous representation of the energy balance at architectural and urban scale possible. CityGML is an open data model and XML-based format for the storage and exchange of virtual 3D city models particularly suited to applications.

The SUNSHINE technology will be the result of the customization and integration of existing software components developed by other EC-funded projects focusing on smart-city technologies, including BRISEIDE, i-SCOPE and i-Tour (DE AMICIS, R., CONTI, G., PRANDI, F 2010).

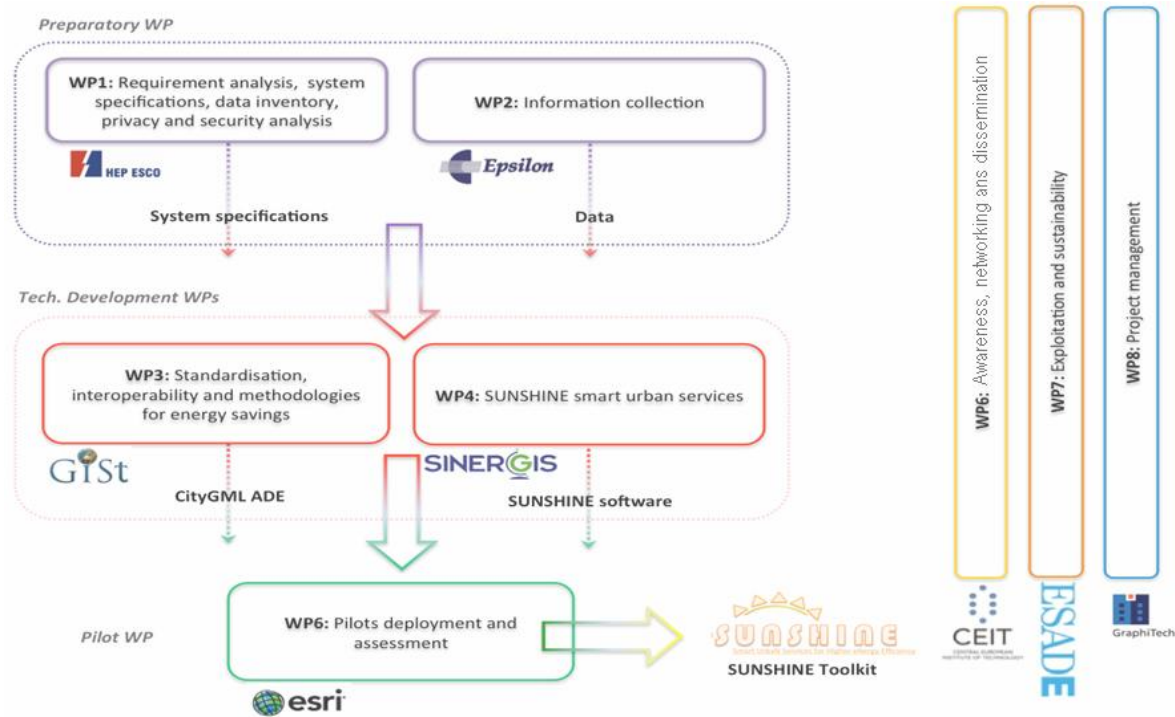
In the SUNSHINE project eight work packages are planned (figure 1) which are basically structured in preparatory work, technical development and the deployment of the pilots. Awareness, networking and dissemination will accompany the project over the entire duration. These activities include the involvement of stakeholders, information linkage with Smart City Portfolio working group and other related EU funded projects. A further aim of this work package is the organisation and coordination of user meetings, seminars, workshops at international, national and local level to be hosted by the various partners of the consortium.


Fig.1: Overview of the work packages (source: GraphiTech)

3 SUNSHINE SCENARIOS – PILOTE USER CASES

Within the SUNSHINE project three different scenarios are planned which will be a desktop-based user-friendly 3D geobrowser supporting OGC standards. In particular, the SUNSHINE platform will allow the three following scenarios.

3.1 Scenario 1: Assessment of energy performances and electronic energy pre-certification

The automatic large-scale assessment of building energy behavior based on data available from public services (e.g. cadastre, planning data etc.) which are involved in the project via letter of commitment. The information on energy performances will be used to automatically create urban-scale "ecomaps" to be used for planning activities and large-scale energy pre-certification purposes.

User case: A building manager from the local public housing agency of Ferrara, Italy, starts a web-client to assess energy behavior of a set of 150 public buildings located city-wide (note that a single public building asset may be a multi-unit dwelling such as an apartment block).

The web-client connects to a SUNSHINE smart service that in turn connects to existing web services run by several departments of the municipality (e.g. cadastre, urban planning department etc.). The latter expose relevant data (including type of building, use category, geometry, size and shape, age and climatic zone, etc.) that has been compiled to ensure compliancy to a single interoperable profile of standards from OGC.

The SUNSHINE smart service uses this information to generate the 3D model of the relevant portion the city encoded as CityGML standard format, including estimation on performances for each building according to the SUNSHINE CityGML ADE (Application Domain Extension) on building energy efficiency. The information calculated by the system can also be double checked against actual consumption values available from the local energy provider.

As result the system returns both a 2D and 3D "ecomaps" (the latter being the full CityGML model), whereby each public building is classified according to their theoretical energy performance.

3.2 Scenario 2: Heating and cooling forecast and alerts

The previous assessment will be then used, together with localized weather forecasts available through interoperable web-services, to ensure optimization of energy consumption of heating and cooling systems through automatic alerts that will be sent to the SUNSHINE App.

User case: January 2013, Schwechat in Lower Austria, located next to Vienna. High-energy consumption was reported in the previous few weeks due to cold weather. Weather forecasts then predicted a sharp and significant increase in daily temperatures from minus ten degrees to around plus eight degrees. The building manager of the Multiversum, a multi-purpose event hall in Schwechat, had previously installed the SUNSHINE App on his smartphone. The App was configured with information on the type of heating system and position of the Multiversum. The building manager had set an alert that would inform him of extreme and unseasonable changes in weather conditions. He receives detailed information on the dynamic rate scheme for the following day which increases significantly costs for energy consumptions. This gives him the possibility to react immediately and to adjust the heating.

The SUNSHINE system receives the weather forecasts predicting the sharp increase in temperature. The system retrieves the list of buildings according to their energy performances and it starts sending notifications, according to the estimated thermal inertia of each single building, warning to turn off the heating system, due to improving weather condition, at a given time of the day to ensure an optimally comfortable transition to higher external temperatures.

The same scenario could be applied both in hot summer days (when air conditioning is at its peak) and during cold winter days to reduce concentration of PM10 due to excessive heating of buildings.

3.3 Scenario 3: Optimization of power consumption of public lighting systems

Lastly SUNSHINE will ensure interoperable control of public illumination systems based on Automatic Meter Reading (AMR) facilities remotely accessible, via interoperable standards, from a web-based client as well as from an App for smartphones or tablets.

User case: An operator of the Municipality of Bassano del Grappa (Italy) wants to optimize illumination (indoor and outdoor) levels of public buildings (e.g. City Council) and building of public interest (e.g. stadium). He starts a 3D web client that shows the map of the city and the public illumination network. The web client operates as a dashboard from which he can control, through an interoperable standard, real time status of public illumination system. This allows him to check, from a single point of access, the functioning of the various parameters of the entire lighting system through an interactive mapping environment, identifying for instance damages, power losses or simply inefficient use (for instance lights being turned on when unnecessary).

The operator can control lighting conditions to avoid unnecessary illumination of common areas whenever not required. He selects one of the lines that surround the local stadium and sets the illumination level down by 50 % in the evening when all activities inside the stadium are finished. Similar optimization is performed for other public buildings. The dimmering (as well as other control) can be performed at control panel level (for the entire line) or at single illumination unit.

4 PILOTS WITHIN SUNSHINE

The three described scenarios will be piloted in the context of nine sites across five countries which includes e.g. for Italy 20 public buildings in Ferrara; 60 technical buildings across the Trentino Province; 4 public illumination lines in the centre of Bassano del Grappa (Italy), 5 public illumination lines in the city of Rovereto (Italy) 3 building complexes in the area of Val di Non (Italy) and their outdoor public illumination systems.

Fig 2: The multipurpose hall "Multiversum" in Schwechat (Source: Multiversum)

For Austria it will be a multipurpose hall "Multiversum" in Schwechat, Austria whose managing director has committed to SUNSHINE. It is a complex opened in 2011 used for sport and cultural events, but also for exhibitions, fairs, congresses, conventions and business events. Within this pilot all three scenarios will be tested. Other pilots are located in Croatia, Greece and Malta.

SUNSHINE will be piloted for a duration of 12 months and it will target at energy and emission savings ranging, within the various pilots, from 10 % to 30 %, with higher savings being foreseen for pilots relying on older buildings, or equipped with older heating, cooling or lighting technologies. Energy savings will be compared to a one-year baseline data acquired, during the first stages of the project prior to the deployment of the pilots.

5 CONCLUSION AND FUTURE WORK

This paper has given details of the initial project plan for the following three years. SUNSHINE is a European project aiming to improve the energy efficiency of public buildings. Local administrations are playing an important role within the project and are constantly involved in the process.

The first step within the project will be to precisely define the use cases to be addressed by the various pilots and collect requirements for the deployment of the SUNSHINE system, including e.g. user, training, service requirements and a definition of the software architecture of the whole SUNSHINE system. Further steps for the SUNSHINE implementation are the identification, collection and harmonization of all available information to support the SUNSHINE pilots.

1 ABSTRACT

In order to stress the development of a low- carbon economy, the situation in the European Cities concerning the transformation of the entire energy system is challenging. Therefor a powerful tool with broad participation process has to be set up, to define the "ideal city" development. The definition of a vision, building up of a set of indicators, drawing of a roadmap, specification of the main actors and the inclusion of the main trends and bariers for urban planning are to tackled. Main indicators are prepared for a city-development up to the year 2050 for social, economic and ecological sustainability. The representation through the indicator matrix will be visualized with a spider map representing the pillars of sustainability for the 7+1 main indicators of the weighted environmental parameters. Outcome will be the representation of the current situation and the targeting of the most urgent measures to improve the the quality of life in urban agglomerations.

2 I LIVE GRAZ, THE PROJECT

2.1 Background

The transition to sustainable energy systems should start in cities. There is no way around: the facts are striking: cities cover about 1 % of the world's surface, but they consume 75 % of the energy and cause 80 % of the emissions of global warming gases. And the cities keep growing. Nowadays about 50 % of the world's population lives in cities, and 60 % are expected by 2025. These cities at present are powered by fossil energies: coal, oil and gas. While the cities contribute to climate change, also the results will be seen here mostly. Within cities an increasing number of hot days and nights can be expected, air quality is decreasing. Moreover, many cities face great problems with growing traffic, blackouts and poor suburbs.

But this is also a chance: measures taken here unfold the greatest effect! Urban systems are the leverage point for solving global energy problems. There is no blueprint for such a "Smart" city, but some rules which are general and they can be transferred into different cultures and climates.

The European Union (EU) is tackling the challenge through a policy whose target is nothing less than the transformation of the entire energy system, with far-reaching implications on how we source and produce our energy, how we transport and trade it, and how we use it. In short, it is necessary to make low-carbon technologies affordable and competitive – a market choice. This is the core idea behind the European Strategic Energy Technology Plan [1] which includes a Smart City Initiative.

The Smart Cities Initiative aims at improving energy efficiency and stepping up the deployment of renewable energy within large cities, going even further than the levels foreseen in the EU energy and climate change policy. This initiative supports cities and regions that take pioneering measures to progress towards a radical reduction of greenhouse gas emissions through the sustainable use and the production of energy and as a result it involves the cities on the forefront of the development of the low-carbon economy.

2.2 Methodology for a participatory process

The Smart City project in Graz has been started in 2011 with a grant from the National Austrian Research Foundation FFG. The project has been managed by the City of Graz through its buildings authority. The main research partner was the Graz University of Technology, which was responsible for mediating the decision processes. The methodological background was a systematic innovation process similar to that proposed by Mann [2]. The project wasnot started with the present situation but by defining the desired outcome: an ideal city for living, working, learning, culture and leisure (comp. fig. 1).

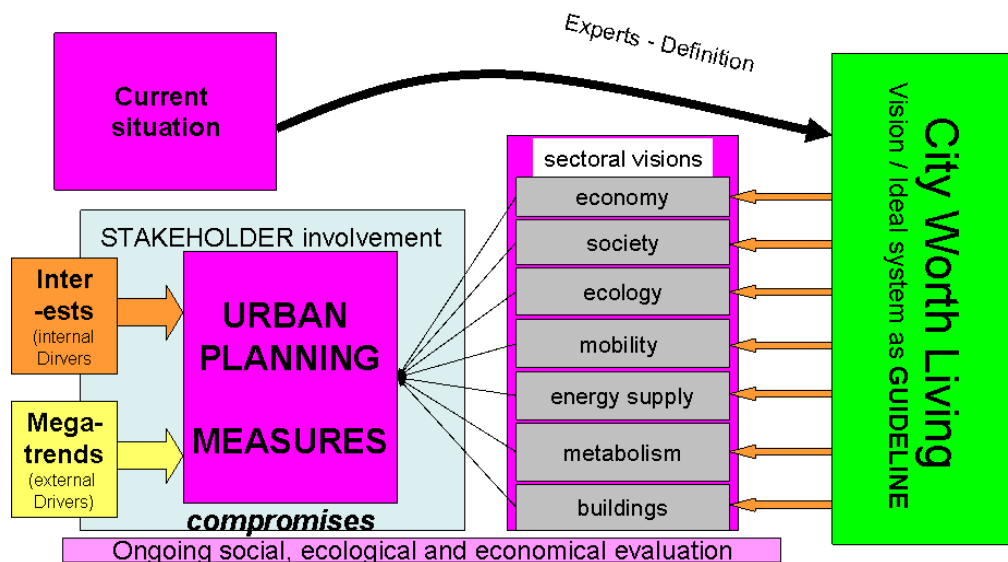
As shown in fig. 2 in order to be able to find the "ideal city" independent of present interests (internal drivers) and (mega-) trends (external drivers), seven expert groups were established. The eighth group, experts integrated the thematic results into the visions and indicators for "urban planning) thus this structure is called the "7+1 Graz Process".


Figure 2. From sectorial visions to urban planning measures

Each of the groups was led by a representative of a (semi-)public institution (city, utility company,…). Researchers of eleven institutes from the Graz University of Technology and representatives from various departments of the City of Graz, business, NGOs and the general public joined the process.

The process management defined the tasks for each of the working groups:

- Definition of the vision of the sector
- Build a set of indicators
    - "Hard" indicators that can be quantified by numbers
    - "Soft" indicators, text only
- Draw a roadmap
- Specify the main actors and assign duties to them
- Assessment of the supporting (mega-)trends and most likely barriers

Based on the results of the seven working groups, the experts defined their visions and measures for urban planning.

2.3 Sectorial visions and indicators

Each of the 7+1 expert groups defined its visions and indicators according to the following fields of action:

Economy: Graz is one of the leading medium-sized cities in Europe; it is dynamic and worth living, furthermore it is an international benchmark for research and innovation sites for green and sustainable technologies (Green Tech Valley) for energy, mobility, resource efficiency, health and design.A Main feature of a smart urban economic development consists in the efficient use of budgetary resources, the maintenance and the selective expansion of existing technical and social infrastructure. Main focus is laid on improving the efficiency and the secured financing of infrastructure management. An effective Smart City Development pursues innovative financing schemes, as well as resource-efficient business models, considering life-cycle costs.Thus the guidelines can be developed for the effective use of resources and public resources through coordinated investment decisions of technical and social infrastructures and also for the promotion of research, innovation and development projects in the field of urban development. Targeted results will be quality agreements with investors for targeted implementation of sustainable urban development, the promotion ofthe establishment of "green economy" companieswith state subsidies, establishment of urban "Revolving" and citizens Funds.The use of financialmeans is linked to the effective action towards the achievement of objectives for individual measures. A second evaluation criteria consists in the integral consideration of the life cycle costs. This approach would lead to sustainable investment decisions and long-term budget savings.Compact and dense development of urban settlement patterns along existing public infrastructure networks leads to the increase of efficiency in the management of technical and

social infrastructure such as: public transport, water, energy, supply and disposal networks, telecommunication networks, road networks, Kindergartens, schools, social housing, retirement homes, swimming pools, sports facilities, etc.Prerequisite for the sustainable management of public facilities provide multifunctional usable building – and infrastructure.Urban development funds are used to support the achievement of Smart City development, concerning investments and projects of individuals and businesses, which have demonstrated long lasting positive effects, conform to an integrated city development approach.

City authorities should initiate and support the establishment of revolving city-development funds and Citizens Funds to strengthen the implementation of climate change projects. This includes the establishment of a municipal information platform where the respective participating opportunities are available. Main indicators in this thematic field are a high quality of life, a sustainable growth, international accessibility and the oportunity for the settlement ofheadquarters for large companies.

Society: Graz should be an attractive place for living in every stage of life. The society is open-minded, child-oriented and democratic. The citizens engage themselves in the development of their living environment. Resource protection and sustainability are accepted guidelines that manifest themselves in daily life. The best possible supply with social infrastructure (schools, kindergartens, nursing homes, ---) is coupled witha corresponding minimum building densities and minimum densities of people. (i.e.: compact development structures).Structures comfortably linked to public infrastructure should be pursued in order to enable a resource-saving, energy-efficient and low-carbon urban development, the promotion of compact and dense housing. Main focus is laid on densification of the existing building stock,additional allotments,the use of vacant lots as well as on targeted and meaningful preparation and development of brownfield sites before any dedication of new land.

The prerequisite for a functioning internal development (densification of existing buildings) is the expansion of public space. This is the most important link between the structural spatial urban structures for the district at a public city level to create attractive public spaces (greens, traffic areas, open space) which has been taken as habitat and identity-support to enter the crucial issue of a vibrant livable compact city.

In particular a growing viable city should respect land saving / space-efficient urban development on which depends a number of effects from the consumption of building areas.A smart city development is accompanied by an early involvement of affected groups (residents, local stakeholders such as businesses, organizations and institutions). The acceptance of the Smart City implementation can be significantly raised and projects become adapted to the requirements and needs of the individual living environment through a transparent information and a targeted participation. A diversified combination of methods should be used in order to reach most of the inhabitants. As outcome guidelines will be drawn up: best is the earliest possible involvement of all affected stakeholders, the targeted public participation and information, an accompanying district management in urban development projects and the promotion of the awareness for sustainable living.

For the purposes of an integrated urban development of the area district management a bridge has to be built for instance between residents, the political-administrative system, the business sector and other local actors (associations and institutions, etc.). High importance has to be dedicatedto the networking and the integration of existing resources within the district, whichis one of the main characteristics of Smart City developments. The district management is coordinated by the City authorities and by all sponsoring associations implemented in the district development, in order to activate the population and to promote joint district identity initiations with all involved initiatives and organizations to carry outdevelopment projects. There are important incentives to increase awareness such as:education priorities in kindergartens and schools, general information activities, events, contests and awards, consultations and coaching measures. Through this policy mix the awareness for a sustainable lifestyle is increasedin order to anchor the following topics in the population: energy-and resource-efficient behavior, application of renewable energy technologies, the awareness for the true costs of infrastructure enhancement and development as a basis for purchasing decisions, gentle mobility behavior, communitarian use of products (eg: carsharing), promotion of regional markets, prevailing sale of fair trade products, etc.

Main indicators for the social thematic field are the amount of neighborhood conflicts, whichare independently solved within the residential community via peer mediation and neighborhood management. Another indicator for the development of construction projects can be actively involved and informed (that

also applies to private projects), which is seen as an asset and involved and concerned persons. Working schedules should be need-based, tailored to the life stageand childcare is adapted to custom models. All people should use communication technologies in everyday life regardless of age, gender or social status. Ideally every technical innovation should be affordable and seen as a positive contribution to a sustainable lifestyle, which is considered as chic and hasa high social prestige. High awareness for resource optimization is a basic life concept for the society concerning leisure activities, both in daily life and on the job.

Ecology: Graz has been developed towards a zero-waste and low-emission city which is CO2-neutral. The quality of the soil and the brooks has improved significantly. Noise pollution is no more a problem and biodiversity has been increased. A dense net of green corridors that can freely be accessed overdraws Graz. The urban public space minimizes the need for motorized mobility. The city development is based on the "duality principle" for an adequate balance between density and open space planning standards, with an aim to rebuildconstantly the quarter in its existing boundaries. The City development has many opportunities thanks to large private open spaces – either individually or collectively private. In these urban areas, green area stabilizing measures and extensions are operated and practiced according to ecological horticulture.The area of the city as part of the region is an absolutely limited resource. The expansion of urban area which goes hand in hand with the expansion of necessary traffic areas which is depending on the use of the outdoor landscape and a increasingland consumption. From an ecological point of view, the urban development was primarily done oriented towards inner development premises. The amount of animals and plant species indicates thebiodiversityin the urban area.

Mobility: Graz has been developed towards a city in which there are multiple choices of mobility technologies. The mobility concept combines resource efficiency with possibilities for social contacts. Local supply of the most relevant goods, services and recreational facilities guarantees short distances that can be covered by foot or bicycle. A substantial fraction of the areas used by cars at present is regained for people. A significant part of land as currently occupied by individual traffic and has to be recovered for residencial functions dedicated to the citizens. The program allows implementing a fundamental change in the modal split in urban and regional areas.Mixed uses (retail, office, housing, food, social infrastructure, ...) are economically functional and stable if the minimal building densities (1.8 – 2.0) with enough housing demand a minimum densitycan be ensured. That leads to a settlement through moderate densification, the part of the required road area of which up to 25 % could be reduced. Part of this spatial savings can be used to supply public green. Main indicators therefor arethe unquantifiable part of the local mobilitysuch as a compact city development, extensive cycling and public transport friendly connections, the recovery of roads as natural habitat, the improvement of the public transport offer, information and communications technology to simplify and speed up public transports, optimized freight logistics for traffic reduction and reduced transport service design.

Energy: In the year 2050 Graz and its environment are in an energetic equilibrium. The energy needed (including mobility, production and services) is produced by 100 % in the region with sustainable technologies. People act correspondingly knowing the value of energy. The utility companies provide the infrastructure for distribution and storage of energy and as a resultthe use of compact development structures leads to significant energy savings for buildings.

The expansion of emission-neutral heat supply networks requires compact development structures to be economically displayed. Main indicators for renewable energy are the ones that the power must be converted by force from the current fossil primary energy sources to renewable energy sources.

Fossil fuels will only be used for special applications.Energy should be decentralized, whereby the decentralization refers to the transfer fee / addition of large power plants with small, consumer-distributed generation units. Major criteria for the indicators are the costs, the availabilityand the security of the energy supply. The energy and power generation technologies, which ultimately define the new security of supply, are cost effective and sufficiently available.Energy costs for renewable energy should not be higher than the current pricing level.

Concerning to the energy awareness the residents should be aware of the value and should behaveaccording to the different qualities of various forms of energy at different times.

Concerning to the energy efficiency the energy is converted from high efficiency technologies and applications in use. Energy is not wasted – the consumption will be stabilized at the lowest possible level

without loosing life-quality.The entire process chain of production, distribution and conversion (use) of energywas taken into account by energy efficiency.The storage for the compensation of (renewable) energy when the demand has adequate available storage capacity is an important issue.

Metabolism: Graz is a waste free city and it uses water efficient technologies. Wastewater is treated and does no harm to the environment. Goods are repaired, reused and recycled. Waste prevention is the first principle and has taken root in all areas of daily life. An appropriate local services and infrastructure are accessible by walking distance for everyday goods supportinthe concept ofthe "compact city". All businesses provide their products in a circuit and conform to the life cycle and the cradle-to-cradle approach. Justice is implemented in all areas of the supply and the disposal is following the principle of 'polluter pays'.

Indicators for the metabolism arethe quotas for reusing goods and materials and also using of the wastewater as a source of energy and materials.

Buildings: Every building is considered over its life cycle and should contribute to the urban quality of life in terms of ecology, economy and social life. Buildings should be multifunctional as far as possible.They should provide possibilities for working, living, leisure and mobility. In 2050 all the buildings are characterized by high quality architecture (design, detail and quality of execution, multiple functionality, insertion into the environment), by taking into account the established architectural quality criteria. This includes processes such as user participation, needs assessment, planning, allocation and the implementation of culture.Indicators for building sustainability are the resource efficient planning which is an integral part in the planningof new construction projects, building skills and awareness of the client, users, planners and contractors.For the energy neutrality the best issue will be the use of all new buildings (except special buildings) as part of the approval process to demonstrate the high quality approach for these development solutions.As far as these visions are rather general, indicators should be developed in order to make the progress measurable for the vision. A general measure had to be found in order to make the indicators comparable. Even for the individual aspects of quality of life, it was difficult to find indicators. This can be discussed at the example of "noise pollution". Noise can be measured by decibel. The decibel is commonly used in acoustics to quantify sound levels relative to a 0 dB reference which has been defined as a sound pressure level of .0002 microbar, or 20 micropascals. The reference level is set at the typical threshold of perception of an average human and there are common comparisons used to illustrate different levels of sound pressure. In each city, there are quiet and noisy areas and it would be possible to define noise levels that should not be exceeded. Such a measure would not be comparable with any other indicator, like air quality, biodiversity or economic activity.Through the definition of present value (2010) and the target value, which has been prescribed in the vision process for 2050, a scale can be defined on the time axis. Noise like today's (2010) average gives 10 points, and noise for the target situation in the year 2050 gives 50 points (areas with more noise pollution than today's average get 0 points).

	Status 2010	Vision 2050	my quarter/ my project	corresponds to value of year 20.. (found by liner interpolation from 10 to 50)
Energy resources	Austria supplies 27 % energy from renewable resources	100 % renewable energy	80 %	39
Energy efficiency	average consumption 6000 W / cap	average consumption 1500 W / cap	2000 W	45
Mobility	1.5 cars per family	0.3 cars per family	1	26
Number of indicators			3	
			result for my quarter 36,7	

Table 1: Examples of how different indicators can be brought on one scale – the time scale towards the ideal state in 2050.

Urban development should not be merely limited to the balancing of interests. Therefore urban development and urban policy are developing prospects and potentials to show that winners of the game are not the story concerned, but the citizens.

The values for 2010 are originating from the acquisition of the real data, while the values for 2050 are the result of the vision-defining process. The corresponding value that provides the "status-year"has been obtained by linear interpolation between the value of 2010 and the value of 2050.

Finally,according to the theory of sustainability the indicators, have been grouped into three categories:

- Set of indicators for social sustainability

- Set of indicators for economic sustainability

- Set of indicators for ecological sustainability

The examples of indicators that can be used are given inTable 2. Values for status 2012 and 2050, as well as the project numbersare left free.For each of the Smart City Project these should be filled in the vision process.

Social	Economic	Environmental /resources
Social integration	Local supply	Air quality
Education, schools	Jobs	Noise pollution
Recreation	Costs of living	Water resources
Cultural activities	Commercial transport	Waste water treatment
Health	Information and communication technologies	Waste management
Safety	Gross national product (generated in the quarter / per person)	Biodiversity
Individual mobility	Value of infrastructure	Locality of food resources
Living, houses		

Table 2: Proposed indicators for Smart Cities

To review the progress and to document the successes and the lessons learned, the activities are actively monitored with the help of theSmart City indicator set. The appropriate use of the indicators are compared and evaluated at the neighborhood level for constant monitoring should be checked and reached, compared to the realized Smart City lighthouse projects and subsequently all observation levels (region, city, district, Qzartier, project).

The aim of the evaluation system is the effective management of the Smart City process in the city development and in particular the Smart City Urban Development in the three target areas (Graz center, Mur West and the Graz fair district). Essential part of the monitoring and evaluation system is an annual report with Smart City Graz consisting of a data summary and withan ongoing constant review progress and recommendations for further activities. The main variables are represented by easily readable graphs, with which the tracking of a constant monitoring of the Smart City development is ongoing.

Figure 3 shows the possible representation of the individual parameters in a spider web diagram for the environmental pillar of sustainability for two competing projects (the numbers reflect the progress from now (2011) to the vision state in 2050).

	my project	competing project
air quality	5	11
noise pollution	35	11
water supply	50	50
waste water	35	11
waste management	35	45
biodiversity	12	35
locality of food	40	11
green corridors	25	0
open water	0	11
traffic free zones	25	11
average	26,2	19,6
Fig. 3: Spider web diagram for the environmental parameters

Fig. 4 shows the presentation of the three pillars in one diagram. Several projects can be displayed in one graph, so that an easy comparison of various concepts or areas is possible. It can clearly be seen how far the progress towards the vision state of 2050 has been reached by the project.
Fig.4: Spider web diagram for the three pillars of sustainability in the Smart City Quarter

As a next step, weightings can be defined for each indicator. As we choose weights between 1 and 10 – a result of a participatory discussion as well – people can define their individual preferences.

	Status 2010	Vision 2050	My quarter / my project	corresponds to value of year 20..	weights
Energy resources	Austria supplies 27% energy from renewable resources	100% renewable energy	80%	39	5
Energy efficiency	average consumption 6000 W / cap	average consumption 1500 W / cap	2000 W	45	2
Mobility	1.5 cars per family	0.3 cars per family	1	26	8
Number of indicators			3		
			result for my quarter	36,7	32,9

Table 3: Examples of indicators with weightings

The resulting value for the project is now lower, since mobility (with a low result) has been weighted stronger than the energy ones.

3   CONCLUSION

It is planned to make the matrix accessible for citizen's trough a web-based systems. We expect that people contribute to new indicators and to new visionary statuses. They are also invited to put weights on the indicators, so that their priorities for an urban development can be seen.

Another objective is to measure the quality of different quarters in the city. People should give their values for the present situation in their living area. From that can be seen, where the most urgent measure to improve the quality of life should be located.

The developed strategies form the basis for the control to reach a "smart and sustainable urban development" in Graz and to speed up the dissemination of the knowledge of good practice and assure the transferability of the results.

Major issue should be the continuous evaluation and further development of the indicators and strategies which will contribute to the transferability to other districts and may also be pursued on citywide level, to integrate smart urban technologies for demonstration purposes and thus to ensure the development of the entire surroundings of the district towards a smart sustainable development.

The Smart City developmentwhich will be developed in Graz consequently will lead to closed-knit networks of cities and common strategies for a variety of topics in the follow-up of the Smart City concept,. International experience exchange through workshops and conferences should be made with the project partner cities.

To achieve the best results, cooperation and partnership cooperation of city and provincial agencies are essential. The province of Styria, and its departments play an important role for the development of good-practice examplesto contribute to the establishment of a Smart City Region. Combined workforce between city, state and federal governments is necessary for the achievemnet of a successful smart urban and regional development is fundamental for the realization of a successful smart urban and sustainably intergral development. Needed for the future is the formulation of a close cooperation and dialogue to set up common goals and to monitor the joint activities.

1 ABSTRACT

The paper intends to investigate how the community involvement in decision planning process could led to successful urban regeneration initiatives.

Starting from the American experience of "smart growth" and going toward the increase of the demand of mixitè in urban settlements, we argue that the involvement of the community could define a mixed approach in decision planning process to support urban regeneration toward more sustainable "supply". Analyzing what meaning the mixed use has acquired, still ambiguous particularly in the US context, where it still represents "the exception, not the rule" (Grant, 2002:79), the core of the paper is to investigate if the community role within the decision making process is a basic and essential factor to assure the quality enhancement of urban regeneration activities.

More in particular, the paper intends to understand the following issues:

- physical interaction vs balance in space and through time of urban transformations
- planning process community-led vs the key factors for successful urban regeneration initiatives
- planning choices vs. functional integration
- the attitudes of local communities officials vs mixed use

Based on some insights coming from the CLUDs project under 7FP Irses 2010, the paper aim at highlighting two USA case studies, Fort Point District in South Boston area (MA), and Jacobs Market Street Village located in Southeastern San Diego (CA). Both of them emblematic case studies on community involvement.

2 INTRODUCTION

The paper drawing from case studies analysis conducted in USA under the CLUDs project – Marie Curie IRSES, intends to demonstrate the connection occurring between successful urban regeneration initiatives and community involvement toward a mixed use of the spatial environment. Particularly, the aim is to investigate if the community role within the decision making process is a basic factor to assure quality enhancement of urban regeneration activities. Urban regeneration has been a concept much discussed in the last years. In particular come authors define urban regeneration as "comprehensive and integrated vision and action which leads to the resolution of urban problems and which seeks to bring about a lasting improvement in the economic, physical, social and environmental of an area that has been subject to change" (Roberts & Sykes, 2000:17). Moreover, according to Turok (2004:111) "urban regeneration process means to change the nature of a place by involving residents and other stakeholders, embracing multiple objectives and activities, with partnership working among different stakeholders".

So that participation and places are linked issues considered part of the process that assumes urban transformations: talking about "community involvement", "civic engagement" or "participatory urban process", here means to investigate how community-led developments drive toward a suitable urban environment. The paper will go through the analysis of community involvement approaches, starting from a general overview of participatory approaches within the policy making process, investigating what community added value is in raising quality standards of urban transformations. Then the community participation in urban regeneration initiatives will be declined through two case sudies analyzed in USA, highlighting the trend toward a mixed use of space under the general umbrella of Smart Growth principles.

3 COMMUNITY INVOLVEMENT OVERVIEW

It is widely recognized the increasing importance of community involvement within planning processes. Participatory urban planning, charette meetings, workshops, laboratories de quartier: more or less cities have

been moving toward this direction since few decades. Then, "current trend toward multi-level governance has created important opportunities for increased community involvement and enhancing local democratic processes" (Bailey, 2010:6) through a wide range of methods used to make people involved within the planning and policy making processes. The reason is that local involvement should be guaranty of efficacy and sustainable initiatives, a chance of being able to create a built environment that satisfy community demands. Nevertheless, the "broad context of community involvement is highly contested" (Bailey, 2010: 13) according to different contexts and belonging to different scales. Arguing that the building of urban identities claim for well-structured civic contents (Talen, 2008 quoted by Vall Casas- Koschinsky- Mendoza, 2011:172), the importance of local community awareness about urban transformation objectives is expected to play a central role. "The results of local visioning/planning efforts are determined by both the preferences of residents and community needs" (Walzer–Hamm, 2010: 154). Moreover, Healey claims for a process of "inclusionary argumentation" in which "participants come together, build understanding and trust among themselves, and develop ownership of the strategy" (Healey, 1997:249).

In USA cities the term "livability" is frequent used: according to Bohl (2002) it "operates at the level of the everyday physical environment and focuses on place making". Particularly, "within the livability arena are both the two-dimensional conceptual aspects emphasized by sustainable development (economy, ecology, and equity) and the three-dimensional aspects of public space, movement systems, and building design. (…) the livability vision expands the sustainability mix to include land use design aspects, ranging down to the micro scale of the block, street, and building, as well as up to the macro scale of the city, metropolis, and region". (Godschalk, 2004:6). Smart Growth and New Urbanism could be considered the general umbrella to which the livability concept refers, since they advocate for participatory planning design and community involvement. To cope with sprawl indeed "the issue is not density, but design, the quality of place, its scale, mix and connections" (Calthorpe – Fulton, 2001:274), all topics that imply sense of place and people awareness of their neighborhood. In North American car-oriented urban contexts, the Smart Growth approach is particularly focused on bridging the gap between urban density and collective transportation. As a matter of facts, retrofitting inner urban brownfield spaces and declined neighbourhoods contributes to preserve urban density, both in economic and financial sense, as concentration of functions and productive activities, and in social sense as sense of community (Calthorpe, 2001). So that, urban areas lacking in mix use functions are often privileged places for retrofitting actions, assuming that "unsustainable urban form could turn into a sustainable place" (Talen, 2011). That is why community participation means reinforcing the possibility of success in regeneration initiatives since "patterns of everyday life not only are mediated in landscapes but are given new meaning as a result of the spontaneous interactions that occur between different people in these places" (Bachin, 2002: 236). Indeed "one of the recurring themes surrounding sustainable cities is the role of public participation and the broader civil society in helping to shape and implement these programs" (K.P Ortney, 2005:1)
Fig. 1: the specific reasons for participation process in urban regeneration initiatives.

4   URBAN REGENERATION AND COMMUNITY ROLE IN US CITIES

A general trend of "retrofitting suburbia" is strongly pushing forward urban regeneration initiatives that involve people in order to cope with the lack of "sense of place" coming from the sprawl direction of the last decades. The so called "return to center" (Herzog, 2006) implies new way of considering urban space, integrated in functions and meaning to reach that kind of balance that allow to live a sustainable urban landscape. The mixed-use in often the answer, however it's not just about densification, rather it claims for a compromise of weights that a urban environment should take into account.

Case Studies Based On Cluds' Model	Jacobs Market Street Village SAN DIEGO (CALIFORNIA)	Fort Point District BOSTON (MASSACHUSSETS)	Discussions
Brief Description of the case studies	The Jacobs market street village is envisioned as a vibrant community, residential, commercial, and cultural district. The case study is planned and operated by community stakeholders: the goal is to provide residents a direct economic stake in neighborhood change.	Fort Point district historically is a light-industry related area along the Fort Point Channel in South Boston, today it's a mixed use area. It is characterized by a strategic position within the city geography: along the Fort Point Channel, within the Boston Innovation District, a big Economic Development Area attracting enterprises and economies from all the Massachusetts.	The case studies, though located in two different contexts, are linked from Smart Growth Rationale, and balanced by a strong PublicPrivatePartnership with the goal to obtain a more equitable benefits distribution for the whole community.
The mixed use approach in urban regeneration projects	J'sMSV is a mixed use area. It was founded around a transit center, Market Street And Euclid Ave, belonging to the category of Transit Village. The core of the mixed use area is the transit station, redesigned as a public space, which has the important function of being a meeting place for the community, a place for special events. Briefly, JsMSV is a modern version of Greek agora (Bernick-Cervero, 1997:5), and the transit station is also considered the connection with the region.	The planning process is the core of this kind of public-private partnership: public management of private money to rich community advantages. In Fort Point, the urban regeneration is considered in its broad sense, since it involves economic aspects, such as job creations and tax revenues, increasing of property values and advantages location for companies, and also a new urban context vision, with an open spaces system of more than 11 acres pursuing a better quality of life for people who live and work there (affordable housing, sustainable policies).	The main output from case study comparison, is that a strong partnership between public and the private community – led, could generate mixed use of space. Urban contexts assuming a new meaning with the role of catalyst for business and social services, fostering higher quality standards of life.
The role of the communities in urban regeneration initiatives	The community has played a key role in the processes of urban regeneration, indeed the case study could be considered as "pilot case study" for community participation. JsMSVshows the ability of individuals to cooperate with the planning forces for a strategic Joint Action. The participative intention has been crucial for the area, once considered as "food desert": a strong social network, financial resources, adequate planning actions, safe neighborhoods perception, with schools and services, improved development of local resources. Local community in particular represents the real driver of change, under a strong dynamic network that crates a virtual bridge of exchange with other communities. In order to support "community leaders", workshop and *charette* meetings made people working together on common goals, involving residents under common visions, solving problems, and developping action plans. A shared decision-making process to create new opportunities, following a consensus based approach, made residents critical mass in drawing, implementing, and evaluating works, preserving the community identity.	In Fort Point district the participation process has been strongly pursued since the BRA main goal, with planning implementation, was to reach public benefits through private investments. The participatory planning process is particularly important from the beginning to the end of the master plan drawing: *charette* and meetings have been regularly done in order to share the urban regeneration attempt of Fort Point District with the local community and all the main stakeholders. The core strategy is the direct involvement of people, companies and landowners of Fort Point District: each of them participated in different ways to realize this initiative. People, cultural and artist associations, through their sensitiveness and their strong sense of belonging; companies through their know-how and financial capability; landowners through their sense of place; public authorities giving the legal framework to which refer, by preserving the existent but encouraging a medium- long term vision of what it could be.	The comparison shows: in urban regeneration projects the involvment of the community has been crucial for the final outcome; two peculiar approaches, in both technical and sociological terms. The technical approach, related with the charrette meeting tool, means to support "community leaders" to work together on common goals, with the challenge to create new opportunities and functions for the master plan implementation; the sociological one consists in to bringing new economic opportunities, improving quality of lifestyle by creating livable neighborhoods, walkable and friendly, with improved health, education and community safety environment.

Table 1: Case studies insights.

In US we can see as this trend is increasingly involving private actors within the planning process, shifting toward a decentralized planning system in which local actors and stakeholders play a crucial role. Frequently, private organizations and planning consultants are hired from public – private coalitions to shape the vision of the future development of cities, or redevelopment, while addressing choices toward a consensus- based approach (McCann, 2001). So that the product is a sort of collaborative planning process

through meetings in which community representatives and local actors have a proactive role in shaping urban development, often institutional places of political struggle to affirm a kind of urban growth instrumental to political choices. As suggested by McCann (2001) the increase in privatization due to the reduced economic resources is improving a sort of lack of accountability of planning services with a wider popular critique of bureaucracy "in favor of a rhetoric in bottom up policy making" so that "urban policy is increasingly left in the hands of corporate-supported organizations" (MacCann, 2001:209) while no profits keep growing. Their role is increasingly gaining the ground in guiding people toward a right lifestyle, since a livable neighborhood is becoming a health related issue. Pedestrian and friendly environments are desirable actions to be pursued in urban regeneration initiatives in most of US cities affected by sprawl phenomenon: community acknowledgement here is a key factor to gain higher standards of urban environment, since the consensus allows to implement those actions easily. In some cases community involvement does not refer to a specific project or master plan, rather it is a mean to sensitize people toward a particular health issue: they are made aware of risks and possibility to be considered with respect to sustainability in urban regeneration initiatives or about gaps to be filled in order to reach higher standards of quality of life.

Then, in suburban landscapes these actions assume the role of physical identity restoration by taking into account the importance of the sense of community (Calthorpe 1993, Calthorpe and Fulton 2001). The outcome is twofold: on one hand social and health related organizations give strength to the social component of the planning process, addressing people to consider the city as a place they have to care of; on the other hand the community participation, oriented from private actors, sometimes seems to be politically influenced toward a decision. Otherwise, studies about community participation show how the more a community is represented by people with high level of culture, with a personal perspective about their neighborhood, the less this kind of guide is determinant for the final outcomes. With respect to the issue they want to face, government acts directly by providing grants or incentives for specific health programs in which no profit organizations are mediators between public and private actors (stakeholders) to teach communities which kind of built environment they should pretend to live in. Particularly, these programs are strongly linked with the spatial outcome they look for, mostly oriented toward mixed-use neighborhoods, to cope with urban sprawl for example, less car oriented rather pedestrian and bicycle enhancers. Consequently, although physical solutions do not allow to solve social and economic problems of communities (Leccese&McCormick, 2000) a supportive urban framework could address the right way to cope with those issues. Moreover, Bachin (2002:237) suggests that "the physical spaces of neighborhood may both encourage and impede the formation of community connectedness and also how the process by which neighbors relate to the physical space around them has implications for their ability to transcend economic, racial, ethnic, class, or religious boundaries". Generally the aim is to create more informed and engaged communities increasing the physical places where people can participate in and lead change following a inclusionary but also proactive approach.

5   CONCLUSION

David Harvey (1989:12) said that cities need to "keep ahead of the game [by] engendering leap-frogging innovations in life-styles, cultural forms, products, and service mixes… if they are to survive." This was a radical change, since it is about lifestyle, not life referred just to environment or air pollutions.

Assuming that spatial transformations inexorably affect social behaviors and cultural values, drawing from evidences of urban low density area characterized by isolation and lack of sense of place, it could be stated that physical interaction among different functions, enhancing a mix of uses and a compact urban environment, improve the achievement of balance in urban contexts previously characterized by strongly separation of functions. Community involvement is about inclusiveness, as far as procedures, transparency, as far as government transactions, accountability of planners to the citizens they work for: to cope with socio-economic inequality, sharing information, giving accessibility to knowledge. Then, the participation process is a way to strengthen a sense of "belonging to" that has to be preserved and enhanced because "The sense of community is formed and sustained over shared resources" (Perdikogianni , 2007:3).
Fig. 2: Community involvement and Public-Private Partnerships relations in implementing successful urban regeneration initiatives.

Drawing from case study evidences we might suggest a strong connection between community planning and urban regeneration initiatives, both fostered by public-private partnerships, in many context the first box of the second one. PPPs act as facilitators for making process decision in urban planning process in general and in urban regeneration initiatives in particular. Within already developed areas, characterized by a blighted built environment, urban regeneration implies community involvement, stakeholders participation, to successful overcome their status of decay; as far as new development areas, community involvement within the policy making process could improve the efficacy of planning implementation, following a consensus based approach. Local experiences of this kind show an empirical relationship between people attachment to place and local economic growth. So that it can be stated that in those particular cases social involvement affects spatial dimension and economic development: urban functions once separated gain a mixing use meaning that allows having healthier urban environments and local economic development. Moreover, the more community are linked each others, under a common network, the more they generate a virtuous circle of positive values and knowledge sharing.

Underground Space – Lost Space Ready to be Reclaimed

Han Admiraal, Antonia Cornaro

(Han Admiraal, Enprodes Management Consultancy, Heemraadssingel 245, NL 3023 CD Rotterdam, han.admiraal@enprodes.nl)
(Antonia Cornaro, Amberg Engineering, P.O. Box 27, CH-8105 Regensdorf-Watt, acornaro@amberg.ch)

1 ABSTRACT

'Lost spaces' can become interesting experimental areas within the urban fabric of cities. An example of this are former inner city docks that provide numerous opportunities for new uses and activities. Can lost spaces add to a city's diversity and also be part of social initiatives that lead to new social structures?

Apart from this question, the authors will be looking at a vast area of lost space, namely the space which exists underneath cities and is often overlooked. In the event that it is acknowledged as a part of the urban fabric, it is often seen as an urban service level, the space where we place the utilities. Those functions which we rather not have on the surface are readily placed below the surface. The authors will provide an overview of cases that demonstrate this, but will also propose a radically new approach which questions the wisdom of this choice.

This new approach is to see underground space not as lost space but as a valuable societal asset which can be integrated into the urban fabric and used in various ways. The value for society is that it provides new and additional spaces that actually compliment or further enhance livability on the surface. This can play a key role in common day urbanism based on density and mixed-use.

We will reveal that just like lost spaces in cities, underground spaces are unappreciated and often misjudged in terms of their potential. But just as with lost spaces, there are citizen initiatives which unlock the potential of underground spaces. The Lowline project in New York is a prime example of this (figure 1). The concept involves reusing a former, now disused underground tramway depot and unlocking its potential as a new public space in form of an underground park.

Figure 1: artist impression of the Lowline NYC (US), courtesy of RAAD Studio

The main difference between underground space and surface development is that below the surface there are no open spaces by definition. In a sense all spaces between underground developments are lost by definition. It means that any development should take this into account and contribute to creating connections and thereby public spaces. This requires not only planning but also management of underground space. The authors argue that just understanding the potential of underground space is not enough. The actual development will require a spatial dialogue between many stakeholders, including planners, engineers, developers and public decision makers. The extensive use of underground space beneath the City of Helsinki was achieved in this way: the creative reuse of former civil defense shelters, connecting them and planning future uses based on sound geological expertise.

Although unlocking the potential of underground lost spaces may seem daunting, the potential rewards for society are enormous. Many cities are struggling to cope with the ever increasing demands on space. Underground space can provide an interesting answer and should really be a standard component of modern urban planning.

2   LOST SPACES: THE CASE OF INNER CITY DOCKS

Inner city docks can become industrial wastelands when they lose their original function. They often influence the urban landscape surrounding them negatively as many examples worldwide illustrate. Revitalizing these areas can be a major challenge. In the city of Rotterdam a former inner city dock was reused in an innovative way. After closing off the dock from the river and pumping out the water, the space which was lost under water was reclaimed. A waste water treatment plant was then built in that reclaimed space. After completion the plant was covered and a city park scape created (figure 2a and 2b). This allowed for further urban development in an area which would have lost all its attractiveness had the plant been built on the surface (Cornaro & Admiraal).

Figure 2a and 2b: Dokhaven redevelopment Rotterdam (NL) before and after completion

In the same city, part of a former rail road yard was redeveloped into an urban farm. The farm produces not only for its own restaurant and shop but also supplies local restaurants and bakers. The urban farm itself attracts customers and serves as an information center on urban farming and on how citizens can become part of an initiative which focusses on creating awareness amongst citizens to seize the initiative and accept responsibility for greening their city (Pötz & Bleuzé). In this way, what at first was a simple initiative to reuse a, for all intent and purposes lost space, suddenly becomes a campaign for new social initiatives and creation of new social structures over time. Part of the success was using crowd funding to acquire the capital needed for the project and to create special advantages for those that contributed like special menus and seating in the restaurant.

The authors emphasize both these examples to underline the potential of what can happen if the concept of underground space is seen as an opportunity to reclaim lost spaces and to create opportunities for civic ecology practices (Krasny and Tidball). It requires us first to accept the concept of underground space, but also to look past that concept in terms of just using it as an urban basement or service level.

3   OUT OF SIGHT – OUT OF MIND

The concept of underground space is not new. It has been around for a long time and looked at from an abstract level as part of mankind's choice in terms of shelter: the cave or the tent. The cave is seen as synonymous for underground space: mankind creating modern day caves and in that way reclaiming lost spaces. Historical examples are the 'Yaodongs' in China, which were already being used before the start of the Common Era and are still in use today (figure 3). They provide shelter against the harsh environment on the surface. The Yaodong is of interest from a conceptual point because it demonstrates the concept of opening up underground space to the surface.

Although these historic examples are well known, it wasn't until the 19th century that engineers started thinking about building tunnels as part of the evolving railway networks. This made it possible to also start thinking about underground railway lines, thus the metro was born. But along with the idea of using underground space for these large conduits carrying trains and passengers, the underground space also proved an effective way of hiding what we didn't want to see on the surface. The Paris Sewers created by Hausmann are a good example of this. In many cities, by the beginning of the 20th Century, chaos was reigning in the underground space through uncoordinated use of it for utilities. By using underground space as an urban service layer, the concept of opening up underground space was lost as well. It was as if underground space was disconnected from the surface and became lost space. It was out of sight and out of mind.

The question which this raises is whether the concept of underground space is so limited that it can only be seen as the ultimate urban service level?

Figure 3: example of a Yaodong, China

4 A NEW APPROACH: OPENING UP UNDERGROUND SPACE

We have shown that the use of underground space evolved through the work of pioneers, exploring this vast lost space beneath cities. Their approach was to develop in a way that was for the larger part disconnected from surface activities. In a publication by the Government Planning Agency of the Netherlands in 2000, underground space was litterally portrayed as the final frontier (RPD, 2001). This comparison was not far from the truth in that in many cases underground space is used on a first come, first served basis. The first to stake his claim can use underground space irrespective of the question whether this is advantageous to society or not. Although the use is seemingly disconnected, at certain points, connections are made   in the case of underground metro lines, the staircases provide access to underground platforms or stations. But imagine if once again we could open up the underground space in such a way that it would be integrated into the urban fabric without citizens consciously thinking about whether they are above or underground. That is precisely what the next two examples propose.

4.1 New York City, Lower Eastside, the Lowline

Krasny and Tidball write about civic ecology practices as: "(…) self-organized stewardship initiatives, often taking place in cities". The Lowline project is an example of such an initiative. It is about pioneers who discover a lost space below the Lower Eastside of New York City. This lost space consists of a structure which extends three blocks and was used until 1948 as a station and balloon loop for streetcars. It has ceilings which are 6 meters high. The core idea of the Lowline is to become the inverse of the High Line initiative. The High Line is a former elevated railway line running through New York City and has been successfully transformed to an elevated linear park stretching over thirty city blocks. It provides the city with much needed public space but also has attracted flora and fauna amongst which endangered species as the Monarch butterfly. The Lowline is proposed to become an underground park by opening up parts of the structure to the surface allowing daylight to enter (see also figure 1). The founders see it as an invaluable public green space, providing the city with what it lacks: open public spaces where people can meet and relax. From a conceptual point of view this is a perfect example not only of reclaiming lost space, but also of how to integrate underground spaces into the urban fabric and how to use these spaces to strengthen social structures through creating places that people can share and where people can meet.

4.2 Osmose, the Paris metro station of the future

In a study commissioned by the Paris Transport Authority RATP, one of the proposals called for a new concept for an underground metro station. By literally opening up the underground to the surface on a grand scale, slopes are created which can perform various uses. These range from just relaxing and enjoying the surroundings to watching movies on a big screen. A density is created focused on a transport hub, but in such a way that quality is achieved and multi-functions are created. In this proposal what in reality often is a

mono-functional hidden and lost space, was dramatically transformed and integrated into the urban fabric and reclaimed for the city to use and enjoy (figure 4a and 4b).

5 APPRECIATING, PLANNING AND MANAGING

Appreciating the possibilities of underground space is just one step. The earlier mentioned concept of shelter illustrates this: tents can be placed, caves have to be created. The use of the underground space asks for an understanding of the geology and other factors which determine the possibilities from an engineering point of view. Underground space use also asks for an understanding of its possibilities. The first come first served strategy could prove to be disastrous in the long term. Not planning it will prove to be non-sustainable. Using underground space from an energy perspective (geothermal applications) can in itself lead to an exploitation that inhibits further use from a space perspective. The authors would like to stress that only through a spatial dialogue on the use of underground space between all parties involved, will it be possible to decide its best long term use.

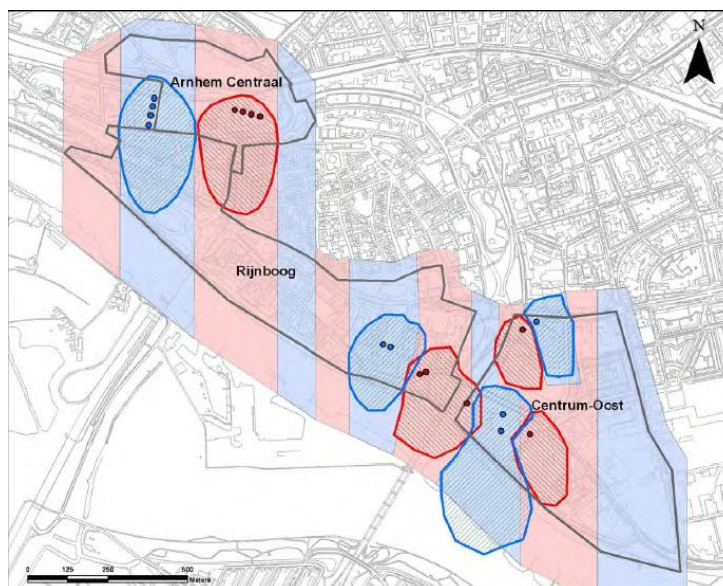
This is further illustrated by the zoning plan shown in figure 5. As the city planners conserve areas for storage of hot and cold water as part of hot-cold extraction schemes, other uses of underground space are ruled out. This could hold true for a larger part of underground space or just one layer, depending on the consistency of the water carrying layers.


Figure 5: underground zoning plan showing hot and cold zones for water storage schemes, City of Arnhem (NL)

The City of Helsinki is one of the few cities in the world that actually has an Underground Space Master Plan. The plan itself was driven by both the geology and existing structures. Large underground nuclear shelters were identified for reuse as car parks but also as a swimming pool (figure 6). The geology identified other areas for future spatial use, making it possible to connect facilities underground. Building underground metro lines provided excavated material which was reused by the city to backfill old docks and redevelop these into new waterfront properties. Helsinki clearly illustrates that to plan underground space one needs to know underground space in terms of its geology and understand the opportunities this gives.

Figure 6: Itäkeskus Swimming Pool, Helsinki (FI)

Planning the use of underground space from a wider perspective is paramount to the sustainable development of underground space. But in itself it's not enough. Underground space also needs to be actively managed because of the various resources that it contains, space being just one of those. Although most of underground space might be seen as lost space, it contains an enormous potential for cities if planned and managed in the right way. Not doing so will ultimately result in chaos and prevent future development and use.

6 CONCLUSION

The authors have shown that in terms of lost space, underground space can be taken to be a prime example of space lost to society. But just as lost spaces on the surface can be transformed, the same can be achieved below the surface with often surprising results. Integrating underground space into the urban fabric is a challenge which, when met, will provide spatial quality to a city. This cannot be achieved by just looking at underground space as a segregated urban service level. Planning and managing underground space is key to its sustainable development and ultimately providing the city with those spaces it desperately needs, but cannot provide at the surface.

1 ABSTRACT

Growing concerns about food prices, food security and the sustainability of the contemporary agri-food system reluctantly places food worldwide on the agendas of the authorities. It is emphasised that a re-integration of food(-production) in the urban system could mutually contribute to the sustainability of cities and agriculture. In highly urbanised countries like The Netherlands food production is a nearly exclusive rural issue, leading to a sharp boundary between the rural and urban environment. Is it possible to re-integrate agriculture, food production, in the urban system and if so what wil be the added value and how can it sustain in an urban environment?

We introduce the Dutch city of Almere, a fast growing city with 190,000 inhabitants 30 km Northeast of Amsterdam. Part of the cities' expansion plans is the transformation of approximately 4,000 ha polder area into a rural-urban fringe with a fixed amount of urban agriculture (50 %), housing (30 %), infrastructure and ditches and public green (20 %). This transformation should occur over the next 20 years through so called organic urban growth in which future inhabitants are evoked to create their own house, estate, neighbourhood, urban farm or enterprise. The development strategy titled "Almere Oosterwold: Estate for Initiatives" is a revolution in Dutch urban planning as it steps away from the current governmental dictate and top down planning. Almere Oosterwold is also a revolution in Dutch urban planning because of the pivotal position of food production -urban agriculture- in the plan. The idea is that world market oriented agriculture in the polder will alternate over the next 20 years to urban oriented agriculture.

We were challenged by the municipality of Almere to support them with elaborating strategies for the development of urban agriculture in Almere Oosterwold. We started with distinguishing the potential features of future urban agriculture in this area. Then these potential features were compared to current urban agricultural initiatives and enterprises in the Netherlands, leading to 12 types of urban agriculture. Subsequently, these 12 types of urban agriculture were detailed in requirements for development, like minimum size, needed infrastructure and legislation. Then we explored the opportunities and threats of developing these types in a rural-urban setting like Almere Oosterwold. Finally, the challenge was rendered to the municipality in a recommendation in which, zoning, pioneering and connecting were highlighted as the key elements of the development of urban agriculture in this area.

In the zoning strategy it crucial to prevent the change of land from urban agricultural use towards other uses, because urban agriculture is still an economically weaker function than housing, recreation or industry. Developing a trust in which the urban agricultural land is accommodated could be a strategy to prevent agricultural land to future urban sprawl. Because of the pivotal role of the urban agriculture on one hand and the lack of familiarity with it on the other hand, it is advised to provide pioneers with free space to experiment and improve. To coordinate and facilitate this free space the municipality should appoint an area manager. The access to the process of experimenting and improving provides the area manager (and the municipality) with new instruments (and rules) which support to conduct the development of this area. The pioneer space also can inspire newcomers. The transition of the environment subsequently will follow the path of both zoning and pioneering. Essential is that Almere Oosterwold from its foundation inextricably is connected to the city, physically as well as mentally, through infrastructure, and produce stream, and in the communication. This not only will be a responsibility of the municipality but of all stakeholders in the area.

2 INTRODUCTION

2.1 Urbanisation and agriculture; from distinct poles towards a re-union

In a highly urbanised country like The Netherlands there is a tendency towards a sharp delineation between the urban and rural environments. To some extent this sharp delineation has been the result of a strict (post

WWII) zoning policy (Koomen et al., 2008). The goal of this policy is to keep the landscape open and undeveloped, to limit travel distance and to support amenities (Van Remmen and van der Burg, 2008). This policy is fuelled by the fact that The Netherlands have to handle a relatively heavy urbanisation pressure; on the 3,4 million ha land, nearly 17 million people dwell, work, recreate and commute. The strict zoning policy has led to scarce space to develop which resulted in large price differences between land designated for housing, recreation or infrastructure and land designated for nature conservation or agricultural purposes (Cotteleer et al., 2007). As a consequence, when areas are labelled for (future) urban sprawl, the weaker economic functions like agriculture are pushed aside in favour of the stronger economic functions like housing and industry (Visser et al., 2009). This makes agricultural land, especially in the urban fringe, hard to safeguard from urbanisation, even as its values are appreciated (Koomen et al., 2008). Nevertheless, the Dutch policy of strict zoning and clustered urbanisation is regarded as successful because it leaves a decreasing, but still substantial, area for agriculture. In 2012 still 68 % of the land is in agricultural use (15 % for cities and infrastructure allotting 17 % for nature and recreation), leaving the floor for the Dutch Agro-food complex to act as second player at the global market (PBL, 2012; Berkhout et al., 2011).

The strict Dutch zoning policy has its drawback. A complete segregation of agriculture and urban development emerges, quite often even enshrined in physical planning theory and practice (Van der Schans and Wiskerke, 2012: 247). This segregation amplifies the already growing mental and physical distance between the city and its agriculture hinterland (Visser et al., 2009: 186). Where urban-rural linkages growing extinct, cities become increasingly dependent on the (global) Agro-food complex (Sonnino, 2009). A typical meal travels 3,000 km from farm to fork in the Western countries (Pearce, 2006). In the Netherlands food consumption accounts for one third of the national Greenhouse Gas emissions, partly due to these food miles (Vringer et al., 2010). Growing concerns about peak oil, food prices, food security and the sustainability of the contemporary global Agro-food complex discards a shade on the segregation between the urban and rural environment (Morgan and Sonnino, 2010; Ilieva, 2013).

We discussed that strict Dutch zoning policies have been safeguarding farm land from urbanisation. However, this policy combined with the development of a global Agri-food complex also has been leading to segregation between the urban and rural world. Recent urban interest in regional food policies could put farming in the peri-urban area in another daylight (Zasada, 2011). Peri-urban farming already differentiated or diversified to some extent their economic activities in the Netherlands over the past years to meet the urban interest (Van der Schans, 2010). However, peri-urban farms still have to compete with strong economic factors like housing, leisure and business & industry development. The question is whether a peri-urban (planning) policy could stimulate the development of these differentiated or diversified farms in the peri-urban zone and at the same time could protect farming against (future) urban sprawl. Based on two cases in Provence and Tuscany Perrin (2012) concludes that farmland protection in peri-urban areas is more effective when top-down policies are connected with bottom-up initiatives. In his literature review Zasada (2011:646) concludes that the peri-urban area needs to be recognised as an individual policy arena to overcome the rural-urban divide and strengthen urban-rural relationships. This stresses that a policy focused at the peri-urban area is needed to develop peri-urban farm activities.

In this paper we introduce the case of Almere Oosterwold (NL) where the transition of world market oriented farming towards diversified or multifunctional (peri-) urban farming is intended by the municipality of Almere (190.000 inhabitants). This transition should take place over the next 20 years in an area of approximately 4.000 ha east of the city boundaries. Starting point is an open polder landscape where 50 arable and dairy farms have been producing for the world market and where diversified farming activities are lacking. How to build a new diversified peri-urban landscape when bottom-up initiatives in peri-urban agriculture are nearly absent? What should a peri-urban policy arena in Almere Oosterwold look like? We argue that only a change in zoning policy is not enough to transform the features of this area. Because of the pivotal role of (peri-) urban agriculture in this area and the lack of familiarity with it, the city should develop a policy plan with three central issues: land ownership, pioneering with multifunctional urban and peri-urban agriculture, and physically and mentally connecting the area with the city.

Before starting with the case of Almere Oosterwold we will discuss urban agriculture, because of its key role in this case.

2.2 (Peri-)Urban Agriculture: definition

The concept of '(peri-)urban agriculture' knows many definitions, with differences regarding the activities it entails, what is being produced, the place where the activities occur, who is involved, and whether the activities are public or not (Mougeot, 2000; Veen et al., 2012). What most scholars agree about, however, is that urban agriculture is different from and complementary to the current rural agriculture: the lead feature of [urban agriculture] which distinguishes it from rural agriculture is its integration into the urban economic and ecological system (Mougeot 2000:9). It is not its (peri-)urban location which distinguishes urban agriculture from rural agriculture. Van Veenhuizen and Danso (2007:6) deduce, referring to Mougeot (2000), that the most important distinguishing feature of urban agriculture is that it is an integral part of the urban economic, social and ecological system. It depends on typical urban resources, competing for land and water with other urban functions, influenced by urban policies and plans, and contributes to urban social and economic development (Van Veenhuizen and Danso, 2007). Hence, urban agriculture uses resources, products and services found in and around the city and supplies resources, products and services for local consumption in return (de Zeeuw et al., 2011).

In this paper we define urban agriculture as Mougeot (2000:10) does:

UA [Urban agriculture] is an industry located within (intra-urban) or on the fringe (peri-urban) of a town, a city or a metropolis, which grows or raises, processes and distributes a diversity of food and non-food products, (re-)using largely human and material resources, products and services found in and around that urban area, and in turn supplying human and material resources, products and services largely to that urban area.

2.3 (Peri-)Urban Agriculture in planning

'Politicians and planners are faced with many competing claims for the use of scarce land in and around cities in industrialized countries' (Deelstra et al., 2001: 1). As argued before, this specifically holds for the Netherlands, where population density is high. When land is scarce, it pays off to combine several functions. That way various demands can be satisfied at once (Deelstra et al., 2001). Therefore it is important for (Peri-) urban planners to find complementary uses of land, creating win-win situations (Campbell, 1996). (Peri-) Urban agriculture could offer these complementary uses because it combines functions. It not only provides urban society with fresh food at short distance, but in the Netherlands it combines this with societal functions like education, recreation or care (Van der Schans, 2010). More importantly, growing food inside or in the vicinity of the city is itself associated with benefits for society. Hence, food production is multifunctional in nature: it links to public health, environment and social justice (Morgan, 2009). Agriculture is therefore an effective tool to make productive use of urban open spaces (Mougeot, 2000). Moreover, there is a reasonable demand among urban public for multiple functions and value from farming (Zasada, 2011: 646).

(Peri-) Urban agriculture, however, is largely ignored in urban and regional planning (Taylor Lovell, 2010). This holds for the Netherlands too (Van der Schans, 2010). One of the reasons is that urban agriculture does not have an institutional home. The obvious home of urban agriculture should be the Ministry of agriculture but this ministry may lack the political mandate for urban agriculture. In the Netherlands spatial and urban planning is part of the ministry responsible for housing and spatial planning. The focus of this ministry is urban development city development, whereas agriculture, conservation and landscape development is the responsibility of the Ministry of agriculture. However, the focus of the national spatial planning is changing. Spatial planning is partly handed towards local authorities, providing them more freedom to facilitate local spatial developments (Koomen et al., 2008). This act leaves the floor, to a certain extent, to cities to develop their own spatial and urban planning, which may open the door to (peri-) urban agriculture.

This is the moment to introduce the Dutch city of Almere, a city where local authorities embraced this freedom in developing its own spatial development plan: Almere 2.0 (Almere, 2009). A plan in which it involved (peri-) urban agriculture as part of a new area: Almere Oosterwold.

In the chapter 3 we briefly introduce Almere and then make a step towards Almere Oosterwold.

3 CASE OF ALMERE OOSTERWOLD

Almere is the youngest city of the Netherlands and is located in the province of Flevoland, 30 km east of Amsterdam (figure 1). Planned in the early 1970s on land reclaimed from the sea at the Western edge of the

latest IJselmeerpolder, the layout and design of this suburban city is completely different from other Dutch cities (Roorda et al,. 2011). The original poly-nuclear design of Almere, inspired by the English garden cities of Ebenezer Howard, is unique in the Netherlands (Remmers, 2011). Almere consists of a city centre surrounded by several satellite towns, with large forests, parks, canals and ponds between them (Jansma and Visser, 2011). The original development plans for Almere started from a clear design hierarchy that put landscape above the urban districts, meaning that the green landscape shaped the framework for the lay out of the city districts (Roorda et al., 2011: 66). The large green spaces between its urban nodes were meant to facilitate the connection of agriculture and nature with urban life (Zalm and Oosterhoff, 2010). Almere has grown from zero inhabitants in 1975 to 190.000 inhabitants in 2010 (Remmers, 2011). In its eagerness to grow residential expansion took over the agenda leaving less space for the development of the landscape and open-space (Ilieva, 2013). However, Almere is still this poly-nuclear city with much more green and blue within its borders than average Dutch cities. 80 % of the total surface of Almere is water, woodlands, parks or nature reserve (Almere, 2006). Although part of its origional lay out, urban agriculture was never developed properly, aside from one commercial city farm in the city's fringe (Dekking et al., 2007; Remmers, 2011).

Because of the growing need for new housing in the Amsterdam and Utrecht areas and the absence of locations on the 'old' land, Almere is expected to expand to 350,000 inhabitants by 2030 (Almere, 2009) This expansion, organised by the Almere 2.0 program in which the city cooperates with national and local partners, is part of a national task to reconstruct the Dutch North Metropolis area (Amsterdam-Almere-Utrecht). In anticipation to this Almere 2.0 program, the city introduced the seven Almere Principles: cultivate diversity, connect place and context, combine city and nature, anticipate change, continue innovation, design healthy systems and empower people to make the city (Almere, 2008). The Almere Principles are a result of a close collaboration between Almere and William Mc Donough (the Cradle to Cradle approach). They are intiated by an ambitious aldermen responsible for the Almere 2.0 plan (Jansma and Visser, 2011). These Principles (Figure 2) were developed to direct the city to a sustainable development, as well as support the retrieval of the city's identity, i.e. developing a peoples' city (Remmers, 2011). Almere coined urban farming as one of the vehicles to achieve these ambitions (Remmers, 2011). Moreover, it is the city's desire to produce 10 % of its food locally by the year 2030 (Almere, 2009; Jansma et al., 2012).

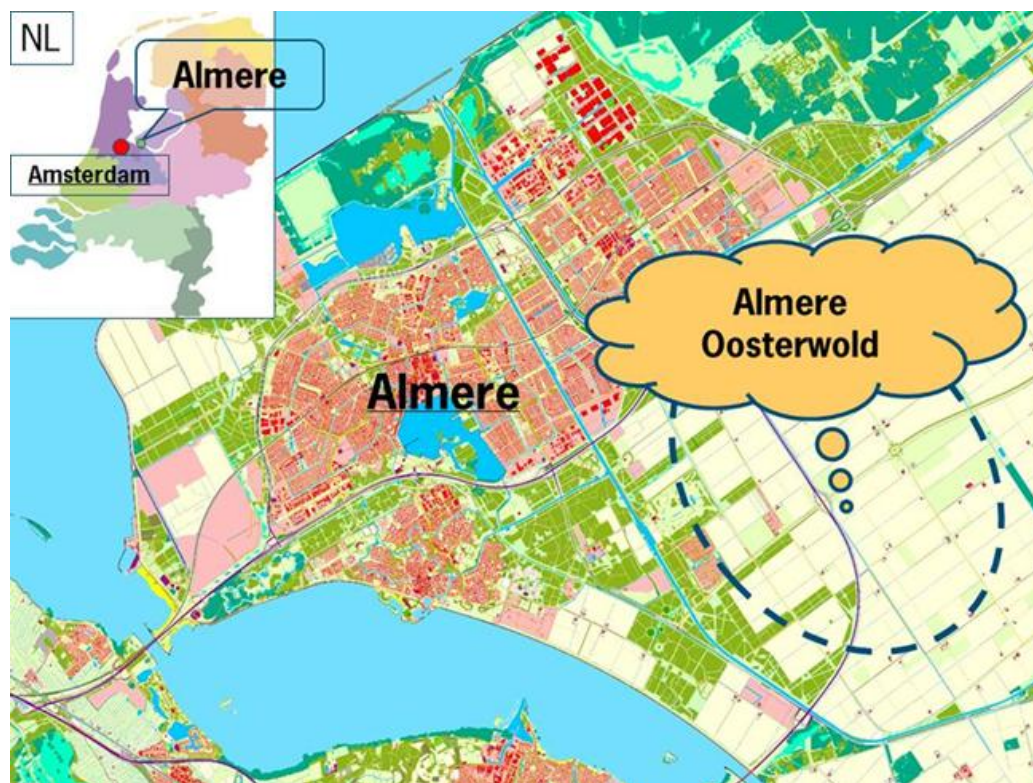

Figure 1. Almere is a new town in the Dutch province of Flevoland with 190,000 inhabitants (2010). As part of its expansion plans, 15,000 new houses on approximately 4,000 ha are planned east of the city: Almere Oosterwold.

Part of the Almere 2.0 program is the transformation of approximately 4,000 ha polder area into a rural-urban fringe with a fixed minimum amount of urban agriculture (50 %) producing for the regional market (Almere, 2012). The remainder is available for housing (30 %) and infrastructure, ditches and public green (20 %). The city's ambition is to develop this conventional agricultural polder area through entrepreneurship and citizens' initiatives towards 'Continous Productive Urban Landscapes' (referring to the CPULs: Bohn and Viljoen, 2005), producing food, energy, resources and water within and for the city (Van Oost and De Nood, 2010). This transformation should ensue over the following 20 years through a so-called 'organic' (i.e. step by step approach or gradual) urban growth. A fundament under this organic development is that there is no fixed development plan. The autorities provide future residents with only a set of rules, the so-called area s' pasport (Almere, 2012). This leaves the floor to future residents to create their own house, estate, neighbourhood, enterprise or urban farm. Moreover, the future residents are challenged to create the area s' genuine identity, the Do It Youtself Urbanism -DIYU- planning paradigm (Almere, 2012; Ilieva, 2013). This development strategy, titled "Almere Oosterwold: Estate for Initiatives", is a revolution in Dutch urban planning as it steps away from the national dictate and top down planning (Almere, 2012). Almere Oosterwold is also a revolution in Dutch urban planning because of the pivotal position of food production – urban agriculture – in the plan (Almere, 2011; Jansma and Visser, 2011).

> **The Almere Principles**
> **For an ecologically, socially and economically sustainable future of Almere 2030:**
> **1. Cultivate Diversity**
> To enrich the city we acknowledge diversity as a defining characteristic of robust ecological, social and economic systems. By appraising and stimulating diversity in all areas, we can ensure Almere will continue to grow and thrive as a city rich in variety.
> **2. Connect Place and context**
> To connect the city we will strengthen and enhance her identity. Based on its own strength and on mutual benefit, the city will maintain active relationships with its surrounding communities at large.
> **3. Combine city and nature**
> To give meaning to the city we will consciously aim to bring about unique and lasting combinations of the urban and natural fabric, and raise awareness of human interconnectedness with nature.
> **4. Anticipate change**
> To honour the evolution of the city we will incorporate generous flexibility and adaptability in our plans and programs, in order to facilitate unpredictable opportunities for future generations.
> **5. Continue innovation**
> To advance the city we will encourage improved processes, technologies and infrastructures, and we will support experimentation and the exchange of knowledge.
> **6. Design healthy systems**
> To sustain the city we will utilize 'cradle to cradle' solutions, recognizing the interdependent, at all scales, of ecological, social and economic health.
> **7. Empower people to make the city**
> Acknowledging citizens to be the driving force in creating, keeping and sustaining the city, we facilitate opportunities
> The words of the Almere Principles will come alive and become meaningful through human action, by incorporating them on each level into every design for the city as whole.

Figure 2. The Almere Principles (source: Remmers, 2011)

The aim of Almere is that over the next 20 years Almere Oosterwold organically transforms to a rural-urban area with at least 50 % regional oriented (peri-)urban agriculture. To establish this huge ambition, Almere founded the subsidiary Almere Oosterwold in which the major regional representatives participate in 2010. The main task of this subsidiary is to develop a strategic development plan (which includes a basic set of rules for developing in the area, i.e. the area's pasport) which supports the start of the organic transformation of Almere Oosterwold. The ambition is to start in 2013 with the first steps of the transformation of the area. However, the current features of this Almere Oosterwold area do not attract people to develop their house, estate or farm there. The area consists of a large-scale polder layout developed in the late 1960s-early 1970s (Figure 3, top left). The majority of the approximately 50 present-day farms in this area are large-scale (>50 ha) modern arable or dairy farms producing for the global market. Because of the the pivotal role of (peri-)urban farming in the future area and the non-inviting features of the area, the subsidairy of Almere Oosterwold decided to start with leaving the floor to the development of urban agriculture.

Figure 3. The intended step by step transformation of current Almere Oosterwold (top left) to the rual –urban area (bottom right) over the next 20 years (source: Almere, 2012).

In 2011 we were challenged to by the susidiary Almere Oosterwold to support them with elaborating strategies for the organic development of urban agriculture in Almere Oosterwold. In the following part we will explain the subsequent steps in the development strategy we adviced to the subsidairy of Almere Oosterwold.

4   DEVELOPMENT OF PERI-URBAN AGRICULTURE IN ALMERE OOSTERWOLD

The starting point of our journey towards peri-urban agriculture in Almere Oosterwold was to distinguish the characteristics of the future agriculture in this area. That isn't easy because, there are few examples in practice of food production properly planned in and around cites as a systematic approach to build greener and more sustainable metropoles (Van der Schans and Wiskerke, 2012: 250). Using the ideas behind the Almere Principles, urban agriculture only can work if it is an integral part of the city's social, economic and environmental system. This directed us to the potential benefits of urban agriculture using the work of Van Veenhuizen and Danso (2007) and de Zeeuw et al. (2011). These authors recognise three dimensions of urban agriculture; 1) a food-secure and inclusive city; 2) an environmentally healthy city; and, 3) a productive city. Just as Van der Schans and Wiskerke (2012: 251) adapted this model (to manifestations and policy aspects of urban agricuture), we also took this model as our starting point. As the three themes recognised in the work of Van Veenhuizen and Danso (2007) and de Zeeuw et al. (2011) have similarity with the three dimensions of sustainability – people, planet and profit – we combined them. This led to three major aspects of urban agriculture; 'our city', 'healthy city' and 'economic city'.

We then combined these three major aspects with current urban policy issues. The idea behind this is that as urban agriculture is an integral part of the urban system, it can contribute to finding solutions to such issues. This would make clear how a city can benefit from urban agriculture, and for what types of issues urban agriculture can be deployed. Starting point for these policy issues was an exploration by Veen and Mul (2010) who studied policy issues of four major cities in the Netherlands (Rotterdam, Groningen, Tilburg and Almere) during the regional elections of 2010. The authors listed and aggregated the main policy issues in these four cities, looking specifically at those issues that could benefit from urban agriculture. Issues that were similar were combined, or joined under the same heading. This process led to six major policy issues to which urban agriculture can potentially contribute; society, learning and working, recreation and leisure, living environment, food and health, and sustainability (Veen and Mul, 2010).

The next step was to combine the three major aspects (our city, healthy city and economic city) with these six major policy issues. Within these six major policy issues, we made six couples of two themes using the list of main poliy issues during the regional elections of 2010. Three of these couples – Added value, sustainability, and participation – fall within one of the three major aspects of the urban agriculture city. The other three couples – learning and working, liveability, and health – fall within two adjacent aspects, that

way connecting our city, healthy city and economic city. By making these connections, we recognise that urban agriculture can contribute to various issues and that such issues cannot be perfectly separated. Graphically represented, this resulted in Figure 4.

Figure 4. The twelve policy themes of urban agriculture based on a survey in four Dutch cities during local elections of 2010.

Subsequently, we coupled each of the twelve themes from Figure 4 with a current initiative, concept or enterprise in the Netherlands. As urban agriculture is multifunctional, a specific initiative would fit several themes, but for each theme we chose an example that would be most explanatory or illustrating. Hence, this is not to say that an example would not fit within another theme. Table 1 shows the twelve themes and the twelve respective examples. In the table we also mention the estimated required size and location for this type of initiative, requirements for succesful development and chances and obstacles for development. This way, the twelve examples can be seen as twelve 'prototypes' of urban agriculture.

At least six of these prototypes have te potential to be a part of future Almere Oosterwold. These prototypes require a minimum size of land starting with 5 ha. The smaller urban agriculture initiatives problably will start in the vicinity of the city, where the more production oriented ones will flourish at a some distance of the city. The land available for urban agriculture should be preserved for a long period (> 10 years). So the zoning policy for this area should provide these minimum sets of land throughout the area and prevent these to future urban sprawl. Developing a trust in which the peri-urban agricultural land is accommodated could be a strategy to prevent agricultural land to future urban sprawl. This land conserving trust could also provide newcomers from outside the area with land to establish their urban agriculture initiative. This new input is possibly needed. A survey carried out in 2011 with 15 current entrepreneurs from the Almere Oosterwold area shows that only a quarter to half of them are potentially interested in a conversion to an urban-oriented agriculture. The different prototypes do face potential obstacles like accessibility, distance to the city, infrastructure and logistics and distribution of the produce (Table 1). A set of rules and instruments could help to overcome these obstacles. The question is which roles urban agriculture on one hande and the susidiary Almere Oosterwold (or municipality) should play in the organic development of the area. Moreover, the question is also who has the lead in solving the obstacles because there will be no fixed plan. In an area unfamiliar with urban agriculture, moreover unfamiliar with organic development, it is hard to indentify who should have the lead. Hence, to develop a dynamic set of rules (and instruments) it is advised to provide the pioneers in urban agriculture with free space to experiment. In order to coordinate and facilitate this free space the municipality should appoint an area manager. The access to the process of experimenting and improving provides the area manager (and the municipality) new instruments

(and rules) to conduct the development of this area. The pioneer space also can inspire newcomers or the current farmers in the area. In the path of both zoning and pioneering the transition of the environment will follow. It this transition proces new residents are challanged to settle in the area. Essential is that from the foundation of Almere Oosterwold the area inextricably is connected to the city, physically as well as mentally, through infrastructure, and produce stream, and in the communication. This not only will be a responsibility of the municipality but of all stakeholders in the area. The (peri-) urban agriculture in the area has a pivotal role because it seduces residents of Almere into the area and also delivers their produces to the city. Urban agriculture in Almere Oosterwold is in a way the first step towards a reconnection of the urban and rural environment.

5   CONCLUSION

In this paper we introduce the case of Almere Oosterwold (NL), an area of approximately 4.000 ha east of the city boundaries. This area should organically alter from a open polder area with world market oriented agriculture towards an (peri-) urban area with diversified or multifunctional (peri-) urban farming and housing. This transition should take place over the next 20 years in. Starting point is a polder landscape where 50 arable and dairy farms have been producing for the world market and where diversified farming activities are lacking. We asked ourselves how to develop a new diversified peri-urban landscape with a central role for (peri-) urban agriculture when bottom-up initiatives in peri-urban agriculture are nearly lacking? Using the ideas behind the Almere Principles, we argued that urban agriculture only can work if it is an integral part of the city's social, economic and environmental system. This directed us to the potential benefits of urban agriculture translated in three major aspects of urban agriculture; 'our city', 'healthy city' and 'economic city'. Based on current policy issues we discerned twelve themes within these three major aspects of urban agriculture. These twelve themes were visualized through connecting each with a current urban agriculture initiative or concept. These are the prototypes of (peri-) urban agriculture which could potentionally be developed in this area. We argued that only a change in zoning policy is not enough to develop these type of (peri-) urban farming. Because of the pivotal role of (peri-) urban agriculture in this area and the lack of familiarity with it, the city should develop a policy plan with three central topics: land ownership, pioneering with multifunctional urban and peri-urban agriculture, and physically and mentally connecting the area with the city. These three topics are the first steps to guide Almere towards a process of reconnecting the urban and rural environment.

A

Policy theme	Example	Optimal/required size	Optimal location	Requirements	Chances	Obstacles
Employment (Economic City)	Ridammerhoeve, an organic goat farm open to the public. 250.000 visitors a year. Offers app. 10 full time jobs. Cheese making, playground, education and conference centre, pet farm (http://www.geitenboerderij.nl/).	5 - 25 hectares	Peri-urban	Flexibility in rules and regulations, e.g. regarding zoning and licenses	Commercially viable	Difficult balance between agriculture and activities
					Many employees necessary	Municipal flexibility needed for room to develop, zoning and permits
				Finding a balance between agricultural work and activities for visitors	Employment in different areas	Specific infra structure needed: accessibility, parking, bike routes
					Farm rents land from municipality	Land is scarce and expensive; long term land lease
				Easy accessible to the public	New business	
Added value	Stadsboerderij Almere, organic urban farm. Beef cattle, arable and vegetable farming. Meadows and fields spread over the city. Care, farmers market, new artisan business and education (http://www.stadsboerderijalmere.nl/).	50 > hectares	Peri-urban	Security of access to land over longer period	Commercially viable, close market	Land is scarce and expensive
					Different activities means involving many people in food production	Difficult to get long-term land lease
				Access to market, small distance to market	Through education sustainable connections with citizens	Building a sustainable distribution system within the city: economically and environmentally
					Connections with citizens gives right of existence	
Indirect benefits	Doarpstún Snakkerburen, community garden. Various vegetables grown, sold in garden shop. Run by volunteers. Cultural activities organised, meeting place for neighbourhood, education (http://www.dedoarpstun.nl/).	< 1 hectares	Urban	Access to volunteers	When indirect benefits known, it is more clear what urban agriculture can bring	Indirect benefits like better health or beautiful neighborhood often unclear
					This particular example does not get subsidies and manages, even pays rent	Sometimes hard to find volunteers for running the garden
				Access to finances	A meeting place for different people	Finances for similar projects are hard to find
Attractive neighborhoods	Community garden Parmenidesstraat, Amsterdam. Community garden surrounded by housing block. Started by housing corporation, twelve residents have private plot. Design made together (http://www.buitenruimtevoorcontact.nl/projecten/moestuin-in-wijsgerenbuurt-amsterdam).	< 1 hectares	Urban	Access to open space for a longer period of time	Involves people in their neighborhood and strengthens feelings of ownership and increases social contacts	Longterm agreements with municipality
					Multifunctional use of land available due to the financial crisis	
				Ambitious people in neighborhood	A way to prevent people from moving out of the neighborhood	People in (mixed) neighborhoods may not be used to work together, takes time and maybe set of rules
					A more attractive neighborhood makes higher rents possible	

B

Policy theme	Example	Optimal/required size	Optimal location	Requirements	Chances	Obstacles
Living environment (Healthy city)	Creatief Beheer, organisation that sees maintenance of green areas as vital for neighbourhood improvement. Works with all neighbourhood stakeholders and improves the quality of the neighbourhood with the residents. Human interaction is central (http://www.creatiefbeheer.nl).	< 1 hectares (area)	Urban	Access to open spots for a longer period of time	Multifunctional use of (derelict) urban spots, opposing degradation	People in (mixed) neighborhoods may not be used to work together, takes time and maybe set of rules
				Freedom to change the neighborhood landscape	A way to prevent people from moving out of the neighborhood	
					Brings people together, increases social contacts	Municipal flexibility needed for room re-furnish neighborhood
Environment	Agromere, a virtual city district on 250 ha. Closing the nutrient cycle is one of the targets of this concept (www.agromere.wur.nl). which integrates living space on 70 ha (for 5,000 inhabitants) with 180 ha urban agriculture.	> 50 hectares	Peri-urban	Closing nutrient cycles requires flexibility in rules and regulations	Closing cycles by (re) using organic waste cycles	It is not permitted to re-use human urine and faeces
					Closing cycles is possible on different scales	Besides using household waste, other ways to close cycles are still far, although small systems are working
					Composting household waste improves soils	
				Closing nutrient cycles requires more technical possibilities	Possible to re-use phosphate and nitrogen	Large-scale waste processing is bound by strict rules
					Agricultural and urban waste can be used to produce bio-energy	Continuity in deliverance of energy can be problematic
					Urban agriculture as incubator for innovations	
Climate	Oregional, short food chain by farmers. Cooperation sells products from the twenty members directly to buyers in the region, like restaurants and hospitals. (http://www.oregional.nl).	Not applicable	Peri-urban	Good cooperation between farmers	Potentionally lower foodmiles	As consumers make most food miles and large-scale food systems are very efficient, it is unclear to what extent food miles are really reduced
					Less links needed in the food chain, higher price for farmers produce	Small-scale local food processing may be less efficient in energy use
				Efficient logistics	Fresher products	
					Added value remains in the local area	
Food and health	Bioakker, organic harvest-it-yourself garden. Maintained by entrepreneur. Members pay initial amount, subtract the value of what they harvest. Members are invited to help with the gardening work. Prices are low to make it widely available (http://www.bioakker.nl).	1 - 5 hectares	Urban	Producing space of good quality, large enough and accessible, long term lease	Awareness of local and seasonal food increases	Space to produce - good quality, accessible, large enough - is scarce in the city
					Multifunctional use of the land available due to the financial crisis	Temporality of land may put entrepreneurs off
					Direct relation with producer of food	Policy and regulation not yet suitable for large-scale
				Flexibility in policies and regulations with regards to commercial food production in the city	Fresh food is available and close by	In this example: garden not close to supermarket which is an obstacle for visiting
					Short supply chain	

C

Policy theme	Example	Optimal/required size	Optimal location	Requirements	Chances	Obstacles
Care and well-being (Our city)	Moestuin Maarschalkerweerd, organic urban care farm. Daily activities and reintegration trajectory for people with distance to employment. Work in garden, lunch cafe and shop. Playground and educational projects (http://www.moestuinutrecht.nl).	5 - 25 hectares	Peri-urban	(Government) funding to pay for care	Various benefits for people when working in green environment; stress release, daily rhythm, working with others	Pressure on income from care due to cuts in funding
				Available space close to public, long-term lease		Land is scarce and expensive; long term land lease
					Care farm in the urban fringe less far than in rural area, less travelling	Specific infra structure needed: accessibility, parking, bike routes
Participation and cohesion	Moestuinjes IJburg, small individual garden containers on unused land in Amsterdam. Allotment complex founded, residents hire three containers. The municipality takes care to furnish the site (http://debrugkrant.nl/volkstuintjes-op-braak-liggende-kavel-haveneiland).	Containers of 1m²	Urban	Effort to include different groups in the project	Project is mobile and can be moved	Some people or groups may be left out
				Flexibility in policies and regulations in order to use public space	People work together to beautify their area	When the project moves, this may lead to disappointment
Leisure and recreation	t Geertje, organic recreational farm. Mostly goats but also milking cows, pigs, chickens and horses. Cheese making, sold in farm shop and farm restaurant. Hiring boats, canoes and bikes. Overnight accomodation, company outings, childrens parties, bachelor parties. 100.000 visitors yearly (http://www.hetgeertje.nl).	25-50 hectares	Peri-urban	Consistency in rules and regulations; recreational farms need to comply with both agricultural and recreational regulations	The target group is close, increases social contacts	Too many visitors can lead to nuisance for local residents
					Diversified activities offers extra income to farmer	Land is scarce and expensive; long term land lease
				Rules to minimise nuisance (noise, smell, traffic)	(Peri-Urban) farms fit with what people are looking for; leisure, green space, animals	Regulation can be an obstacle, as farms need to comply with agricultural and recreational regulation, which may be contradictory
Education	Burdje op 'e Skoalle, agriculture lessons in schools. Primary school students get one full day and two half days workshops on food and agriculture from secondary vocational students, for whom this is part of their curriculum (http://vimeo.com/45890484).	Not applicable	Both are suitable	Flexibility in school programmes so that there is space for these types of classes	Offers opportunities to teach children how food grows	Schools have to comply with strict programmes in which it is hard to find space
					Education is possible in diverse urban agriculture initiatives	Schools do not always have the financial means or staff to join
					Especially working with the harvested food is a tool to involve parents and local residents	It may be harder to reach adolescents through urban agriculture
				Classes should be free and staffed as most primary schools may not have financial means or staff	Agriculture can be used for various subjects, from maths to biology and drawing	
					Especially useful for children for whom cognitive learning is harder	

Table 1. Three major aspects of urban agriculture; A: 'economic city', B 'healthy city' and C 'our city' divided in twelve policy themes. Each of the twelve themes is coupled with a current initiative, concept or enterprise of (peri-) urban agriculture in the Netherlands. The table also mentions subsequently the estimated required size and location for this type of initiative, requirements for succesful development and chances and obstacles for the development. This table was adjusted from Veen et al. (2012) and Jansma et al. (2011).

Urban Dimension of Territorial Cohesion: Perspective Facing the Crisis

Maria Prezioso, Angela D'Orazio

(Prof. Maria Prezioso, University of Rome 'Tor Vergata', maria.prezioso@uniroma2.it)
(Dr. Angela D'Orazio, University of Rome 'Tor Vergata, ad_orazio@yahoo.it)

1 ABSTRACT[1]

The Territorial Agenda highlighted in 2007 the increasing influence of European policies on the territory.

On one hand these policies, adopting an integrated and strategic territorial approach, should take into account as soon as possible the development potentials at local, regional and national level as well as the stakeholders directions. On the other hand the strategies devoted to specific development of cities and regions have to enter more explicitly both in national and European framework. It was considered essential that regional, local and national issues were articulated with Community policies, with particular reference to rural development policies, environmental and transport policies but also to cohesion. In this context, the Leipzig Charter on Sustainable European City was fully inserted in the Territorial Agenda since the Chart promoted an integrated policy for urban development as a task of the European dimension. Integrated urban development policy and territorial cohesion policy were seen then as two complementary contributions to the realization of sustainable development. The entry into force of the new Treaty of Lisbon (2009), provided a more solid basis for action on territorial domain: Cohesion policy aims to articulate more and more according to a multidimensional view that aspires to be economic, social and, above all, territorial.

Meanwhile, the global economic and financial crisis occurs. A crisis affecting Europe, too, and that in part undermines the macroeconomic convergence achieved by cohesion policy.

Economic, social and territorial cohesion remains at the center of the most recent policy document prepared by the Commission: Europe 2020, which should be the reference for the next ten years as at the time was for the Lisbon-Gothenburg Strategy. The vision for Europe is that of a smart, sustainable and inclusive 'growth'.

The Territorial Agenda renewed in 2011, which not surprisingly is called TA 2020, taking as fundamental the objectives assumed in the Leipzig Charter (and in the other documents on urban development as the Declarations of Marseille and Toledo), however, considers the cities as engines for smart, sustainable and inclusive 'development' and promotes them as attractive places to live, to visit and where to invest. But the TA sees also as the deprived urban areas, the existence of which is often hidden from official statistics, can be a special place of exclusion. The urban regeneration policies are seen as a potential support for local development where it is necessary to adopt an integrated and multi-level approach.

The development process of European policy is profoundly affected by the ongoing processes of change at the global scale. On one side are recognized structural characteristics of the economic crisis and, on the other, there is a clear need for choices no longer be postponed in relation to 'energy model' development both in terms of security of supply and the fight against climate change.

The dialogue between macroeconomic policies and territorial development policies seems increasingly involve a local development model that refers to different disciplines and different social practices.

The starting point is the idea that the development of different regions follow different paths and that the residual factors not explained by classic or Neo-Keynesian economic theory are of endogenous nature and often intangible. Regarding the contribution of local development to cohesion policy, the Barca report on a place-based policy emphasizes that local development is likely to increase the efficiency of Community funding through increased concentration of structural funds at the local level and by virtue better management of local projects, selected on the basis of eligibility criteria and subject to monitoring and evaluation.

The current phase is crucial for the determination of the guidelines for the next programming period post-2013. The proposal for a New Regulation 2014-2020 precisely in relation to the 'new objective' territorial cohesion refers to the need to address the role of cities, functional geographical areas and sub-regional territories which have specific geographic or demographic problems. To this end, in order to better enhance the potential at the local level, the local development initiatives should be strengthened and facilitated,

---

making sure they are participatory, establishing common standards and providing close coordination for all the funds of the Community Support Framework.

Territorial cohesion implies here explicitly sustainable urban development to which the ERDF allocates at least 5 % of the resources devoted to integrated actions in this field for each Member State (with investments from different channels). In addition, the Commission will launch calls for innovative actions in urban areas and make ESF human capital investments in cities easier.The framework laid down in the new Partnership Agreement implies a structured participatory process and the definition of strategies and priorities at the national and regional level for the construction of local development strategies at the urban scale. To do this requires elements of 'knowledge of the land' and the construction of a knowledge base for the development and monitoring of the actions that require a new focus on the ability of local authorities in driving initiatives.

Starting from these considerations, the contribution aims to investigate the past and current areas of action of the European policy and to explore which dimensions of territorial cohesion are typical of urban scale and what kind of policies should be taken.

2 IL QUADRO DI RIFERIMENTO

Nel 2007 la Territorial Agenda dell'Unione Europea sottolineava l'influenza crescente delle politiche comunitarie sul territorio. Le politiche comunitarie dovevano prendere in considerazione il potenziale di sviluppo locale, regionale e nazionale insieme alle indicazioni degli stakeholders adottando un approccio territoriale strategico e integrato. Inoltre le strategie di sviluppo specifico per le città e le regioni avrebbero dovuto iscriversi più esplicitamente sia nei quadri nazionali che in quello europeo. Si riteneva fondamentale che le questioni regionali, nazionali e locali trovassero un'articolazione diretta con le politiche comunitarie, in particolare con le politiche di sviluppo rurale, quelle ambientali e dei trasporti ma anche con le politiche di coesione.

In questo quadro la Carta di Lipsia sulla città europea sostenibile (2007 e 2010) si iscriveva pienamente nell'Agenda Territoriale in quanto in essa si promuoveva una politica integrata di sviluppo urbano come un compito di dimensione europea.

La politica integrata di sviluppo urbano e la politica di coesione territoriale venivano viste quindi come due contributi complementari alla realizzazione dello sviluppo sostenibile.

L'entrata in vigore del nuovo Trattato di Lisbona (2009), ha fornito una base più solida all'azione in campo territoriale: la politica di coesione da quel momento mira ad articolarsi sempre di più secondo una visione multidimensionale che aspira ad essere economica sociale e, soprattutto, territoriale.

Nel mezzo interviene la crisi finanziaria e poi quella economica globale che investe anche l'Europa e che in parte vanifica i risultati macroeconomici di convergenza ottenuti dalla politica di coesione.

Oggi la coesione economica, sociale e territoriale rimane al centro del più recente documento strategico elaborato dalla Commissione, Europa 2020 (2010), che dovrebbe costituire il riferimento per i prossimi dieci anni come a suo tempo fu per la Strategia di Lisbona-Gothemburg. La visione per l'Europa è quella di una 'crescita' smart, sustainable and inclusive.

La Territorial Agenda rinnovata nel 2011, che non a caso prende il nome di TA 2020, assumendo come fondamentali gli obbiettivi della Carta di Lipsia (così come degli altri documenti di principio sullo sviluppo urbano come le Dichiarazioni di Marsiglia e di Toledo), considera tuttavia le città motori di sviluppo smart, sustainable and inclusive e le promuove come luoghi attrattivi, per viverci, visitarle ed investire su di esse. Ma vede anche come le aree urbane degradate, la cui esistenza è nascosta spesso dalle statistiche ufficiali, possano essere un luogo privilegiato dell'esclusione.

I termini in gioco sono allora dimensione urbana, politica di coesione, sviluppo sostenibile: la questione della scala pertinente delle politiche di sviluppo viene chiamata in causa dall'emergere del concetto di coesione territoriale.

3 IL RUOLO DELLA DIMENSIONE URBANA NELLE POLITICHE DI SVILUPPO

Un riferimento diretto alle città nelle politiche europee si sviluppa soprattutto a partire dagli anni '90 con il Libro verde del 1990 sull'ambiente urbano (COM(1990) 218) nel quale si analizzavano le problematiche di uno specifico 'ambiente urbano' proponendo un approccio globale e una serie di azioni a livello europeo da

inquadrarsi in una migliore cooperazione e integrazione tra le politiche. Negli stessi anni il rapporto "Città europee sostenibili" (con l'Agenda 21 locale) pone le basi per un quadro di azione a livello locale imperniato su quattro principi di base per la sostenibilità nelle aree urbane: gestione urbana, integrazione delle politiche, approccio ecosistemico e cooperazione e partnership. La comunicazione "La problematica urbana: orientamenti per un dibattito europeo" (COM(1997)197) analizzava le problematiche economiche, sociali ed ambientali delle città europee, mettendo in luce la necessità di contemplare una prospettiva urbana nelle politiche comunitarie.

Nel 1998 il "Quadro d'azione per uno sviluppo urbano sostenibile nell'Unione europea" (COM(1998)605) per la prima volta, ha adottato un'impostazione esplicitamente orientata allo sviluppo sostenibile, definendo quattro obiettivi principali di indirizzo politico: migliorare la prosperità economica e l'occupazione nelle città; promuovere la parità, l'integrazione sociale e il rinnovamento nelle aree urbane; tutelare e migliorare l'ambiente urbano (verso la sostenibilità locale e globale); contribuire a un'efficiente gestione urbana e al rafforzamento dei poteri locali. In particolare ha fissato una serie di obiettivi politici precisi per migliorare l'ambiente urbano che sono ancora validi e che vengono inclusi sempre nei documenti successivi (dalla strategia tematica sull'ambiente urbano, alla Carta di Lipsia, alle serie delle strategie europee sullo sviluppo sostenibile 2001, 2006, 2009). Nel corso degli anni 2000 l'importanza delle questioni urbane è stata riconosciuta sotto le successive presidenze dell'Unione (per es. Consigli informali di Rotterdam 2004 e Bristol 2005).

Nel rapporto su 'La dimensione urbana nel contesto dell'allargamento' (2004/2258(INI)) del Parlamento Europeo, lo sviluppo urbano sostenibile, in virtù del ruolo giocato dalle città per il perseguimento degli obiettivi di Lisbona e Gothenburg, viene integrato nell'ambito della politica di coesione e l'esistenza di una politica urbana implica l'esplicito riconoscimento della dimensione urbana e la sua integrazione (orizzontale con le altre politiche) nelle competenze della Commissione Sviluppo Regionale.

Nello stesso documento si domanda di introdurre insieme al dialogo sociale e civile un 'dialogo territoriale' che permetta alle diverse autorità (regionali e locali) e alle loro associazioni di partecipare alle negoziazioni e alle decisioni che riguardano politiche e azioni in ambito urbano nel quadro della politica di coesione.

L'Inter-service Group on Urban Development (2005), sotto il coordinamento della DG Regio, avrà lo scopo di: promuovere un approccio integrato allo sviluppo sostenibile urbano nella programmazione e nell'implementazione di Fondi strutturali; identificare nell'ambito delle diverse politiche europee le iniziative volte a sostenere lo sviluppo sostenibile delle aree urbane garantendo la cooperazione tra i diversi servizi della Commissione; assicurare il partenariato tra Commissione, Parlamento Europeo, Comitato delle Regioni, le associazioni di città e di aree urbane.

Le politiche di rigenerazione urbana sono viste allora come un potenziale supporto allo sviluppo locale[2] e l'approccio da adottare è quello integrato e multilivello.

La letteratura grigia considera giustificate le azioni di sviluppo locale in quanto: consentono una reazione di compensazione, correttiva o resiliente per superare gli impatti negativi di delocalizzazione dei posti di lavoro, chiusura delle imprese, crescente disoccupazione ed esclusione sociale; consentono un riequilibrio rispetto a cambiamenti istituzionali come i processi di decentramento e inducono il coinvolgimento dei governi locali nello sviluppo economico e dell'occupazione; costituiscono un trampolino per strategie di sviluppo che siano adattate localmente alle circostanze, al contesto e ad una visione condivisa di futuro.

Il modello che ne risulta è in linea con il paradigma della nuova politica regionale veicolato dall'OECD (1992, 2004, 2008) e con il contenuto del Rapporto Barca (2009) sulla coesione territoriale. Per quest'ultimo in un'ottica placed-based, lo sviluppo locale è suscettibile di aumentare l'efficienza del finanziamento comunitario grazie a una maggiore concentrazione dei fondi strutturali a livello locale e in virtù di una

---

[2] Il dialogo tra politiche economiche e politiche di sviluppo territoriale sembra sempre più passare oggi per un modello di sviluppo locale che si nutre di diverse riferimenti disciplinari e differenti pratiche sociali. Alla base vi è la concezione che lo sviluppo di differenti territori segua diverse strade e che i fattori residuali non spiegati dalla teoria economica classica o da quella neo keynesiana siano di natura endogena e spesso immateriale. Gli elementi comuni a queste scuole di pensiero risiedono nelle affermazioni: le opportunità di crescita esistono in tutti i differenti territori e il potenziale sottoutilizzato può essere sfruttato; tali opportunità e potenziali possono essere trasformati in progetti di sviluppo integrato; attori locali dinamici e impegnati, cooperando all'interno di un partenariato, possono fornire assistenza e incoraggiamento da parte di livelli di governo sovralocali e da altre istituzioni come le università.

migliore gestione dei progetti locali, selezionati sulla base di criteri di eligibilità e sottoposti a monitoraggio e valutazione.

4   L'EMERGERE DEL CONCETTO DI COESIONE TERRITORIALE

La coesione è sempre localizzata e strettamente legata, in Europa, al comportamento del sistema socio-economico territoriale. Questo legame era già stato individuato a partire da J. Brunhes e C Vallaux (1921), G. Jaia (1938), J. Schumpeter (1954), W. Sombart (1967), P. George (1967) rispetto a contenuti e categorie divenuti poi un insieme di variabili nel campo della geoeconomia (Lo Monaco, 1983)

Innestando su questo approccio ulteriori parametri – derivanti dall'attenzione che l'Unione Europea dedica alla nozione di "sistema economico" in quanto espressione di valori coesivi nazionali e regionali (struttura e organizzazione politica, storia, identità) – la coesione può essere stimata in rapporto alla dimensione territoriale che essa assume in sede regionale.

Nuovi metodi di stima (Prezioso, 2006) consentono oggi di valutare ex ante la coesione stimando rapporti di interdipendenza tra variabili economiche tradizionali e non, senza concentrare l'attenzione sui soli indicatori di ricchezza regionali (come il PIL). Secondo questo nuovo approccio, la coesione è stimata come effetto quali-quantitativo della scelta politica dello Stato o delle regioni; essa influenza l'efficienza e la massa (popolazione, risorse naturali, ecc.) di un territorio, senza tuttavia esserne influenzata (Prezioso, 2008).

L'economia e la geografia del secolo scorso hanno definito i principali caratteri della coesione: come sistema (base per l'interpretazione della sua dimensione territoriale) che contribuisce a gestire, disciplinare e integrare le attività individuali e collettive, nella direzione di un regime economico; un sistema nel quale le unità geografiche dovrebbero identificare le unità politiche ed economico-territoriali, così come la capacità di diffondere principi insediativi territoriali socio-economici, che abbiano attraverso i programmi operativi il potenziale di influire sul complesso degli indicatori (reddito, prodotto interno lordo, salute..).

Agli indicatori che nel tempo ne sono derivati, si è aggiunto (2007), lo spazio geografico e geo-economico, cioè quella dimensione territoriale entro cui si realizzano le esperienze quotidiane della coesione. Meno astratto dello 'spazio' economico, il territorio può essere studiato in modo multidimensionale, ed essere direttamente percettibile dai cittadini e dalle cittadinanze.

Il rapporto tra territorio e sistema politico-amministrativo coeso, cioè la "regione", ha coinvolto sino ad oggi solo indicatori di densità, efficienza e gestione delle infrastrutture, stima del capitale fisso sociale (Camagni et al. 2010) dimostrando che la coesione è influenzata, in Europa, dalle determinanti geografiche, secondo il livello di scala e di approfondimento tecnico della cultura di appartenenza e la produttività delle attività svolte dai singoli o dalle istituzioni, stimolata ed assicurata dalla presenza di valori comuni di orientamento socio-culturale.

In ogni contesto territoriale, la coesione economica diventa "geograficamente" rilevante solo quando viene assunta come "criterio ordinatore" del paesaggio e in esso si organizza transformando in "razionalità tecnica" i rapporti posizionali e funzionali tra elementi biotici e abiotici che lo compongono.

La coesione è stata considerata dal 2000 un nuovo strumento di intervento per la diffusione nazionale della solidarietà economica, monetaria, sociale. Beneficiare dei fondi di coesione ha significato dunque dichiararsi territorio non coeso, spingendo i territori a mostrare le proprie disparità regionali (Grecia, Irlanda, Spagna e Portogallo) con la volontà di ridurle agendo/progettando attraverso i settori operativi dell'ambiente e delle infrastrutture di trasporto. Nelle esprienze di planning che ne sono conseguite, il risultato non è sempre stato positivo.

Dal 2005-2006, la coesione è stata ri-definita nei contenuti e nelle modalità attuative in vista del nuovo ciclo di sviluppo 2007-2013, acquisendo un significato positivo ed attivo di forza attrattiva capace di resistere agli impatti, alla rottura ed alla separazione di un'economia o di una società. Analizzare un territorio ed il suo grado di coesione interna ed esterna significa rilevare e valutare le risorse di cui esso è dotato, i legami di interdipendenza che tra di esse si creano. Ai fini della misura della coesione, gli indicatori a disposizione (database EUROSTAT, ESPON, OCSE, JRC, etc.) permettono di rilevare risorse naturali, finanziarie, umane e culturali, in termini quali-quantitativi, distributivi, temporali, evidenziando le modalità endogene con cui tali indicatori – territorializzati – interagiscono tra di loro. Le tradizionali regioni amministrative UE (le

NUTS) hanno poco a che fare con la coesione; per valutare la quale si deve però necessariamente collocare un dato all'interno di una unità statistica e territoriale di riferimento (georeferenziazione).

L'inserimento di indicatori territoriali di coesione, preceduto da una serie di indagini e da 4 Rapporti (2001-2006) ha posto in luce tre ambiti: integrazione, coerenza e sostenibilità (temi focali anche del "VII Framework Comunitario 2007-2013"). Sintetizzare i principali indicatori utilizzati a livello europeo e nazionale per misurare la coesione non è dunque semplice. Ne esistono di vario tipo e molti si incrociano con quanto elaborato nel 2000-2006 per l'attuazione della Strategia di Lisbona. Una buona misura del livello di coesione deve prevedere: a) la territorialità: il campo dell' intervento sociale presenta innanzitutto una valenza geografica a livello dell'origine della misura. Infatti il livello di territorialità gioca un ruolo molto importante. Alcune misure sono iniziate e condotte autonomamente a livello locale spesso sulla base di bisogni specifici e puntuali. Altre misure, pur in una logica di pianificazione nazionale sono modulate in base alle specificità locali; b) la dimensione intersettoriale che concerne in particolare i settori di intervento: economico, sociale in senso stretto, sociosanitario, educativo/formativo e del mercato del lavoro. La dimensione locale favorisce spesso l'incrocio virtuoso delle diverse politiche messe in campo.

Il "sistema Europa" ha trovato nella coesione un elemento regolamentato di spinta all'azione collettiva (multilevel governance), per contrastare gli effetti della mancanza di competitività per il 2007-2013. Il nuovo approccio alla coesione ha richiesto una lunga fase di riconversione e di sviluppo delle politiche europee e nazionali tra il 2005 ed il 2007, che hanno anche recepito indicazioni sul potenziale di inclusione sociale, sullo sviluppo bilanciato, sulla qualità della vita.

Il rinnovo delle istituzioni, garantito dall'entrata in vigore del nuovo Trattato di Lisbona (2009), ha fornito una base più solida all'azione in campo territoriale: oggi la politica di coesione mira ad articolarsi sempre di più secondo una visione multidimensionale che aspira ad essere economica sociale e, soprattutto, territoriale.

Ma la politica di coesione è anche il campo nel quale si confrontano visioni politiche contrastanti in merito all'idea di Europa che si vorrebbe costruire, ai modelli di sviluppo economico ai quali fare riferimento, alle azioni da implementare per perseguire gli obiettivi (D'Orazio, 2011).

5 LA DIMENSIONE URBANA DELLA COESIONE TERRITORIALE

Sul piano della dimensione europea, la coesione è stata stimata quasi esclusivamente alla scala dei comportamenti urbani. Questa misurazione ha spesso utilizzato indicatori di segno diverso, a volte temporalmente sfasati, creando un forte divario tra esperienze empiriche alla scala locale e politiche territoriali regionali. Più il fenomeno è studiato e scomposto, più ci si allontana dal rapporto sussidiario che anche la coesione deve rispettare in campo amministrativo (multilevel governance).

Tuttavia è proprio alla scala urbana che la coesione si manifesta sotto forma di policentrismo (Prezioso, 2011), attraverso cui assume forma territoriale insediativa e organizzativa; per questo è difficile poter contare su una tipologia univoca di coesione territoriale, perché le dimensioni regionali e sub-regionali ne cambiano la connotazione nel tempo.

Lo "sparpagliarsi" della coesione sul territorio e la frammentazione delle funzioni urbane ha la sua scala di lettura nei sistemi regionali e sub-regionali policentrici. Essa procede o recede parallelamente all'andamento di altri fenomeni: mercato del lavoro (il livello di coesione è funzione delle dinamiche lavoro salariato/lavoro autonomo oltre che andamento occupazione/disoccupazione); disagio sociale, visibile nei quartieri delle grandi agglomerazioni polarizzanti e nei crescenti processi di segregazione spaziale ed esclusione sociale; esplosione e diversificazione dei bacini di mobilità/accessibilità casa-lavoro che divaricano i modelli spazio-temporali (bacini di prossimità convivono con quelli metropolitani del Daily Urban System e con quelli globali); "regolamentazione urbana e territoriale", con il sovrapporsi di territori e ambiti di competenza.

La coesione prende forma da una regione geografica integrata e dà forma a una regione geografica integrata, a un'area, cioè, occupata comunque da insediamenti, imprese, servizi, spazi naturali, rurali, urbani, montani. Molti hanno pensato di individuare la coesione regionale utilizzando tipologie di interazione funzionale (metropoli, megalopoli, sprawl come Londra, Parigi, Tokio, Milano, Ruhr-Renania, Boston-Washington), per fissare e standardizzare regole di reciprocità economica e gestionale tra aree economicamente interdipendenti (cross-border zones). In realtà, la coesione urbana dipende dalla sua esistenza a scala sub-regionale (NUTS 3), segnata in molte regioni europee, in alcuni contesti, dalla trasformazione in sistemi locali di originari localismi.

Fonti differenti richiamano sempre più l'attenzione su questa capacità, dovuta a: l'intensificarsi della concorrenza a livello internazionale; l'aumento dei processi di delocalizzazione produttiva; la propensione ad una veloce innovazione di processo, di prodotto e organizzazione generata dall'adozione di nuove tecnologie (ICT). Da questo punto di vista, la dimensione territoriale della coesione è rappresentata sempre da un'azione di interesse collettivo locale.

Nel quadro della politica di coesione, il ruolo delle città si è affermato sostanzialmente a partire dagli anni 2000. Il coinvolgimento della scala urbana, dai progetti pilota urbani dell'inizio degli anni 90, si è strutturato durante due generazioni di programmi dell'iniziativa comunitaria URBAN (fino al 2006) per poi costituire uno degli elementi portanti di molti programmi operativi del periodo 2007-2013. I fattori di successo del 'modello URBAN' sono stati individuati in coordinamento intersettoriale delle azioni, partenariati orizzontali, responsabilità locale rafforzata, concentrazione dei finanziamenti su aree geografiche bersaglio. La principale novità della politica di coesione del periodo 2007-2013 è stata quindi identificata nell'integrazione del modello URBAN (del tipo di interventi e di approcci previsti da quel tipo di iniziativa) nel sistema dei fondi strutturali: esso permette di coinvolgere tutte le città nell'ambito di diversi assi tematici. La finalità è quella di integrare al meglio le diverse politiche settoriali agenti sulla città e di migliorarne la governance. Attualmente nei programmi operativi del ERDF la dimensione urbana è esplicitamente considerata, in relazione alla possibilità per Stati membri e regioni di concepire, come in URBAN, programmi integrati urbani.

La definizione di coesione territoriale in relazione alle usuali dimensioni della sostenibilità – cioè economia, società e ambiente – può essere declinata in tre macro-componenti e cioè l'efficienza territoriale, la qualità territoriale e l'identità territoriale (Camagni et .al. 2010). L'efficienza territoriale si riferisce all'uso efficiente delle risorse rispetto a energia, suolo e risorse naturali; competitività e attrattività, accessibilità interna ed esterna di ciascun territorio. La qualità territoriale si riferisce alla qualità dell'ambiente di vita e di lavoro; standard di vita comparabili attraverso i territori; accesso ai servizi di interesse generale e alla conoscenza. La identità territoriale si riferisce alla valorizzazione del capitale sociale; lo sviluppo di un visione condivisa del futuro; salvaguardia delle specificità e rafforzamento delle vocazioni produttive e dei vantaggi competitivi di ciascun territorio. Nell'enunciazione delle priorità di intervento relativi agli Obiettivi Convergenza e Competitività possiamo agilmente identificare le questioni legate all'ambiente urbano e alla gestione dei servizi di interesse generale insiti nella concezione di coesione territoriale.

Un'analisi preliminare applicata al primo periodo della presente programmazione (DG Regio, 2008) su programmi operativi ERDF evidenzia alcuni risultati interessanti. In particolare:

1) le azioni previste per le città sono molto variegate ma considerano aree bersaglio sia in termini di riqualificazione di aree svantaggiate oppure di potenziamento competitivo di poli di innovazione; in questo senso si tratta di azioni conformi agli obbiettivi di coesione legati a crescita ed occupazione;

2) la possibilità di includere azioni urbane e di coinvolgere direttamente le città ha avuto molto successo dal momento che un buon numero di regioni e di Stati membri le ha inserite nei programmi operativi;

3) invece di comporre strategie integrate di sviluppo urbano le tipologie di intervento sono settoriali;

4) nonostante le ampie possibilità offerte dal regolamento 2007-2013 per il miglioramento della governance nelle operazioni di sviluppo urbano raramente esse sono state considerate nei documenti di programmazione: in particolare manca sia un coinvolgimento locale efficace nella concezione e implementazione dei programmi sia la partecipazione attiva dei cittadini;

5) la maggior parte delle città coinvolte riveste un ruolo molto limitato nel processo decisionale e nella gestione dei flussi finanziari sul territorio.

6   CONCLUSIONI

L'attuale crisi economica e finanziaria investe tutti i settori dell'economia. Le misure prese a partire dal 2008 mirano a recuperare livelli di reddito e di occupazione puntando su una crescita intelligente, sostenibile ed inclusiva, secondo Europe 2020. La sostenibilità (complessiva) del modello rappresenta un fattore chiave: è infatti cruciale che gli interventi di sostegno all'economia e di mitigazione degli impatti sociali della crisi siano compatibili con gli obbiettivi di sostenibilità di lungo termine. La scelta strategica sembra essere quella di cogliere la crisi come opportunità per sviluppare un modello di società che sia a bassa emissione di

carbonio, efficiente nell'uso delle risorse, basato sulla conoscenza e sull'inclusione sociale. Nel breve periodo questo si deve tradurre nell'adottare misure 'green' (supporti, incentivi..) che rivitalizzino l'economia e creino occupazione. Nel medio e lungo periodo ciò dovrebbe aiutare la creazione di nuove tecnologie e ridurre l'impatto delle azioni antropiche sul cambiamento climatico, l'impoverimento delle risorse naturali e il degrado degli ecosistemi.

In questo momento la fase è cruciale per la determinazione degli orientamenti relativi al prossimo periodo di programmazione post 2013. Le indicazioni contenute nella proposta di nuovo regolamento 2014-2020 proprio in relazione al 'nuovo obiettivo' della coesione territoriale fanno riferimento alla necessità di affrontare il ruolo delle città, delle aree geografiche funzionali e dei territori subregionali che hanno specifici problemi geografici o demografici.

Per molti, la città, e non il territorio, emerge come veicolo di coesione a due velocità: degli esclusi e dei vincenti. Questo si rileva in tutte le città fordiste, dove però il fenomeno della segregazione è "associato" con una forte solidarietà di classe e possibilità di socializzazione dovuta alla ridotta ampiezza dei bacini di mobilità. Nella città "esplosa", al contrario, la segregazione è "dissociata", con isole di povertà ed esclusione localizzate casualmente all'interno del tessuto urbano, quasi a formare un arcipelago.

Per ricomporre questa coesione destrutturata serviva, secondo i modelli di fine '900, un tessuto connettivo organizzato su 3 elementi: l'accessibilità interna (tempo medio di mobilità inferiore ad un'ora, diversificazione e specializzazione delle attività, offerta di beni completa, complementarietà complesse organizzate a rete); la presenza di nodi di interconnessione di reti differenziate che permettano l'accesso ai nodi esterni del sistema globale; l'autorganizzazione, che dà luogo ad un paesaggio fortemente interconnesso dove i bacini di mobilità si allargano e si sincronizzano (come suggerisce il caso olandese).

In questo modo sembrava possibile personalizzare modelli coesivi policentrici in termini di residenza-lavoro lasciando che l'individuo si costruisse una città "à la carte" in sostituzione della integrazione fordista e della dsintegrazione post-fordista. Questo nuovo modello, definito di metropolizzazione-regionalizzazione, sancisce un'idea di coesione in accordo con la riforma degli Enti locali in alcuni paesi europei (Francia, Italia, Spagna), enfatizzando il ruolo del territorio e costringendo ad interrogarsi su quale modello di integrazione realizzare attraverso il piano, a quali costi collettivi, quali le scelte irreversibili, quali sistemi di governance e government più adatti alla complessità, quali le criticità delle scale da trattare: micro-territoriale per ottenere una coesione compatta e co-operativa; macro perché sia coerente.

La coesione comincia ad essere rappresentata e misurata da un tipo di regione nella quale la vita economica e sociale è direttamente influenzata dai caratteri di sufficiente integrazione e interdipendenza intra e transfrontaliera. Importanti in questo ottica le riflessioni contenute nello Schema di Sviluppo dello Spazio Europeo (CEC, 1999), dove, per diverse ragioni, si sono fissati i principi guida di natura etico-culturale che dovevano regolare l'azione dei soggetti (pubblici e privati) che concorrono alla definizione del modello di sviluppo coeso. Quindi un interesse comune europeo per il mantenimento di uno sviluppo territoriale equilibrato e sostenibile – fondato sul rispetto delle aree sensibili e ad elevato pregio naturalistico, su un'organizzazione degli insediamenti umani attenta al consumo di suolo e ad un equilibrato rapporto con il territorio – e l'acquisizione alla cultura policy-making europea di due concetti:

- la città e l'armatura urbana complessiva sono solo strumenti della competizione fra sistemi territoriali in epoca di globalizzazione, è al contrario la coesione l'elemento portante della capacità competitiva;

- le reti di città possono rappresentare un modello di organizzazione territoriale coeso a livello intermedio, ma non necessariamente policentrico, che consente ad un sistema di città di medie dimensioni di raggiungere elevati livelli di competitività attraverso rapporti di sinergia e di complementarietà, economie di rete e di specializzazione solo se il sistema è già potenzialmente in essere un sistema.

La risposta che molti hanno dato, sia nel caso delle reti regionali di città, sia nel caso delle metropoli maggiori, è la connessione alle grandi reti di trasporto e comunicazione trans-europee come scelta policentrica equipotenziale coesa. Tutto il contrario della condizione posta dall'UE per il raggiungimento di uno sviluppo equilibrato e di obiettivi complessivi di equità territoriale: intervento in aree di esclusione e di povertà; competitività migliorando l'efficienza e l'accessibilità esterna a disposizione di investitori esterni alla città; la sostenibilità agendo sulla rete energetica e l'uso di risorse scarse come suolo e spazi aperti.

Questa divergenza si deve probabilmente alla spiccata 'propensione culturale' mostrata dal Comitato di Sviluppo Spaziale Europeo a privilegiare (anche finanziariamente) la trattazione di temi urbani rispetto alla coesione (rigenerazione con interventi integrati di quartieri in crisi; partecipazione dei cittadini alle scelte di pianificazione e di progettazione urbana; gestione strategica della riqualificazione del centro-città; scambio di esperienze di best practice nelle politiche urbane) come se si dovesse fare di tutto per ribadire che la metropoli esiste veramente, o si deve costruirla laddove non c'è mai stata.

La risposta è invece includere la Territorial Agenda 2020 nelle azioni di pianificazione, in particolare alla scala urbana per superare meta-modelli space-blind o metafore di indirizzo generaliste sulla coesione.

1 ABSTRACT

Urban Nexus is a 3 year €1m, multi-partner Coordination Action (2011-2014), funded by the European Commission (FP7), that aims to enable and further strategic urban research which can address the challenges facing European cities today. These challenges include the current economic crisis, sprawling urban development and pressures on the natural environment, as well as the longer-term implications related to climate change and resource scarcity e.g., peak oil and water.

Urban Nexus supports the development of a structured dialogue with all relevant stakeholders, including civic leaders, policy-makers, businesspeople, researchers and educators to enable rich communication, knowledge transfer and partnership-building around these challenges.

This form of direct engagement will help to build upon and strengthen the relationship between various stakeholders and policy-makers through engagement, collaborative prioritisation, and knowledge transfer, to secure long term strategic partnership. Framed by these principles, the Coordination Action pursues the following objectives:

- Increase awareness, knowledge exchange, cooperation and collaboration through structured dialogue;

- Promote innovative problem-solving approaches to the complex and interrelated policy issues concerning sustainable urban development and;

- Further the long-term strategic framework for scientific cooperation through the enabling and building of strategic partnerships.

This in turn should lead to integrated perspectives for sustainable and resilient urban communities.

2 URBAN NEXUS – STRUCTURED DIALOGUE

Urban Nexus is developing structured dialogue with stakeholders in relation to the key dimensions of sustainable urban management including energy, water scarcity, transport, tourism, technology and innovation, governance, social equity and cohesion, and sustainable consumption. These are prioritised according to stakeholder consultations, conducted via the project Stakeholder Advisory Board.

The scope of the Coordination Action does not permit all issues to be addressed equally, nor indeed is this desirable. The political priorities for the territorial management of cities and city region's provide the basis for understanding and structuring of the interconnected complexity of urban life and thereby the effective management of the city towards sustainable development. Cities in Europe today respond to a variety of sometimes conflicting (political) demands. In responding to the political imperative of climate change mitigation and adaptation cities must also ensure that cities fulfil their role as motors of economic development whilst securing appropriate conditions for a socially cohesive and healthy population, and quality of life. The Urban Nexus conceptual framework provides the basis for ordering and prioritisation of the various challenges faced, highlighting the strategically critical elements, and also providing principles to define the interconnectedness of all elements. This framework is derived directly from the legacy of the URBAN-NET project (ERA-NET).

The URBAN-NET framework promoted the vision of the sustainable city by focusing on future research needs and activities that stimulate the planning, financing, performance, dissemination and utilisation of research amongst all stakeholders at all levels including local, regional, national, transnational and European. This framework includes:

- adapting to climate change;

- health and quality of life;

- sustainable land-use;

- integrated urban management;
- integrated information and monitoring.

2.1 Adapting to Climate Change

Anthropogenic climate change and its consequences are major challenges for European cities. European cities are traditionally built in strategic geographical locations along major rivers or next to the sea, consequently a substantial number of European cities are likely to experience the direct impacts of climate change including flooding as well as extreme temperatures. Climate change has severe implications for urban populations including heat stress, cardiorespiratory complications, parasitic and infectious disease, flooding, and drought. There is therefore a strong need for the establishment of resilient cities, urban areas able to absorb changes, reorganize and integrate economic, socio-cultural and ecological developments. Strategies are needed to improve the collective responsiveness and preparedness of individuals, institutions and services to the inevitable consequences of climate change. Education, health care, public health initiatives, infrastructure and economic development will become increasingly important in maintaining acceptable levels of quality of life.

There has been a lot of research attention focused on the mitigation of climate change. Mitigation aims to reduce emissions of greenhouse gases and curb further anthropogenic climate change by reducing energy consumption, improving energy efficiency, the substitution of fossil fuel use and changes in land-use practice. However, adaptation is a necessary imperative for responding to climate change. Urban areas and cities are particularly vulnerable due to the complexity and interdependency of activities and relationships between actors. Urban-specific characteristics serve to amplify climate change impacts, e.g. the urban heat island effect, increased flood risk due to greater impermeable surface area and, in the majority of cases, the proximity of urban areas to coasts, rivers or watersheds. Adaptation is often overlooked in favour of mitigation, witness the international efforts of the Kyoto Protocol to address emission reductions at a global scale. However, the scale and sophistication of day-to-day relationships and interactions in urban areas across Europe and other continents belies the fragility and susceptibility of urban society, economy and infrastructure to seemingly remote or even minor perturbations arising from climate change. Changing climate trends and an increasing frequency of extreme events, such as forest fires, drought, heat waves, excessive precipitation and storms, are pushing urban societies ever closer to unpredictable and potentially chaotic futures.

2.2 Health and Quality of Life

There has been increasing recognition that the planning, design and management of urban areas has significant implications on the health and quality of life of urban populations. Reliance on cars, high levels of pollution and poorly designed and planned neighbourhoods has exacerbated problems with health and health related behaviours. Research has focused on a number of areas including for example, sustainable transport, the design of cities and suburbs, and the promotion of physical activity and the exposure of urban populations to contaminants in water, air and soil. Despite a raft of evidence and guidance, the recommendations for how to achieve healthy lifestyles remain disconnected and ineffective. What is needed is the development of an integrated understanding and problem-solving orientation for issues concerning quality of life and sustainability in the urban realm through bringing challenges and risks to health into the foreground. In addition, this could include a synthesis of evidence of risks and challenges to people's health arising from spatial planning as manifest in urban form and urban design in an accessible form. However, health and quality of life remains a complex issue which cannot be solved by one agency alone. Therefore, consultation is required with a range of stakeholder communities including planners, those in the health care sector, education institutions and so on, to develop a common understanding of the integration and synergy between the wider determinants of health, economic resilience and urban ecosystem services.

2.3 Sustainable Land-Use

Land-use and land management practices have a major impact on natural resources including water, soil, nutrients, air, plants and animals, landscape and landform. One of the most important tasks of a sustainable land-use policy should be to minimise environmental impacts and in particular the consumption of natural resources. It is still unclear how this goal could be reached and what measures would be appropriate. The

polycentric city region model has been suggested as a basic orientation model and vision of urban sustainability in which autonomous cities create a continuum of densely developed and mixed-use areas and landscapes; integrating energy, food production, open space and spatial concentration of buildings. The model of a polycentric city region appears to combine the advantages of a compact city such as density, mix of functions, public transport with the individual qualities of suburban areas e.g. green spaces, child-friendly environments and home ownership. This model seems more valid for some parts of Europe than for others, for example not immediately for the lower density parts of Europe. However, research is needed to understand the driving forces, interactions and dependencies and to find innovative solutions as part of a participatory decision-making process between citizens, local government and other actors. The achievement of sustainable land-use and settlement structures seem to be mainly a question of decision-making and implementation. Thus, research should also contribute to implementation through scientific analyses, advice and evaluation. Research for and about implementation has a role other than implementation alone. It is about observing or preparing and analysing decisions and their implementation which in turn will also be about lessons learned and best practices.

2.4 Integrated Urban Management

The interconnectedness of the social, economic and environmental dimensions of urban life and the associated drivers of change at the urban level, also create complex conditions for urban management, and fundamental barriers to the effective implementation of sustainable urban development. In response to this interconnectedness and complexity, the principles for integrated urban management have become the pre-eminent framework for the development of appropriate policy responses to these urban challenges.

One basis for policy failure in relation to the land-use – transport – environment nexus can be attributed to difficulties of securing an integrated policy response between the responsible agencies. Two fundamental poles of this integrated policy response concern first, the horizontal policy integration necessary between the sectoral agencies responsibilities for land-use management, and transport and environmental planning, at the local and regional levels of governance. Failure to secure an integrated policy response is attributed to variety of factors including notably organizational and procedural barriers to achieve central coordination, as well as problems of communication between organisations.

The second dimension of policy integration concerns vertical coordination between agencies responsible for policy delivery at local, regional, national and EU levels. The factors identified above operate in the horizontal perspective and are equally applicable, but in land-use management in the European context in particular, a special focus is required on how to reconcile subsidiarity with necessary coordination of actions.

2.5 Integrated Information and Monitoring

Effective monitoring of the pressures, state and impacts at the urban level, as well as the effectiveness of policy responses in controlling urban development, is clearly essential. One of the prime barriers to integrated urban management is identified in the opportunity to address and overcome these deficiencies in policy responses necessary to secure sustainable urban development.

2.6 Structuring Principles and Structured Dialogue

The concepts reviewed above provide a prime basis for analysing the various interconnected issues that define the complexity of the city and the challenges of city management. These concepts deliver structuring principles, and a basis for prioritisation of the thematic focus for knowledge transfer and the delivery of structured dialogue to the urban stakeholder communities. The thematic focus for knowledge transfer and structured dialogue in Urban Nexus is also developed according to stakeholder assessment of the priorities for the delivery of sustainable urban development, difficulties of measurement via indicators, and in the creation of assessments of urban impacts that effectively relate to policy needs. The complexity of urban interactions is clearly a major challenge in this regard, but the generation of integrated information and effective monitoring of policy implementation is also undermined by information management systems that are primarily designed to meet the needs of a particular agency and which do not communicate with other agency information systems. The fragmentation of the information and intelligence essential to support integrated policy solutions and policy implementation seriously impedes the effective response of cities and regions of Europe to these challenges.

3   STRUCTURED DIALOGUE AND SUSTAINABLE URBAN COMMUNITIES

On the basis of the structured dialogue developed in the urban Nexus Dialogue Cafes focused on the themes of Urban Climate Resilience (Glasgow, May 2012) and Health and Quality of life (Barcelona, October 2012), the following challenges related to resilient communities have been identified by the stakeholder communities:

3.1 Integrated Approach beyond Individual Policies

An integrated approach is needed to support policies. Of course this is not new, but we need to go beyond the level of individual prolicies. Structured partnerships between policy-makers, the private sector, researchers and civil society are necessary to address cost issues and to mobilise wide societal support for sustainable urban development, especially as these are under pressure in these times of economic crisis. An integrated set of indicators is also needed in order to ensure better measuring of potential hazards for cities (climate, land use, air pollution etc.). Harmonization of different data bases between different city sectors, between city and governmental administration and between cities on trans-border and transnational level is also a target. Upgrading city management with an objective permanent monitoring of urban change, territorial management and efficient use of different financial mechanisms, including European funds, should also be considered. Integrated sets of indicators, correlated to local and regional priorities, traditions and territorial and environmental capacity, will allow for better cross-boundary cooperation and territorial development within Europe.

3.2 Green Infrastructure

Promoting green infrastructure is an effective way to increase health and quality of life in cities. It also has capabilities to address climate issues: it helps to decrease urban heat island effects and could act as a buffer for water retention. Green infrastructure has the power to mobilise support for sustainable development because of its appeal at the local level. Green infrastructure could be the leverage for securing more attention to resilience and adaptation, rather than the current focus on mitigation.

3.3 Built Environment

Health and quality of life in cities is not only about implementing technological improvements in order to ensure less noise and better air quality. Good urban design will lead to better traffic flows and should lead to more lively urban areas at the same time. This, together with green infrastructure, improves the quality of life in cities. Upcoming activities on the theme of urban land use will surely add more knowledge to this. Advanced investigation into tendencies for urban sprawl or shrinking cities together with risk assessment on natural and anthropogenic disasters or catastrophes provide further potential for better strategy and action planning on sustainable urban management.

3.4 Bottom-up Initiatives

Often bottom-up initiatives in neighbourhoods result in the development of more sustainable characteristics of the area while fostering social cohesion among citizens. Interestingly, many promising initiatives happen in areas confronted with demographic decline. It is a cost-effective way to improve the general quality of life in cities. Moreover, large-scale political action on sustainability can only be enforced if there is wide support for it among the population. Bottom-up initiatives can create such support, in tandem with the wider partnerships between business, research, civil society and policy-makers mentioned above, and regional networks are a potential solution.

4   CONCLUSION

The urban Nexus long-term strategic partnership aims to respond to a dynamic of self-organising governance in forging a new conceptual basis for long-term strategic partnership, and in facilitating partnership formation in the framework of Dialogue Cafe interactions. The conceptual framework for the long-term strategic partnership is identified with the public, private and 'third' sectors. Partnership between these sectoral interests combine the innovation of the private sector, the collective values of the public sector, and the human desires of the third sector. These partnerships and linkages can be classified into three basic combinations – public-private, private-community and public-community – where each sector has certain strengths, weaknesses, opportunities and threats:

- Public-private linkages include various partnerships and consortiums, ethical procurement, supply chain initiatives, and much of mainstream economic development activity.

- Private-community sector linkages include local business or regeneration partnerships, social investment funds, 'mutual' or cooperative finance firms, corporate trusts and companies, consumer clubs and networks, cooperatives, community development trusts and other forms of social enterprise.

- Community-public sector linkages include voluntary sector compacts, neighbourhood partnerships, customer charters, intermediate labour markets, social trading, and other forms of community enterprise.

Urban Risk Assessment using Intelligent Geoinformation System

Oksana Smirnova

(Oksana Smirnova, St. Petersburg Institute for Informatics and Automation of the Russian Academy of Sciences (SPIIRAS), 39, 14 Linia VO, St. Petersburg, Russia 199178, sov@oogis.ru)

1 ABSTRACT

Urban safety became one of the important components of a city government work in the whole world. It is connected with growth of megalopolises and agglomerations, globalization of terrorist and criminal structures, increase of number of natural and technological disasters. Therefore information system is necessary for management of urban areas that will allow to reduce resources spent on organization of situation monitoring in the cities and to increase overall performance of city services.

In the paper questions of development and implementation of urban safety information system on the basis of intelligent geoinformation technologies are considered.

2 INTRODUCTION

Hundreds of various catastrophes happen every day in the world. It is natural disasters (earthquakes, floods, tornado, snowfalls and others), technological disasters (fires, oil spill, dike burst, electric power system accidents), and transport accidents (shipwrecks, car accidents, air crash, railway accidents). Modern cities are complex, suballocated areas. Selection of megacities, agglomeration, coastal, dryaland, islands and high-altitude cities as places of residence make people particularly vulnerable in terms of their safety. As a consequence, urban population is less protected and urban areas are more vulnerable in case of catastrophe. All that leads to death of many people, heavy economic and environmental damage. In the past few decades the number and immensity of natural disasters increased approximately in 5 times, and their danger – in 9 times. Also it is important to note that in underdeveloped countries losses on natural disasters is significantly higher, than in economically developed regions (McGranahan G. et al., 2007).

Urban safety problem is one of the key problems considered in the most part of publications. The greatest contribution to the development of the concept of cities security is made by C. Moser (Moser C. et al., 2008) and G. McGranahan (McGranahan G. et al., 2007). Also the problem of risk assessment from natural and technological disasters is often discussed at CORP conferences. For example, the damage caused to large cities by floods is estimated in (Aubrecht, et al., 2009; Liao, et al., 2011).

Therefore development of effective system for risk of urban areas safety forecasting and assessment now is needed. Such system will allow:

- in some cases to prevent catastrophes;
- to provide recommendations to implement timely behavior in case of disasters;
- to estimate accident consequences.

In the paper one of the risk assessment methods for suballocated areas and variants of risk map creation using GIS-technologies is discussed.

3 RISKS' ASSESSMENT METHOD

The risk is understood as possibility of an event occurrence with negative implications. Risk assessment assumes calculation of a set of quantity characteristics, i.e. definition of possible implications of risks realization for different groups of population and infrastructure. Risk assessment includes following main aspects: estimation of damage from influence of one or several hazards, probability of disasters and others.

The risks assessment related to consequences of natural and technogenic disasters in a given region can be described as a set of features. So, the number of natural and technogenic disasters for the region has distribution density of this event time.

Risks assessment of natural and technological disasters consequence for a given region is proposed to be made using the method that includes the following steps:

(1) Dividing the entire set of possible natural and technological disasters variants into groups according to their parameters. Building groups is based on available statistics for these groups as well as on initial states

of infrastructure objects and population density for the given region. Groups are used in order to define matching probabilities of the events' occurrence.

(2) Defining based on statistics distribution density of event time (natural and technological disaster) taking into account disaster intensity (for example, earthquake magnitude, square of inundation area et al.). Event probability depending on time can be defined by the corresponding distribution density.

(3) Assessing risks for each variant of the natural and technological disaster with regards to infrastructure objects and population of the given region.

(4) Calculating the mean value of possible natural and technological disaster risks for these objects in a given time range taking into account uncertainty of event time.

Let us dwell upon the features of each step. Definition of density functions of i dangers occurrence time $f_i(t)$ can be carried out in advance and in future they are only improved. For recognition of natural and technological disasters current conditions on the basis of registered data analysis known methods (Ayvazyan S.A. et al., 1989) can be used.

For calculation of initial parameters of natural or technological disasters in some cases the known models and methods can also be applied (Stallings R.A., 2003). Each variant of initial condations leads to receiving $B_i(t)$ - parameters of i-th dangers in the given region using this models and methods. These parameters include the number of human losses, the number of earthquake induced failures, the square of ecological pollution et al.

Risk assessment of each natural or technological disaster at time instant T provides accounting its properties (for example, disaster intensity, damage by disaster et al.), as well as accounting the characteristics of the inflicted facilities. In the interests of such assessment taking into account natural or technological disaster event time uncertainty $\overline{B}_i(T)$ – mean values for parameters of i-th dangers at time instant T are calculated as:

$$\overline{B}_i(T) = \int_0^T B_i(T-t) f_i(t) dt \qquad (1)$$

It is suggested to calculate conditional risks $W_{ij}(\overline{B}_i(T))$ - of i-th dangers at time instant T for specific j-th objects depending exactly on the parameters $\overline{B}_i(T)$. These especial conditional risks can be, for instance, determined by experts. They can be also received as a result of the processes' modeling based on advanced geoinformation technologies and special analytical problems' solutions. Among these problems are the assessment of area flood level, the environmental threats occurrence and other.

The resulting predicted risk from natural or technological disasters at time instant T taking into account previous conditions and probabilities P_i of i-th dangers occurrence are calculated using the following equation:

$$W_\Sigma(T) = \sum_{i=1}^n \sum_{j=1}^m W_{ij}(\overline{B}_i(T)) P_i \qquad (2)$$

where m – the number of analysed objects or regions.

Risk $W_\Sigma(T)$ according to (2) is a current risk. Risks' prediction for specified time intervals is possible using integral estimates derivation.

Unlike the known methods the proposed approach allows to predict the risks from natural or technological disasters in the current situation under a significant uncertainty of risk emerging time. The new method can be successfully implemented in modern geoinformation systems. However, the method application is associated with a number of features.

4 SOME FEATURES OF THE METHOD APPLICATION FOR GEOGRAPHIC INFORMATION SYSTEMS

Application of GIS-technologies for the solution of risks assessment problems of natural or technogenic disasters assumes application of effective methods of gathered geophysical data visualization, results of their modeling and forecasting.

Use of the risk assessment method allows operatively to reflect in geoinformation systems risk dynamics and to estimate damage values depending on type of a natural or technogenic disaster or their set. The spatial analisys performed by GIS tools allows:

- to represent the results of risk prediction as a series of thematic maps. On these risk maps taking into account spatial accessory to specific region zones that are defined by specific values $W_\Sigma(T)$ both separated objects and groups of objects can be displayed. Creation of the thematic maps assumes development of qualitative scale for $W_\Sigma(T)$ values that reveals the relation between risk level and level of destruction. On the basis of the developed dynamic maps the decisions aimed to decrease risks and to plan actions for coasts protection against disasters can be made.

- to classify regions by hazards level for each of disasters variants for specific infrastructure objects and for specific life environment.

- to carry out adoption of the rational and operational decisions directed on timely realization of actions complex, directed on reduction of risk, preservation of life and human health, decrease of damage from catastrophics.

Using intelligent GIS allows to imorove decision support on alarm, to predict possible consequences and to carry out offers on protection actions.

5 CASE STUDY

5.1 Study area

Let us consider a problem of a risk and safety assessment for Italy urban areas. The country is administratively divided into 20 regions (Table 1). The largest cities and towns of Italy are Rome, Milan, Naples, Turin, Palermo. It is known that the territory of Italy is the subject of such natural disasters, as earthquakes, floods, volcanic explosion and a tornado.

The strongest earthquakes which occurred in Italy are: Sicily earthquakes 1693 (more than 60 000 of people deaths), the Great Neapolitan Earthquake (11 000 deaths), 1908 Messina and Reggio earthquake (100 000 deaths), 1915 Avezzano earthquake (killed more than 30 000 people), the 1980 Irpinia earthquake (2570 deaths). The last happened in April, 2009 L'Aquila earthquake.

Region	Capital	Area (km2)	Population
Abruzzo	L'Aquila	10763	1342177
Aosta Valley	Aosta	3263	128129
Apulia	Bari	19358	4090577
Basilicata	Potenza	9995	58768
Calabria	Catanzaro	1508	2011537
Campania	Naples	1359	5833131
Emilia-Romagn	Bologna	22446	4429766
Friuli-Venezia Giulia	Trieste	7858	1235761
Lazio	Rome	17236	5724365
Liguria	Genoa	5422	1616993
Lombardy	Milan	23844	9909348
Marche	Ancona	9366	1564866
Molise	Campobasso	4438	319834
Piedmont	Turin	25402	4456532
Sardinia	Cagliari	2409	1675286
Sicily	Palermo	25711	5050486
Tuscany	Florence	22993	3749074
Trentino-Alto Adige	Trento	13607	1036639
Umbria	Perugia	8456	906675
Veneto	Venice	18399	4936197

Table 1: Administrative divisions.

5.2 Earthquake risk assessment for Italy region

On the basis of earthquakes data (Earthquakes, 2013) which have occurred in Italy since 1693 we will allocate nine categories of possible consequences from an earthquake (Table 2): I – instrumental to moderate; II – rather strong; III – strong; IV – very strong; V – destructive; VI – ruinous; VII – disastrous; VIII – very disastrous; IX – catastrophic.

Scale	Category	Magnitude	Estimate Number Each Year	Description
instrumental to moderate	I	<=4.3	900 000	No damage.
rather strong	II	4.4-4.8	30 000	Damage is negligeable. Small, unstable objects are displaced or upset; some dishes and glassware are broken.
strong	III	4.9-5.4	20 000	Damage is slight. Windows, dishes, glassware are broken. Weak plaster and masonry are cracked.
very strong	IV	5.5-6.1	500	Damage is moderate in well-built structures; considerable in poorly-built structures. Furniture and weak chimneys is broken. Masonry is damaged. Bricks, tiles, plaster and stones fall down.
destructive	V	6.2-6.5	100	Structural damage is considerable, particularly in poorly-built structures. Chimneys, monuments, towers, elevated tanks may fail. Frame houses are moved. Trees are damaged. Cracks appear in wet ground and steep slopes.
ruinous	VI	6.6-6.9	50	Structural damage is severe, some structural elements may collapse. General damage to foundations is caused. Reservoirs are seriously damaged. Underground pipes are broken. Conspicuous cracks are observed in ground; liquefaction.
disastrous	VII	7.0-7.3	10	Most masonry and frame structures foundations are destroyed. Some well-built wooden structures and bridges are destroyed. Serious damage is caused to dams, dikes. Sand and mud is shifting on beaches and flat land.
very disastrous	VIII	7.4-8.1	10	Few, if any (masonry) structures remain standing. Bridges are destroyed. Rails are bent greatly.
catastrophic	IX	>8.1	5-10	Damage total. Lines of sight and levels are distorted. Objects are thrown into the air.

Table 2: Categoty and number of possible earthquakes.

Fig. 1 displays histogram which demonstrate probabilities of earthquake events in each of Italy regions. Probabilities are defined on the basis of the statistical data received from http://earthquake.usgs.gov/earthquakes/map with use of statistical analysis methods. Generally, as it is seen from bar graph, Italy regions are subjects to earthquakes in a varying degree. It is possible to allocate two most dangerous regions: Sicily and Emilia-Romang. The calculations are also made for these regions.
Fig 1: Probabilities of earthquake events in the Italy regions.

These calculation results are used for risk level assessment in relation to concrete components of environment or infrastructure connected with human life. The risk assessment from impact of a possible earthquake was estimated taking into account danger and damage to people health, danger and negative influence on environment for two regions: Sicily and Emilia-Romang.

Overall risks summary is made taking into account weight coefficients which have been set by an expert for each of allocated territories. In Fig. 2 the predicted risk from natural disaster at time instant , probabilities of -th dangers occurrence and earthquake magnitude for two most dangerous Italy regions: Sicily and Emilia-Romang is given.

Fig 2: Results of risk assessment for Sicily and Emilia-Romang regions.

The obtained results indicate first of all that some territories become eventually more and more steady against certain types of disasters while others on the conversely, they only start meeting certain difficulties. As can be seen from Fig. 2, in recent years the earthquakes magnitude on Sicily decreases, and in Emilia-Romagn increases.

While the earthquakes magnitude on Sicily decreases, disaster hazards are preserved to be high. All this is first of all due to that over the past ten years Italians have become more prepared for possible earthquakes and eruptions of volcanoes. The researches concerning the reasons of these phenomena are continuously conducted, early warning systems are improved, and danger of underground fluctuations when constructing roads, houses and office buildings is considered.

Let's create a qualitative scale for the resulting predicted risk, using nine point grading scale of earthquakes (Table 2). This scale connects risk levels with nature of destroying influences, danger and damage to health of people. The qualitative scale for risk values is given in Fig. 3.
Fig 3: Qualitative scale for $W_\Sigma(T)$ values

Risk level	Risk value
VI – catastrophical	0.186-0.833
V – maximum	0.127-0.186
IV – high	0.103-0.127
III – medium	0.07-0.103
II – small	0.005-0.07
I – minimum	0-0.005

Table 3: Results of risk assessment

Negative influence degree (risk level) is estimated with a qualitative scale for the resulting predicted risks taking into account their weight coefficients. Weight coefficients are defined by experts such as city managers or other experts.

The results of risk assessment for Italy region is given in Table 4. Fig.4. illustrates a risk map. On the basis of the received risk maps further actions for region protection from the subsequent disasters are planned.

Fig 4: Risk map for Italy region.

6 CONCLUSION

The paper proposes a new approach to a risks assessment from natural or technogenic disasters taking into account specific features of regions. In future work it is supposed for risk assessment to consider not only such factors as damage to health of the person, danger and negative influence on environment, the built-up territories hazards but also social and economic risks. Also possibility of animation and 3D maps development can be discussed.

Urban Space Patterns and Homelessness in Bucharest, Romania

Mirela Paraschiv

(PhD. Student Mirela Paraschiv, University of Bucharest, Faculty of Geography, 1 N. Balcescu Blvd, Sector 1, 010041 Bucharest, Romania, mirela.paraschiv@ymail.com)

1 ABSTRACT

Urban poverty continues to represent a concern in cities' territorial planning as it alters the quality of life and it disrupts the development process in some cities. Homelessness reflects the extreme manifestation of urban poverty resulted from housing and social exclusion, even in developed European Union countries. The post-socialist transformation processes and the current economic crisis increased poverty and inequalities in Romania. Homelessness intensified and became visible after 1990, especially in Bucharest – metropolitan city that attracts both investors for development actions and poor population seeking for solutions to get out of poverty. The study investigates the urban space of Bucharest to differentiate the characteristics that influence the homeless living on the streets to locate in certain places in the city. The empirical analysis included a three-level urban space categorisation. The functional types of space were correlated to the homelessness presence according to three space characteristics: property type, physical structure and state of use. The resulted space typology was used to assess the Bucharest territory and to analyse the homelessness hot spots. The main findings argue that the characteristics that define the urban space correlate with the homelessness locations so that homeless people localisation in Bucharest depends on the urban space capacity to meet the homelessness housing and living needs. The analysis' conclusions evidence the homeless location patterns and they help urban planners and policy makers to understand the correlates between the homelessness behaviour and territory so that to include urban space modelling and to use the information to improve policies and actions to alleviate extreme poverty in Bucharest.

2 INTRODUCTION

Urban poverty represents a result of globalization and economic restructuring (Knox, McCarthy, 2012) that conducted to social polarization. Homelessness stands out as extreme poverty in the urban environments and it reflects the effects of long term unemployment, under-qualification, occupation in the informal economy and inadequate housing and living conditions (Fitzpatrick et al., 2011). The homeless suffer from severe housing deprivation and social exclusion (Eurostat, 2010) and they lack any form of proper accommodation so that they are forced to sleep in unofficial places – derelict buildings, in informal places – outdoors, or in specially destined places – night and emergency shelters (Brousse, 2004).

Current research on homelessness includes mainly studies about the people living on the streets (May, 2009) – they explain the relation between different spaces (based on functionality) and homelessness and they investigate the conflict raised by the homeless presence in the public space (Cloke et al., 2010; Paasche, 2012; Radicchi, 2012; Schmidt, 2012; Tompsett, Toro, 2010; Young, 2012). While the international literature finds some correlations that explain the homeless location preferences (Lee, Price-Spratlen, 2004; Cloke et al., 2010; Rukmana, 2011; Radicchi, 2012), studies focused on homelessness in Romania (Dan, Dan, 2005; O'Neill, 2010) lack such a geographical approach to evidence the interdependencies and connections between homelessness and territory.

Based on the Bucharest territory assessment, we aimed to identify the urban space patterns that influence the homeless to locate in certain places in the city. The typology of spaces occupied by the homeless reveals the multilevel relation between population, extreme poverty and territory in the Bucharest urban environment.

3 METHODOLOGY

3.1 Study area

The restructuring processes during the transition period (Ceccato, Lukyte, 2011; Göler, Lehmeier, 2012) and

the current financial crisis resulted in increased poverty and homelessness in Romania. Bucharest represents the homeless concentration area in Romania as a side effect of being the main investment area and the most populated urban area. Quantitative studies (Dan, Dan, 2005) estimated 11000 – 14000 homeless people in Romania, with around 5000 homeless persons in Bucharest. The profile of the homeless in Bucharest consists of adult men, between 31 and 60 years old, with secondary education (Paraschiv, 2012), but the

share of women and families living on the streets is increasing. Familial conflicts and former child care residents represent the main causes of homelessness in Bucharest and the main accommodation choices include the underground canals, the improvised shelters and the interior of blocks of flats (Cărăboi, 2011).

3.2 Urban space typology and homelessness

Based on direct field observation, the Bucharest territory was investigated to detect the main areas where the homeless concentrate (Fig. 1). Then, the urban space in these areas was assessed to construct a typology of the space characteristics that act in the homeless location options.

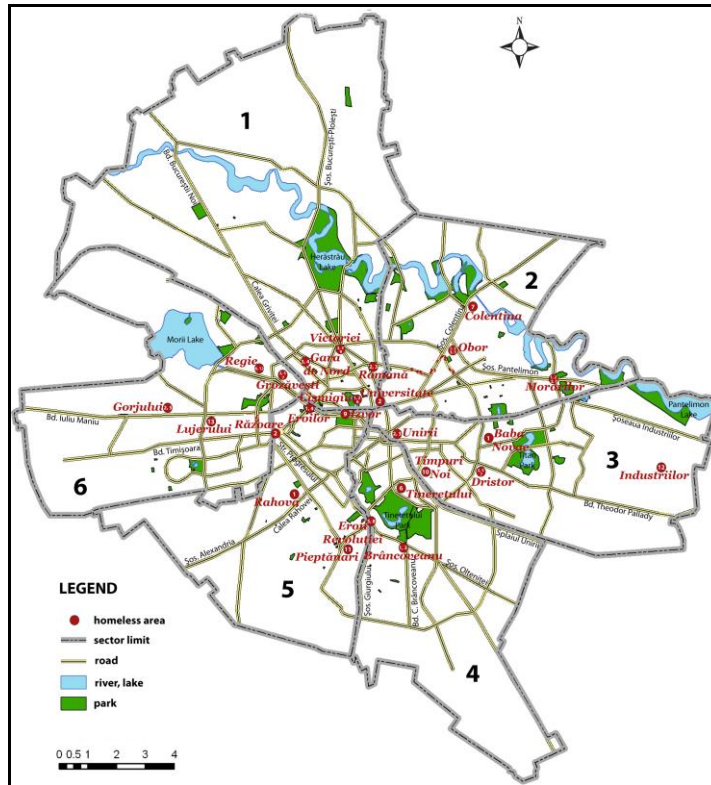

Fig. 1: The homeless concentration areas in Bucharest

The Bucharest urban space assesssment was based on the urban space characteristics resulted from three criteria considered (Fig. 2). The property type of a certain space states for two main and two secondary urban space types: (1) public spaces – semi-public spaces; and (2) private spaces – semi-private spaces. According to their physical structure, urban areas may be open or closed spaces, and their state of use depicts used or derelict spaces. The interrelation between all these characteristics helped to evaluate the homeless areas and to identify the urban space patterns that intervene in the homeless territorial distribution within the city of Bucharest.

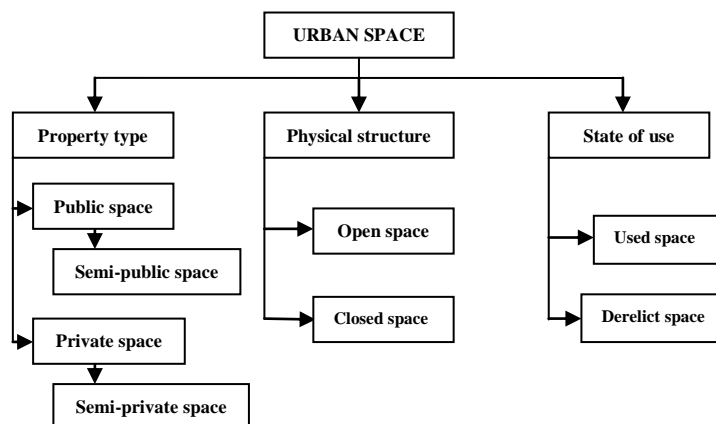

Fig. 2: Characteristics employed in the urban space assessment. Source: adapted after Paraschiv (2013)

4 RESULTS

Homelessness concentrates mainly in the central and the pericentral areas of Bucharest. The analysis of the Bucharest homelessness areas in relation to their space characteristics evidences the typology of functional spaces (Table 1) the homeless use to satisfy their housing and living needs. The public, open and used (in use) spaces include three different functional categories: (1) green spaces – parks frequented by the whole city's population or by the district's population; or neighbourhood gardens and squares; (2) intersections – in the city centre or near commercial areas; pedestrian space – sidewalks in the city centre or around residential spaces; and (3) transport infrastructure space – railway or public transport (metro, bus, tram) stations. The public, open, but derelict spaces where the homeless locate include undeveloped or neglected green spaces – ussually small sized and near institutions (a hospital) or high traffic areas (a railway station). Semi-public places, open and used, refer to commercial spaces like markets, hypermarkets, shopping malls and shops that the general population accesses freely, but the homeless may face restrictions due to their physical appearance. But the homeless locate near these commercial spaces to get money or food. The sewerage infrastructure space represents a public property, but without being destined for public use, so that it constitutes a semi-public, closed and used space the homeless largely choose for sheltering. The sewerage canals gather the group homelessness, formed generally by the homeless people with substance dependencies (drug, alcohol). The homeless utilise the residential space in every state it may be found – in use or abandoned. The only used residential spaces the homeless may employ for sheltering are the blocks of flats, where they find shared spaces – the hallway, the stairs, the basement, the attic – available to use if the inhabitants agree. Otherway, the homeless may live in derelict individual houses or apartment buildings.

Urban space patterns		Homelessness areas
Public/Open/Used space	*Green spaces*	Obor, Morarilor, Baba Novac, Rahova, Cişmigiu, Eroilor, Brâncoveanu
	Intersections, Pedestrian space	Gorjului, Răzoare, Grozăveşti, Romană, Universitate, Obor, Morarilor, Dristor, Cişmigiu, Victoriei, Unirii
	Transport infrastructure space	Gara de Nord, Romană, Obor, Morarilor, Eroii Revoluţiei, Victoriei, Unirii, Brâncoveanu
Public/Open/Derelict space	*Green spaces*	Gara de Nord, Eroilor
Semi-public/Open/Used space	*Commercial spaces*	Gorjului, Grozăveşti, Obor, Dristor
	Religious space	Tineretului
Semi-public/Closed/Used space	*Sewerage infrastructure space*	Grozăveşti, Morarilor, Dristor, Colentina, Gara de Nord
Private/Closed/Used space	*Residential space*	Regie, Eroii Revoluţiei, Cişmigiu
Private/Closed/Derelict space	*Residential space*	Izvor, Victoriei
Semi-private/Open/Used space	*Garbage bin*	Timpuri Noi
	Waste deposits space	Pieptănari
Semi-private/Open/Derelict space	*Vacant space*	Regie, Industriilor
	Brownfield space	Lujerului

Table 1: Homelessness localisation spaces in Bucharest. Source: adapted after Paraschiv (2013)

The semi-private spaces refer to publicly owned spaces destined to private use or without a public functionality – the outdoor garbage bins inside residential areas (used by the inhabitants) and the waste deposits spaces (controlled – used by the sanitation companies; uncontrolled – companies and population deposit waste on vacant spaces). The vacant and the industrial brownfield spaces represent privately owned spaces, inside the city or at the periphery, that are underdeveloped or not yet exploited by the owners, so that the homeless may appropriate and build informal housing – improvised shelters and barracks.

Among the 25 areas in Bucharest identified with homeless presence, 18 areas (72 %) enter the category of public, open and used spaces, so that the homeless locate mostly in parks (7 areas – 28 %), in intersections, on the pedestrian space (11 areas – 44 %), and near the transport infrastructure space (7 areas – 28 %).

Obor and Morarilor, Gara de Nord, Grozăveşti and Cişmigiu represent the areas in Bucharest that gather four and respectively three different urban space patterns used by the homeless to shelter or to find food and money opportunities.

5 DISCUSSION

The distribution pattern of homelessness in Bucharest shows territorial diffusion, but the 25 concentration areas represent spaces with more than 5 homeless people (Paraschiv, 2012). The homeless locate in these places as a response to what these spaces offer to their housing and living needs. The public, open and used spaces give free access to the homeless, without impediments from the general population. They constitute also high traffic areas that may provide better ways to obtain money – through begging or informal work (cleaning car windshields, directing the cars in the parking lots, helping the locals, selling small objects) and food – by begging or by finding leftovers. The green spaces represent the best choice to improvise shelter, but the homeless use also the pedestrian and the transport infrastructure spaces for sleeping.

The commercial areas represent also spaces with high cars and population traffic and they present attraction to the homeless for the same reasons as the public spaces. Religious spaces – churches and cemeteries – represent quick and certain sources of money and food, as the population that frequent these places is used to help the people in need. The sewerage canals are oftenly occupied by the young homeless people and they are associated with the first generation of homeless young people and children (the "street children") that appeared after the 1990s (while the transition period started), due to their escapes from the state child care institutions. The homeless that live in the underground canals form groups and homeless communities in which the individuals rarely conduct behaviours that could lead to reintegration in the society (sobriety, working) – they depict the chronic state of homelessness and homelessness as a way of life, involving huge efforts (financial, time, human resource) to make changements to a normal, more responsible, living and housing condition. Residential spaces, wheter in use or derelict (Fig. 3), and their homelessness utilisation constitute the main reason of conflict between the general population and the homeless people. The homeless depend on the other inhabitants' acceptance and support when they need to shelter in used multifamilial residences.

Fig. 3: Urban localisation patterns of homelessness in Bucharest (2012). (a. derelict green space; b. derelict residential space; c. brownfield space; d. pedestrian space)

The largest share of derelict houses are located in the central part of Bucharest, they represent former nationalised houses (in the socialist period, they were taken from their owners and transformed in public housing) and they are currently in an ambiguous (de jure or de facto) state: (1) these houses are whether in a juridical process to return to their former owners or (2) they are already in the possession of their former owners but not yet in use – they abandon for a while the houses, they allow the homeless to appropriate the space and they wait for the building to be destroyed, case in which the solution is to sell or to develop the space with new, modern and more profitable constructions. The homeless people usually locate in the residential areas or they shelter near the space destined to residential waste deposits in the neighbourhoods where they used to live or to frequent before their state of homelessness. The vacant land and the industrial brownfield sites give the highest degree of freedom to the homeless to appropriate the space, to use the largest land surfaces and to exploit it to satisfy most of their housing and living needs.

The main findings of the research show that the urban space patterns interact with the homeless population and it support their subsistence in different ways, according to the urban space characteristics that define their accessibility and functionality.

6 CONCLUSION

Urban poverty and homelessness reflect deficiencies in conducting a sustainable relation between population and territory and they represent current challenges in the territorial systems development. The geographical approach contributes to evidence the complex interconnection between homelessness and urban space, to explain the exchanges involved and the results that act in the functioning of the entire urban environment. The urban space patterns influence the homeless decisions to locate in certain places and they explain the homelessness territorial distribution. The urban planners and the policy makers may use the main findings of the study to construct more integrative strategies to end homelessness in Bucharest.

1   ABSTRACT

VIATOR (lat. "the traveller") is a mobile platform for smartphones that guides disabled (i.e., blind or physiaclly impaired) persons on their journeys using means of public transportation. It appropriately provides up-to-date information concerning connections, delays and alternative transportation options across different transportation companies. It considers physical obstacles and hints for each particular target group (e.g., stairs vs. elevators for wheelchair users), triggers re-planning if required, and provides an open interface for leaving self-created location-bound hints for each desired target group (e.g., blind people guide blind people) such that the mobile phone appears as an active companion throughout the journey. This paper presents the technical architecture for VIATOR, which is based on an open, extensible framework for mobile location-based services (named Digital Graffiti) and illustrates the results of a first prototype implementation.

2   INTRODUCTION

Disabled persons are facing a manifold of disadvantages when using public transportation. On the one hand, stairs and raised vehicle entrances are considered insuperable obstacles for wheelchair users. On the other hand, missing tactile lines or path descriptions prevent blind or visually impaired people from maneuvering on their own at public transportation nodes. Existing information- and navigation systems for public transportation only instruct their users in terms of transportation means, departure times and departure platforms. Instructions considering the way to and from public vehicles for handicapped persons especially at larger transportation nodes are lacking or outdated due to ponderous and inflexible content management mechanisms at the backend of such systems. Moreover, most of the systems are proprietary and unable to link to competing transportation companies in order to provide a closed information chain for a journey.

In the course of the research project ways2go within the framework of the strategic initiative IV2Splus funded by the Austrian government (FFG) a prototype for a mobile travel companion for disabled persons informing them not only about means of transportation but also guiding them through stations regarding their needs has been developed. It consolidates diverse travel information systems and provides navigation instructions from arbitrary sources, even from the users themselves (self-organizing content management).

The technical basis for implementing this research issue is a mobile location-based and context-sensitive information-, communication-, and collaboration system (Digital Graffiti) (NARZT 2013) developed by the University of Linz, in association with Siemens Corporate Technology in Munich, and the Ars Electronica Futurelab also in Linz, which enables its users to arbitrarily place and consume information in both public and private locations using state-of-the-art mobile tracking-enabled cell phones and the current location of a user as a contextual input for appropriate delivery of information. Travel information (including up-to-date actual data of delays, cancellations or detours, etc.) is provided, classified and made generic for shared networking by the project partners ÖBB (Austrian Federal Railways Company), OÖVG (Upper Austrian Transport Association) and Linz AG (Local Traffic Line Service Provider in Linz). In cooperation with the Department Integriert Studieren at the University of Linz and CEIT Alanova (Central European Institute of Technology in Vienna) new paradigms for barrier-free interaction have been created not only guiding users but also offering them an instrument to provide self-created content for other users. Blind people shall be able to annotate their way for other blind people regarding their special needs.

3   STATE-OF-THE-ART

Unaided free movement for people with disabilities using public transportation is the focus of research in a project called NAVCOM (BISCHOF 2012). Blind persons are required to find the right vehicle or to signal their wish to enter or leave a vehicle. The authors propose a WLAN-based system communicating between public transportation vehicles and smartphones, an extension to navigation systems for pedestrians, the

functionality of which ends at the entrance door of the vehicles. In general, this project group investigates the potentials of technical support for navigating handicapped people in public spaces. Within the project ways4all (funded by the Austrian government), they explore indoor navigation for visually impaired persons using RFID, in order to compose navigation instructions not based on absolute coordinates (KIERS 2011).

MofA – Mobility for All (MOFA 2010) is a project that goes a step beyond when planning public transportation nodes. The project provides tools for creating accessible squares, entrance areas and accessible public transport buildings. It employs weak-point analysis in order to manifest rating systems for travel information services, evaluating form and up-to-dateness of the provided information (e.g., real-time capabilities, elevators, width of doors, stairs and level differences, etc.). The project focuses on mobility in public space and compares existing approaches and comes up with new description-, observation- and classification methods for accessibility-checks including recommendations to solve the discovered problems.

A similar approach is examined as the key issue in the project MoViH (MOVIH 2011) trying to identify both mobility and hindering factors for persons with visual or hearing impairments. The outcome of the findings is a catalogue of effective and efficient measures to be depicted in recommendations and standards supporting public transport companies in planning environments considering special needs of blind or acoustically disabled persons. BIS – Barriere Informations System (BIS 2012) especially focuses on the requirements of wheelchair users. The project aims at developing a barrier-free interactive routing system in close coordination with the target group, technology experts and administrative and political stakeholders throughout the research process in order to calculate and visualize the most suitable ways to go for wheelchair users.

In terms of closed information chains across different transportation companies, hardly any reasonable solution exists for commercial usage, yet. Public transportation service providers offer proprietary information systems enabling their users to consume provider-specific travel information on their mobile phones when entering their desired start and target coordinates into a provider-related mobile app (e.g., Scotty – a route planning service of ÖBB (SCOTTY 2011). The integration and consolidation of various proprietary information systems is a particular challenge.

Target-oriented automatic delivery of information to the traveler (e.g., for indicating a transfer or delay) is the next field of investigation. Most systems do not inform their users about changes in the time schedule, once the trip has been calculated. Travel information has to be requested from scratch at every transition point or is difficult to handle due to a complex system of rules across transportation providers. Until today, to the authors' knowledge, there is no automatic mobile travel information system that continuously guides the passenger during his journey and context-sensitively keeps him up-to-date considering transfers or delays.

However, reference to actuality and automatic delivery of personalized travel information (and consequently the difficulty of a closed information chain) are already recognized as key issues in a series of current research projects: WISETRIP – Wide scale network of e-systems for multimodal journey planning and delivery of trip intelligent personalized data (FOSTIERI 2007) is an approach within the course of an EU project to connect different travel information systems and transmit personalized data in real-time. Similarly, i-Travel – service platform for the connected traveler (KOMPFNER 2007) is trying to develop a virtual travel assistant providing current travel information for passengers during their journey. OASIS – Open architecture for accessible services integration and standardization (BONFIGLIO 2007) even goes a step beyond and develops a generic platform for integrating different information services.

As a summary, we already recognize a series of isolated research subjects dealing with navigation aspects for disabled persons or closed information chains. The VIATOR project aims at integrating all these issues with a different and innovative approach based on utilization of a smart location-based information system, which is capable of triggering specific actions due to regional closeness of its users to selected locations.

4 ARCHITECTURE

The technological basis for VIATOR is a location- and context-based platform named Digital Graffiti (NARZT 2013), which connects any position in three-dimensional space to arbitrary information ele-ments (e.g., text, images, sound, videos, links, or even executable code). This data tuple (geo-position and information element) is provided with a visibility space and a set of recipients and is transferred when any of the recipients crosses the visibility space. For related developments see e.g., (AIT-CHEIK-BIHI 2011). In

particular, the technology platform enables depositing information in the form of Digital Graffiti on mobile devices at any location in public and private space and consuming such. As a special feature, the platform offers automatic control of electronic actions (e.g., opening a gate, starting or stopping a machine, triggering a measurement or transaction) without any additional manual action, when a given device is in the vicinity of a Digital Graffito containing executable code (see NARZT 2009, NARZT 2011), presuming adequate access privileges that relate to a person, a device, a software system, etc. or that results indirectly through the settings of a certain interest profile.

Applying this platform as the technological basis for a mobile public transportation guide means utilizing the location-based action control mechanism for up-to-date calculations regarding transpor-tation schedules. In particular, the transportation companies have to provide standardized interfaces for requesting their schedules, enabling their users to site-specifically and automatically perceive appropriate departure information when they arrive at a station or stop (similar to the big screens showing the departing trains). The user is consequently able to pick the desired destination by a single click and thus to anonymously specify a route.

Concerning travel routes across transportation companies, the system does not invent routing algorithms and scheduling procedures from scratch. Instead, it utilizes existing services and triggers them on demand in the same way as the time schedule example given above. So, the system continuously (and also location-sensitively) re-initiates calculations regarding the selected route by the location-based action control mechanism. This means, that a user automatically triggers the route planning service of the appropriate vendor at spatial proximity to his next stop and is informed about his schedule and connecting means of transport, giving the passenger a continuous information chain during his journey.

Barrier-free and target group-related routing is based on the same mechanism: Whenever a user enters a station or stop he automatically triggers navigation calculations due to his user profile (i.e., specifying the type of disability), selected route and schedule. These calculations are externally sourced out to special route computing services with centralized data collections to be updated either via CMS operators or by the users of the system themselves, who are able to edit these instructions due to their experiences on-site via the inherited mechanism of the basic system for editing Digital Graffiti information elements.

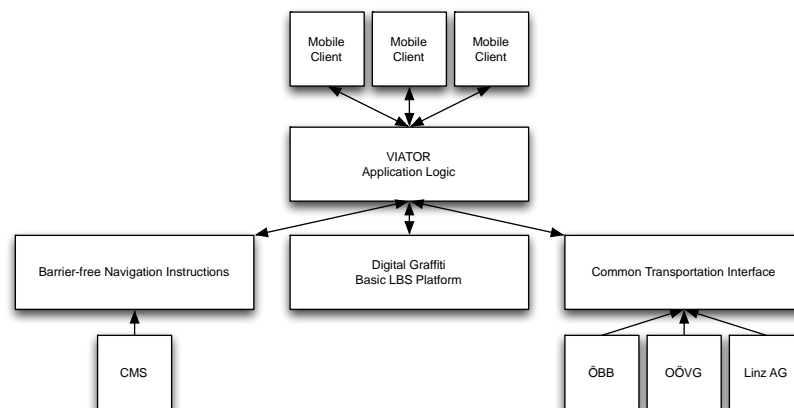

Fig. 1: VIATOR system architecture (simplified excerpt)

Thus, the general mechanism for barrier-free navigation across transportation companies providing up-to-date travel information and offering an active notification- and feedback instrument for direct interaction and self-organization of the information content is based on location-based action control, a function available from the basic platform Digital Graffiti. Thus, the VIATOR system does not contain complicated new algorithms for managing complex collaboration of different information providers. Instead, it utilizes a simple mechanism applied for all tasks, which makes the entire system easy to understand, maintain and extend.

Fig. 1 gives an impression on the collaboration of involved components, neglecting details due to space limitations: The application logic is encapsulated within the main VIATOR server component, communicating to its basic platform Digital Graffiti, which remains completely unchanged in its elementary behavior and is executed as a separate process. The mobile clients connect to the main VIATOR server component, which delegates all Digital Graffiti-related functions to its underlying platform, enabling the

clients to create and consume location-based information elements. The system is extended by two separate processes consolidating travel information from different transportation providers on the one hand (right side) and providing barrier-free navigation instructions on the other (left side). The latter can either be managed through CMS or via the VIATOR application logic indirectly by the clients.

5 PROTOTYPE

The system architecture as shown in Fig. 1 has been prototypically implemented by the University of Linz using JBoss AS7 Java Enterprise Application for the server components and Android for the clients. The project partners ÖBB (Austrian Federal Railways Company), OÖVG (Upper Austrian Transport Association) and Linz AG (Local Traffic Line Service Provider in Linz) have provided their data through the Common Transportation Interface (see Fig. 1) and CEIT Alanova has provided route calculations for disabled persons to be retrieved from their server component.

For the users, the system depicts as follows (the user interface is kept rather simple in order to comply with requirements concerning blind users, for whom only the texts in appropriate order are essential, see Fig. 2):

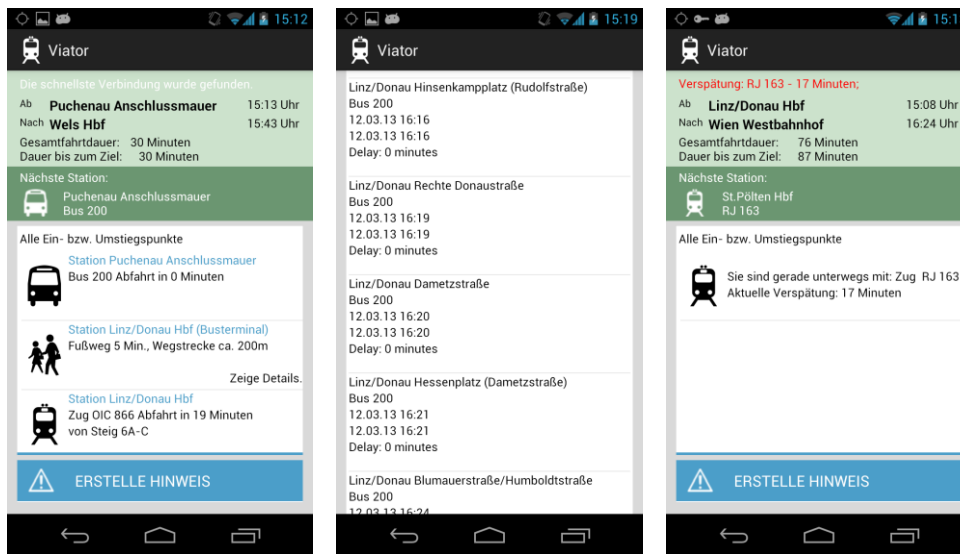

Fig. 2: VIATOR user interface. (a) display route, (b) display details on route, (c) automatic announcement of a delay

The system starts with a screen requesting the desired destination (not depicted here). The user can either enter (and auto-complete) a destination or select from a list (considering the transportation options due to the user's current location). A summary of the input, the next station and all subsequent maneuvers are listed (Fig. 2b). For each list item, the user is able to take a detailed look and experience the consecutive stops and times during his journey (Fig. 2c).

Fig. 3: Barrier-free usage: (a) select impairment, (b) maneuver instructions for blind persons, (c) self-created content

So far, the VIATOR looks similar to existing travel information systems. The first difference is noticeable, though, when unforeseen events occur and the route changes (i.e., either means of transportation or the schedule). In these cases, VIATOR actively reacts, informs the traveler about the change and immediately calculates and displays the traveller's new options without manual intervention. Fig. 2c gives an example of a delay immediately announced via sound to the user.

In terms of barrier-free usage, VIATOR offers to select the type of impairment as part of the user profile. The prototype implementation contains two options for blind and disabled persons (see Fig. 3a). Fig. 3b shows a (pretended unstructured) flow of text representing navigation instructions for blind people. A visual format is unnecessary, though, because this text is meant to be read by screen readers and is only considered for the target group of blind persons. Fig. 3c finally gives an impression of an editing tool enabling its users to create or update those navigation instructions (self-organization).

Fig. 4: First experiments: (a) blind person instructed by VIATOR, (b) announcement during journey, (c) finding tactile lines

At this time of writing, the project consortium has conducted first experiments using VIATOR by either blind persons or wheelchair users. Fig. 4 shows impressions caught during those tests, where a blind person is acoustically instructed by VIATOR regarding his next means of transport (Fig. 4a), actively informed about his next steps during the journey (Fig. 4b), and prepared to find the tactile lines when leaving the transportation vehicle (Fig. 4c).

6 CONCLUSION

VIATOR is an approach of integrating both provider-related transportation information and barrier-free navigation instructions based on a location-sensitive platform. It does not apply complicated rules for providing up-to-date information and announcements, but uses the mechanism of location-based action control from its underlying core Digital Graffiti for initiating calculations regarding a user's destination, his current whereabouts and disabilities. A first prototype implementation has proven applicability in the course of several tests (improvements due to experienced weak points are still to be incorporated) conducted by the target group of disabled persons.

1 ABSTRACT

Während die Kosten des Kfz-Verkehrs meist keiner Rechtfertigung bedürfen, stehen die Kosten für Radverkehr und öffentlichen Personennahverkehr (ÖPNV) regelmäßig in der öffentlichen Diskussion. Einer der Gründe ist, dass die Kosten der einzelnen Verkehrsmittel (Investitions-, Unterhaltungs- und Betriebskosten) und ihr Verhältnis zueinander nicht bekannt sind: Verkehrsrelevante Kosten sind in deutschen Kommunen auf verschiedene Teilhaushalte und Haushaltsstellen verteilt und damit für die verschiedenen Verkehrsmittel nicht transparent. Außerdem existieren wesentliche Unterschiede in der haushälterischen Berücksichtigung, die bestimmte Verkehrsmittel systematisch benachteiligen.

Es soll daher eine Methode entwickelt werden, mit der aus kommunalen Haushalten die Aufwendungen und Erträge für Investition und Betrieb differenziert nach Verkehrsmitteln (Radverkehr, Fußverkehr, Kfz-Verkehr, ÖPNV) in einer Stadt angegeben und einander gegenübergestellt werden können. Diese Methode soll anhand der Haushaltspläne der Städte Bremen und Kassel erarbeitet und exemplarisch dargestellt werden.

Im ersten Schritt wird untersucht, welche Relevanz verschiedene Haushaltspositionen jeweils für einzelne Abschnitte des Verkehrsnetzes haben. Beispielsweise ist der Winterdienst für Erschließungsstraßen von geringerer finanzieller Relevanz als für Hauptverkehrsstraßen oder Fußgängerzonen. Bei der Straßenbeleuchtung und der Straßenreinigung sind etwa Hauptgeschäftsstraßen anders zu behandeln als Straßen in Gewerbegebieten. Im folgenden Schritt werden den Verkehrsmitteln – Fuß-, Rad-, Kfz-Verkehr und ÖPNV – jeweils die Netzabschnitte zugeordnet, die sie nutzen können.

Eine wesentliche Herausforderung in dem Vorhaben ist die Entwicklung sachgerechter Aufteilungsverfahren, da der Verkehrsraum in den meisten Fällen von mehreren Verkehrsmitteln genutzt wird. Mit Hilfe von digitalen Netzdaten lassen sich Teilnetze für verschiedene Verkehrsmittel bilden und Aufteilungsschlüssel für Aufwendungen und Erträge differenziert nach (gewichteter) Netzlänge und verschiedenen Typen von Straßenquerschnitten erarbeiten. Für die verschiedenen Netzelemente sind Aufteilungsschlüssel für z. B. Betriebs-, Unterhaltungs- und Abschreibungsaufwendungen zu ermitteln. Die Eingangsgrößen und die getroffenen Annahmen wurden in einem Expertenworkshop diskutiert und weiterentwickelt, darüber hinaus fanden Experteninterviews mit Vertretern der Stadtkämmerei, der Fachabteilungen und der städtischen Betriebe (Stadtreinigung, Energieversorgung, Verkehrsbetriebe) aus den Beispielkommunen statt.

Die zu entwickelnde Methode soll in erster Linie als Entscheidungshilfe dienen und dazu beitragen, dass in Städten Haushaltsmittel effektiver eingesetzt werden können. Das Forschungsprojekt wird im Rahmen des "Nationalen Radverkehrsplans" vom deutschen Bundesministerium für Verkehr, Bau und Stadtentwicklung gefördert und vom Fachgebiet Verkehrsplanung und Verkehrssysteme der Universität Kassel bearbeitet.

Im Vortrag sollen die vorhandenen Systeme zur verkehrsmittelbezogenen Kostenermittlung vorgestellt, ein Überblick über die verkehrsrelevanten Aufwendungen und Erträge aus der Analyse der kommunalen Haushalte der Beispielstädte gegeben und die zentralen Ansätze der zu entwickelnden Aufteilungsmethode erörtert werden.

2 PROBLEMSTELLUNG/MOTIVATION

2.1 Motivation und Ziel

Radverkehr und Fußverkehr spielen eine Schlüsselrolle für die umwelt- und stadtverträgliche Mobilität. Die entscheidende Rolle spielen dabei die weltweit wachsenden Städte: In den Städten werden die politischen

Entscheidungen getroffen, welche Bedingungen für welche Mobilitätsformen geschaffen werden. Auf der kommunalen Ebene fallen auch die wesentlichen Entscheidungen, wie und für welche Verkehrsmittel die finanziellen Mittel eingesetzt werden. Darüber hinaus liegen in Städten die wesentlichen Potentiale für die Verlagerung von Verkehr auf umweltfreundliche Verkehrsmittel, da gerade im Nahbereich nicht-motorisierte Verkehrsmittel ihre Stärken ausspielen können. Gleichzeitig ist in Städten das öffentliche Verkehrsangebot in der Regel gut ausgebaut, sodass Potentiale für multimodales Verkehrsverhalten vorhanden sind.

Aus verschiedenen Gründen sind dabei bestimmte Verkehrsmittel gegenüber dem Kfz-Verkehr benachteiligt: Zunächst herrscht keine Transparenz über die Höhe der Aufwendungen und Erträge für die verschiedenen Verkehrsmittel. Ein zweiter Punkt ist, dass sich die Finanzierung je nach Verkehrsmittel wesentlich unterscheiden: Während etwa für kommunale Verkehrsunternehmen ohne Weiteres ein jährliches Defizit als Aufwendungen der Stadt (bzw. ihrer Bürger) angegeben werden kann, sind Kosten für Straßenbau- und Unterhaltung auf verschiedene Teilhaushalte und Haushaltsstellen verteilt und damit weder insgesamt noch verkehrsmittelspezifisch bekannt. Eine wichtige Rolle spielen in Deutschland auch Fördermittel, die eine Stadt von Land oder vom Bund erhält. In der öffentlichen Diskussion kann dies dazu führen, dass geförderte Infrastrukturprojekte aufgrund eines relativ kleinen Eigenanteils der Kommune als kostengünstiger wahrgenommen werden als Projekte, die vollständig von der Kommune finanziert werden müssen. Häufig sind Infrastrukturprojekte, die der Verbesserung des nicht-motorisierten Verkehrs dienen, allein aufgrund der relativ geringen Kosten nicht förderfähig. Damit wirken sich die Unterschiede in der Finanzierung nachteilig aus und führen zu Fehlanreizen und Fehlentscheidungen. Transparenz und Kostenwahrheit kann daher die Akzeptanz fördern und umweltfreundliche Nahmobilität stärken.

Umwelt- und Klimaschutzziele sowie das Ziel einer Entlastung von negativen Folgen des Verkehrs können in Städten aber meist nur im Bestand erreicht werden. Der in Deutschland vorhandene Trend zur Reurbanisierung führt in der Mehrheit der größeren Städte zu einem Bevölkerungszuwachs. Dies bedeutet aber auch, dass im gleichen Straßenraum zusätzlichen Nutzungsansprüchen begegnet werden muss und dass die Nutzungskonkurrenz zwischen verschiedenen Verkehrsmitteln herrscht.

Eine Chance, mehr Transparenz zu erreichen, liegt in der Einführung der Doppik (Doppelte Buchführung in Konten), wodurch erstmals für den Stadtkonzern, bestehend aus der Kernverwaltung und den privatrechtlich geführten städtischen Unternehmen ein einheitliches Rechnungswesen vorhanden ist. Durch die Einführung der Doppik ist es möglich, die Entwicklung des Vermögens einer Stadt zu betrachten. Die Doppik wird in zwölf von 16 deutschen Bundesländern bis 2016 eingeführt, in vier Bundesländern gibt es eine Wahlmöglichkeit zwischen einer erweiterten Kameralistik und der Doppik [BERTELSMANN STIFTUNG/KOMMUNALE GEMEINSCHAFTSSTELLE FÜR VERWALTUNGSMANAGEMENT].

Ziel ist es daher, eine Methode zu entwickeln, mit der Aufwendungen und Erträge in kommunalen Haushalten für Investition und Betrieb differenziert nach Verkehrsmitteln (Radverkehr, Fußverkehr, Kfz-Verkehr, öffentlicher Nahverkehr) in einer Stadt angegeben werden können. Der Aufwand für Datenbeschaffung und Durchführung soll dabei angemessen und handhabbar sein. Die Methode soll anhand der Haushaltspläne der Städte Bremen und Kassel erarbeitet werden, allerdings soll sie im Ansatz auch auf andere Städte übertragbar sein. Die Ergebnisse sollen exemplarisch anhand der Beispielstädte dargestellt werden.

2.2 Stand der Forschung

2.2.1 Studien der Organisation ICLEI zu Subventionen des Autoverkehrs

Das Europasekretariat der Organisation ICLEI – Local Governments for Sustainability hat mit finanzieller Förderung des deutschen Umweltbundesamtes 2001 die Haushalte der Städte Bremen, Dresden und Stuttgart untersucht. Ziel war es, die offensichtlichen und die versteckten Einnahmen und Kosten des motorisierten Individualverkehrs (MIV) zu ermitteln. Im Mittelpunkt stand die Abschätzung von Anteilen mit MIV-Relevanz an den einzelnen Haushaltsabschnitten auf Basis von Haushaltsanalysen und Experteneinschätzungen.[ICLEI-EUROPASEKRETARIAT 2001] Im Jahr 2006 veröffentlichte ICLEI Ergebnisse für neun weitere deutsche und drei ausländische Städte.[ICLEI-EUROPASEKRETARIAT 2005] Diese Vorgehensweise griff das Verkehrswissenschaftliche Institut Stuttgart auf und verglich im Auftrag der Stadt Stuttgart die kommunalen Kosten der Stadt Stuttgart für verschiedene Verkehrsmittel in den Jahren 2002 bis 2006. Diese Studie wurde allerdings nicht veröffentlicht.[FAIRKEHR]

2.2.2   Least Cost Transportation Planning (LCTP)

Im Jahr 2002 wurde das Konzept der „Least Cost Transportation Planning (LCTP)" vorgestellt, das im Auftrag des Umweltbundesamtes entwickelt wurde. Mit Hilfe dieses Konzeptes können Verkehrsprojekte hinsichtlich ihrer Kosten (private und öffentliche Kosten) und Umwelteffekte beurteilt werden. Das Verfahren basiert auf einer „virtuellen Firma" mit den verschiedenen Verkehrsträgern MIV, Lkw-Verkehr, ÖPNV, Fußgängerverkehr und Fahrradverkehr als Abteilungen. Ausgabenträger der „Firma" sind die Nutzer und die öffentliche Hand, unterteilt nach Gebietskörperschaften und kommunalen Verkehrsunternehmen. Es werden auch Mittelflüsse innerhalb des öffentlichen Sektors berücksichtigt (z. B. Zuschüsse). Betrachtungsgegenstand sind die Ausgaben und Einnahmen aus den kameralistisch geführten Haushalten; Kapitalkosten werden als Gemeinkosten betrachtet, die nicht dem Rad- und Fußverkehr, sondern nur den anderen Verkehrsmitteln angelastet werden. Gleiches gilt für externe Kosten. Auswirkungen auf die Umwelt werden in originären Messgrößen erfasst. Für die Aufteilung wird ein „Straßennutzungsindikator" verwendet. Dieser wurde für die Städte Freiburg und Schwerin ausgearbeitet und gibt die Beanspruchung der Verkehrsfläche und die Abnutzung von Infrastruktur an. Die Verteilung der Gesamtausgaben erfolgt pro Personen-, Platz- oder Fahrzeugkilometer. Daher sind auch Jahresfahrleistungen der einzelnen Verkehrsmittel als Eingangsgrößen für die Anwendung der LCTP erforderlich. Die LCTP wurde in vier Modellkommunen (Görlitz, Göttingen, Hannover und Heidelberg) testweise angewendet und evaluiert.[UMWELTBUNDESAMT]

2.2.3   Weitere Studien

Für die Berechnung von Mautsätzen wurden verschiedene Verfahren für Wegekostenrechnungen entwickelt. Diese beziehen sich allerdings auf Fernstraßen und unterschiedliche Fahrzeugklassen und sind daher nicht ohne weiteres auf die vorliegende Fragestellung übertragbar.

Das Deutsche Institut für Urbanistik (Difu) und die Planersocietät Dortmund haben in einem Forschungsprojekt im Auftrag des Bundesministeriums für Verkehr, Bau und Stadtentwicklung einen „Verkehrsfolgekostenschätzer" entwickelt, mit dem für Neubaumaßnahmen neben den Herstellungs- auch die Folgekosten von Verkehrsinfrastruktur für öffentliche Haushalte angegeben werden können. Zur Kostenermittlung werden Elemente der Infrastruktur geplant, so z. B. für die innere Verkehrserschließung die Verkehrsflächen, Straßenlängen, Leuchtpunkte und Straßenbegleitgrün.[BUNDESMINISTERIUM FÜR VERKEHR, BAU UND STADTENTWICKLUNG, 2011a] Aufgrund der Zielsetzung des Vorhabens ist allerdings kein Vergleich verschiedener Individualverkehrsmittel mit dem Verkehrsfolgekostenschätzer möglich, sondern lediglich von IV und ÖPNV.[BUNDESMINISTERIUM FÜR VERKEHR, BAU UND STADTENTWICKLUNG, 2011]

3   METHODISCHES VORGEHEN

3.1 Gegenstand der Betrachtung/Methodische Vorüberlegungen

Gegenstand der Untersuchung sind die verkehrsrelevanten Aufwendungen und Erträge der Städte. Dabei reicht es nicht aus, den kommunalen Haushaltsplan zu betrachten, da verkehrsrelevante Aufwendungen und Erträge nicht vollständig im Haushalt dargestellt sind. Ein Beispiel hierfür ist der in Deutschland übliche Defizitausgleich des kommunalen Verkehrsunternehmens aus Gewinnen aus Wasser- und Stromversorgung innerhalb des Stadtwerkekonzerns. Daher müssen außer den Haushaltsplänen der Städte auch die Bilanzen der städtischen Unternehmen betrachtet werden. Somit kann man von einem „Stadtkonzern" sprechen, in dem ein einheitliches doppisches Rechnungswesen angewendet wird. Betrachtet wird die gesamte kommunale Leistungserbringung für Bau, Betrieb und Unterhaltung der Verkehrsinfrastruktur bzw. Verkehrssysteme. Dazu gehören auch Aufwendungen für Verwaltung. Für die Leistungserbringung können verschiedene Organisationseinheiten dieses „Stadtkonzerns" zuständig sein. Daher müssen die Rechnungsunterlagen der Stadt, ihrer kommunalen Unternehmen und der Eigenbetriebe betrachtet und später im Aufteilungsverfahren berücksichtigt werden. Tabelle 1 zeigt die Rechnungsunterlagen und die jeweiligen Organisationseinheiten des „Stadtkonzerns".

Organisationseinheit	Rechnungsunterlage
Kernverwaltung	Haushaltsplan
kommunale Unternehmen	Geschäftsbericht
Eigenbetriebe	Wirtschaftsplan

Tabelle 1: Organisationseinheiten und Rechnungsunterlagen im "Stadtkonzern"

Die Betrachtung als „Stadtkonzern" lehnt sich an die Vorgehensweise der LCTP an, in der alle Verkehrsdienstleistungen von einer fiktiven „Firma" erbracht werden. Allerdings gibt es wesentliche Unterschiede: In der hier zu entwickelnden Methode werden als Eingangsgröße doppische Haushalte betrachtet und nicht mehr kameralistische geführte. Kapitalkosten werden daher den Verkehrsmitteln anders zugeordnet. Zudem werden hier u. a. Nutzerkosten nicht betrachtet.

Prinzipiell können folgende Kostenarten unterschieden werden:

- Investitionskosten (z.B. für Neubaumaßnahmen der Verkehrswegeinfrastruktur, für Anschaffung von Fahrzeugen des ÖPNV),
- laufende Kosten (z.B. Betrieb und Unterhaltung der Verkehrswegeinfrastruktur und der Fahrzeuge des ÖPNV, Personalkosten),
- Kapitalkosten (Abschreibungen, Zinsen).

3.2 Grundzüge des doppischen Haushaltes

Vor der Einführung der Doppik führten die Kommunen ihre Haushalte nach der Kameralistik. Die Kameralistik ist eine Geldverbrauchsrechnung, in der kalkulatorische Kosten (z. B. Werteverzehr des Vermögens) außer Acht bleiben. Demgegenüber hatten die privatrechtlichen städtischen Unternehmen ein doppisches Rechnungswesen. Die Doppik führt also zu einer Vereinheitlichung des Rechnungswesens innerhalb des „Stadtkonzerns". Die Einführung der Doppik bedeutete auch, dass erstmals der Wert des Vermögens einer Stadt bilanziert werden musste.

Bestandteile des kommunalen Haushaltes sind der Ergebnisplan, der Finanzplan und die Teilpläne. Der kommunale Haushalt nach dem Prinzip der Doppik setzt sich zusammen aus der Bilanz, dem Ergebnishaushalt und dem Finanzhaushalt. Die Bilanz bildet die Struktur des Vermögens ab. Im Ergebnishaushalt stehen alle Aufwendungen und Erträge; er bildet Kosten und Leistungen ab und folgt damit betriebswirtschaftlichen Prinzipien. Der Ergebnishaushalt beeinflusst die Abschreibungen und das Jahresergebnis in der Bilanz. Der Finanzhaushalt erfasst alle Zahlungsströme – alle Einzahlungen und Auszahlungen; er folgt kameralistischen Prinzipien und wirkt sich auf die liquiden Mittel in der Bilanz aus. Der Ergebnishaushalt und der Finanzhaushalt werden jeweils in Teilpläne untergliedert.[SCHWARTING 2006] Die kommunalen Aktivitäten werden als Produkte aufgeführt. Die Produkte gliedern sich in Produktgruppen über mehrere Stufen bis zu den einzelnen Produkten. Eine Schwierigkeit des Produktplans ist, dass die Gliederung im Vergleich zum früheren Haushaltsrecht weniger verbindlich vorgeschrieben ist. So können die Kommunen Teilhaushalte entweder nach Produktbereichen und Produktgruppen (produktorientiert) oder nach Organisationsbereichen (organisationsorientiert) gliedern.[SCHWARTING 2006].

Die Strömungsgrößen in Ergebnis- und Finanzplan sind in Tabelle 2 dargestellt.

Ergebnisplan	Finanzplan
Erträge Steuern Zuweisungen und Zuschüsse für laufende Zwecke öffentlich-rechtliche Leistungsentgelte aktivierte Eigenleistungen Auflösung von Sonderposten	Laufende Einzahlungen Steuern Zuweisungen und Zuschüsse für laufende Zwecke öffentlich-rechtliche Leistungsentgelte
Aufwendungen Personalaufwendungen Aufwendungen für Sach- und Dienstleistungen Abschreibungen	Laufenden Auszahlungen Personalauszahlungen Auszahlungen für Sach- und Dienstleistungen
	Einzahlungen aus Investitionstätigkeiten
	Auszahlungen aus Investitionstätigkeiten
	Einzahlungen aus Finanzierungstätigkeiten
	Auszahlungen aus Finanzierungstätigkeiten

Tabelle 2: Strömungsgrößen im kommunalen Haushaltsplan nach der Doppik. Quelle: Schwarting, Gunnar: Den kommunalen Haushaltsplan – kameral und doppisch – richtig lesen und verstehen, 3. Auflage, Mainz 2005

3.3 Grundsätzliche Vorgehensweise der Aufteilungsmethode

In diesem Abschnitt wird die Aufteilungsmethode in Grundzügen vorgestellt, die es ermöglicht, die in den kommunalen Haushalten verbuchten Verkehrskosten anteilig den einzelnen Verkehrssystemen (Kfz-Verkehr, Fußgängerverkehr, Radverkehr) zuzuordnen.

Betrachtet wird der Ergebnishaushalt: In ihm sind Aufwendungen und Erträge dargestellt. Die Betrachtung des Finanzplans ist für die vorliegende Fragestellung nicht sachgerecht, da er lediglich Geldflüsse darstellt. Ein wesentlicher Nachteil ist, dass im Finanzplan Abschreibungen nicht aufgeführt sind, weil ihnen kein Mittelfluss gegenübersteht. Zweitens sind aus Geldflüssen im Finanzplan oft keine Rückschlüsse auf den tatsächlichen Werteverbrauch, ausgedrückt als Abschreibungen, möglich. Beispielsweise werden Investitionsmaßnahmen oft erst nach Jahren vollständig abgerechnet.

Demgegenüber können für die Abschreibungen im Ergebnisplan und das Vermögen Aufteilungsschlüssel entwickelt werden, mit denen die Beträge aufgeteilt werden können, die nicht direkt einem Verkehrsmittel zurechenbar sind. Die folgenden Aufwendungen und Erträge sollen differenziert für folgende Verkehrssysteme dargestellt werden:

- Fußverkehr: insbesondere Aufwendungen für die Infrastruktur

- Radverkehr: insbesondere Aufwendungen für die Infrastruktur

- Kfz-Verkehr: Neben Aufwendungen für die Infrastruktur kommen vor allem Aufwendungen für Verkehrsüberwachung, Straßenverkehrsbehörde und Kfz-Zulassungsbehörde zum Tragen. Im ruhenden Verkehr spielen vor allem auch Erträge aus der Parkraumbewirtschaftung und Gebühren oder Pacht für Parkhäuser oder Tiefgaragen eine Rolle.

- ÖPNV: Zum ÖPNV zählt der Verkehr mit öffentlich zugänglichen Verkehrsmitteln, für den die betreffende Kommune Aufgabenträger ist und damit die Finanzverantwortung trägt. Dies umfasst in der Regel den straßengebundenen öffentlichen Personennahverkehr, d. h. Linienbus-, Straßenbahn- und U-Bahnverkehr. Regionalverkehr, für den Dritte (z. B. das Land oder ein Zweckverband) Aufgabenträger sind, sowie der Fernverkehr auf der Schiene zählen nicht dazu. Für Bau und Betrieb der Straßenbahn- bzw. U-Bahninfrastruktur sowie für die Erbringung der Betriebsleistung sind in der Regel kommunale Verkehrsunternehmen zuständig. Allerdings verursacht der Linienbusverkehr auch Aufwendungen für die Straßeninfrastruktur, die bei der Aufteilung der Straßeninfrastrukturkosten berücksichtigt werden müssen.

Betrachtet werden also jene Aufwendungen und Erträge, für die die Stadt oder ihre Unternehmen die finanzielle Verantwortung haben. Besondere Verkehrsinfrastrukturen wie Häfen oder Flughäfen werden nicht berücksichtigt. Es entstehen zwar durch diese Verkehrsinfrastrukturen Aufwendungen und Erträge in kommunalen Haushalten (entweder bei der Kommune selbst oder einer kommunalen Betreibergesellschaft),

die zweifellos verkehrsrelevant sind, allerdings zählen Häfen und Flughäfen weder zur allgemeinen Infrastrukturausstattung der Städte noch dienen sie der alltäglichen Mobilität.

Tabelle 3 zeigt die zuständigen Organisationseinheiten und deren Aufgaben am Beispiel der Stadt Kassel.

	Kfz-Verkehr, Radverkehr, Fußverkehr	ÖPNV
Kernverwaltung	Straßeninfrastruktur Straßenverkehrsbehörde Zulassungsbehörde Führerscheinbehörde Ordnungsbehörde	Aufgabenträger
Verkehrsunternehmen		Straßenbahninfrastruktur Erbringung der Betriebsleistung

Tabelle 3: Verkehrsrelevante Zuständigkeiten und jeweilige Organisationseinheit am Beispiel der Stadt Kassel

3.4 Entwicklung der Methode zur sachgerechten Aufteilung der Aufwendungen und Erträge

Im Folgenden wird vorgestellt, wie aus kommunalen Haushaltsplänen eine Aufteilung der relevanten Haushaltspositionen nach Verkehrsmitteln vorgenommen werden kann. Die gleiche Vorgehensweise ist bei städtischen Unternehmen ebenso anzuwenden, wenn dort verkehrsrelevante Positionen vorhanden sind. Es wird hier davon ausgegangen, dass sich das städtische Verkehrsunternehmen auf den ÖPNV beschränkt. Das Prinzip der Zuordnung von Aufwendungen und Erträgen zeigt Abbildung 1. Die Vorgehensweise besteht aus vier Arbeitsschritten.

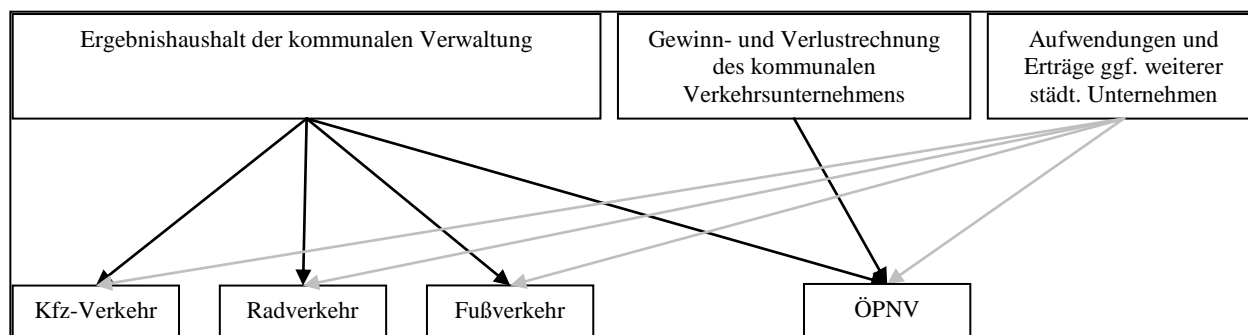

Abbildung 1: Zuordnung der Aufwendungen und Erträge aus den Rechnungsunterlagen zu den einzelnen Verkehrsmitteln (Prinzipskizze)

3.4.1   Schritt 1: Analyse der Teilhaushalte und Festlegung der Aufteilungsschlüssel

Im ersten Arbeitsschritt werden die verkehrsrelevanten Ertrags- und Aufwandspositionen der Haushaltspläne identifiziert. Für jede verkehrsrelevante Haushaltsposition wird anschließend ein verursachungsgerechter Aufteilungsschlüssel definiert. Die Aufteilungsschlüssel geben an, wie viel Prozent einer Ertrags- bzw. Aufwandsposition den einzelnen Verkehrsmitteln zugeordnet werden können. Der Hintergrund ist, dass bestimmte Positionen nur für bestimmte Verkehrsmittel oder bestimmte Gruppen von Verkehrsmitteln unterschiedlich relevant sind.

Beispiel: Die Straßenbeleuchtung ist für Fußgänger anders zu dimensionieren als für den Straßenverkehr. Oder: Ein hoher Schwerverkehrsanteil erfordert eine aufwändigere Dimensionierung des Straßenoberbaus.

3.4.2   Schritt 2: Entwurf des Straßenraums und Planung der Bauelemente

Im zweiten Schritt wird die Verkehrswegeinfrastruktur in einer Stadt durch eine fiktive Entwurfs- und Bauplanung nachgebildet. Dies ist notwendig, weil zwar in Geoinformationssystemen Verkehrsnetze vorhanden sind, aber nur wenige Daten enthalten sind, die eine Differenzierung nach Verkehrsmitteln ermöglichen. Beispiele sind die Breiten von Straßenräumen der Netzabschnitte, unterschieden nach Fahrbahn, Gehwegen und Anlagen des Radverkehrs, oder die Führungsform des Radverkehrs (gemeinsamer Fuß- und Radweg, Schutzstreifen, Radfahrsteifen, Fahrradweg). Die fiktive Planung umfasst die Definition von spezifischen Straßentypen, den Entwurf von Straßenraumquerschnitten und die Planung von Bauelementen. Zentral ist die Aufteilung des Straßennetzes in „Fahrbahn" und „Seitenraum", beiden Teilräumen werden jeweils die Verkehrsmittel zugeordnet, die sie nutzen können. Zusätzlich wird auch

Infrastruktur geplant, die für Linienbusverkehr erforderlich ist, um dessen Aufwendungen und Erträge später dem ÖPNV zurechnen zu können, sofern diese nicht bereits beim kommunalen Verkehrsunternehmen verbucht sind. Diese so geplante Straßeninfrastruktur liefert die wesentlichen Eingangsgrößen für die Kostenermittlung im dritten Schritt.

3.4.3   Schritt 3: Ermittlung der Wiederbeschaffungswerte und der Abschreibungskostensätze

Im dritten Arbeitsschritt werden Wiederbeschaffungs- und Abschreibungskostensätze für die Bauelemente der Teilräume ermittelt. Anhand dieser lassen sich im nächsten Arbeitsschritt Aufteilungsschlüssel entwickeln, die es ermöglichen, die Abschreibungskosten in den Haushalten sachgerecht den Verkehrssystemen zu zuordnen

Die Berechnung der Wiederherstellungskostensätze wird anhand der in Schritt 2 festgelegten Planungsdaten der Bauelemente sowie mit Hilfe von Einheitspreisen der einzelnen Bauelemente durchgeführt. Die Kosten werden für Teilraumlängen von 100 m errechnet, sodass Wiederherstellungskostensätze in der Einheit Euro pro 100 m [€/100m] vorliegen.

Zur Ermittlung der Abschreibungskostensätze wird die Methode der linearen Abschreibung angewendet. Hierbei wird von einem jährlich konstanten Werteverzehr über die Nutzungsdauer ausgegangen. Die Nutzungsdauern der Bauelemente werden anhand von Richtlinien der Forschungsgesellschaft für Straßen- und Verkehrswesen sowie weiteren Abschreibungstabellen angesetzt. Das Verfahren der linearen Abschreibung wurde gewählt, da der Zustand und das Alter der Elemente im Bestand nicht bekannt ist. Daher werden auch Wiederbeschaffungswerte zu Neupreisen angesetzt, statt eine finanzielle Bewertung des Bestandes zu einem bestimmten Zeitpunkt vorzunehmen.

3.4.4   Schritt 4: Erarbeitung der Aufteilungsschlüssel

Im vierten Arbeitsschritt werden anhand der Planungsdaten des Arbeitsschritts 2 sowie der Kostensätze des Arbeitsschritts 3 sachgerechte Aufteilungsschlüssel für die Ertrags- und Aufwandspositionen des Arbeitsschritts 1 bestimmt.

Dies verdeutlichen folgende Beispiele:

- Aufteilungsschlüssel für die Aufwandsposition Abschreibungen: Anhand der straßentypspezifischen Abschreibungskostensätze der Verkehrssysteme und der Netzlängen der Straßentypen (aus den digitalen Verkehrswegenetzdaten) lassen sich die verkehrssystemspezifischen Abschreibungskosten sowie die gesamten Abschreibungskosten der fiktiven Straßeninfrastruktur errechnen. Der Quotient aus verkehrssystemspezifischen Abschreibungskosten und gesamten Abschreibungskosten der im Verfahren geplanten Straßeninfrastruktur ergibt schließlich die prozentualen Anteile der einzelnen Verkehrssysteme.

- Aufteilungsschlüssel für die Aufwandsposition Straßenentwässerung: Die Kosten der Aufwandsposition Straßenentwässerung lassen sich über verkehrssystemspezifische Flächenanteile sachgerecht aufteilen. Anhand verkehrssystemspezifischer Querschnittbreiten der Straßentypen und der Netzlängen der Straßentypen (aus den digitalen Verkehrswegenetzdaten) lassen sich die verkehrssystemspezifischen Flächen und die Gesamtfläche der fiktiven Straßeninfrastruktur errechnen. Der Quotient aus verkehrssystemspezifischer Fläche und Gesamtfläche ergibt schließlich den prozentualen, verkehrssystemspezifischen Flächenanteil.

Für die Erarbeitung der einzelnen Aufteilungsschlüssel werden zunächst für die einzelnen Teilräume (Fahrbahn und Seitenraum) die Querschnittsbreiten und die Bauelemente mit den zugehörigen Kostensätzen sachgerecht den Verkehrssystemen zugeordnet. Verlaufen in einem Teilraum lediglich Verkehrswege eines Verkehrssystems, so ist die Zuordnung eindeutig.

Beispiel: Wird die Fahrbahn ausschließlich vom Kfz-Verkehr genutzt, werden diesem die Querschnittsbreite der Fahrbahn, die Bauelemente der Fahrbahn und die gesamten Wiederherstellungs- sowie Abschreibungskosten der Fahrbahn zugeordnet.

Werden die Teilräume hingegen von mehreren Verkehrssystemen genutzt, müssen die Querschnittsbreiten, die Bauelemente und die Kostensätze sachgerecht aufgeteilt werden. Hierfür werden u.a. Planungsvorgaben aus Richtlinien benutzt.

Beispiel: Nach den Richtlinien für die Anlage von Stadtstraßen dürfen Fußgänger- und Radverkehr nur dann gemeinsam geführt werden, wenn der Anteil der Radfahrer nicht mehr als ein Drittel der Gesamtbelastung beträgt. Somit werden im Aufteilungsverfahren die Querschnittsbreiten, die Bauelemente und die Kostensätze zu einem Drittel den Radfahrern und zu zwei Dritteln den Fußgängern zugeordnet.

Die einzelnen Aufteilungsschlüssel werden schließlich mit den Netzlängen der jeweiligen Straßentypen multipliziert, um damit die Anteile für die Aufteilung der verkehrsrelevanten Aufwendungen und Erträge vornehmen zu können.

Bei der Interpretation der Ergebnisse ist zu beachten, dass im Gegensatz zu den anderen Verkehrsmitteln die Flächen des Fußgängerverkehrs auch verkehrsfremden Funktionen dienen, insbesondere dem Aufenthalt, in Geschäftsstraßen oft auch als Ausstellungs- und Auslageflächen. Teilweise ist der Flächenanspruch für die nicht-verkehrlichen Funktionen sogar höher als für die Verkehrsfunktionen. Fußgängerzonen dienen darüber hinaus auch dem Liefer- und Ladeverkehr.

3.4.5   Aufwendungen und Erträge des ÖPNV im kommunalen Haushalt

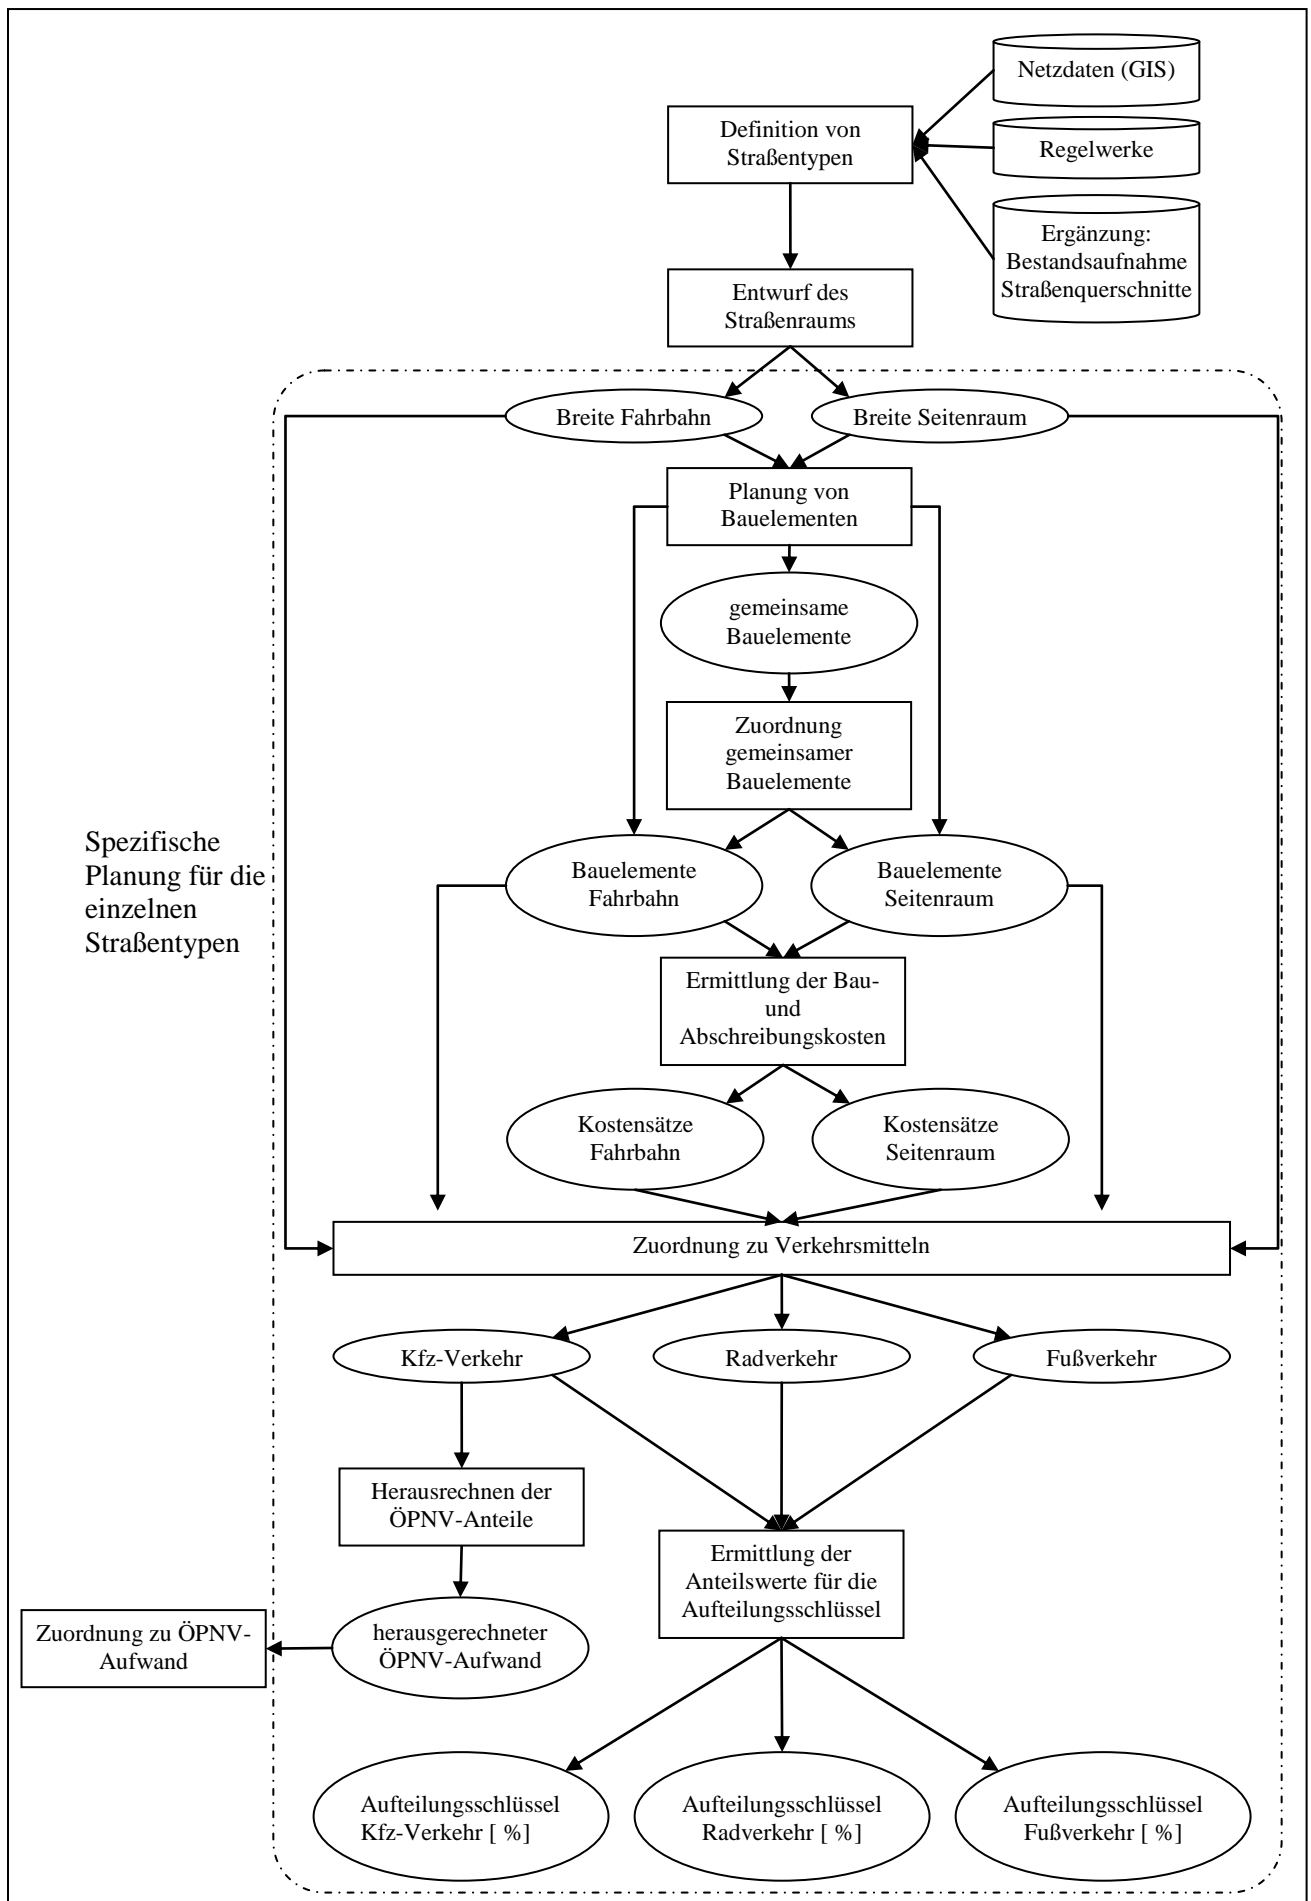
In kommunalen Haushalten sind auch Aufwendungen enthalten, die durch den Linienbusverkehr entstehen. Beispielsweise kann der Linienbusverkehr aufgrund hoher Achslasten zusätzliche Abschreibungs- und Unterhaltungskosten im Straßennetz verursachen. Dies fällt insbesondere auf Straßen mit einem geringen Anteil des übrigen Schwerverkehrs ins Gewicht. Diese Mehrkosten werden nicht von den kommunalen Verkehrsunternehmen, sondern vom Straßenbaulastträger getragen und sind damit in den kommunalen Haushaltsplänen verbucht. Diese Mehrkosten werden mit Hilfe von Berechnungsverfahren für die Dimensionierung des Oberbaus nach RStO (Richtlinien für die Standardisierung des Oberbaus von Verkehrsflächen), unter Zugrundelegung von Achslastdaten sowie Verkehrsstärken des Linienbusverkehrs abgeschätzt. Gleiches gilt für auf der Fahrbahn geführte Straßenbahngleise.


Abbildung 2: Prinzipskizze des Aufteilungsverfahrens

4 AUSBLICK

Als erstes Arbeitspaket wurde die Analyse der Haushaltspläne abgeschlossen. Dabei wurde der Aufbau der Haushaltspläne der Beispielstädte Kassel und Bremen untersucht. Derzeit wird darauf aufbauend die Aufteilungsmethode entwickelt. Die ersten methodischen Ansätze wurden in einem Workshop mit 15 Experten diskutiert, sodass deren Anregungen und Erfahrungen aus ähnlichen Fragestellungen in die weitere Bearbeitung des Forschungsprojekts einfließen können.

Ein zentraler Bestandteil der Aufteilungsmethode ist die Entwicklung von Aufteilungsschlüsseln, die im Wesentlichen auf standardisierten Straßenraumquerschnitten basieren. Mit Hilfe von Geoinformationssystemen sollen Teilnetze für die verschiedenen Verkehrsmittel gebildet werden, um diese Aufteilungsschlüssel auszuarbeiten. Da Daten zu Breiten des Straßenraums und Angaben zu Anlagen des Rad- und Fußgängerverkehrs im Besonderen in Geoinformationssystemen nicht vorhanden sind, ist vorgesehen, die erforderlichen Eingangsgrößen aus Richtlinien abzuleiten (z. B. Fahrbahn- und Gehwegbreiten). Da insbesondere im Altbestand nicht davon auszugehen ist, dass Regelbreiten aus den Regelwerken zum Straßenentwurf vorhanden sind und zudem in den meisten Fällen Bandbreiten vorgegeben sind, wird das Forschungsvorhaben durch eine Bestandsaufnahme von ausgewählten Straßenraumquerschnitten (u. a. durch Luftbildauswertung, Pläne und Messungen vor Ort) ergänzt. Damit können verlässlichere Werte als Eingangsgrößen für das Aufteilungsverfahren verwendet werden, die Ergebnisse sind besser auf andere Städte übertragbar und die generelle Anschlussfähigkeit für die weitere Forschung wird erhöht.

Mit ihrer umfassenden Betrachtungsweise stellt diese erweiterte Methode einen sachgerechten Ansatz für die Aufwandsseite dar und verbessert die Anschlussmöglichkeiten für die weitere Forschung auf dem Gebiet der Nachhaltigkeit und des umweltverträglichen und kosteneffizienten Verkehrs in Städten.

1 INTRODUCTION

Nowadays, urban development is experiencing new phases: a territorial widening from the district to the city, from the city to the agglomeration, from the agglomeration to the metropolitan area.

The existence of the metropolitan area is still under question and the answer varies depending on the scale and the governance and economic trends and actors in the different territories.

INTA's Community of competence Metropolisation[1] departing from new understandings on the urbanization processes works together with its members, including urban development actors who are confronted with metropolitan practical experiences, leading a reflection on the following lines:

(1) Limits of the metropolisation

(2) From making the city to being the city

(3) Metropolitan identity and representations

We refer here to recent activities INTA run in the context of urbanisation processes underway. The international seminar "A city for all made by all! The future of social contract in the scattered city" held in France and the International programme In-between metropolitan strategies.

2 THE RIGHT TO THE CITY IN THE SCATTERED CITY

"Making metropolis, it means probably also to allow those who live far away or nearby to keep in touch, to receive information, to keep a voice on the territory which belongs to them. Leaving, coming back, welcoming, staying connected, are images that shape metropolitan identities."[2]

The shifting of the concept of inhabitant to the one of "territoriant" was defined by Nicolas Tixier, professor at the National School of Architecture of Grenoble at the Congress INTA35 where INTA first approached the topic of the intermediate metropolises, their development strategies and alliances drawing new territorial settings. Intermediate cities are facing new governance issues and developing new models of cooperation with their local partners (who are those partners?), the challenge being to have more regional relevance while maintaining significant local connections at the municipal level.

"We do not live in cities anymore, but in territories. […] Each of us has its own territorial map, on which it draws its own routes. One has his tricks, tactics, strategies to make use of the territory.

Which kind of tools do we have today to explain these practices and routes sudden or intended, sometimes passive but often inventive? A Catalan researcher, Francesc Muñoz, coined for it a neologism, the world "territoriant" to complete the word inhabitant and meaning by this that the space where we declare we live, is not obviously the only meaningful space for us.

Shifting from the idea of inhabitant to that of territoriant, leads in different places to redefine spaces in which his involvement is legitimate - political involvement as much as physical.

But this also refers more widely to the idea that it is possible to be attached to a territory and its future even if we do not live in it (physically).[3]

In this new territorial context then Which are the responsibilities of the metropolis towards its neighbouring territories and areas of influence? And what are the relationships between urban and suburban, urban and rural?

The multiple interactions of actors, geographical scales and functions draw the components of a living, productive and cultural space that goes beyond the administrative limits - the metropolitan area.

---

[2] Nicolas Tixier, professor at the National School of Architecture of Lyon, addressing World Urban Development Congress INTA35 in Grenoble during Opening Session "Representation and metropolitan identity"

[3] Contribution of Nicolas Tixier at INTA35 in the opening speech titled "Representation and metropolitan identity"

However, this concentration of economic, political and social activities, creating wealth, and economic and cultural influence is also the root of a worsening of social segregation, exclusion and relegation. They are growing to the point of challenging the "social contract" by the juxtaposition of "societies" who oppose or who often prefer to ignore each other.

What emerges today with increasing force are issues that concern the relationship between urban and rural areas. The same issues that call into question the "social contract" are stressed but refer to the relation metropolis/periphery.

These issues are raised in a particular way in the suburban area that, according to the definition given by Eric Charmes:[4] "... has an essential feature: it is a space of urban dynamics, since its growth is clearly related to the proximity of a metropolis. But at the same time it keeps its own identity, something quite close to the order of the rural."

Those territories between rural and urban dimension are struggling to find their place in the process of metropolisation. It shows a gradual withdrawal of public services and favorable conditions for the development of social relations and activities. We are witnessing there a decline in the "Republican conquest of territory"; territorial solidarity being undermined by the concentration of development and services in the most efficient territories as the metropolitan heart, to the detriment of its periphery.

So we see in these suburban areas different forms of breaks, bursts: a gradual creation of the "scattered city": a political and landscape fragmentation and the social and economic disintegration.

3 WE LIVE TERRITORIES

"Where do you live? How to do you live and to which territory you fell you belong?" This is what INTA asked camera in focus and a map of the daily commuting of the interviewed supporting to discover the habits from the inhabitants of five among European and Latin America cities. This video entitled " The scattered city" opened the 2 days international seminar A city for all made by all ! The future of social contract in the scattered city" we run in France last December in collaboration with the City of Vaulx-en-Velin, ENSAL (National School of architecture of Lyon), ENTPE (National School of Public Works of the State) and the UNESCO Chair Urban policies and citizenship. Open the video a Dutch woman coming from a "big village" ...of 45,000 people!, who moved in the "satellite" of the Randstad where property prices are lower, allowing her to "buy a real home. Although the train is overloaded she takes it every day for work or for shopping. She sees herself as a "suburban". On the other hand, the couple living in the hills around Givors, small town between Lyon and Saint-Etienne (France), did not "feel as living in the suburbs" but still "on the outskirts of Lyon." The husband is used to take his car daily to access the urban services located in the center of Givors ... 10 minutes away. Third witness, the resident of a community located 6 km from the town of Brignoles in Var (south of France), always takes her car to go to the nearby town of Toulon and she feels she "belongs to the Var hinterland." Scale change with the testimonies of people from Latin American. Colombia, Bogotá, the man interviewed is pleased to live "isolated" in the countryside, even if he is confronted with intense traffic jam to reach the city centre for his daily courses. Another one lives in one of the 500 000 houses built without permission on the flanks of mountains overhanging Lima, Peru. In a chain, it takes him daily 2h taxi, walk and a bus trip to reach his work.

Journey that might be improved with the creation of a cable line that also might provide many other socio-economic changes.

How do we give a representation to this reality? How to build solidarity within the scattered city ? With these many small towns beyond the suburbs, we should come up with new governance models".[5]

The parallel raising of both metropolitan and local scales (globalisation and decentralisation) facing each other, competing and sometimes mixing, recompose territories and powers.

Moving and overlapping borders are putting into question planification tools, plans, programmes and projects and governance systems.

4 IS THE METROPOLITAN LEVEL THE ANSWER?

Mobility, according to our members experience is one key element of the debate on periurbanity and able to make solidarity among territories effective and thus one key factor on which the metropolitan level can be built.

In the Netherlands, the Randstad, the metropolitan area is made by hundred of small towns, four main cities, counting some 7 million inhabitants. " Everything takes place at a small scale, says Paul Gerretsen, director of Deltametropolis Associaton, which focuses on the metropolitan development of the Randstad. Mobility and multimodal commutings structure the territory. "Many people have chosen to live in small towns and take the train every day to go to work. "They made a compromise that is built around the mobility system."

But the integration of mobility it is enough to build political solidarity across the metropolis?[6]

The answer is difficult for the Netherlands where the level of the Randstad is not politically represented. Although there is no official metropolitan governance for Randstad Holland, it does continuously work as a metropolitan system in reality. The mobility flow between the four cities is increasing more rapidly than the mobility between the cities and their own region.

In Medellin, the urban integrated programme for the metropolitan region AMVA (Area Metropolitana Aburrà Valley) including all modes of urban transportation also plays a fundamental role in "building a territorial equity."[7] It is in this framework that was created a line of "metro cable." Passing through the "illegal/not planned" neighborhoods, it enables them to develop socially and economically. In fact along its way has emerged a library, colleges and pedestrian paths.

In Bordeaux Urban District major projects and infrastructures representing public and private investment have been undertaken (Bordeaux's decade 2010-2020) strengthening the exceptional features of exchange, innovation and quality of life of Bordeaux among which the tramline system that has unified territories, in physical terms, giving space to multiple occasions of movement within the metropolitan area.

Whether you're in Medellin, in the Randstad or Bordeaux, mobility and transport infrastructure are essential to solidarity between territories, " especially because those peri urban territories go far beyond the municipal limits". Territories whose representation is still missing.[8]

The examples we got from our members show how difficult and complex are processes of construction of metropolitan governance and its capacity to adapt to global and local changes. Metropolitan strategy means that there is a metropolitan governance that can take decisions. How those processes work, who are the actors and what makes them very sensible models?

5 BUILD ON YOUR STRENGTHS

Apart from the major metropolises worldwide, the creation of the metropolitan areas rely on governance strategies and alliances among surrounding territories[9] to achieve the objectives of resources management, urban quality or attractiveness. Creating networks of cities and agglomerations with their suburban territories, metropolises make different patterns of alliance to implement policies and projects to enhance their development. These diverse modes of cooperation allow, depending on the case, to associate additional resources, to create mass effects, to define and manage the "values of the metropolis" that are the natural resources, water, energy, know-how, the driving forces for the economic activity or for the livability of the territory.

In a complex institutional landscape, marked by multiple levels of competence, territorial co-operations exist as "spaces" for debates, coordination and projects enabling public actors to overcome the institutional barriers, while maintaining their legitimacy with their level of competence.

---

[6] Eric Charmes, RIVES lab Director, ENTPE
[7] Medellin metropolitan, interview with Françoise Coupé
[8] Eric Charmes, RIVES Lab
[9] INTA first approached this topic at its 35th Congress in France (Grenoble and Lyon) focused on metropolitan development strategies and alliances worldwide

Who benefits from the resources and public services, and who is excluded? The issue of social choices, for those who are governed and those who are not, is a key point to understand the metropolitan process (Le Galès 2011).[10]

This scaling has not only morphological or territorial consequences, it raises also other dynamics. First, the transformation of socio-technical infrastructures necessary to ensure the robustness of these conurbations then flows of huge investment and financing projects to be realised (the case of the Bordeaux's decade can be mentioned here), and most importantly, socio-territorial inequalities (as the role of the city of Medellin within the AMVA, Metropolitan Area of Aburrà Valley or the role of Amsterdam in the Randstad), visible or insidious, exacerbated by powerful metropolitan dynamics.

Although scales and conditions are different from country to country, the work undertaken by local authorities pose the question of the "good" level of governance. On the topic of new territorial dimensions, several interviews have raised the issue of the regional dimension and its meaning, its identity, its ability to be identifiable.

Paris Region is trying to work on a territory that includes the metropolitan level (now concerning only the built urban areas and run by Paris Métropole created in 2009).

Currently there's not a proper regional identity as the Region, as this administrative entity is quite new but the debate ongoing is exactly on which should be, in this case, the right perimeter for the metropolitan level to be managed.

In this regard, the question of adaptation of the planning instruments to the new condition, the importance of coordination, organization and linkage, is as decisive as the central role of political guidance.

Completely another case, Bordeaux Urban District, driving the construction of the metropolitan project, asked itself and all local actors involved the following question: "What kind of city do you want in 2030? ". The dialogue has been adopted as a key tool to intertwine scales. The small-scale heart of the Bordeaux Urban District (la Cub) is acting to build the metropolitan vision on a wider level. The metropolis is already a spatial (geographic) reality because there are people who live together and have daily metropolitan practices (they commute every day from one town to another for their work, recreational activities etc.). The metropolitan area is made thus by flows, mobility functions, projects and a multiplicity of actors who interact, however today Bordeaux metropolitan has no institutional basis (no metropolitan status). There are not elected representatives.

Building a strategic vision based on the mobilization of local actors and citizen participation has emerged a collective and shared representation of the metropolis, "a metropolitan consciousness" that does not stop at the borders of the 27 municipalities.

As part of the development of the metropolitan strategy, the 27 municipalities of the CUB have been involved, as well as the County of Gironde, Aquitaine Region and the State, to help drawing this common destiny. Through the metropolitan project, policy makers agree on the path of cooperation with municipalities, major institutional partners, neighbouring districts, businesses, and all the metropolitan actors. The metropolis does not deny what exists already and it seeks to understand the issues in a systemic logic, combining actors, ambitions and territories, over passing all notions of contrasts and competition. However, some municipalities may continue to be frightened by the metropolitan process in which they can see a loss of autonomy and the weakening of the municipal level.

The Urban Community of Bordeaux has adopted a metropolitan project, whose principles and objectives are ambitious: to affirm the metropolitan dimension of Bordeaux while avoiding the dangers of an unbridled urban growth. This is likely making a metropolis, but respectful of the identity and diversity of the different municipalities, mindful of the inhabitants' future and with consideration for the environment. Because this goal can be achieved only with the involvement and permanent support of the population and with a constant dialogue between the partners based on trust and mutual respect, this metropolitan project will be implemented as it was developed: in a spirit of cooperation and consensus.[11]

---

[10] Quel pouvoir pour les territoires métropolitains? Par Frédéric Gilli, Christian Lefèvre, Nathalie Roseau and Tommaso Vitale, 19/12/2012
[11] La Fabrique Métropolitaine de la CUB

In Jakarta the most visible phenomena of the most recent urban development initiatives is the leadership took by the private sector in developing new economic clusters (new housing, new-towns, industrial estates, leisure, commercial, health & institutional facilities) as well as infrastructure (toll-road, public-transport, water & sanitation) and even urban services. There is a booming of young and a more consumptive middle-class that has a voracious appetite for international-standard urban goods, services and lifestyles.

This trend has meant that governments have to adopt a new role and thus be able to change their habits which means better service-delivery abilities and optimizing infrastructure to create better business climates.

The increasing competition for private investments has meant that public goods management has to be more effective. A request of change moving from an old vertical political hierarchy towards a innovative and accountable territorial governance.

Complementarity, solidarity, cooperation together with consensus and participation are key elements to build upon a metropolitan strategy. This the case of the Coastal Development Territory (Cotonou-Porto Novo, Benin) or in the Randstad (NL) where the four main cities used to cooperate, to increase their chances of being more competitive in the context of a globalised economy and receiving more funding from the central government. But locally it translates in informal cooperations between cities, coperations of very dynamic nature and depending on the economic and political conditions. Although there is no official metropolitan governance for Randstad Holland, the cities recognised that global competition lay in the larger Metropolitan regions.

To conclude the metropolitan dimension implies coordination between actors of different kinds, relies on their ability to make decisions together, the heterogeneity and inequality between powers and new ways in which public and private actors interact. Metropolises do not just think of themselves as cities extended: they require to conceive horizontally and transversally the relations between territories, actors and institutions related to the same space. Uniqual access to services, lack of resources to implement comprehensive plans, difficulties to modernize and equip the infrastructure, emphasize the vulnerability of a metropolitan governance to be built. All these questions, too often considered strictly at a local level should be addressed at the metropolitan scale.

Sustainable Mobility in Urban and Touristic Areas

Gianluca Fabbri, Fabio Massimo Frattale Mascioli, Maurizio Paschero, Marco Dessì

(Gianluca Fabbri, Pole for Sustainable Mobility – POMOS, Sapienza University of Rome, Italy, gianluca.fabbri@pomos.it)

1 ABSTRACT

Clean and efficient urban transport systems are essential for the economic, social and environmental health of a successful future Europe. However, built-up urban areas continue to be significant contributors to congestion, accidents and environmental impact and offer significant scope for improvement. Most cities and towns are confronted with a common core of environmental problems, such as poor air quality, high levels of traffic and congestion, high levels of ambient noise and greenhouse gas emissions. These problems can increase in touristic areas due to the fact that many tourists each year choose those areas as the venue for their holidays, thus resulting in a considerable increase in energy and mobility needs. The environmental problems in those areas are particularly complex as their causes are interrelated. Local initiatives to resolve one problem can lead to new problems elsewhere and can conflict with policies at national or regional level. Some regions in Europe are dynamically developing in the last decade due to the growth in tourism and the fast development is accompanied by increased traffic and rapid deterioration of the regions' natural resources on which tourism growth depends. Traffic congestions and the negative impact of transport on environment are recognized as the biggest risks to the sustainable development of the tourism sector. The problem is particularly acute in the resort complexes which expand to urban settlements during summer and early autumn. This paper aims to provide a general overview on the thematic of urban and sustainable mobility and on the related EU policies and research programmes. Moreover the activities of three projects developed in Italy by the Pole for Sustainable Mobility will be presented and compared: these projects concern the development and experimentation of electric powered vintage carriages in Rome and sustainable mobility solutions for the small Island of Ventotene and for the Pontine territory in Italy.

2 INTRODUCTION

New transport technologies offer at present a wide selection of low-impact solutions with regard to emissions and noises. Hybrid and electric powered vehicles (HEVs), show an enriching future for tourist centres and cities. These technologies will reach their maximum efficiency in combination with advanced methods of transport information and management and with the use of Renewable Energy Sources (RES). Initiatives that could be completed by decisive policies of restraint on traffic and integration of the different forms of transport, favouring pedestrian areas, primacy of public transport and incentives for the inhabitants to buy electric cars. Sustainability of transport activities is one of the main objectives pursued by the European Commission to improve environmental quality in the European Union and sustainable development has become a building block of economic policy at local, national and international level. Sustainable mobility and urban environment are currently high on policy makers' agendas for its importance in determining the quality of life in cities or in protected areas like national parks or nature reserves and for the central role played by local governments in shaping environmental policies. In order to deal with the risks deriving from the high level of pollution in these areas, the European Commission has funded several projects aimed at studying and managing the transport/environment link. One of the main goals of these projects is to identify best practices and appropriate policies to enhance sustainable transportation. However, different policies vary enormously in their effectiveness in achieving a reduction of pollution, and the time spans of the effects differ as well. Promotion campaigns need to be designed to identify the possible forms of sustainable mobility in the touristic areas and to promote them as a new service to the tourists and the citizens. General rules and objectives to obtain these results can be the followings:

- The activities need to be supported by both municipal and regional administrations in the target region.
- Alternative modes of transport and eco-friendly tours and routes need to be promoted.
- A mobility management services is required.

3   POLICY RECOMMENDATIONS AND MEASURES

To fulfill the market of EVs will require a commitment to public education, helping consumers understand the vehicles' benefits and overcome concerns that hinder their use. The media must be engaged to report on infrastructure development, and public support from influential leaders in the state and nation is critical. Also, it is vital for initial adopters to have a positive consumer experience that will contribute to widespread acceptance. It must be easy for consumers to purchase vehicles and access charging stations, be aware of relevant tax credits, get charging stations installed and become educated on the location of charging stations outside the home. Measuring the impact of these new technologies on consumers, businesses, economic prosperity and our environment is a key component in their sustainability. It is also anticipated that an influx of new technology, as well as the products and services associated with it, will encourage job growth.

3.1 Integration of policies

The establishment of synergies with other local initiatives and policies directly or indirectly related to mobility can justify the start up of a Sustainable Mobility project and help its implementation, as well as ensure its long-term viability. In this context it is essential to show a concrete link between Mobility and other issues of concern like the use of Renewable Energies. Three examples of best practices will be presented in Section 3. These projects were not stand-alone projects but were well integrated into a wider strategy of the city or the municipality. These projects demonstrated that objectives of Sustainable Mobility are more achievable if they fit into a wider strategy with respect to issues such a sustainable urban development, tourism or environmental issues.

3.2 Towards a European common charger for electric vehicles

It is important that the European Standardization Organisations bodies (CEN-CENELEC and ETSI) continue in developing a common charging system for electric cars, scooters and bicycles. European standards are developed by the European Standardisation organisations through voluntary cooperation among industry, consumers, public authorities and other interested parties for the development of technical specifications based on consensus. Standardisation tackles the interoperability of complementary products/services, requirements for safety, health or environmental performance. The standard has to ensure that all types of electric vehicles and their batteries are charged both safely and easily in all EU Member States. Thanks to this mandate plugs and connectors will use the same standard all across Europe, providing a true European solution independently of brands or countries. On the Communication of 29 April 2010 the European Commission established a roadmap for a coherent framework encouraging the market launch of electrically chargeable vehicles. In this strategy, the mandate that the Commission addresses now to CENELEC, CEN and ETSI to develop a European common solution for the charging of electric vehicles is crucial. This mandate has three objectives:

- To ensure that electric vehicles can be safely charged by their drivers.
- To ensure that electric vehicle chargers (including their removable batteries) interoperate with the electricity supply points and all types of electric vehicles. This would allow users to recharge their electric vehicles anywhere in the EU by using the same charger.
- The mandate requests the standardization bodies to consider the so-called smart-charging issues. Smart-charging will allow users to charge vehicles at off-peak times to get the lowest price and most efficient use of energy.

The design of the European standard will take into account ongoing activities in international standardization. The European Commission will continue to work closely with the standardization bodies and industry to ensure the timely development of the standard.

3.3 Regional and local level

It can be observed that many measures can be taken at regional and local levels, close to the citizen. Action on sustainable mobility will only produce all its potential gains if operations to be undertaken at Community and national levels are reflected locally and vice versa. The EU has already taken numerous initiatives in this area. An example is the Civitas programme, launched in 2000, which has helped 59 European cities with urban mobility projects. Support programmes have also been put in place to encourage public and private

investment in rational transport use (pilot actions, creation of local agency networks, etc.). Furthermore, the specific activities that are integrated into the operational development programmes for the EU cohesion policy, notably in those regions lagging behind in development, give the regions strong instruments which could be used for a wide range of different projects. Support and investments in clean urban transport, support to small and medium sized enterprises as well as related research and development are options to be mentioned. When this potential for transport efficiency is mobilized, one has, however, to respect the specific provisions of cohesion policy programming, partnership and management. It should also be further discussed how to find solutions for the growing problems caused by city centre congestion. City transport is above all a matter for local and national authorities, the EU should contribute to find solutions in the face of the deterioration in the quality of life which this problem causes, and which goes hand-in-hand with a truly enormous waste of energy. Local authorities have then an important role to play by providing and promoting sustainable solutions in their cities. Then again, there is the eternal problem of financing. Regulatory measures are certainly needed, but we must also be able to back them up with investments. Currently available financing products as developed by banks are not always suitable for the scale of many small projects, whereas the aggregate benefit such smaller projects can provide as a whole is substantial. There is a huge potential for investments in small-scale sustainable mobility projects throughout Europe. They will often be highly feasible, especially when including the aspects of Intelligent Transport Systems and environmental benefits. But financing of such projects, especially in the less developed regions of Europe, needs 'facilitation' to happen. Given the small scale and dispersed nature of the projects to be funded, it would seem that action is in any event best initiated at local or regional level. Funds to support the projects for the improvement of transport efficiency have been very successful in many Member States, and it should be considered how best practices can be repeated and improved.

3.4 Outlook on Research: what next?

Further technology - and policy oriented research to develop sustainable mobility in urban areas should allow to obtain the following needs and goals:

- Increased interoperability of transport infrastructures for different modes.
- Alternatives to traditional fossil fuels and increased fuel efficiency of vehicles.
- Noise and pollutant emission reduction technologies.
- Intelligent Transport Systems.
- Increased accessibility and comfort of public transport.
- More sustainable urban structures.
- Public acceptance of measures to create more sustainable transport systems.

Urban mobility can be improved through the developing of new ICT based services like travel information, positioning systems for vehicles, cyclists and pedestrians, fleet management systems and more attractive car and bike sharing schemes. Research should also aim at better integrate different public and private transport systems (sharing of infrastructure between passenger and freight transport, tram-train systems, bus rapid transit lanes, park&ride facilities, urban freight distribution logistics terminals, electric and hybrid vehicles, etc.).

4 THE EXAMPLE OF THREE RESEARCH PILOT PROJECTS

In this paragraph the activities and the results of three projects developed in Italy will be described. The three projects have been selected to illustrate different sustainable mobility applications. The projects are the following:

- Project 1: Developing and Experimentation of Electric Powered Vintage Carriages in Rome.
- Project 2: Sustainable Mobility Solutions for the Island of Ventotene.
- Project 3: Sustainable development of the Pontine territory: the 'Pianura Blu' project.

The three projects have the common characteristics to be implemented in touristic areas and to test 'greener' transport solutions. Project 1 has the goal to analyze the possibility of substituting the traditional touristic horse powered carriages in Rome with innovative electrically powered ones; Project 2 aims to stimulate the

use of sustainable mobility solutions on the small island of Ventotene introducing electric and hybrid vehicles in the Municipal fleet and realizing the appropriate infrastructures. Project 3 foresees the design and implementation of a large integrated mobility system in the Pontine territory in the region of Lazio. The three projects can be considered best practices and represent examples that can be repeated and improved elsewhere.

4.1 Project 1: Development and Experimentation of Electric Powered Vintage Carriages in Rome.

The main goal of the project is the development of an innovative electrically-powered vintage carriage (Botticella) and its experimentation in the touristic centre of Rome. For the realization of the project two different phases have been foreseen: the first phase have seen the designing and the construction of two prototypes of the electric vehicle and it will be concluded in 2013; the second phase will be later carried out and sees the integration of the first two prototypes in the municipal fleet. Actually Rome Municipality is already testing electric assisted rickshaws for freight and passenger transport in the inner zone of the city. Public charging stations have been already installed at selected sites in the city to charge private and public electric vehicles. Moreover in the city centre there are 44 traditional horse-drawn carriages that, according to the urban plans drawn up by the Municipality, will be confined to parks during the week and allowed in the centre only at weekends. The plans foresee also the replacement of the horse-drawn carriages on weekdays by a fleet of electrically-powered vintage cars. Results from the first phase have seen the complete design of the electric vehicle and the analysis of the related regulations and standards. Figure 1 shows the final design of the vehicle: particular attention has been given in using innovative and sustainable materials and technologies trying to respect and maintain the vintage style of the traditional roman Botticella.

Figure 1 ad 2: The design of the new electric powered Botticella and its main components.

Figure 2 illustrates the main components of the prototype. A list of guidelines and specific indicators has been individuated in order to monitor and evaluate the activities that will be carried out during the experimental phase. The indicators will allow to evaluate the success of the measures and services demonstrated within the Project, in terms of technical features, energy and environmental issues, user acceptance, impacts and financial issues. Assessment objectives, expected impacts, measures of performance, reference cases and measurement methods have been also identified. This will allow to highlight the overall performances of the measures and services that will be demonstrated within the Project. Moreover, georefential mobile units and safety and touristic information unit have been identified and will be installed on the prototypes (rickshaws and electrically-powered vintage cars) and will be integrated with a set of sensors used to monitor the territory and the service. This pilot service will be monitored in order to measure strengths and weaknesses of the scheme. This will involve measurement of energy use, distances travelled, numbers of passengers transported, and the analysis of the data to measure efficiency and effectiveness of the scheme in relation to the organizational and management costs, the safety of drivers and passengers and environmental and energy efficiency indicators. Other objectives will be to support, co-ordinate and monitor the local assessment activities in order to guarantee their consistency with the joint overall evaluation approach and to analyze and report the project results, highlighting also similarities and differences of results among other cities in Italy and Europe (cross-comparison), and drawing conclusions on their transferability. The project has been financed by the Municipality of Rome through the Bioparco Foundation and is being developed by the Pole for Sustainable Mobility (POMOS), Sapienza University of Rome.

4.2 Project 2: Sustainable Mobility Solutions for the Island of Ventotene.

The main purpose of this project is to study pathways that lead to sustainable energy systems for the small island of Ventotene in Italy. The project looks into several aspects such as renewable energy penetration, efficient energy use, clean transportation options, monitoring and fleet management. The project has been financed by the Lazio regional government with the participation of the Municipality of Ventotene and it has been developed by POMOS and various private partners. The project had a duration of six month split up in two periods of 3 months corresponding to the 2009 and 2010 summer seasons. The main goals of the project were to analyze sustainable mobility models on the island through the implementation of a local sustainable mobility programme and the introduction and development of the following systems:

Electric Vehicles Fleet: The first activity was to add seven 100% electric vans to the Municipal fleet. These are commercial Porter Piaggios using a pure electric drive train which only consumes electric energy (see Figure 3).

Figure 3 and 4: The electric vehicles fleet and some of the hybrid and electric prototypes experimented in the project.

The vans will be mainly used during the touristic season for transportations from the port to the centre of the island with an estimated average of 15 daily kilometers traveled on the island for each vehicle. The vans will be also used to test the on board systems. Moreover a selection of other commercial electric and hybrid vehicles and prototypes developed by POMOS will be also tested on the island as well as the use of different kind of batteries (see Figure 4).

Experimental on board systems for the telemetry and the control of the vehicles: The fleet was equipped with on board telemetric device to locate the vehicles, and send that data over network. Direct connection of the device diagnostic bus can allows the automatic collection of vehicle performance data to support preventive maintenance. The on board system also includes a PC with a touch screen that is used to show data and information. A multimedia software was developed to provide to the drivers and the travelers audio and video messages according to the position of the vehicle. The system calculates the real-time location of any vehicle, then data are transmitted to a central server situated in the City Hall building and can be used immediately for daily operations and archived for further analysis too. The system can be used to monitor on-time performance and can be used for service planning, safety and security, traveler information and entertainment, vehicle component monitoring, and data collection.

Environmental monitoring system: The use of a compact air pollution analyzer was planned for environmental monitoring. The analyzer has an air quality sensors module for several kinds of gaseous pollutants (CO, NO_2, SO_2, O_3). It can be easily installed either on outdoor fixed emplacements or onboard of any kind of mobile vehicle (car, van, scooter, bicycle, segway) and operated both as a kinematic and static units to create an air quality monitoring control network. The air pollution analyzer is made to operate under software control by an external controller unit dealing with satellite positioning and data transmission to a remote control centre. Data are sent to the server and displayed and analyzed using a software tool.

Wireless communication system: An outdoor Wireless Mesh Network (WMN) was designed and created to cover most of the territory of the island.

Intelligent charging systems and integration with Renewable Energy Sources: Charging stations have been installed at selected sites on the island to create a small Intelligent Networked Charging Infrastructure for

EVs. The charging stations keep track of charging times and other data to allow remote monitoring of their utilization and correct functioning. The project foresees the installation of a main charging station located in the night deposit of the vehicles and of a public network of three charging stations integrated with photovoltaic generators (PV) with the general objective to study and promote the use of PV energy to charge EVs on the island territory. A first integrated PV station has been designed, built and installed for charging the electrical vehicles and other two stations will be afterwards installed (see Figure 5).

Figure 5: The integrated photovoltaic charging station

The charging stations have been used during the experimental phases of the project to charge the Municipal electric fleets and the experimental prototypes. In the future, citizens with plug-in electric vehicles will be also able to charge their cars or scooters at these stations, located at convenient places around the island. All the experimental results and data coming from the charging infrastructure will be used to learn more about what is needed to support electric vehicles as they become more common on the island. The increased use of electric vehicles will impact electric utilities and the infrastructure for providing electricity to customers. The installation and the utilization of the Charging Stations will help to understanding of things such as how this infrastructure works, how consumers want to use it, driving and charging patterns, and interconnection with the electricity grid and with RES.

4.3 Project 3: Sustainable development of the Pontine territory: the 'Pianura Blu' project.

This project, named 'Pianura Blu", aims at the touristic exploitation of a large naturalistic area configuring mixed routes (waterways, channels and bicycle/pedestrian paths) out of the road network paths and expanding the concept of land sustainable mobility to waterways and coastal lakes that characterize all the Pontine area. The goal is the restoration of historical, archaeological and natural zones in an innovative way and with the use of new technologies and environmentally sustainable means of transportation. A mobility system integrated with the mainland will be studied and implemented. The system will allow to manage the fleet and the infrastructures assuring safe routes and the exploitation of historical / cultural sites. The project foresees the following main phases:

- Study of the navigability of the channels and lakes and their integration with pedestrian and cycle paths.

- Study of the accessibility of the channels with land transportation systems.

- Study and implementation of full electric propulsion boats and electric assisted bicycles.

- Implementation of charging infrastructures integrated with renewable sources.

- Integration of telecommunication infrastructures and related fleet management services.

- Development of monitoring systems and on board sensors.

- The project will represent an open-air laboratory for testing new mobility solutions and to validate results of research activities carried out at POMOS.

The projects foresees the use of small electric boats for the navigation of inland waters and terrestrial zero emission vehicles like conventional and electric assisted bicycles and other types of light electric vehicles developed specifically for the project. The whole mobility system will be supported by charging infrastructures also integrated with renewable energy systems and telematic infrastructures for fleet tracking and other functions. Figure 6 shows the current navigable general plan of the Pontine Area and Figure 7 illustrates the possible future development of all the navigable routes including the excavation of new small watercourses connecting the main channels and rivers and the exploitation of ancient navigable routes.

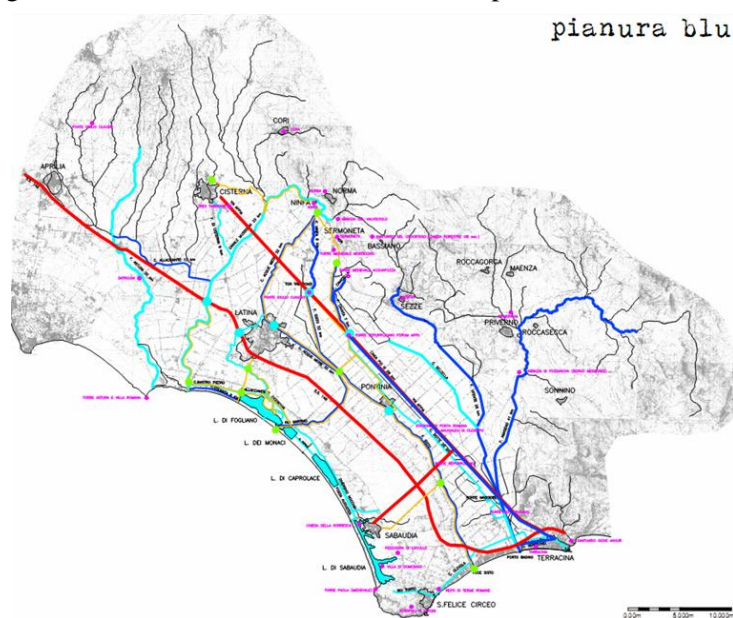

Fig. 7. Future development of the navigable routes.

An ambitious objective is also the historical and archeological enhancement of the area through the use of the latest sustainable technologies in order to attract a higher number of tourists. The project should also stimulate the growth of local production, promoting local activities and products in the territories along the touristic routes. With the configuration of the mixed routes (channels-paths) the tourists will be able to come into a deep contact with local production and resources. The project involves the construction of 100% environmental-friend boats. This eco compatible boats will be realized with recycled materials and will use low consumption electric propulsion motors integrated with renewable energy systems and with a limited use of chemical accumulators. A first prototype, named Valentino I, has been developed by POMOS and it is shown in Figure 8.

Fig. 8. Valentino I: the first developed boat prototype integrated with photovoltaic generators.

The boat's structure has been designed taking into account universal design concepts (mainly ergonomics and accessibility) and presents a particular system of rotor blades to allow navigation even in those sections of the channels in which the abundant algae would not allow the use of a classic propeller. Everything is set to safeguard the protection of flora and fauna. In addition, the boat it is equipped with a photovoltaic roof and it is prepared for the installation of a series of sensors capable of monitoring the quality of water.

To summarize, the realization of this project will lead to:

- Actions to raise public awareness on the issue of ecomobility.
- Tourist use of a wide geographical area.
- A significant enhancement of the image of the territory.
- The exploitation of natural and archaeological resources of the landscape.
- The development of trade and stimulus to the creation of consortium activities.
- An increased value of local products.
- A strong visibility at national and international level.

5 CONCLUDING REMARKS

Three projects aiming at using clean vehicles in touristic areas have been presented in the previous section. The three projects represent a concrete example of how the concept of sustainable mobility can be applied in touristic centers and territories. The projects have significant effects in social terms: the electric Botticella in Rome, the electric fleet in Ventotene and the ambitious Laguna Blu project, represent strong and effective examples to make citizens and tourists aware of the concrete possibility of use clean transport systems in their holidays. The projects have significant effects as well as in terms of air pollution and noise. The results so far have proved that the proposed solutions can offer high benefits to the environment. However, the successful implementation is only possible with the help of public funding in the beginning, especially in the field of Electric Vehicles (EV) promotion. Today the use of EVs can contribute significantly to the reduction of the environmental pollution and despite the history of EVs being as old as the internal combustion engines, the recent technological evolution can make electric transport competitive with respect to conventional transport. Nevertheless, an effort should be made by the industry and governments to protect the environment, through economical incentives to develop and acquire EVs. From the analysis of the first two projects emerges that to implement electric fleets in urban or touristic areas it is absolutely essential the creation of an electric infrastructure to park and charge the vehicles. In fact electric and plug-in hybrid vehicles must be charged while parked and to successfully implement projects like the ones presented in this paper, the parking/charging infrastructure need to be considered and created. It can be useful to identify three main categories: Residential, Private and Public.

- Residential includes single and multi-family housing, as well as apartment complexes. Charging should be accessible for all forms of parking: garage, driveway or parking lot.

- Private Sector charging includes parking at workplaces, shopping centers or other locations where neither the vehicle owner nor the municipality owns the parking space.

- Public charging includes on-street parking and any public lot or parking deck.

A number of issues need to be considered in response to these needs. Though there may be variation in cost for the vehicle or parking space owner, the infrastructure for the charging stations is consistent. To ensure proper installation and safeguard consumers, training and certification need to be provided. The upfront costs that can sometimes slow adoption of new technologies need to be minimized. Along with infrastructure, support will also be needed for maintaining and servicing the vehicles. While these vehicles are projected to have lower maintenance costs, a trained workforce must be available to service them and to enable maintenance-providers with the tools and training necessary to support these new vehicles.
