PREFACE

Manfred Schrenk

Chairman CORP,
Managing Director of CEIT – Central European Institute of Technology &
CEIT ALANOVA – Institute of Urbanism, Transport, Environment and the Information Society, Schwechat, Austria
Vice President ISOCARP – International Society of City and Regional Planners

WELCOME to REAL CORP 2013, the 18th International Conference on Urban Planning, Regional Development, Information Society and Urban/Transport/Environmental Technologies.
When holding an urban planning conference in Rome, one cannot but think about the great history testified by the many monuments, the rise and fall of many Empires and powers that the city has absorbed in its changing form but also about the future challenges that cities are confronted with when dealing with the management of human and natural resources or by their fragility, as shown by the many natural disasters that have hit also cities in the Country hosting us. The past CORP conferences discussed the concept of constant change in cities which we would like to now enrich by exploring the relationship between space and time.

It's 'Planning Times'!

It is therefore a pleasure to discuss with all our participants how we all constantly work between space and time when planning our cities, when defining projects that may improve the conditions of our society, when proposing decision processes that manage the space around us, when implementing techniques to foster development.

But 'Planning Times' also means that we must plan today for a long term future, regardless of the contingent economic interests or the administrative changes. Time has come to plan for the society we wish future generations live in: hopefully inclusive, sustainable and just. How to arrange the steps along the way?

During the four conference days we will explore this complex synergy by discussing how planning practice and theory have dealt with concrete issues such as:

- How to plan taking into account time, both past history and future development?
- How to integrate monitoring within the planning decision processes, such as in the case of natural disasters?
- How to handle time that cannot be planned, such as long decision processes or real time decisions?

REAL CORP 2013 in Rome is a moment of discussion and reflection about theories and methods but also hands-on experiences from all over to world on how planning deals with space in time in order to plan our cities and regions.

A city with such a long planning tradition and with such diverse challenges like Rome is a great occasion to have the city itself giving valuable input and inspiration to the conference, making every walk through the city, every espresso in some café and each conversation with Romans an occasion to bring back to the conference table even more content and reflections, which we are looking forward to sharing.

As when thinking of Urbanity and Time, the Eternal City of Rome appears to be the perfect location to hold this conference, even more so it is within the House of Architecture of the Acquario Romano, where our local partner the Chamber of Architects of Rome and Province is based and who we would like to thank for their support.

The building we stay in already shows some of this complex relationship between past and future of cities as this was the Roman Aquarium. Only for a few years it hosted an aquaristic show, the project failed only little later to then be used as storage room of the nearby Opera House. Besides that, it temporarily served as venue for fairs and exhibitions, to then be a storage space until in 1984 when the renovation works started which were funded by the city administration. Now the building is usable as museum and event facility und currently hosts the House of Architecture and the Chamber of Architects of Rome and Province.

We are happy to say that we add a new role to this building by opening a window on 5 continents thanks to all the people from around the globe that are here.

REAL CORP 2013 brings together nearly 350 experts from different fields and from all over the world and provides the stage for meeting and learning from each other how to deal with city structures and prepare them for a sustainable future enhancing their resilience.

REAL CORP 2013 covers many different topics in more than 200 presentations. The proceedings comprise about 1,500 pages of hand-picked knowledge for planners and for cities.
Since our first conference in 1996, REAL CORP has turned into a real interdisciplinary and international event. During the upcoming four days, The Acquario will be the host of an incredible exchange of planning knowledge, face to face networking and development of new thoughts, ideas and projects.

Welcome to Rome and the beautiful Acquario Romano!

Have a great conference!

Manfred SCHRENK, Daniela PATTI. Christian EIZINGER, Clemens BEYER and the REAL CORP Team

1 ABSTRACT

There are multiple ways to visualize geotagged information. The most commonly used tools are GIS (Geospatial Information Systems) to show the data on a 2D map. For 3D visualization of geospatial information only a few systems exist, e.g. Google Earth, NASA World Wind, etc., which only provide basic visualization techniques and also only allow to visualize a small number of data attributes at the same time. In addition the user has to put a lot of effort into producing meaningful visualizations to be able to compare and analyze the data. In this paper we present a new approach to the visualization of geotagged sensory data in the context of spatial planning. We use a tool called GeoVisualizer, which aims at providing planners the possibility to show and analyze their multivariate sensory data in a 3D geospatial context.

In a cooperation project between DFKI and CPE, a variety of human sensory assessment test data sets, recorded with the BMS Smartband, were visualized. The Smartband is a small wristband that can detect negative arousals of test people. In combination with a GPS device, it is possible to geotag "stress hotspots" in a city. Recorded situations in this paper are for example how people feel during a hike in the forest, watching a football game, going through the city in crowded situations or walking along a touristic path. The focus of the presented new workflow is not only to integrate sensor data, but also traditional sources like WebMapSevices and 3D-content from KMZ files in order to combine them in a way which can be used for various kinds of urban planning projects. The paper will give a short overview of GeoVisualizer and present a planner's workflow how to integrate their data and how they can edit the look of the integrated data in a fast and easy way.

2 INTRODUCTION

The visualization of sensor-based geotagged data in spatial planning increased considerably in the last few years. Virtual globe systems like NASA World Wind and Google Earth, virtual 3D-city models as well as new approaches of immersive techniques became important not only in spatial planning, but also gain increasing importance in social, cultural and everyday context (ZEILE 2010). According to experts, virtual globes became a 3D-GIS standard (RUSH 2006), and stimulated the discussion about visualization and benefits of geodata for all user groups, even besides spatial planning (ZEILE 2010).

Last but not least with the help of automated calculation of traffic density, supported by the data of mobile phone users and the works of MIT SENSEable City Labs like LIVE Singapore! and Copenhagen Wheel (MARTINO ET AL. 2010, RESCH ET AL. 2011) this field of research entered general publicity. These systems present the vision, what would be possible with these techniques in the future, but they are still not designed for daily use. In practice, planners need a tool, which can import sensor data and visualize them in realtime in an easy way. This easy to use feature is essential, because the results of these sensor based data should be used in political decision processes and serve as a basis for communication between planners and stakeholders.

One solution is the "GeoVisualizer" which delivers very good results for this kind of work in a planning context. In this paper, some use cases will be presented which were results of a cooperation project about "human sensory assessment" between DFKI and the University of Kaiserslautern, CPE. In these use cases, all data belong to the research field of "spatial psychophysiological monitoring". Metaphorically, the „Citizen as Sensor" (GOODCHILD 2007) learns to walk virtually. The required methods and techniques, in an especially tailored workflow for spatial planning, will be presented in the following chapters.

3 STATE OF THE ART

Following some backgrounds and state of the art developments concerning the research field of Digital Globes / Virtual Earth Browser as well as state of research in the field of psychophysiological urban

monitoring (measurement of humans' emotions in urban environment/ human sensory assessment) were elaborated.

3.1 Visualizing Geodata and Virtual Earth Browser

The most important prerequisite for planning activities was and is knowledge that planners collect, sort, constantly renew and prepare to get complex and compressed information for a specific planning decision (STREICH 2005:11). Digital Globe Systems meet these requirements and offer the possibilities to planners to get own spatial information to geotag a special planning task and redistribute these datasets to a specific circle of users (ZEILE 2010). The idea of a "digital earth" was described for the first time in 1991 by Neal Stephensons' novel „Snow Crash": „A globe about the size of a grapefruit, a perfectly detailed rendition of Planet Earth, hanging in space at arm's length (…) It is a piece of (…) software called, simply, Earth. It is the user interface that (…) uses to keep track of every bit of spatial information that it owns -- all the maps, weather data, architectural plans, and satellite surveillance" (STEPHENSON 1992: 127).

In 1994, the Berlin company ART+COM developed „TerraVision", inspired by Stephensons' novel as a standalone system on SGI-units. TerraVision is a 1:1 virtual copy of planet earth. One significant feature of TerraVision is the human machine interface. With the help of an interface, designed like a globe, the so called Earthtracker, the user gets the possibility to navigate to every desired spot on earth interactively and in realtime over the virtual globe (ART+COM 1994).

The first and free consumer based virtual globe system was developed by NASA and was called World Wind (NASA 2013). For the first time, it was possible to import and export spatial data through a user interface. In addition, the integration of Web Map Services and the visualization of textured meshes were realized. Keyhole Earth Browser, in the beginning operated by Keyhole, was the initiation point for the development of Google Earth, which is today the best-known and widespread software for digital globes. As associated programming language, the Keyhole Markup Language (KML), also developed by Keyhole, is established as an Open Geospatial Consortium (OGC) standard by now.

All the above-mentioned systems offer different import and export functions, but there are only a few options to develop some additional new types of visualization. There are some software tools available, which can transform collected data into 3D visualizations, which need to be combined manually for an appealing look. An integrated and interactive 3D-GIS application, which allows the easy integration, visualization and animation of heterogeneous data is not available today.

3.2 Human Sensory Assessment

Human sensory assessment in spatial planning is based on the approach to use people as sensors and at the same time as producers for emotional data in real time (Exner et al. 2011). This approach aims to deepen the knowledge of continuous interdependencies between humans and their environment. Here, the aim is to identify specific stress-inducing structural or environmental situations and also places having positive effects on the well-being. Based on this, comprehensive measures can be identified to optimize the respective study area.

The used sensor for the measurement of human emotions is the BMS Smartband (Papastefanou 2009), which is used to detect psychophysiological values of the body according to the environmental circumstances. The approach of psychophysiological monitoring enables to correlate physiological data (e.g., skin temperature and skin conductance changes) to emotional states of the people (Kreibig 2010). A GPS-logger is used additionally for simultaneous localization of the emotional data.

The major challenge is to get the combined spatial data across to decision makers as well as visualizing it adequately for the academic sector. Existing visualization software reaches its limit especially when multiple data attributes have to be visualized simultaneously. For that reason, it is interesting for the academic sector to visualize various data attributes within a presentation, either individually or simultaneously. This includes, the skin temperature, skin conductance, and the combination of both which can be used to derive stress events. Policy makers on the other hand want focused information that is limited to the essential content.

Until now, many manual steps had to be made with various software products such as ArcGIS, the GPS-Visualizer or Google Earth to achieve a high quality and precise visualization of georeferenced human sensory data. That complex procedure was accompanied with a large amount of time.

4 GEOVISUALIZER

3D data visualization is a common feature of modern GIS. There are a multitude of standalone applications as well as plugins allowing the user to visualize his three dimensional data in a geographic context. However, the use of state of the art visualization techniques and methods are usually reserved for expert users due to the complex nature and complicated setup of these visualizations. This is where GeoVisualizer ties in by giving even non-visualization experts the tools and possibilities to produce meaningful visualizations based on state of the art techniques and to get a better insight into the underlying georeferenced data.

GeoVisualizer is based on the Open-Source NASA World Wind SDK (NASA 2013) which provides a 3D virtual globe and different import plugins for geodata. In addition, GeoVisualizer is realized with the Java Web Start Technologie (ORACLE 2013a), which allows starting the application on every computer connected to the internet and providing the basic Java libraries. Once installed, GeoVisualizer resides on the hard disk of the computer and can be run in offline mode. However, if the computer is connected to the internet GeoVisualizer will execute a check for updates to ensure that the user always has the latest, up to date components.

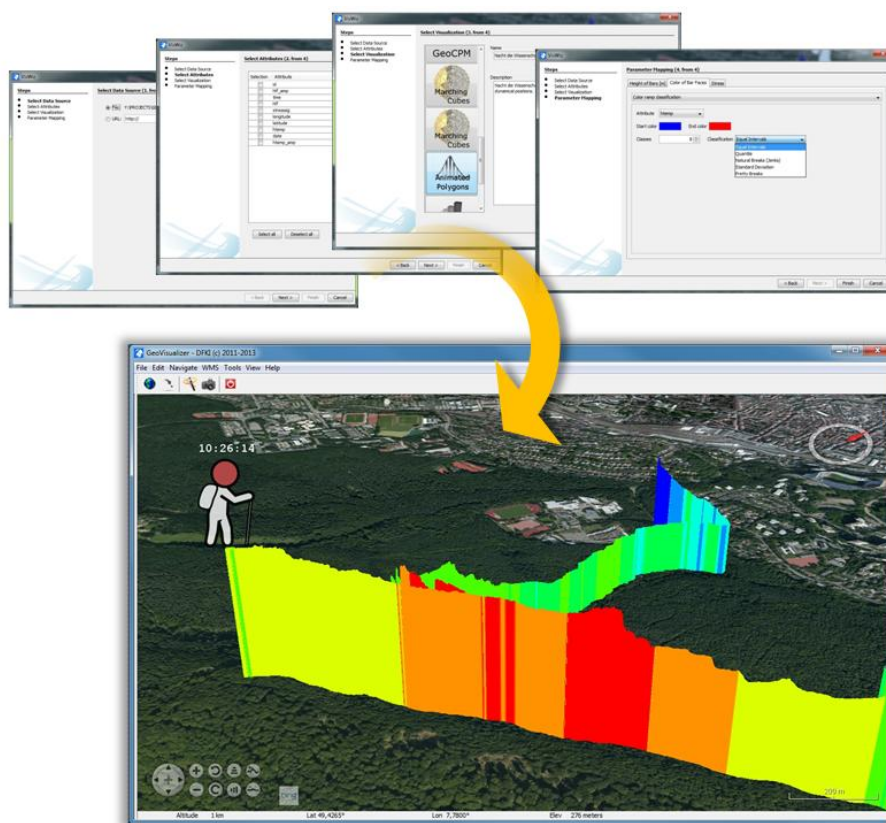
GeoVisualizer uses an intuitive and easy to use graphical user interface (GUI) as well as a flexible and extendable architecture for the visualization of 3D and 4D (3D plus time) georeferenced data sets. Using the time dimension allows animated presentations and the interactive exploration and analysis of the data.


Figure 1: By using the visualization wizard "VisWiz" (top) the user is able to produce different 3D visualizations without the need of expert knowledge (bottom).

4.1 GeoVisualizer Components

GeoVisualizer is split into two main components, the GeoVisualizer-UI and GeoVisualizer-Core.

The GeoVisualizer-UI component provides the necessary methods and functions for the graphical user interface. Besides the functionalities like the integration and management of GIS web services (i.e. Web Map Service and Web Feature Service) already integrated into the NASA World Wind SDK, the component provides the visualization wizard VisWiz which guides the user through the process of generating 3D and 4D representations based on his own data (see Figure 1). In addition, the GeoVisualizer-UI allows the use of stereoscopic displays (Side-by-Side, horizontal and vertical interlaced) for presenting the visualization on real 3D hardware.

The GeoVisualizer-Core component provides the basic visualization techniques and the interface specification for the extension of the application with new visualization techniques for different georeferenced data sets. The interface uses the Service Provider Interfaces (SPI) (ORACLE 2013b) which allows the easy integration of new extensions. Within GeoVisualizer SPI is used to integrate user specific visualizations, data import and export modules. The combination of Java Web Start and SPI technologies allows the use of private, local visualization concepts next to the always up to date public GeoVisualizer components. Besides the basic visualization techniques (e.g. point clouds) the GeoVisualizer-Core component provides different color palettes and color encodings (see e.g. BREWER 2013). For more details on the technical implementation of GeoVisualizer please refer to (STEFFEN ET AL. 2013).

4.2 Visualization Components

Within this cooperation project, we developed different visualizations for static, stationary as well as dynamic sensor data. The two visualization extensions "Animated Polygons" and "Scrolling 3D Bars" are depicted in Figure 2. "Animated Polygons" (see Figure 2 left) is used for the visualization of continuous-dynamic or spatio-temporal data. To visualize time-dependent variables "Animated Polygons" offers the attributes height, color and spatial position of the polygon. All time steps are visualized and a new time step usually refers to a new spatial position.

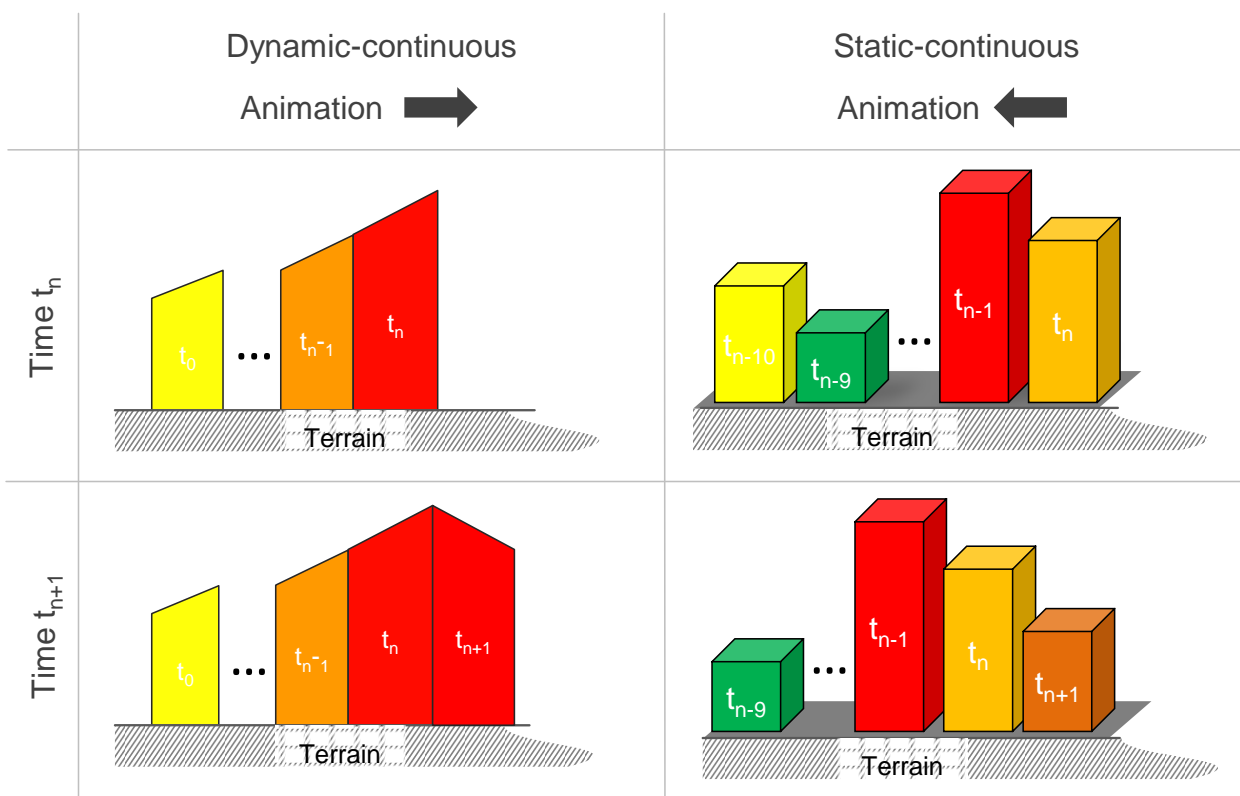
For the presentation of continuous-static sensor data "Scrolling 3D bars" has been implemented as a visualization extension (see Figure 2 right). Attributes for mapping different variables are height, depth, width and color of the three-dimensional column. As the position of the sensor data is static, older data points are moved (scrolled) away from the spatial location, so the latest time step is always visualized at the real data position. In contrast to the "Animated Polygons", only a user defined time span is shown, e.g. the last 10 time steps.


Figure 2: Visualization „Animated Polygons" (left) and „Scrolling 3D Bars" (right) for time steps t_n and t_{n+1}.

5   WORKFLOW FOR PLANNERS

The planner is relying on clear and understandable visualizations for the presentation of his complex analysis. The workflow to achieve this goal consists of a number of individual steps (see Figure 3). This embraces the equipment of test people with various kinds of sensor devices, the measurement of the data as well as its analysis and interpretation. As a first step, the determination of the required data is necessary. For the case studies mentioned this means that relevant geodata (the tracked paths), human sensory data, personal

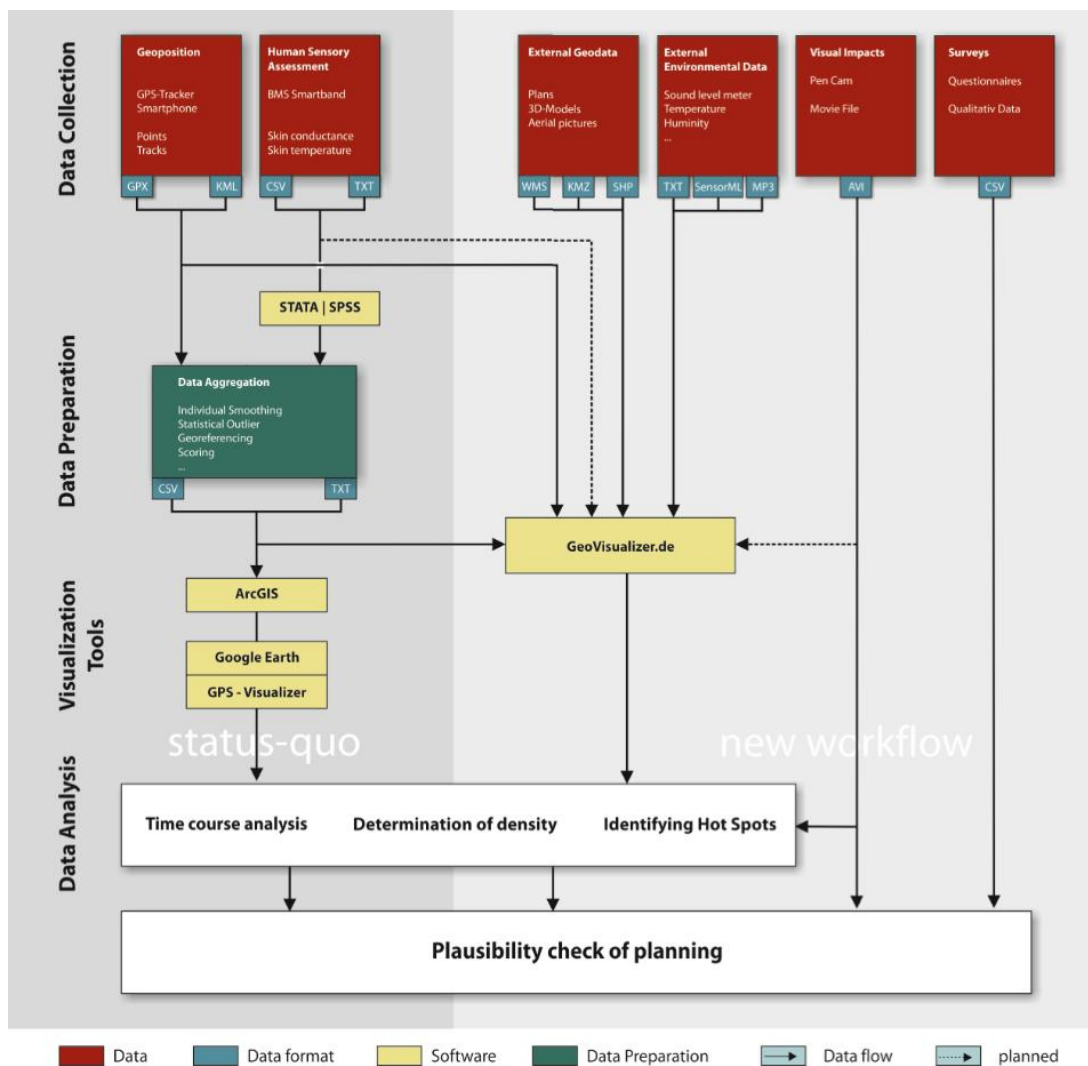
video material and data extracted from the questionnaires must be processed and merged. For correlating geodata with human sensory data (skin conductance, skin temperature), it is necessary to use statistical methods (statistical outlier removal, smoothing, scoring) to clean the human sensory data.


Figure 3: Workflow Human Sensory Assessment & GeoVisualizer (Source OWN FIGURE 2013)

In previous studies, the workflow for visualization was separated in complicated steps with different data formats using different programs. Statistical methods and geodata-analysis had to be made separately and were merged together under a complex approach. By using GeoVisualizer it is now possible to combine these steps into one workflow within a single software solution. The GeoVisualizer can easily read and process different data formats. This embraces data like various kinds of geodata (e.g. SHPs, KMLs) and external environmental sensor data like temperature or humidity for example. The functionalities replace the need for the obligatory use of ArcGIS or Google Earth at this point. The necessary statistical methods will be also part of the GeoVisualizer in the future.

In test studies Shapefiles with embedded emotional data were created. .The GeoVisualizer is able to represent the respective attributes directly with his component VisWiz. It provides a variety of different visualization options as output, such as timing analysis or density determination of e.g. stress responses. Stress hotspots of test people or other spatial patterns can be identified and a plausibility check for planning purposes of the examined phenomenon can be made.

6 INTEGRATION OF SENSOR DATA – USE CASES

In order to test the developed approaches, suitable use cases were designed. Following a pre-study, the first test study took place during a football match. It provides interdependencies between external triggers inducing emotional reactions and the immediate environment. In the case studies, the measured and derived physiological values were assigned to specific attributes which can be seen in the subsequent figure (see

Figure 4): The measured skin conductivity is represented by the height of the column, the skin temperature by the color of the column. The software also provides additional project-based visualizations. The perception of stress, for example, is represented by a red-colored head of the visualized icon, respectively the hiker.

6.1 Pre-Study for dynamic-continuous sensor data

Before conducting the main study, a pre-study was set up to check the functionalities of the GeoVisualizer. This was done in the context of a hike through the Palatinate Forest, where a test person had to wear the sensor devices. The results have shown that the functionalities of the GeoVisualizer are suitable to illustrate the emotional arousal in multiple ways for further analyzing processes. Furthermore, the graphical analysis provides comprehensive possibilities to detect and display emotional stress, or in case of a solely high skin conductivity, exhaustion.
Figure 4: Virtual Globes enable visual analysis from different angles (Source OWN FIGURE 2013)

6.2 Static-continuous sensor data – Results and visualizations

In the main study, two different scenarios were designed. First scenario was a test setup with static sensors that were subsequently visualized with the GeoVisualizer. The limitation to a determined location also offers the advantage that no location inaccuracies due to unstable GPS signals will occur. The test people were equipped with the BMS Smartband and visited a football match of the local team of Kaiserslautern on the 30th of September 2012. In this test scenario, psychophysiological measurements of the volunteers were taken and validated in the aftermath. The emotional reactions of the participants can easily be connected to the course of the match. Based on the presentation of the data, the correlation of emotional stress reactions and specific situations in the match can be identified (e.g. goal and red card). Both goals show effects in the physiological data. Due to the chosen visualization mode (see Figure 5), it was easier to illustrate specific situations (peak of the 3D bars to the right in Figure 5a & b) as well as the time period before the situation (3D Bars scroll from the right to the left over time). The influencing factors for the participants were mainly limited to the events of the match, because the location was static. Furthermore, video data from the match as well as the match-ticker were used to compare the specific events with the measured data sets.

6.3 Dynamic-continuous sensor data – Results and visualizations

In addition to the first experiment, the second one is characterized by using a dynamic component, namely the walk down from the football stadium to the inner city of Kaiserslautern. The participants were equipped with the same instruments, but additively with a GPS logger, which was used to locate the collected physiological values.

After the end of the match, the study participants went on a pre-defined route to the inner city together with the other spectators from the stadium (see Figure 6). The first third of the walk was right in the flow of the crowd, while the rest of the walk was in a quieter area of the city. The data shows that the arousal level of the person's stress in the early part is much higher than at the end of the trail, which was less crowded. Based on these measurements, it can be observed that there is a connection between the stress signals and the local circumstances of the route (Fig. 6 a). By creating a density map with places of stress reactions, critical points of the walk were pointed out. Those were mainly in the first part of the route where a dense crowd still was present (risk of congestions). These congestions reducing the walking speed and the feeling of being trapped

in a crowd are impacts to induce emotional stress for the participants. People of the research group without measurement devices confirmed this impression of the crowded and congested route in a retrospective interview. The findings are useful hints in further urban planning projects, like evacuation scenarios.

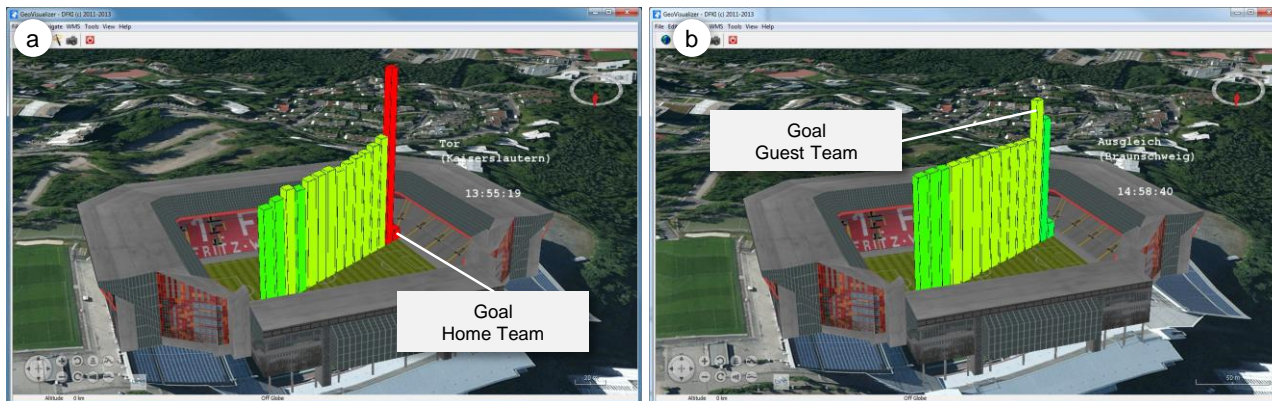
In addition, this approach was used for two other participants, who had to walk a pre-defined route while passing some touristic and architectural hot spots of the city. Due to manifold influences on the participants during such a trip, it is still very complicated to detect specific urban patterns. Results of this study example will be used for further research.


Fig 5: Visualization of sensor data during a soccer match. „Scrolling 3D Bars" help to identify on which specific situations emotions occur for the participants (Source OWN FIGURE 2013)
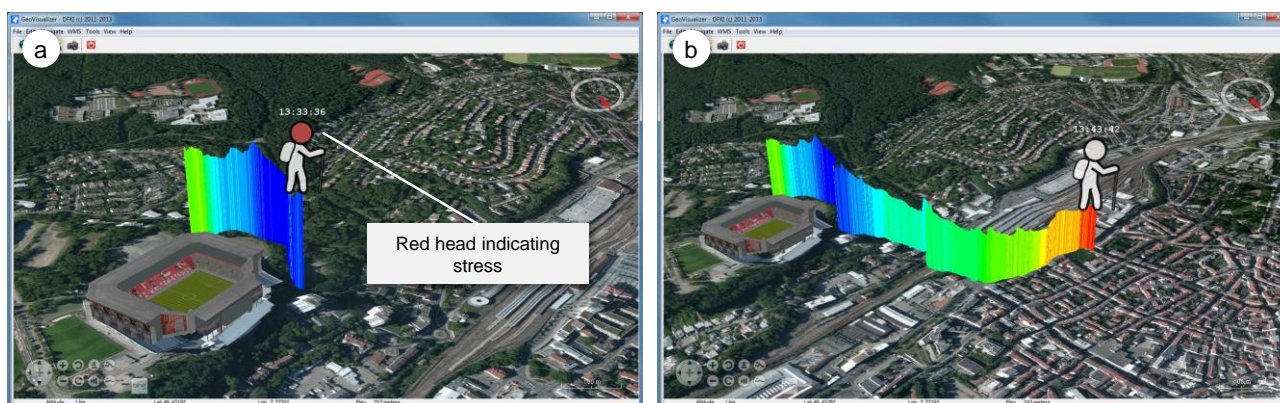

Fig. 6: Enhancement of the „Animated Polyons" with a specific user-icon. The reddish head (a) emphasizes the stress-reaction during the congested street part (Source OWN FIGURE 2013)

7 CONCLUSION

The GeoVisualizer turned out to be a suitable tool for the complex requirements of the representation of (human) sensory data for spatial planning. This includes in particular the modular functionalities and the various display modes for the observation of phenomena in urban spaces during time. The previously mentioned approach offers chances for planners to allow emotional monitoring and to use its results for urban planning. The study cases gave a glance on how such approaches can be integrated in planning processes.

For both study cases, the GeoVisualizer was able to execute the complex analysis tasks. It reduces the complexity of the previously used workflow: It is an easy-to-use tool, which has a modular structure and allows quick changes between the different modes of visualizations. This offers opportunities for planners to perform spatial monitoring using multiple spatial data sources. Hence, human sensory data, characterized by a high spatial and temporal complexity, can be visualized easily and in a sophisticated way. Communication of these sometimes very complicated facts and results is easier with this kind of presentation, especially for laymen. Presenting this system on an open scientific night (Lange Nacht der Wissenschaft), a large number of citizens were interested in this new approach. During the event, a large number of visitors gave positive feedback that GeoVisualizer is a kind of catalyst to transform complex data in an easy, transparent and understandable format.

In the future, there will be more visualization features for the complex human sensor data analysis: The direct integration of human-sensor measurements without a primary use of statistical programs is the main goal. In addition, an automatic creation of small video clips for a retrospective assessment of stress responses is a further goal as well as the integration of other (environmental) sensor data via a SensorML interface in order to achieve a better understanding of the processes and interactions in the system of human sensory data and the environment.

1 ABSTRACT

The purpose of this study is to increase thermal comfort within a detached housing area by improving the thermal environment. Therefore, it suggests application of various greening methods, taking into account the materials and shape of the outdoor space, as a systematic approach to reducing sensible heat by lowering the surface temperature.

As to Case 1 and Case 2, there was no significant difference in the surface temperatures within the detached housing area, but Case 1 showed lower surface temperature distribution around the fence due to shade during the daytime. Case 3 showed the low surface temperature distribution of 10℃ around the planted trees during the daytime and temperature of 15℃ around the green roof. With respect to MRT the green roof showed a temperature difference of 3℃ or more and the vacant land covered by the grass also showed a difference of 2~3℃. In addition, Case 3 with increased green coverage showed the temperature 10℃ lower than Case 2.

Meanwhile, changes in the wind velocity may cause dispersion of sensible heat and thus affect the temperature. And higher trees are more effective in blocking solar radiation and lowering the temperatures.

2 INTRODUCTION

2.1 Backgrounds and Purpose

Temperature rises in detached housing area are caused by various climate factors including not only a temperature but also wind and humidity, which all affect human senses and behaviors. And creating a thermal comfort environment by considering such various climate factors is critical to designing detached housing area. In particular, the surface temperature of the components of an actual detached housing area such as a building or the ground is closely related with space design involving materials or the shape of outdoor space, indicating that outdoor space should be carefully designed by taking the thermal environment into account.

The purpose of this study is to examine how fence demolition affects the thermal environment of outdoor space in a detached housing area and to highlight the positive effects of greening, which is expected to improve the thermal environment. This can provide a basis for a continuous fence demolition campaign by assessing the thermal environment of outdoor space in a detached housing area.

In addition, this study suggests greening methods considering the materials or shape of outdoor space as a systematic approach to improving the surface temperature with the purpose of increasing thermal comfort within a detached housing area by controlling sensible heat. To that end, we have reproduced the materials or the shape of the outdoor area, which affects the surface temperature of a case study area, with 3D-CAD and applied relevant climate factors to a computer simulation.

3 METHODOLOGY

The simulation process is outlined in Fig. 1. The simulation is performed using 3D-CAD models (shown at the upper left in Fig. 1) for buildings, trees and other structures in the area being analyzed. As shown at the top right corner of Fig. 1, three-dimensional spatial forms of buildings, trees and other structures, and two-dimensional ground surfaces are divided into mesh grids. Thermophysical data of construction materials such as albedo, conductivity, and solar transmittance are assigned to the grids. An automatic mesh-dividing process with a spatial resolution of 0.05-5m(a practical size is 0.1-0.4m) has been designed and only uniform mesh can be used in the present version of the tool. A uniform mesh size of 0.4m was used in this study.

Three-dimensional radiation (solar radiation and longwave radiation) from surroundings (the sky, ground and surroundings) was considered in the heat balance calculation for each mesh. Conduction heat was assumed to

be transferred in one direction which is normal to the mesh surface. The following assumptions were also used in the thermal simulation. Ambient air temperature and wind velocity are uniformly distributed in the outdoor spaces at an analysis time. Indoor air temperature is uniform in a room at an analysis time. The effect of heat bridges is not considered in the building heat load simulation.[1]
Fig. 1: Diagram of the simulation tool.

3.1 External surface temperature simulation

The energy balance equation at each mesh surface can be written as Eq. (1). The left term of Eq. (1) is the conductive heat at the mesh. The first right term is the absorbed shortwave (solar) radiation by the mesh. The second right term is the net longwave radiation. The third right term is the convective heat transfer from ambient air. The fourth right term is the latent heat from evaporation Eq. (1) accounts for three-dimensional radiation irradiated on the surface. Short-wavelength radiation on the surface includes direct solar insolation, sky solar radiation and reflected solar radiation. Reflected solar radiation includes both specular reflection and isotropic diffuse reflection. The first reflected solar radiation is considered in the calculation. Atmospheric radiation and longwave radiation from the surroundings are considered in the longwave radiation irradiated on the surface. Sky solar radiation and atmospheric radiation are calculated from the sky view factor for each mesh.

The sky view factor is calculated by the multi-tracing simulation from the mesh toward multiple hemispherical directions. The tracing direction is established so that the tracing density (interval) comes to have the same shape factor. The sky view factor is estimated by counting the number of tracers reaching the boundary surfaces. The shape factor for calculating the reflected solar radiation and long-wavelength

---

[1] He J, Hoyano A, Asawa T. A numerical simulation tool for predicting the impact of outdoor thermal environment on building energy performance. Applied Energy 2009; 86; 1597-1600.

radiation from the surroundings is determined by the same method used in the estimation of the sky view factor. A detail description of the calculation methodology can be found in Asawa et al.[2]

Convective heat transfer is calculated on the assumption that ambient air temperature and wind velocith are uniformly distributed in the outdoor spaces at the time of analysis. This assumption is valid under weather conditions with low wind velocity. The convection coefficient is considered as a function of wind velocity, and is given by Jurges' equation.[3]

The non-steady-state one-dimensional conduction equation inside each mesh is expressed by Eq. (2). The external and internal surface temperature for each mesh can be determined by solving Eq. (2), using Eqs. (1) and (3) as boundary conditions for external surfaces and internal surfaces, respectively. Boundary conditions for internal surfaces are indoor air temperature for buildings, and underground temperature for the ground, respectively. Rooms on the same floor of a building are assumed to be single rooms, as the influence of internal partitions is not taken into consideration. The indoor air temperature is assumed to be uniform at an analysis time, and its hourly data is given as follows. For the first calculation, the indoor air temperature is assumed to be equal to the ambient air temperature or setpoint temperature for the non-air-conditioned or air-conditioned period. Eq. (3) is a boundary condition for an internal surface. The energy exchange at the internal surfaces is considered to by radiative and convective exchanges with indoor air, where a combined heat transfer coefficient α_o is used and assumed to be constant at 9.3W/(m²K). In the second calculation, the indoor air temperature is given from the results of the building heat load calculation described below. The underground temperature at a depth of 0.6m is considered to be constant during the day, and is given from the input data.

The backward-difference method is used to solve the non-steady-state heat conduction equation (Eq. (2)). The calculation time-step used in this study is 5-min.

The tree shape is modeled as a 3D-CAD model and the crown is composed of meshes containing solar transmittance data. Solar transmission radiation decreases as it passes through the tree mesh model. As shown in Fig. 2, this mesh model makes it possible to quantify the influence of the position and distance of sunlight passage within the crown on solar transmission. The surface temperature of a tree's crown is calculated by empirical formulas derived from the experimental data, and can be expressed as a function of the solar radiation incident on the surface, ambient air temperature, and wind velocity.

$$H_G = H_S + H_L + H_C - H_E \qquad (1)$$

$$H_G = -\lambda \frac{\partial T}{\partial x}\bigg|_{x=0} \qquad H_S = a_{su}(\cos\theta \cdot I_{DR} + F_{sky}I_{SR} + I_{RR})$$

$$H_L = F_{sky}R_{La} + R_{LW} - \varepsilon_s \sigma T_s^4$$

$$R_{La} - \varepsilon_s \sigma T_s^4 = \varepsilon_s \sigma T_s^4 (a + b\sqrt{e}) - \varepsilon_s \sigma T_s^4 \text{ (clear sky)}$$

$$R_{La} - \varepsilon_s \sigma T_s^4 = \left(\varepsilon_s \sigma T_s^4 (a + b\sqrt{e}) - \varepsilon_s \sigma T_s^4\right) \times (1.0 - (1 - m_c)C/10))$$

(cloudy sky)

$$R_{LW} = \varepsilon_s \sum_{i=1}^{Nw} F_i \varepsilon_i \sigma T_{wi}^4$$

$$H_C = \alpha_c(T_a - T_s)$$

$$H_E = \iota\beta K(X_s - X_a)$$

$$pc_p \frac{\partial T}{\partial t} = \frac{\partial}{\partial x}\left(\lambda \frac{\partial T}{\partial x}\right) \qquad (2)$$

$$-\lambda \frac{\partial T}{\partial x}\Big|_{x=L} = \alpha_o \big(T_{ri} - T_{sl}(i,j) \big) \qquad (3)$$

3.2 Simulation output

As outputs of the simulation, temperatures of all external surfaces can be predicted and visualized on the 3D models (see the lower left corner of Fig. 1). From the calculated results of surface temperatures, mean radiant temperature (MRT) at a point can be estimated. The mean radiant temperature at a point is defined as the uniform temperature of an imaginary enclosure in which radiant heat transter from the human body of object equals to the radiant heat transfer in the actual non-uniform enclosure. The MRT at a height of 1.5 m dbove the fround was used to evaluate thermal comfort in outdoor human activity spaces in the present study. In addition, diurnal variations of indoor air temperature, internal surface temperature and heating/cooling loads can also be obtained.[4]

4 ANALYSIS OF THERMAL ENVIRONMENT

4.1 Outline of study area

The exampled site is a fence demolition campaign district within Daegu Metropolitan City when has played a central role in the southeast areas, as one of 3 metropolitan cities in Korea. This site is limited to the first-type general residential areas where low-rise detached houses in good condition are concentrated. Preferably, the area should be the one intentionally formed for the purpose of providing additional houses to solve the housing shortage problem. Therefore, we have selected Daemyeong District, one of the land readjustment project districts formed between the 1960's and 1970's, after examining land readjustment project districts developed before the 1990's and land development project districts developed from the 1990's and up to now.

There was a clear street hierarchy in the area and a gridiron road pattern, directly connected with residence units, but street parking was threatening pedestrians' safety. In addition, there was a small number of a multiplex house but a large number of typical low-rise (two-story) detached houses with fences, which abutted on a road whose width is 10m or below.
Fig. 2: Case study area.

4.2 Outline of study assumes

As described in Table 1, a simulation was run on the three conditions.

---

[4] Jiwon R et al. Study on evaluation of thermal environment following alleviation of limit on number of floors of apartment complex. Real CORP2011;929.

Cases		Conditions
Before the fence demolition	Case1	- Surface: concrete - Road: asphalt - Vacant land and parking lot: vacant - Wall: cement bricks, R.C - Roof: concrete, slates - Green coverage: 5 %
After the fence demolition	Case2	– 8 houses removed walls - Green coverage: 7 % - Surface: grass and water retaining pavement - Tree planting
Greening after the fence demolition	Case3	- 16 houses removed walls - Green coverage: 25 % - Surface: grass and water retaining pavement - Tree planting and a green roof

Table 1: Simulation input conditions for the analysis of the thermal environment.

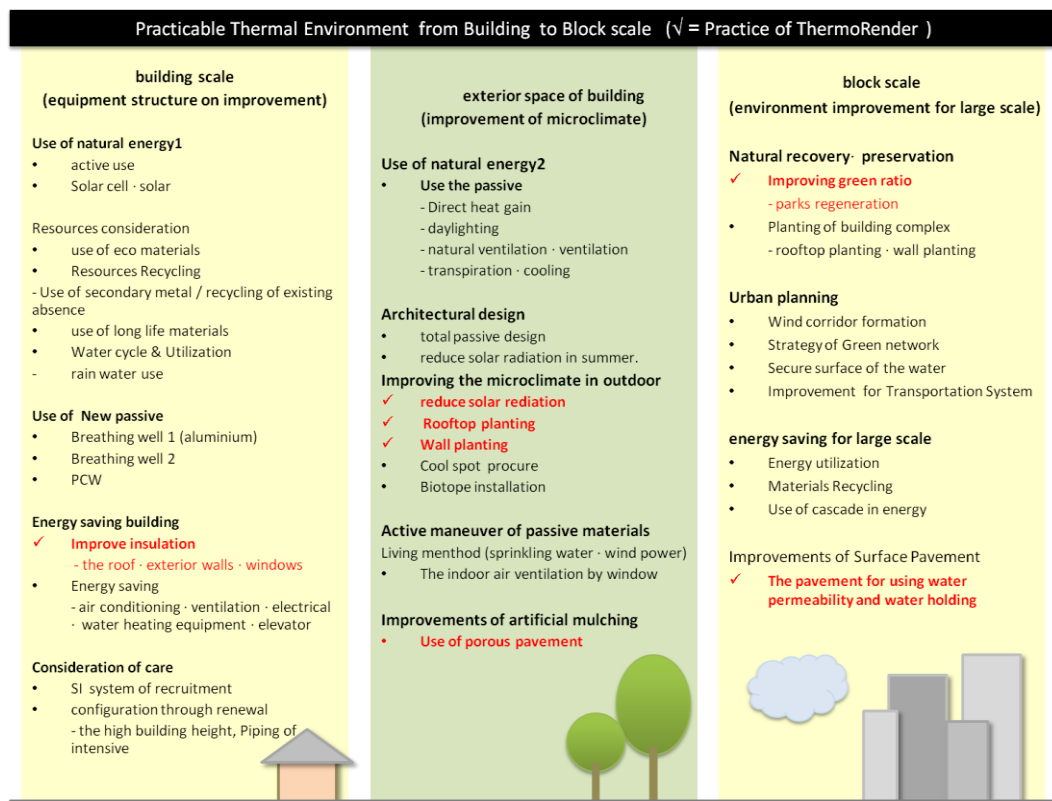
Based on these conditions, this study focused on reducing sensible heat generated by the surface and, especially, the effects of greening on the thermal environment of the outdoor space in the detached housing area. This study applied various greening methods such as vegetation, tree planting, improved artificial ground coverage, and a green roof in the detached housing area based on Figure 2, which shows thermal environment improvement methods by the scale.


Fig. 3: Thermal environment measures of according to the scale.

4.3 Analysis of Thermal Environment

4.3.1 3D Surface Temperature Distribution

According to the 3D surface temperature distribution simulation for Case 1 and Case 2 (Figure 4), Case 1 showed the low surface temperature distribution during the daytime (15:00) because of the shade around the fence. Meanwhile, Case 3 showed the low surface temperature distribution of 10℃ around the planted grass/trees during the daytime and temperature of 15℃ around the green roof.

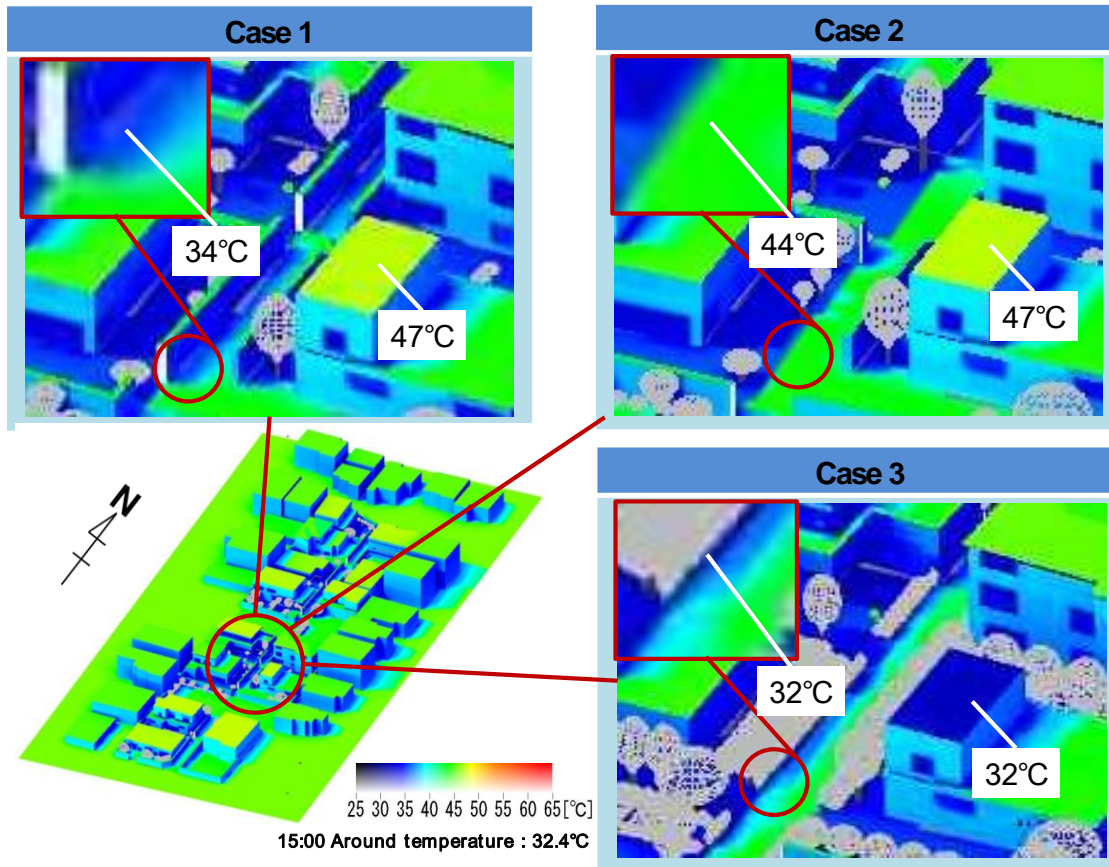
This result shows that the shading effects and evapotranspiration of planted vegetation/trees can lower sensible heat in the area and that use of ground coverage with bright colors and high reflectivity as well as increased greening with tree planting can reduce air/surface temperatures, eventually improving the thermal environment within the detached housing area. In addition, Case 3 shows that the green roof can also maintain the low surface temperature distribution of 15℃, which should be considered in order to improve the thermal environment and increase thermal comfort within a detached house as well as to save energy through enhanced insulation.


Fig. 4: Surface temperature distribution.

4.3.2 MRT Distribution

Mean Radiant Temperature (MRT) is the omnidirectional effect of radiant heat (which humans feel) converted into a mean temperature. According to Figure 5, Case 3 showed the low temperature distribution because of green coverage increased by tree planting and improved artificial ground coverage. In particular, the green roof showed a temperature difference of 3℃ or more and the vacant land covered by the grass also showed a difference of 2~3℃.

Higher MRT indicates a greater amount of radiant heat, which allows humans to feel higher temperatures than actual temperatures. In order to increase thermal comfort within a detached housing area, therefore, various methods to lower the surface temperature of a built-environment should be applied such as solar radiation blocking by trees, improved artificial coverage, a green roof, and so forth.

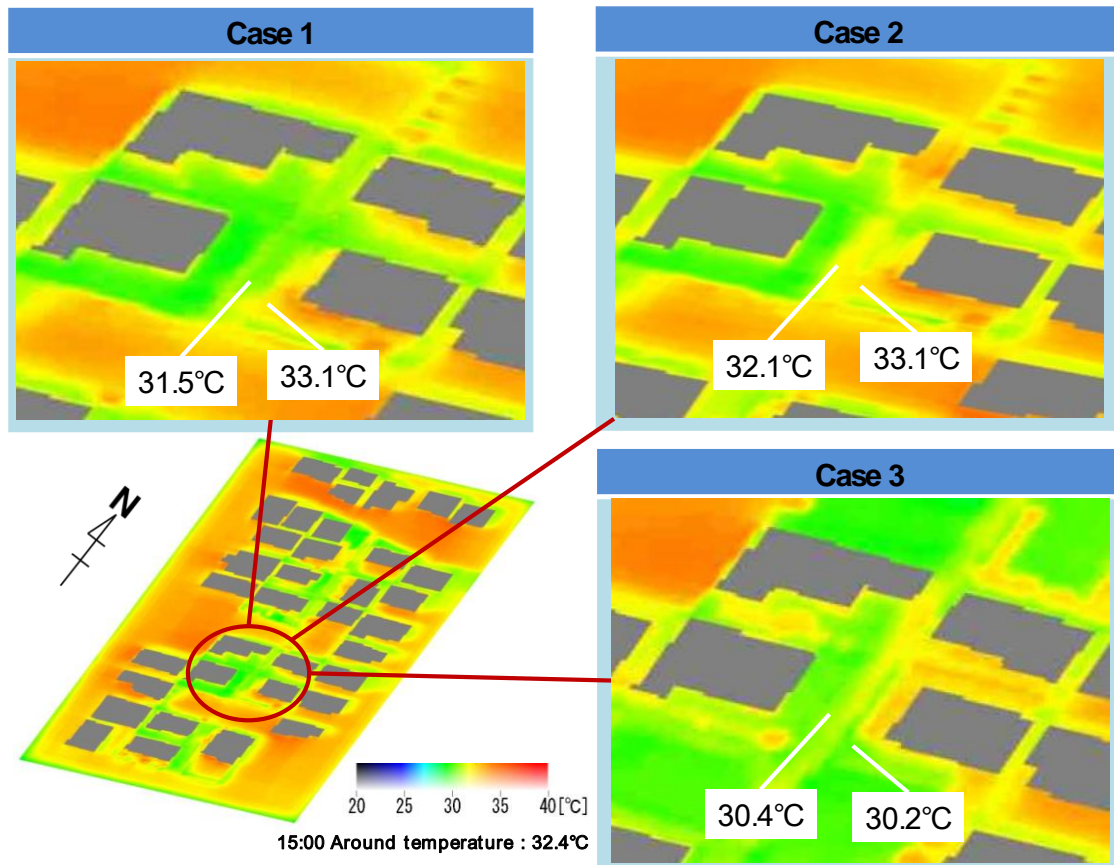
In particular, the radiant heat of the wall surface facing the west is enormous, which requires active efforts to find solutions. For example, high trees can be planted around the walls to block sunlight and radiation heat, and the greening of the wall facing the west with a green roof can produce similar effects as well.


Fig. 5: MRT Distribution.

4.3.3 HIP Distribution

Figure 6 shows the HIP distribution of Case 3, in which the entire asphalt surface was compared with the grass/permeable pavement and green coverage was increased with vegetation, tree planting, improved artificial coverage, and a green roof. As a result, Case 3 with increased green coverage showed the temperature 10℃ lower than Case 2, and 5℃ lower than the grass pavers.

That is, higher HIP means a greater difference between the surface temperature and air temperature and also a greater amount of sensible heat emitted into the air, which is a major cause of a heat island. Such a situation may occur due to artificial coverage, the shape of the surface, a heat source, a water source, and so on. In particular, Figure 6 shows that artificial materials such as concrete and asphalt greatly contributed to heat accumulation and emission. The shape of the surface is closely related with radiant heat and cooling effects of wind may affect the temperature as well. In conclusion, increasing green coverage within the entire built environment is effective in improving the thermal environment than partial greening in the area.
Fig. 6: HIP Distribution.

4.3.4 Wind velocity

Not only the air temperature but also wind velocity affects the human senses and behaviors, and wind is an important factor in creating a thermal comfort environment especially within a detached housing area. Figure 7 shows how the wind velocity affects the surface temperature during the daytime. It was observed that the surface temperature of the built environment went down when the wind velocity increases.
Fig. 7: Surface temperature distribution according to the wind velocity

The HIP values in Table 2 indicate the same results. Table 2 shows changes in the HIP values as the amount of sensible heat, emitted from the surface of the outdoor space, is high in the air due to direct solar radiation from sunrise to sunset. The direct solar radiation increased the surface temperature of the outdoor space during the daytime, which led to a rise in sensible heat in the air, and the changes in the wind velocity may cause dispersion of sensible heat and thus affect the temperature.

Time (h)	Wind velocity(m/s)				Time (h)	Wind velocity(m/s)			
	1.0	1.6	2.0	2.5		1.0	1.6	2.0	2.5
0	2.15	2.10	2.09	2.05	12	15.89	15.45	14.96	14.21
1	1.84	1.79	1.76	1.74	13	19.45	18.14	17.36	16.35
2	1.14	1.08	1.06	1.02	14	15.88	14.73	14.49	13.53
3	1.00	0.94	0.93	0.91	15	12.26	11.91	11.81	11.49
4	1.70	1.67	1.66	1.61	16	8.69	8.51	8.43	8.26
5	1.78	1.76	1.75	1.70	17	5.45	5.30	5.26	5.11
6	3.62	3.57	3.56	3.54	18	3.93	3.83	3.78	3.67
7	5.02	5.00	4.99	4.95	19	3.44	3.35	3.30	3.21
8	5.94	5.90	5.90	5.88	20	3.62	3.53	3.51	3.44
9	6.63	6.59	6.58	6.57	21	3.20	3.12	3.10	3.03
10	10.11	10.08	10.07	10.06	22	2.68	2.62	2.60	2.54
11	12.88	12.83	12.79	12.70	23	2.82	2.74	2.73	2.66

Table 2: HIP by changes in wind velocity. Unit : HIP(°C)

However, it was observed that existence of a fence did not significantly affect the temperature. Figure 8 shows that with the same wind velocity (2m/s) the surface temperature distribution was not significantly affected by the existence of fence but by materials of the ground, vegetation, trees, and so forth.
Fig. 8: Surface temperature distribution due to the presence of the fence.(wind velocity: 2m/s)

4.3.5 Tree planting

Various circumstances and methods should be taken into account in order to improve the thermal environment. Particularly, a site facing the west, which has the highest reflected heat from the ground or built structures around 15:00 should be considered sufficiently when greening methods are used to lower the surface temperature. Hence, this study also examined the temperature distribution according to the height of trees. Figure 9 shows that higher trees are more effective in blocking solar radiation and thus lowering the temperatures.
Fig. 9: Surface temperature distribution according to the height of trees

5   CONCLUSION

The purpose of this study is to increase thermal comfort within a detached housing area by improving the thermal environment. Therefore, it suggests application of various greening methods, taking into account the materials and shape of the outdoor space, as a systematic approach to reducing sensible heat by lowering the surface temperature.

As to Case 1 and Case 2, there was no significant difference in the surface temperatures within the detached housing area, but Case 1 showed lower surface temperature distribution around the fence due to shade during the daytime. Case 3 showed the low surface temperature distribution of 10℃ around the planted trees during the daytime and temperature of 15℃ around the green roof. With respect to MRT the green roof showed a temperature difference of 3℃ or more and the vacant land covered by the grass also showed a difference of 2~3℃. In addition, Case 3 with increased green coverage showed the temperature 10℃ lower than Case 2.

Meanwhile, changes in the wind velocity may cause dispersion of sensible heat and thus affect the temperature. And higher trees are more effective in blocking solar radiation and lowering the temperatures.

The study results indicate that controlling the surface temperature of the built environment is critical to improving the thermal environment and increasing thermal comfort within the detached housing area. Because wind and humidity as well as temperatures affect human senses and behaviors, the shape and layout of space should allow a constant and effective flow of wind within a detached housing area.

Therefore, it is important to predict and assess the thermal environment at an early stage, using computer simulations, to design pleasant space in terms of the thermal environment. However, it may not be practical to identify thermal characteristics of a detached housing area within limited time. Hence, we can analyze thermal characteristics identified from simulations in order to provide effective feedback for space design.

It is possible to identify and analyze thermal characteristics, using the data of HIP or the surface temperature distribution provided by simulations, and to utilize the results for another space design. Therefore, it is significant that this study has identified the thermal characteristics of an actual detached housing area and explored the possibility that the results can be used as effective indicators for designing general residential space and for determining when to carry out thermal environment analysis.

Alpine Stadt-Landschaften. Beobachtungen zur Rolle von Freiräumen im Tiroler Inntal aus Sicht des Landscape Urbanism

Wolfgang Andexlinger

(Ass.-Prof. Dr. Wolfgang Andexlinger, Institut für Städtebau und Raumplanung, Universität Innsbruck, Technikerstraße 13, 6020 Innsbruck, wolfgang.andexlinger@uibk.ac.at)

1 ABSTRACT

Die rasante Entwicklung der baulichen Strukturen des Tiroler Inntales treibt den Prozess des Zusammenwachsens von Siedlungsgebieten weiter voran. Dies wirft die Frage auf, welche Rolle den noch unbebauten und zum Teil agrarisch genutzten Flächen in Zukunft zukommen kann und wie mit diesen Flächen aus planerischer Sicht umgegangen werden soll.

Der von Rem Koolhaas im Wettbewerbsbeitrag zum Parc de la Villette in Paris und im Zusammenhang des Projektes Melune-Sénart formulierte Ansatz und die von Charles Waldheim James Corner formulierten Idee des landscape urbanism bilden dafür die theoretische Grundlage. Durch die Auswertung von Luftbildern, qualitativen und quantitativen Daten wie auch durch planliche Darstellungen wird gezeigt, dass im Umgang mit der weiteren Entwicklung des Inntales dem Thema der Landschaft eine neue Rolle zugewiesen werden muss.

Freiräume können nicht mehr alleine als landwirtschaftliche Produktionsflächen bzw. als Restflächen betrachtet werden. Vielmehr ist ein Perspektivenwechsel notwendig, der die heute noch unbebauten Flächen als zukünftige Parklandschaften eines immer stärker urbanisierten Raumes definiert.

2 EINLEITUNG

Der Prozess der Urbanisierung schreitet mit höherem Tempo, steigender Intensität und in globalem Maßstab voran. Zunehmend befinden wir uns in landschaftsverbrauchenden, automobilabhängigen Siedlungsstrukturen, in denen der historisch geprägte Kern nur mehr einen Bruchteil der Gesamtfläche ausmacht. Das Ensemble von Funktionen, die ursprünglich Wesen des Zentrums ausmachten, hat sich inzwischen entlang der Mobilitätsachsen auf das gesamte Stadtgebiet verteilt. Diese Entwicklung weicht dramatisch von den seit Jahrzehnten als erstrebenswert formulierten Zielen einer nachhaltigen Stadtentwicklung ab.

Klassische Methoden und Instrumente, wie etwa ein Bebauungsplan, stoßen bei Planungsaufgaben im Zusammenhang mit der Stadt von heute oftmals die Grenzen ihrer Effektivität bzw. unterstützen diese Instrumente das inselhafte Betrachten und Entwickeln von Städten. Häufig verstreichen lange Planungsphasen, bis Pläne von der Idee bis zur Umsetzung gelangen. Nicht selten verändern sich aber die Ausgangsbedingungen schon während der Planung, sodass ein Nachjustieren oftmals nur schwer möglich ist.

Aus diesem Grund konzentriert sich die Aufmerksamkeit von Theoretikern verstärkt auf das Thema Landschaft. Immer mehr Planerinnen und Planer bezweifeln die Lösungen des – nahezu ausschließlich vom Hochbau geprägten – Städtebaus des 20. Jahrhunderts. Als Alternative propagieren sie den freiraumbasierten Städtebau.

Gerade in einem – von der Natur und der Landschaft stark geprägten – Raum wie den Alpen, liegt es angesichts fortschreitender Urbanisierung nahe, Landschaft wesentlich stärker einzubeziehen, als das bei der Entwicklung des Siedlungsraumes seit dem Beginn des 20. Jahrhunderts der Fall war. Bis dahin waren die ebenen Flächen für den Anbau landwirtschaftlicher Produkte die wichtigste und wertvollste Voraussetzung. Bei der Wahl der Standorte von einzelnen Gebäuden und ganzen Ortschaften versuchte man möglichst flächensparend vorzugehen, die Gebäude wurden meist regelrecht in die Landschaft eingebettet. In einigen hochalpinen Siedlungen ist dieses ressourcenschonende Prinzip nach wie vor erkennbar und wird – wie etwa das Beispiel Vrin, einem Ort in den Schweizer Alpen zeigt –, bis heute beachtet.

In den meisten alpinen Regionen haben in den letzten Jahrzehnten aber dramatische Veränderungen in die genau entgegengesetzte Richtung stattgefunden. Die Region Nordtirol und hier vor allem der Raum Inntal können dafür geradezu als Paradebeispiel gelten. Fast nirgends mehr entspricht das Siedlungsbild den Vorgaben des Landschaftsraumes, im Gegenteil, innerhalb der letzten Jahrzehnte haben sich die Siedlungsräume immer weiter in noch unbebaute Landschaftsflächen hineingefressen. Es scheint mehr als zweifelhaft, ob hier sowohl die vorhandenen Regelwerke als auch die angewandten Planungsinstrumente

überhaupt geeignet sind, den fortschreitenden Prozess der Urbanisierung flächensparend und nachhaltig zu steuern.

In diesem Beitrag wird das Konzept des landscape urbanism, auf einen konkreten Ausschnitt des Tiroler Inntales angewandt. Die Annahme lautet, dass sich landschaftsorientierte Ansätze zur Analyse und Lösung der Probleme dieses Raumes besonders eignen. Es wird deutlich, dass es beim planerischen Umgang mit dem fortschreitenden Urbanisierungsprozess einer radikalen Neuorientierung bedarf. In diesem Sinne wird hier der freiraumbasierte Städtebau als mögliche Alternative zu den bisherigen Planungsansätzen für das Inntal vorgestellt.

Der Beitrag gliedert sich in drei Teile. Im ersten Teil rekonstruiere ich die Entstehung der landschaftsorientieren Ansätze im Kontext der Städteplanung. Der zweite Teil beschreibt die Phänomene der Urbanisierung im Raum Inntal. In Teil drei werden die Möglichkeiten der praktischen Anwendung dieser Ansätze erörtert.

3   LANDSCHAFT ALS PLANUNGSINSTRUMENT

Diejenigen Kräfte, welche die massive Ausbreitung der Siedlungsräume weiter vorantreiben, sind durch herkömmliche Planungsinstrumente nicht mehr zu bewältigen. Es bedarf neuer Ansätze, die auf das weiter beschleunigende Wachstum der Städte und den fortschreitenden Prozess der globalen Urbanisierung reagieren. Gerade hierin liegt nach Ansicht der Protagonisten des landscape urbanism dessen eigentliche Bedeutung.

Schon in den 1980er Jahren hatte Rem Koolhaas bemerkt, dass das „Gebaute, das Volle [...] unkontrollierbar geworden" sei, „dem Strudel der politischen, finanziellen und kulturellen Kräfte ausgeliefert und damit einer unaufhörlichen Veränderung unterworfen". Seiner Meinung nach gelte das nicht für Leerräume und vielleicht seien sie sogar „der letzte Ort, wo Gewissheiten noch Sinn machen können".[1]

In der Diskussion um die Stadtentwicklung und den damit verbundene Wandel des „Urbanen" wurden seit dem Beginn der 1990er Jahre eine Reihe von Begriffen eingeführt. Unter Bezeichnungen wie Edge City[2], Exopolis und Fractal City[3], Netzstadt[4] versuchte man, die verschiedensten Facetten und die Pluralität von Städten zu fassen. All diesen Konzepten gemeinsam ist, dass Stadt nicht mehr als ein klar ablesbares Konstrukt aus Zentrum und Peripherie verstanden wird. Vielmehr schieben sich die verschiedensten Bereiche und Themen der Stadt in- und nebeneinander und erzeugen damit insgesamt zersplitterte Stadtstrukturen. Gleichzeitig überlagern sich auch urbane und rurale Strukturen, wodurch sich die Grenzen zwischen „Stadt" und „Land" mehr und mehr auflösen. Neben den infrastrukturellen Einrichtungen, die bis vor kurzem noch ausschließlich in Städten und deren Zentren anzutreffen waren, sind es vor allem urbane Lebensstile, die in vermeintlich ländlichen Räumen Fuß fassen und mit dem Wandel sozialer Milieus auch die Entstehung von Hybridräumen bewirken.

Colin Rowe wie auch Thomas Sieverts haben in den 1990er Jahren Raumstrukturen beschrieben, die weder als Stadt noch als Land zu verstehen seien und Merkmale von beidem aufweisen würden. Sie prägten dafür die Begriffe middle landscape[5] und Zwischenstadt[6]. Als dem verbindendenden Element zwischen urbanen und ländlichen Räumen spricht Sieverts dabei dem Thema der Landschaft eine besondere Rolle zu: Solange die Zwischenstadt „insgesamt in ihrem Erschließungsnetz lesbar" und insbesondere „wie ein ‚Archipel' in das ‚Meer' einer zusammenhängend erlebbaren Landschaft eingebettet" bleibe, könne sie „eine beliebige Vielfalt von Siedlungs- und Bebauungsformen entwickeln".[7]

1997 prägte Charles Waldheim bei der gleichnamigen Konferenz und Ausstellung in Chicago den Begriff des landscape urbanism. Er beschreibt die Praktiken verschiedener Disziplinen, für welche die Landschaft – im umfassenden Sinne verstanden – die Architektur als wichtigstes Planungsinstrument im Städtebau ersetzt hat. Die Vorstellung der dezentralen, post-industriellen Stadt rückt den übriggelassen Raum, also den leeren Raum, in den Vordergrund. Die Landschaft, so Waldheim, wird damit zur Linse durch welche sich die zeitgenössische Stadt repräsentiert und zum Medium, durch welche sie konstruiert wird.[8]

Unter landscape urbanism versteht man mit Waldheim demnach eine auf den Zwischenraum fokussierte Planungsdisziplin, die mit den Räumen zwischen den Gebäuden, mit Infrastruktursystemen und natürlichen Ökosystemen arbeitet. Vor allem im Kontext der Dezentralisation, dem Ausufern der Siedlungsräume und der abnehmenden Siedlungsdichte erweisen sich traditionelle Planungsstrategien als unbrauchbar, weil sie zu kostenintensiv, zu langsam und auch zu unflexibel sind, um sich den rasch verändernden Bedingungen der heutigen Stadt anpassen zu können.

Die aktuellen Vertreter des landscape urbanism aus dem Umkreis von Charles Waldheim und James Corner kritisieren die Unfähigkeit von Architektur und Städtebau, kohärente und kompetente Erklärungen für die zeitgenössische Stadt anzubieten. Sie stellen dem das Konzept des landscape urbanism gegenüber, bei dem die Landschaft als das Organisationselement der Stadt fungieren soll und zusammenhängende Strukturen schaffen kann.

Für James Corner liegt der Ursprung des landscape urbanism in der Kritik der Postmoderne an der modernistischen Architektur und am modernen Städtebau [9]. Bekanntlich warfen ja vor allem Jane Jacobs [10] und auch Robert Venturi[11] den Modernisten vor, dass sie mit ihren Ideologien und realisierten Projekten nicht nur keine sinnstiftenden und lebenswerten öffentliche Bereiche schaffen, sondern sogar noch dazu beitragen würden, den Prozess der Dezentralisierung massiv zu beschleunigen.[12] In der Postmoderne wurden die Werte der historischen Stadt geradezu wieder neu entdeckt. Werte bzw. Konzepte wie die Stadt der kurzen Wege, die Bedeutung des durchgehenden Straßenrasters oder auch das Thema der kontextuellen Architektur wurden damals als wesentlich erachtet.[13] Allerdings konnte auch die Rückbesinnung auf diese Werte das weitere Ausufern der Städte nicht verhindern.

Im landscape urbanism wird die Landschaft zum Medium, das nicht nur den Umgang mit temporären Situationen, Transformations- und Anpassungsprozessen, sondern auch mit deren unterschiedlichen Intensitäten ermöglicht. Die wahrnehmbare Landschaft erscheint darin nicht nur als das formale Ergebnis fortschreitender Urbanisierung, sondern auch als Modell für den Prozess selbst. [14] Insofern als er nicht nur die naturgegebenen Bereichen, sondern auch die technischen Infrastrukturen, Industrieflächen und solche Flächen umfasst, die im Zuge des Wachstums der Städte entstehen, ist der Begriff von Landschaft in einem weiteren Sinn zu verstehen. Für landscape urbanism ergeben Freiraum und Landschaft eine Gesamtheit. Corner stellt fest, dass die verschiedenen Disziplinen der Landschaftsarchitektur, des Städtebaus und der Raumplanung sich in bestimmten Aspekten einander nähern und mit ihren Arbeitsweisen „toward a shared form of practice"[15] tendieren. Auch Corner räumt dem Thema der Landschaft zentrale Bedeutung ein. Die Verbindung der Begriffe landscape und urbanism in landscape urbanism unterstreicht den Zusammenhang und die Vielschichtigkeit des Konzept.[16]

Rem Koolhaas beschritt diesen Weg schon viel früher. Sein Wettbewerbsbeitrag zum Parc de la Villette in Paris im Jahr 1982 gilt als eines der ersten Projekte, in dem das Thema der Landschaft als strukturgebendes Element entfaltet wurde. Koolhaas wollte einen Park, der sich – um den immer schneller und häufiger

wechselnden Anforderungen der Gesellschaft gerecht zu werden – ständig verändern und den Bedürfnissen anpassen können sollte. Je stärker die Veränderungs- und Anpassungsprozesse das Wesen des Parks und seine sozialen Angebote bestimmen würden, desto besser würde der Park funktionieren. Koolhaas schlug deshalb ein Programm vor, in dem sich Bestimmtheit und Unbestimmtheit miteinander verbinden. Als bestimmendes Element sah er die Landschaft, die er streifenförmig über die gesamte Fläche einteilte. Diese Streifen wurden mit unterschiedlichen Inhalten versehen, wobei die Inhalte selbst an veränderte Bedürfnisse angepasst und mit neuen Inhalten versehen werden könnten. Der Park sollte durch die vorgegebene Infrastruktur organisiert und strukturiert sein und gleichzeitig unterschiedlichen Nutzungsansprüchen gegenüber offen sein.[17] Es blieb beim Konzept, das Projekt wurde nicht realisiert.
Fig. 1: Parc de la Villette. Rem Koolhaas/OMA

Ein weiterer Meilenstein auf dem Weg zum Konzept des landscape urbanism ist das von Koolhaas im Jahr 1987 erarbeiteten Projekt für die französische Stadt Melun-Sénart. Hier entwickelte Koolhaas seinen Ansatz der strukturschaffenden Organisation durch Landschaft weiter. In diesem Zusammenhang bemerkt er dazu:

„Der Kern unseres Projekts ist ein System von Leerräumen mit öffentlichen Funktionen die zugleich den Zugang zu den urbanen Nutzungen garantieren. Einige Leerräume konservieren Teile der existierenden Landschaft.“[18]
Fig. 2: Melun-Sénart. Rem Koolhaas/OMA

Den politischen, kulturellen und finanziellen Unsicherheiten, die bei der Planung einer neuen Stadt gegeben sind, stellte er ein tragfähiges Gerüst zu Verfügung. Die Basis bildeten mehrere, mit einander verwobene Landschaftsstreifen. Die zwischen ihnen liegenden Inseln waren für den Bau der Stadtviertel vorgesehen. Welche architektonische, städtebauliche Ausprägung diese Inseln auch immer bekommen würden, mit der

[18] KOOLHAAS, Rem: Melun-Senart. In: Arch+ Zeitschrift für Architektur und Städtebau, Nr. 105/106, Arch+ Verlag GmbH, Aachen 1990, Seite 79

Zeit würde durch die vorgegebene Landschaft als Verbindungselement eine Stadt werden, die auf Unsicherheiten und den ständigen Wandlungsprozessen reagieren könne.

Koolhaas war damit einer der ersten, der den landschaftsorientierten Entwurfsansatz im Rahmen eines Stadtentwicklungsprojektes anwandte. Seit den 1990er Jahren setzten auch andere Entwurfsbüros diese Ansätze fort. Das niederländische Büro West8 mit ihren vielschichtigen Projekten, wie auch das Schweizer Büro Latz und Partner, die für Projekte im Rahmen der Entwicklung des IBA Emscherparkes (D) verantworlich zeichnen, können hier als wichtige Protagonisten genannt werden. Es zeigt sich damit, dass dieser aktuelle Trend der Stadtentwicklung im Kontext mit der Thematik der Landschaft vor allem im europäischen Kontext zunehmend an Bedeutung gewinnt und aus diesem Gesichtspunkt stellt sich die Frage, ob das theoretische Konzept des landscape urbanism auch dazu geeignet ist, dem durch die alpine Bergwelt stark geprägten und immer stärker urbanisierten Raum Tirol eine neue planerische Perspektive geben zu können, die mit den wechselnden lokalen und globalen Einflussfaktoren produktiver umgehen kann, als es bisherige Planungsinstrumente können.

4 RESTRAUM TIROL

Zur Überprüfung der These, dass sich landschaftsorientierte Ansätze zur Analyse und Lösung der Probleme dieses Raumes besonders eignen, wurde ein Ausschnitt des Inntales in Tirol (Österreich) ausgewählt, in dem der Prozess der Urbanisierung zu einem mittlerweile unklaren Siedlungsbild geführt hat. Das Untersuchungsgebiet liegt zwischen dem östlichen Rand der Stadt Innsbruck und der etwa 15 km davon entfernten Gemeinde Wattens. Auf Grund seiner Nähe zu Innsbruck und seiner Einbettung in die eindrucksvolle Bergwelt Tirols gilt dieser Raum als besonders attraktiv.

Fig. 3: Projektgebiet

Bei der Untersuchung des Projektgebietes kamen mehrere Forschungsmethoden und Auswertungswerkzeuge zur Anwendung. Neben der quantitativen Auswertung statistischer Daten wurden historische und aktuelle Luftbilder ausgewertet und die Veränderungen grafisch markiert. Während des Untersuchungszeitraumes fanden mehrfach Begehungen innerhalb des Projektgebietes statt, die mittels Fotografien dokumentiert wurden. Zu den Fragen der strategischen Ansätze für die räumliche Entwicklung der Gemeinden wurden die Örtlichen Raumordnungskonzepte ausgewertet. Die erhobenen Daten bildeten die Grundlage für den daran anschließenden Schritt der Anwendung des Konzeptes des landscape urbanism im Rahmen eines Konzeptentwurfes für ein räumliches Entwicklungskonzept für die Projektregion.

Das Inntal insgesamt ist der Hauptsiedlungsraum Tirols. Die siedlungsräumliche Entwicklung dieses Tales hängt eng mit der Entwicklung der gesamten Region zusammen und dem damit verbundenen Wandel vom landwirtschaftlich geprägten Raum hin zu einem Raum der heute von den Anforderungen der Dienstleistungsgesellschaft geprägt ist.

Der Prozess der fortschreitenden Urbanisierung wird vor allem durch die steigende Bevölkerungszahl (1951: 27.781 EW; 2012: 53.635 EW[19] im Untersuchungsraum) und den steigenden Raumansprüchen der Menschen deutlich. Alleine im Zeitraum zwischen 1993 und 2012 wurden im Projektgebiet 1026 Gebäude mit Wohnungen errichtet.[20] Außerdem erfolgte ein massiver gesellschaftlicher Wandel von einer bäuerlich geprägten Gesellschaft hin zur Dienstleistungsgesellschaft. Ebenso hat der Ausbau der Mobilitätsachsen im

[20] Statistik Austria, Wohnbaustatistik

Unterinntal – hier ist vor allem die Inntalautobahn zu erwähnen – und die massive Ausbreitung der Gewerbegebietsflächen unverkennbar Spuren hinterlassen.

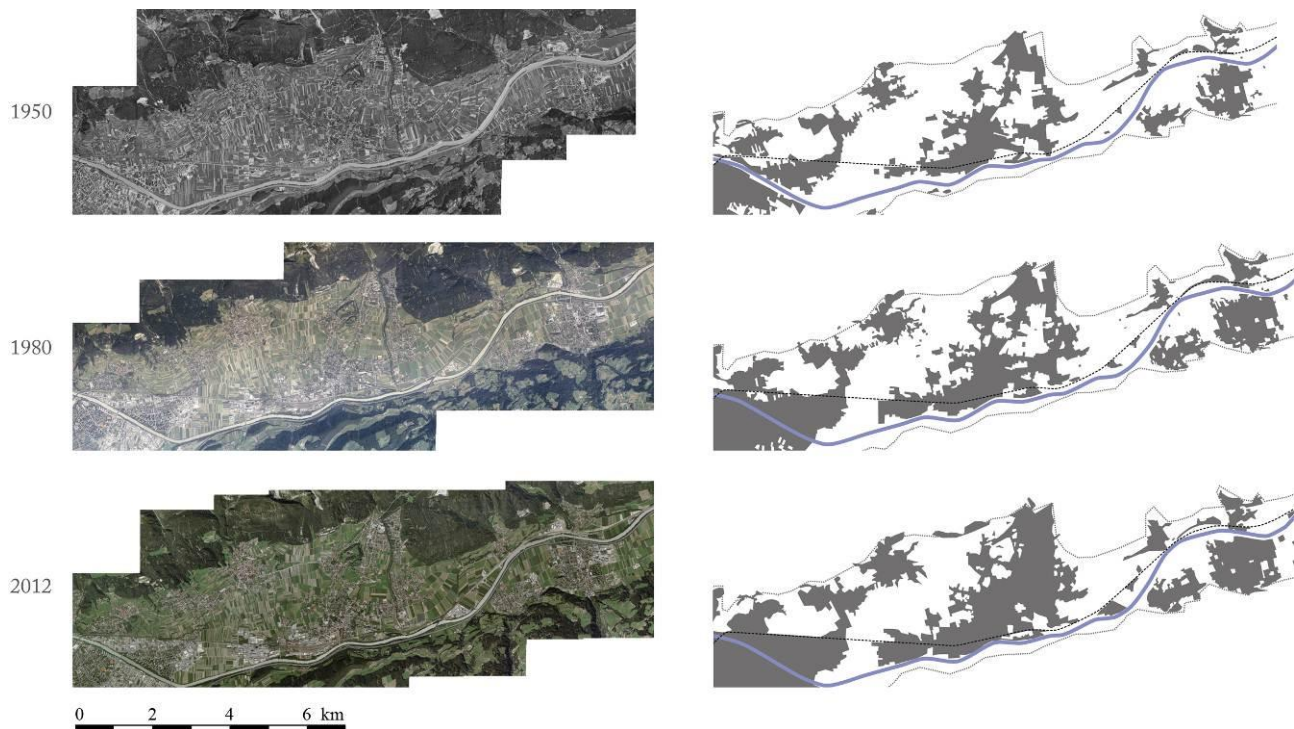
Anhand der Auswertung historischer Luftbilder werden die Auswirkungen dieser Entwicklung deutlich sichtbar. Der Vergleich lässt unmissverständlich erkennen, dass in 1950er und 1960er Jahren noch relativ kompakte Siedlungsräume zu finden waren, während wir heute auf Siedlungsräume stoßen, in denen die Ortschaften miteinander verwoben und verwachsen sind. In der Abbildung Fig. 4 ist dieses Zusammenwachsen der Siedlungsstrukturen klar zu erkennen. Vor allem die Siedlungsform des Einfamilienhauses in Kombination mit dem steigenden Mobilitätsgrad hat zu dieser heute vorhandenen Siedlungsstruktur geführt. Ebenso haben aber auch die Entwicklungen entlang der Hauptmobilitätsachsen dazu beigetragen, dass sich der bebaute Raum massiv ausweitete. Hier wurden die Gewerbeflächen stetig ausgeweitet und so nehmen diese heute große Bereiche des Talbodens ein. Vor allem in den letzten 25 Jahren hat diese Entwicklung eine ziemliche Beschleunigung erfahren. Dies nicht zuletzt, weil auf Grund der finanziellen Situation vieler Gemeinden diese regelrecht gezwungen waren und heute immer noch sind neue Flächen für die Ansiedlung von Unternehmen bereitzustellen. So ist mittlerweile ein fragmentierter Raum entstanden, in dem die ursprünglichen Ortszentren nur mehr zum Teil als solche ablesbar sind. Viele Funktionen, die bis vor kurzem noch im Ortskern lagen, sind heute entweder entlang der Mobilitätsachsen angesiedelt oder im gesamten Raum verteilt zu finden.


Fig. 4: Luftbildauswertung 1950, 1980, 2012

Auch die landwirtschaftlichen Flächen haben ihren Bedeutungsgehalt im Laufe der Zeit verändert. Prägten diese Flächen auf Grund ihres flächenmäßigen Anteils lange Zeit das Inntal, so werden diese Gebiete heute von der Bevölkerung oftmals nur mehr noch als Restflächen betrachtet. Diese Restflächen werden zwar landwirtschaftlich hochinfrastrukturell genützt und auch gewinnbringend bewirtschaftet, bei entsprechender Nachfrage und Druck werden sie aber stückchenweise immer weiter in bebaubares Gebiet umgewidmet.

Dieser Umwidmungsprozess erfolgt meist unter dem Gesichtspunkt, dass die Bebauung höhere finanzielle Einnahmen bringt als eine weitere landwirtschaftliche Nutzung. Das Ergebnis ist ein durch hunderte von Einzelentscheidungen geprägter Raum, in dem viele der vorhandenen räumlichen Qualitäten, wie beispielsweise differenzierte Siedlungs- und Naturräume sowie abwechselnde Raumsequenzen tendenziell zu verschwinden drohen oder sogar teilweise schon für immer verschwunden sind.
Wohngebiete   Gewerbegebiete   Grünräume
Fig. 5: räumliche Funktionsverteilung

Die Steuerung der räumlichen Entwicklung des Inntals passiert vor allem auf Gemeindeebene. Die räumlichen Überlegungen dazu werden zum Großteil aus dieser Sicht erarbeitet und umgesetzt. Der an sich richtige Ansatz, dass lokal gebundenes Wissen wichtig ist, um auf die vor Ort Gegebenheiten reagieren zu können, führt aber auch zu gewissen Problemen. Die Anzahl der Gemeinden, deren Planungen sich auf die Gesamtstruktur auswirken, sagt alles: 279 Gemeinden entscheiden darüber, wie die räumliche Entwicklung Tirols aussehen soll.

Im Rahmen von Örtlichen Raumordnungskonzepten sind die Gemeinden rechtlich verpflichtet, ihre zukünftige Entwicklung zu reflektieren und sie müssen dazu alle 10 Jahre strategische Ansätze für die weitere Entwicklung erarbeiten. Diese Örtlichen Raumordnungskonzepte müssen auch von der zuständigen Landesbehörde bewilligt werden. Der an sich richtige Ansatz, die Entwicklung der einzelnen Gemeinden über lokal gebundenes Wissens zu steuern, hat aber auch Nachteile. Die Örtlichen Raumordnungskonzepte betrachten nämlich jeweils nur das Gebiet innerhalb der jeweils eigenen Gemeindegrenzen. Gemeindeübergreifende Überlegungen spielen dabei so gut wie keine Rolle. Verstärkt wird dieses Problem dadurch, dass die jeweiligen Gemeinden meistens unterschiedliche Planungsbüros mit der Erarbeitung der Örtlichen Raumentwicklungskonzepte beauftragen. So weiß die eine Gemeinde nicht, was die Nachbargemeinde plant. Deutlich wird dies beispielsweise bei der Auswertung der aneinander grenzenden Gemeinden Wattens und Fritzens, die innerhalb des Projektgebietes liegen. Obwohl in Fritzens ein Regionalbahnhof liegt, an dem täglich allein 42 Züge halten die von hier nach Innsbruck fahren und die Gemeinde Wattens keine 100m von diesem Bahnhof entfernt auf der anderen Seite des Flusses Inn liegt, steht im Örtlichen Raumentwicklungskonzept, dass Wattens kein Öffentliches Personennahverkehrssystem (ÖPNV) besitzt und deshalb die Straßen weiter ausgebaut werden sollen.[21]

Um dem rein auf sich selbst bezogenen Planungsansatz der Gemeinden entgegenzuwirken ist im Jahr 2005 von Seiten der Tiroler Landesregierung die Bildung von insgesamt 36 Planungsverbänden (sowie einem eigenen Planungsverband für Innsbruck) beschlossen worden. Ein solcher Planungsverband wird durch den Zusammenschluss mehrerer Gemeinden gebildet. Aufgabe der Planungsverbände ist es an der Erstellung von Regionalprogrammen und -plänen mitzuarbeiten. Gleichzeitig sollen die Organe der Planungsverbände die Gemeinden in Angelegenheiten der örtlichen Raumordnung unterstützen. Eine zusätzliche fachliche Betreuung der Planungsverbände erfolgt durch die räumlich zuständigen Sachverständigen für Örtliche Raumordnung der Abteilung Landesentwicklung und Zukunftsstrategie des Landes Tirol.[22]

Dieses Instrument der Planungsverbände ist ein wesentliches Instrument zur Erarbeitung regionaler Entwicklungsansätze. Es wird jedoch nicht in dem Ausmaß eingesetzt, wie dies sinnvoll wäre. Vielerorts existieren die Planungsverbände (fast) nur auf dem Papier. Überlegungen, die über die Entwicklung von gemeinsamen Altenheimen und gemeinsamen Sportstätten hinausgehen, werden kaum angestellt. Ideen und Konzepte für eine gesamthafte räumlichen Entwicklung werden überhaupt nicht erörtert.

5 ALPINE LANDSCAPE URBANISM

Es wurde deshalb der Versuch unternommen im Sinne des landscape urbanism das Projektgebiet zu betrachten und dazu ein Konzeptentwurf für ein räumliches Entwicklungskonzept erarbeitet. Anhand dieses Entwurfes wird deutlich, dass die heute vorhandenen Siedlungsräume nicht von landschaftlichen Resträumen umgeben sind. Vielmehr bieten diese Freiräume gemeinsam mit den im Raum vorhandenen Mobilitätslinien (Autobahn, Eisenbahn, Bundes- und Landesstraßen), dem Fluss Inn, wie auch unter Beachtung der Topografie des Raumes eine freiraumbasierte Struktur, die in weiterer Folge als tragfähiges Gerüst für den planerischen Umgang der Region dienen kann.

Damit die heute noch vorhandenen räumlichen Potentiale des Inntales auch noch für künftige Generationen zur Verfügung stehen, erscheint ein Paradigmenwechsel unumgänglich. Es ist dringend geboten, die Rolle der räumlichen Entwicklung aus einer neuen Perspektive heraus zu denken. Das Thema der Landschaft kann dafür der Schlüssel sein. Die Landschaft Tirols muss im umfassenderen Sinn des landscape urbanism verstanden werden.

Fig. 6: Inntal Parks

Die Grünräume sind gemeinsam mit den vorhandenen Infrastrukturen, den Siedlungsräumen und den Bergen als Landschaft zu verstehen. Erst durch dieses umfassende Verständnis von Landschaft werden die neuen räumlichen Potentiale der Region deutlich. Aus dieser Perspektive sind Grünräume nämlich nicht mehr „nur" landwirtschaftliche Restflächen, die zwischen den Siedlungsgebieten liegen. Stattdessen hat aus der Perspektive des landscape urbanism das Inntal viel mehr mit Räumen wie dem Ruhrgebiet oder auch der niederländischen Randstad gemeinsam als bisher angenommen. Die landwirtschaftlich genutzten und ungenutzten Flächen können als die Tiroler Variante des Parc de la Villette betrachtet werden. Sie sind die zukünftigen Parkanlagen (Inntal Parks) eines urbanisierten Inntales und bilden so eine tragfähige Struktur bei der weiter fortschreitenden Urbanisierung des Inntales.

Alte Terre – Aree agricole di versante, nuovi modelli di sviluppo

Stefania Staniscia

(Research Fellow Stefania Staniscia, Università degli Studi di Trento, DICAM – UNITN, Via Mesiano, 77, 38123 Trento, stefania.staniscia@ing.unitn.it)

1 ABSTRACT

Il "Manifesto per lo sviluppo della Montagna" – redatto ad Asiago nel 2009 – fa rilevare i costi economici, ambientali e sociali prodotti dall'abbandono delle regioni montane e rurali e propone un'inversione di marcia oltre che di sguardo nei confronti di queste regioni. I territori montati e rurali possono essere considerati come portatori di nuovi modelli di sviluppo che si basano su filiere innovative e orientate ai temi della green economy, luoghi di nuove opportunità economiche e sociali. Ma ciò potrà avvenire solo cambiando i modelli di riferimento. Sono necessari l'emancipazione dal modello di sviluppo tradizionale e l'orientamento verso un modello che metta al centro la qualità e la sostenibilità assecondando l'urgenza di un approccio che sia attento alle questioni ambientali e che le trasformi in priorità. Lo studio "Indicazioni metodologiche per le trasformazioni delle aree agricole di versante a nuove tecniche produttive" – commissionato dalla Provincia Autonoma di Trento al gruppo guidato dallo studio RicciSpaini Architetti Associati srl – va nella direzione appena tratteggiata. Il paper presenta la ricerca evidenziandone in particolare gli aspetti metodologici e strategici.

2 TERRITORI MARGINALI (?)

"Negli ultimi '50 anni si sono manifestati in Italia rilevanti fenomeni di espansione delle aree urbane e metropolitane, a cui è corrisposto il progressivo abbandono della montagna e dei territori rurali meno accessibili. (...) È arrivato il momento di invertire questo processo, facendo della montagna e dello spazio rurale i fattori di un nuovo sviluppo dell'Italia. (...) si tratta di guardare alla montagna e allo spazio rurale come straordinarie risorse per il rilancio di processi di crescita nazionale basati sulle filiere più innovative e promettenti anche dal punto di vista economico. (...) Questo significa, perciò, un cambiamento di prospettiva nel guardare al ruolo della montagna e dello spazio rurale. Da aree marginali, a località centrali di un nuovo modello di sviluppo. Da luoghi di abbandono, a nuovi spazi di opportunità economica e sociale. Da condizioni di arretratezza che chiedono compensazioni economiche, a fattori di modernizzazione in grado di produrre servizi di mercato a domanda pagante. Da modelli insediativi in concorrenza con i sistemi urbani e metropolitani, alle complementarità ambientali, energetiche, sociali."

"Manifesto per lo sviluppo della Montagna", Asiago 2009

Il Manifesto è la chiara espressione di una tendenza in atto negli ultimi anni in ambito economico, sociale e territoriale a riconsiderare il ruolo delle regioni marginali, siano esse montane o rurali. L'idea sottesa a questa tendenza è che questi territori possano diventare, e che in parte già lo siano, fattori di un nuovo modello di sviluppo costituendo spazio di accoglienza e di incubazione per la filiera di quelle economie che si fondano sui nuovi paradigmi emergenti: ambiente, sostenibilità, identità, qualità, equità. E le possibilità sono molte, basti pensare a: fonti rinnovabili di energia, riduzioni di emissioni di carbonio, produzioni alimentari tipiche e/o biologiche, turismo culturale o naturalistico, funzioni ricreative e sociali sul modello dei grandi parchi urbani, bio-edilizia, sistemi di trasporto sostenibile, sviluppo intensivo di servizi alle persone e alle imprese basati sulle Ict.

"Tra la sfera indebolita dello stato-nazione e lo spazio finito dei sistemi locali protagonisti della riscoperta del territorio, prendono forma spazi intermedi in cui si sperimentano accordi e alleanze territoriali finalizzate a realizzare economie di scala nella produzione di servizi e beni competitivi comuni." Così Bonomi (2009) spiega l'emergere dei territori marginali che secondo Rullani (2009) "non sono tanto importanti per il peso oggettivo che (per ora) hanno, quanto per la loro capacità di prefigurare un futuro diverso da quello a cui ci ha finora abituato la lunga storia della modernità industriale che oggi è in crisi".

I territori marginali, considerati anticiclici rispetto alla grande congiuntura negativa dei centri urbani e metropolitani, si configurano così come nuove nicchie di produzione per la green economy il cui potenziale di crescita è tanto più elevato quanto più, rigettando il modello di crescita finora dominante, è orientato verso

quell'insieme di attività a elevato contenuto di conoscenze che pone al centro dei meccanismi dello sviluppo economico la riproduzione delle risorse – naturali, energetiche, sociali – necessarie allo sviluppo stesso.[1]

3   CONVENZIONE DELLE ALPI – PROTOCOLLO AGRICOLTURA DI MONTAGNA

L'agricoltura di montagna, se si mantiene questo punto di vista, può essere sicuramente definita come un'attività a elevato contenuto di conoscenze nella quale si riconoscono valori paesaggistici, culturali e ambientali da preservare, incentivare e riprodurre.

Anche la Convenzione delle Alpi [2] riconosce questi valori e la necessità di un impegno per la sua sopravvivenza. Nell'articolo 2 in cui si obbligano "Le Parti contraenti, in ottemperanza ai principi della prevenzione, della cooperazione e della responsabilità di chi causa danni ambientali, assicurano una politica globale per la conservazione e la protezione delle Alpi, tenendo equamente conto degli interessi di tutti i Paesi alpini e delle loro Regioni alpine, nonché della Comunità Economica Europea, ed utilizzando le risorse in maniera responsabile e durevole." (Art. 2 Obiettivi generali. Paragrafo 1) al paragrafo 2 si legge "Per il raggiungimento dell'obiettivo di cui al paragrafo 1, le Parti contraenti prenderanno misure adeguate in particolare nei seguenti campi" (Art. 2 Obiettivi generali. Paragrafo 2) e segue un elenco tra cui è presente l'agricoltura di montagna.

Nel dicembre del 1994 a Chambéry, viene firmato il Protocollo di Attuazione "Agricoltura di Montagna". Si tratta di un documento molto importante che trova fondamento nel riconoscimento dell'importante ruolo svolto dall'attività agricola nel territorio alpino e del contributo che questo settore dà "al mantenimento di un'adeguata densità di insediamenti, all'approvvigionamento alimentare della popolazione, alla produzione di prodotti tipici di qualità, alla conservazione e alla cura del paesaggio rurale – tra l'altro per la sua valorizzazione turistica –, alla difesa del suolo contro erosioni, valanghe e inondazioni" (Preambolo). Nel Preambolo, da un lato, si riconosce la grande utilità che le attività agricole hanno ai fini della tutela dell'ambiente e del paesaggio e, dall'altro, si evidenzia che le condizioni di vita e di produzione degli agricoltori nelle zone montane presentano molte difficoltà a causa delle caratteristiche geomorfologiche e climatiche dei territori. Per garantire la permanenza degli agricoltori e delle loro aziende nelle aree montane, affinché si possano conseguire gli obiettivi di cui sopra, si rende necessario un intervento degli Stati a scala economica e sociale.

Nel Protocollo vengono individuate misure che hanno, quindi, la finalità "di conservare e di incentivare l'agricoltura di montagna adatta ai siti e compatibile con l'ambiente, in modo che venga riconosciuto e garantito nel tempo il suo contributo sostanziale: alla permanenza della popolazione e al mantenimento di attività economiche sostenibili, – specie mediante la produzione di prodotti tipici di qualità, alla salvaguardia delle basi naturali della vita, alla prevenzione dei rischi naturali, alla conservazione della bellezza e del valore ricreativo del paesaggio naturale e rurale, nonché alla cultura nel territorio alpino." (Art. 1 Finalità) Quello che viene più volte rimarcato nel Protocollo è che l'agricoltura deve essere adatta e compatibile, sono proprio questi i termini che ricorrono maggiormente nel documento. L'agricoltura che va supportata e incentivata è un'agricoltura "adeguata ai luoghi e in armonia con l'ambiente" (Convenzione Quadro. Art. 2 Obiettivi generali. Paragrafo 2) in cui si svolge. Ed è anche un'agricoltura multifunzionale che è in grado di integrare nell'attività agro/pastorale vera e propria anche attività di tipo artigianale, turistico, energetico-ambientale, paesaggistico e culturale.

4   "FONDO PER IL PAESAGGIO"

Nel quadro di questa più ampia riflessione sull'attività agricola in contesto alpino si colloca la ricerca progettuale "Indicazioni metodologiche per le trasformazioni delle aree agricole di versante (AAV) a nuove tecniche produttive" che la Provincia Autonoma di Trento ha finanziato nell'ambito del "Fondo per la riqualificazione degli insediamenti storici e del paesaggio" (FP). Il Fondo viene istituito con la Legge Provinciale n. 1/2008 e ha come finalità il recupero, la valorizzazione e lo sviluppo degli insediamenti

---

[1] Questo primo paragrafo è una rielaborazione di una parte del saggio: S. Staniscia, C. Ricci, M. Ricci, C. Rizzi (2011). Il paesaggio rurale dentro un obiettivo di qualità. PLANUM, vol. 23, ISSN: 1723-0993

[2] Trattato di diritto internazionale sottoscritto a Salisburgo il 7 novembre 1991 dagli 8 Stati alpini – Austria, Francia, Germania, Italia, Liechtenstein, Monaco, Slovenia e Svizzera – e dall'Unione Europea. Il processo di ratifica si è concluso il 27 marzo 2000.

storici, e la conservazione e la tutela del paesaggio; è destinato a finanziare sia interventi di recupero del patrimonio edilizio, pubblico e privato, sia attività di conservazione e ripristino del paesaggio, alla scala puntuale e territoriale.

È per attivare il FP che nel novembre 2010 il Servizio Urbanistica e Tutela del Paesaggio della PAT indice un bando per la presentazione di studi e proposte progettuali relativi ad alcuni temi individuati dalla Giunta Provinciale. Lo scopo degli incarichi è "di declinare efficacemente una politica attiva di intervento rispetto ad alcune tematiche particolarmente rilevanti nell'assetto paesaggistico del territorio provinciale" [3]. Il concorso [4] vede vincitori otto gruppi di ricerca – spesso numerosi, molto compositi e interdisciplinari, in alcuni casi provvisti di consulenti di fama internazionale – che hanno prodotto un importante patrimonio di riflessioni critiche, metodologiche e progettuali, frutto di una qualificata expertise professionale. Lo studio sulle AAV viene commissionato al gruppo multidisciplinare [5] guidato da RicciSpaini Architetti Associati srl.

Il bando per la presentazione degli studi contiene un allegato attraverso il quale vengono meglio definiti i contenuti dei progetti e degli studi messi a concorso. L'impostazione del documento è di natura quasi esclusivamente puro-visibilista ed estetizzante. Si riconosce il valore patrimoniale, culturale e identitario delle AAV – in particolare delle zone terrazzate frutto della cosiddetta agricoltura eroica – e si riconoscono i rischi ai quali sono sottoposte a causa delle nuove esigenze – per esempio la meccanizzazione e la variazione delle tecniche colturali – e dei cambiamenti climatici. Si tratta di fattori di trasformazione che incidono profondamente sugli aspetti visivi e percettivi ed è questa la maggiore preoccupazione della committenza che considera "importante conservare alcuni paesaggi rurali ritenuti di particolare testimonianza storica, culturale, agendo con regole, con incentivi, con interventi di manutenzione o ripristino." [6] In sintesi, si chiede al gruppo di lavoro di individuare le AAV maggiormente significative, di determinarne l'estensione, di valutarne le relazioni rispetto al contesto paesaggistico e di definire strumenti per il governo della loro trasformazione e "per assicurare il mantenimento della qualità paesaggistica complessiva del predetti versanti".

5 LA RICERCA ALPTER

Le aree agricole terrazzate sono state già oggetto di un lavoro importante e ampio che ha fatto il punto della situazione in tutto l'arco alpino: il progetto Alpter "Paesaggi terrazzati dell'arco alpino" – finanziato dal programma Interreg IIIB "Spazio Alpino" – che aveva come obiettivo la definizione di una metodologia per il rilievo dei terrazzamenti, lo studio di tecnologie e modelli gestionali specifici e la realizzazione di alcuni esempi di recupero produttivo. Questa ricerca, innanzitutto, dimostra che quello terrazzato è un paesaggio ricorrente ed emblematico del contesto alpino che ha vissuto fasi alterne di sviluppo e declino e che si trova, in questo momento, in una fase di deciso abbandono prodotto dai cambiamenti delle condizioni economiche, culturali e ambientali. Di fronte, però, a questi paesaggi storici non può che porsi il problema di definire strategie di restauro e recupero che vedono nel carattere integrato delle politiche e delle azioni l'unica possibilità di sostenibilità e di efficacia degli interventi.

---

[3] Dal documento di affidamento di incarico dello studio alla Facoltà di Ingegneria dell'Università degli Studi di Trento – Corso di Laurea Edile-Architettura.

[4] Il Bando per la presentazione degli studi è stato approvato dal Servizio Urbanistica e Tutela del Paesaggio della PAT nell'ottobre del 2010. La Commissione tecnica di valutazione degli studi, nominata nel febbraio 2011, era composta da: Dott. Pier Giorgio Mattei – presidente (PAT), Arch. Angiola Turella (PAT), Arch. Giorgio Tecilla (PAT), Arch. Furio Sembianti (PAT), Arch. Chiara Bertoli (Scuola per il Governo del Territorio e del Paesaggio STEP), Ing. Giulio Andreolli (STEP), Prof. Arch. Giuseppe Scaglione (UNITN). Cinquantadue sono i gruppi che hanno partecipato al concorso, 8 quelli selezionati. La Commissione tecnica di valutazione si è riunita 9 volte da febbraio a giugno del 2011 quando sono stati nominati i vincitori. La spesa complessiva prevista per gli otto studi era di 800.000,00 euro.

[5] Gruppo composto da: Arch. Filippo Spaini (coordinatore della ricerca), Prof. Arch. Mosè Ricci (consulente per la pianificazione urbanistica e paesaggistica), Arch. [6] Allegato A "Determinazione dei contenuti dei progetti e studi di cui alla deliberazione della Giunta Provinciale n. 2880 del 31 ottobre 2008 ai fini dell'affidamento degli incarichi."

Il tema sotteso a tutte le sperimentazioni progettuali avviate nella ricerca è: "come rendere coerente con i modi e le esigenze del vivere, del lavorare e, soprattutto, dell'abitare contemporaneo un ambiente di difficile, costosa e faticosa gestione come quello delle aree terrazzate. Il riconoscimento di valenze territoriali, come la difesa dal rischio idrogeologico, la tutela della biodiversità e della sostenibilità degli assetti territoriali, sono indispensabili ma non sufficienti per favorire l'avvio di un processo di recupero e riqualificazione di questi paesaggi." (Fontanari, Patassini, 2008) Le soluzioni individuate attraverso le esperienze progettuali fatte nell'ambito di Alpter sono, innanzitutto, il coinvolgimento delle comunità locali e, in secondo luogo, l'integrazione tra i vari strumenti messi in campo – progetto vero e proprio, alcune forme di incentivo, norme di governo del territorio e di intervento sugli edifici –. Si tratta, quindi, di associare agli interventi di trasformazione di carattere fisico la promozione di politiche di tipo economico e sociale.

Le azioni progettuali sulle aree terrazzate devono, per essere efficaci, basarsi su due componenti principali. Da un lato un lavoro di conoscenza delle caratteristiche e dei valori – di carattere storico, ecologico-ambientale, socio-economico, estetico-percettivo – di questi paesaggi singolari, dall'altro l'identificazione delle componenti di progetto e degli attori che saranno coinvolti dentro una visione progettuale coerente con gli obiettivi di salvaguardia e tutela insieme ad un'azione di riprogettazione e rivitalizzazione che ha precise finalità di tipo operativo.

6 AREE AGRICOLE DI VERSANTE TRENTINE

È a partire da questo contesto teorico di riferimento che muove la ricerca sulle aree agricole di versante. Il lavoro viene strutturato prevalentemente come un contributo teorico-metodologico e non unicamente come proposta di soluzioni progettuali specifiche. Il tema delle AAV, come dimostra lo studio Alpter, è complesso e molteplice per poter essere banalmente ricondotto alla sommatoria di singoli interventi locali che, seppur ben congegnati, non sono in grado di avere effetti sistemici e di definire un progetto di territorio. Per questa ragione l'approccio alla ricerca è di tipo multidisciplinare – le numerose figure professionali presenti nel gruppo e le competenze specifiche lo testimoniano – e integrato, così come emerso anche dalle sperimentazioni di Alpter.

L'obiettivo del lavoro di ricerca è di individuare possibili modalità di gestione delle trasformazioni che stanno investendo le AAV trentine e che, spesso, hanno esiti negativi sul paesaggio e sull'ambiente. Lo studio segue un percorso metodologico che parte dal riconoscimento dei valori e dei rischi delle AAV, per arrivare a definire alcune strategie di intervento per il recupero, la salvaguardia, la valorizzazione e il potenziamento delle aree stesse. Si prevedono anche politiche e forme di incentivazione per garantirne la fattibilità.

Il paesaggio è una risorsa – culturale, naturale ed economica – un bene patrimoniale da tutelare, valorizzare e gestire, ma è, allo stesso tempo, sottoposto a forti pressioni che costituiscono fattori di trasformazione spesso insostenibili e incoerenti con la matrice consolidata del paesaggio. Negli ultimi anni si è venuta a creare una profonda separazione tra tutela-conservazione del paesaggio e gestione-pianificazione dello stesso. Lo studio sulle AAV tenta di individuare una modalità per superare questa separazione con la proposta di un metodo che è in grado di stabilire, in modo quasi matematico, una sorta di gradiente degli interventi e delle priorità.

Quello che più interessa, in questa sede, è l'aspetto metodologico e strategico ed è per questa ragione che saranno approfonditi questi aspetti a scapito dei risultati specifici emersi.

6.1 Questioni di metodo

La Convenzione Europea del Paesaggio (Firenze, 2000), all'articolo 6 Misure specifiche, traccia un possibile percorso di lavoro per gli interventi di pianificazione sul paesaggio. All'attività di identificazione dei paesaggi nazionali e alla successiva valutazione degli stessi, "tenendo conto dei valori specifici che sono loro attribuiti dai soggetti e dalle popolazioni interessate", segue la fase della definizione "degli obiettivi di qualità paesaggistica riguardanti i paesaggi individuati e valutati" che porta, infine, all'attivazione di "strumenti di intervento volti alla salvaguardia, alla gestione e/o alla pianificazione dei paesaggi".

Il Codice dei beni culturali e del paesaggio (D. Lgs. 22 gennaio 2004, n. 42) recepisce e specifica il percorso proposto dalla Convenzione ai fini dell'elaborazione dei piani paesaggistici. Si ribadisce l'articolazione dell'iter nei tre momenti fondamentali: identificazione, valutazione e definizione degli obiettivi di qualità. È interessante, però, notare che all'articolo 143 Piano Paesaggistico l'aspetto estimativo viene declinato in

termini di valutazione della vulnerabilità e del rischio. Infatti, nell'enumerare, al comma 1, i contenuti minimi del piano paesaggistico, al punto f il legislatore precisa: "analisi delle dinamiche di trasformazione del territorio ai fini dell'individuazione dei fattori di rischio e degli elementi di vulnerabilità del paesaggio".

Diventa, quindi, necessario – ai fini degli interventi di pianificazione sul paesaggio – dotarsi di metodi e strumenti, teorici e operativi, di valutazione che richiedono l'uso di indicatori qualitativi e quantitativi, ossia di parametri in grado di descrivere il paesaggio nella sua dimensione ambientale, storico-culturale, estetico-percettiva, territoriale ed economica. Se l'Inghilterra e la Scozia hanno una tradizione nel Landscape Character Assessment, altri Stati, quali ad esempio la Germania, hanno mutuato l'approccio alla valutazione del paesaggio dalle scienze ambientali che già dai primi anni '90 elaboravano strumenti per l'Ecological Risk Assessment [7]. L'Italia, come noto, ha una tradizione molto forte nella tutela del patrimonio culturale, ed è da questa che si è avviato il tentativo di costruire un metodo per l'analisi del rischio del paesaggio.

Con la Legge n. 84 del 19 aprile 1990 "Piano organico di inventariazione, catalogazione ed elaborazione della carta del rischio dei beni culturali" si affida all'Istituto Centrale del Restauro (ISCR) la responsabilità scientifica di elaborare la carta "per l'analisi e prevenzione del rischio, finalizzato alla programmazione e attuazione di interventi atti a ridurre i possibili fattori di pericolosità ambientale e antropica sui beni culturali." (Ricci, 2003; p. 145) Il rischio viene definito come l'eventualità, per un bene, di subire un danno connessa a circostanze più o meno prevedibili ed è espresso in funzione di tre fattori: pericolosità e vulnerabilità – la presenza o la probabilità che si verifichino eventi dannosi per il bene e l'attitudine del bene ad essere danneggiato – e attribuzione di valore al bene.

L'attività dell'ISCR, ad oggi, ha prodotto un Sistema Informativo Territoriale della Carta del Rischio che costituisce il più ampio sistema di banche dati riguardanti un grande numero di beni distribuiti sull'intero territorio nazionale. Si tratta, però, di uno strumento che non fornisce un indice di rischio bensì un indice di sola vulnerabilità; la sperimentazione finora condotta si è, infatti, limitata a definire il grado di rischio attraverso processi di sovrapposizione tematica e non attraverso operazioni di interazione tra i dati di vulnerabilità e di pericolosità.

6.2 Rischiopaesaggio

La ricerca "Fattori di rischio ed elementi di vulnerabilità del paesaggio" coordinata nel 2001-2002 per l'ISCR e per il Ministero per i Beni e le Attività Culturali da Mosè Ricci ha verificato l'applicabilità della Carta del Rischio, elaborata per il patrimonio culturale, ai temi del paesaggio. Si tratta di estendere la filosofia della prevenzione, propria dell'approccio ai beni culturali, al patrimonio paesaggistico con le implicazioni conseguenti in termini di monitoraggio dello stato di conservazione del bene. Se, quindi, il paesaggio è assimilato al patrimonio culturale, l'applicazione del metodo Rischiopaesaggio, così come definito dal gruppo di ricerca, implica la valutazione dell'esposizione al rischio – di cancellazione, alterazione o di perdita di integrità – del bene paesaggio. Il metodo indaga, quindi, la possibilità di definire, in modo "certo", i rapporti tra conservazione del bene e fattori di trasformazione che investono la realtà territoriale in cui il bene si localizza per arrivare "a definire le politiche di intervento e a orientare gli investimenti tenendo conto sia delle risorse che dei valori" (Ricci, 2003; p. 14). L'applicabilità della Carta del Rischio si gioca tutta nella possibilità di "definire la natura e individuare la consistenza del bene. In altri termini non è possibile parlare di pericolo di compromissione dei paesaggi locali se non è chiaro il valore a rischio" (Ricci, 2003; p. 36).

Questo metodo è stato applicato già in alcuni casi, per esempio per la costruzione della carta del rischio per i paesaggi vitivinicoli di Langhe-Roero e Monferrato (Bertini et al., 2011).

6.3 Struttura della ricerca

La ricerca per l'ISCR fa da riferimento fondamentale alla proposta metodologica per lo studio sulle AAV. Lo sforzo fatto, nel corso della ricerca sulle AAV, è stato quello di determinare nello specifico contesto trentino sia i fattori di rischio che i valori intrinseci del paesaggio per arrivare alla definizione di strumenti e strategie

---

[7] "Landscape indicators have only recently been used in the field of analysis and for the assessment of territorial transformation. These indicators derive from more consolidated and structured models, referring to environmental indicators in general" (Bottero, 2011; p. 15).

che coniughino tutela, valorizzazione e costruzione di nuovi paesaggi in una visione progettuale attenta e sensibile al contesto.

Il lavoro viene articolato in sei parti contraddistinte da successivi gradi di approfondimento. La prima dà una definizione di AAV e ne descrive gli elementi caratteristici. La seconda costituisce un censimento delle AAV dell'intera provincia – si tratta della fase di identificazione –; a questa fase segue l'elaborazione della carta dei valori e di quella dei rischi; è questo il nucleo centrale della ricerca perché è attraverso queste due mappe che vengono definite le cinque aree sensibili, oggetto della quarta fase di approfondimento analitico. La quinta è costituita dalle strategie di intervento. La sesta, infine, dai progetti pilota in cui vengono declinate le tattiche locali, interventi puntuali da applicare ai diversi contesti.

6.3.1   Definizioni

AAV non è una definizione che corrisponde a un'entità territoriale riconosciuta e ben identificabile neppure a livello di strumenti urbanistici locali. AAV è una definizione di nuovo conio alla quale lo studio ha avuto il compito di associare un corrispettivo in termini geografico/territoriali. Questo è stato, quindi, il primo impegno: distinguere, nell'ambito delle aree agricole, quelle che potevano essere definite "di versante". Queste sono connotate dalla convergenza/concorso di alcuni elementi distintivi: l'altitudine, una certa pendenza, la presenza di opere di sistemazione del terreno e di manufatti – i muri a secco, il sistema di accessibilità, il sistema di gestione delle acque, i manufatti e gli elementi accessori connessi alla coltivazione –, alcune specifiche caratteristiche agronomiche, paesaggistiche e colturali.

Una volta definite le AAV, sono state descritte le tendenze in atto che ne stanno determinando la trasformazione – in particolare i processi di abbandono e di hobby-farming –. Le dinamiche di trasformazione sono lette in continuità con l'evoluzione storica dell'agricoltura trentina che è stata ricostruita, per tratti salienti, soprattutto leggendo la relazione tra attività agricola e struttura del paesaggio.
Fig. 1: Un esempio di scheda large

6.3.2   Apparato analitico | Contesti di area vasta

Alla definizione di AAV doveva corrispondere anche un lavoro di identificazione e perimetrazione alla scala del territorio provinciale. È stato prodotto un vero e proprio censimento delle aree attraverso un lavoro di

rilievo da fonti e sul campo e di interpretazione di informazioni derivanti da elaborazioni GIS. In particolare i sistemi informativi geografici sono stati utilizzati per identificare la probabile distribuzione territoriale delle AAV sulla base di alcuni criteri significativi – altitudine, pendenza, esposizione del versante, uso del suolo –. Questa operazione è servita a escludere dal rilievo sul campo interi territori dove era altamente improbabile la presenza di AAV.

Sono state censite oltre 200 AAV, ogni area è stata identificata e descritta attraverso una scheda – cosiddetta large con riferimento alla scala della lettura –. La scheda fornisce informazioni rispetto alla localizzazione dell'area, alle caratteristiche dimensionali – estensione, superficie coltivata, quota massima e minima, pendenza media ed esposizione –, alle condizioni orografiche, paesaggistiche, di uso del suolo e di visibilità, allo stato di conservazione – in uso, in trasformazione, in abbandono –. La scheda è, inoltre, corredata da documenti fotografici che mostrano la qualità del contesto nel quale l'area è inserita.

6.3.3   Valori e rischi del paesaggio delle AAV

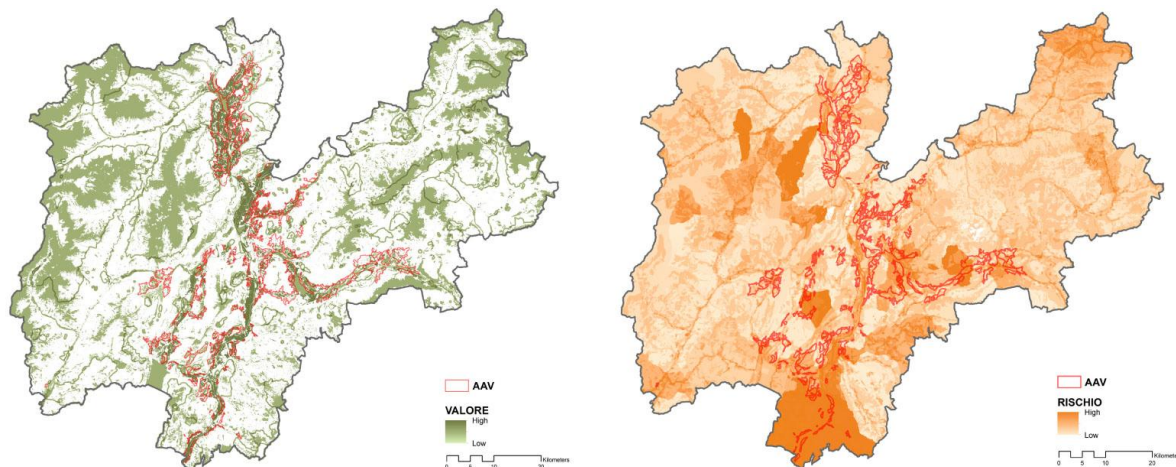
Una volta identificate e descritte le AAV risulta necessaria la costruzione di mappe che aiutino a definire, rispetto a ogni singola area, i valori e i rischi presenti per arrivare a determinare il grado di tutela e il livello di intervento. La carta dei valori è il risultato della combinazione del valore ecologico, paesaggistico e produttivo. La carta dei rischi, invece, prende in considerazione i rischi: statico-strutturale, ambientale e antropico. Valori e rischi aggregati sono il risultato di un'operazione di normalizzazione che ha fornito un dato sintetico facilmente valutabile per ogni AAV.


Fig. 2: Mappa del valore aggregato e mappa del rischio aggregato

6.3.4   Apparato analitico | Contesti locali

La lettura critica dei valori medi – corrispondenti alla media aritmetica dei valori e dei rischi all'interno della singola area – associati a ogni AAV ha consentito la valutazione dell'importanza relativa delle singole aree in termini di rischi che corrono e di valori, più o meno alti, da preservare. Questa lettura ha, quindi, consentito l'individuazione di cinque aree definite sensibili [8] che sono oggetto di un approfondimento analitico e progettuale. Si tratta di quelle aree che presentano una combinazione di maggiore rischio e maggior valore, alle quali, quindi, devono "essere prioritariamente destinate le risorse per la tutela e per la valorizzazione."[9]

Le aree sensibili vengono descritte dalle cosiddette schede medium, attraverso disegni, mappe, fotografie e schemi che danno indicazioni sulle caratteristiche generali – informazioni di tipo quali-quantitativo – sull'uso del suolo, sulle condizioni di visibilità e di accessibilità, sugli elementi del paesaggio presenti e sulle variazioni stagionali, sui valori e sui rischi specifici.

---

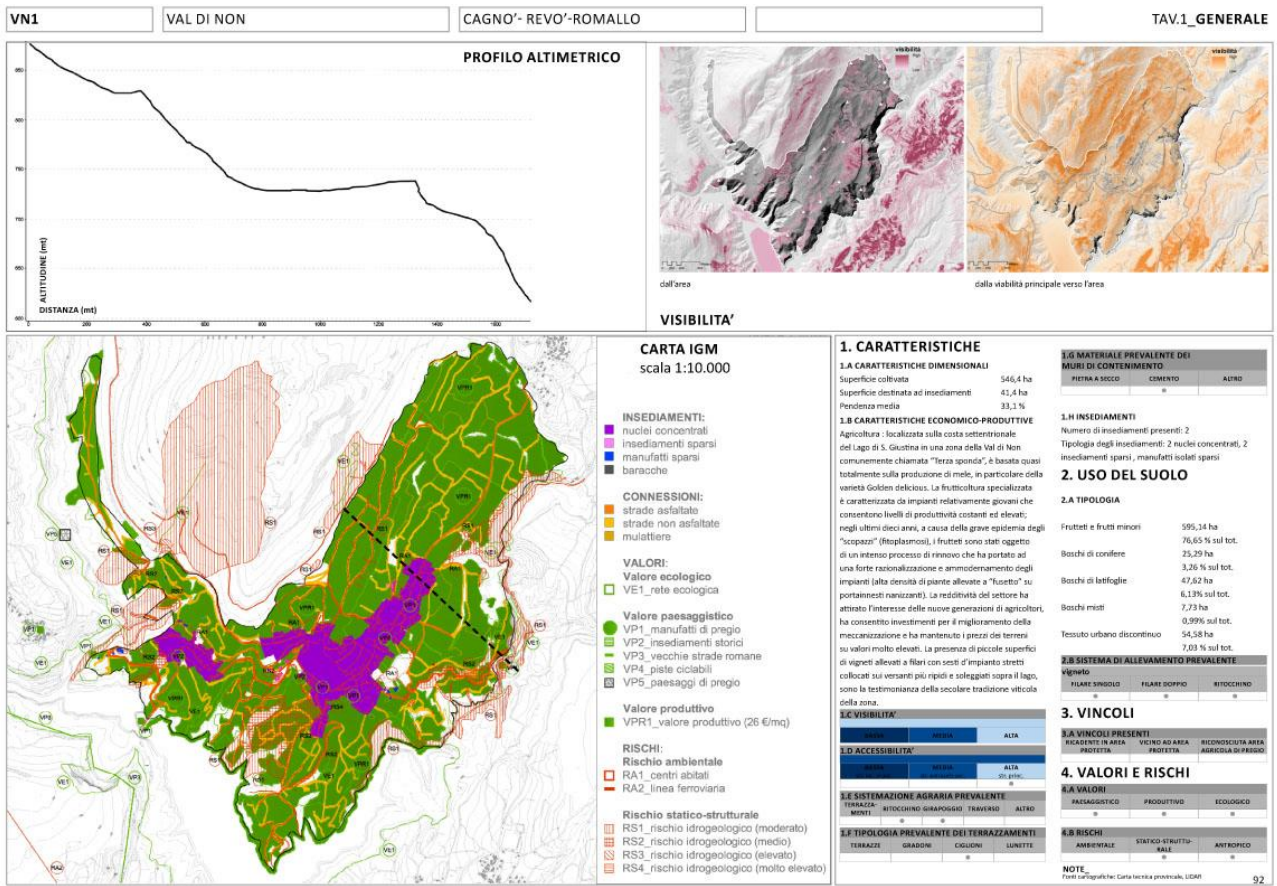
[8] Con questo termine non si fa riferimento alla definizione di aree sensibili quali "aree richiedenti specifiche misure di prevenzione dall'inquinamento e di risanamento" (Art. 91 D.lg. 152/06).
[9] Tratto dalla Relazione Generale del lavoro di ricerca.


Fig. 3: Un esempio di scheda medium – caratteristiche generali
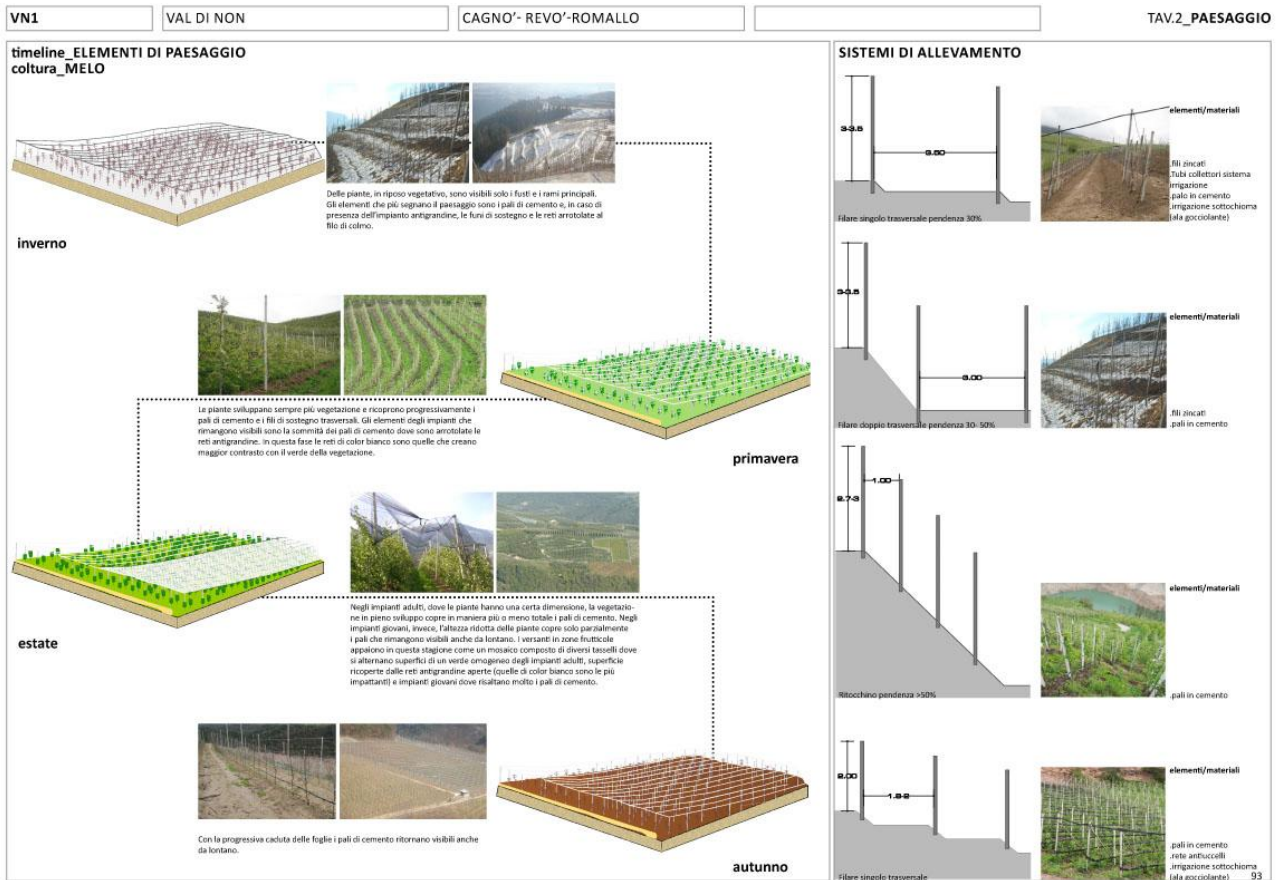

Fig. 4: Un esempio di scheda medium – elementi di paesaggio

6.3.5   Disciplinari | Strategie specifiche

Sulle aree sensibili vengono, in questa quinta fase, elaborate le proposte strategiche di intervento che si muovono su tre indirizzi principali: incrementare la tutela – su manufatti e colture –, incrementare il turismo – creazione di un sistema per l'ospitalità diffusa, introduzione di mercati a Km0 –, incrementare la sostenibilità – dei sistemi di produzione, dell'accessibilità, dell'edilizia –. Le strategie generali trovano applicazione su tre settori di intervento – i manufatti, i sistemi di produzione, l'accessibilità – e si declinano, in questo modo, in strategie specifiche.

6.3.6   Progetti pilota | Tattiche locali

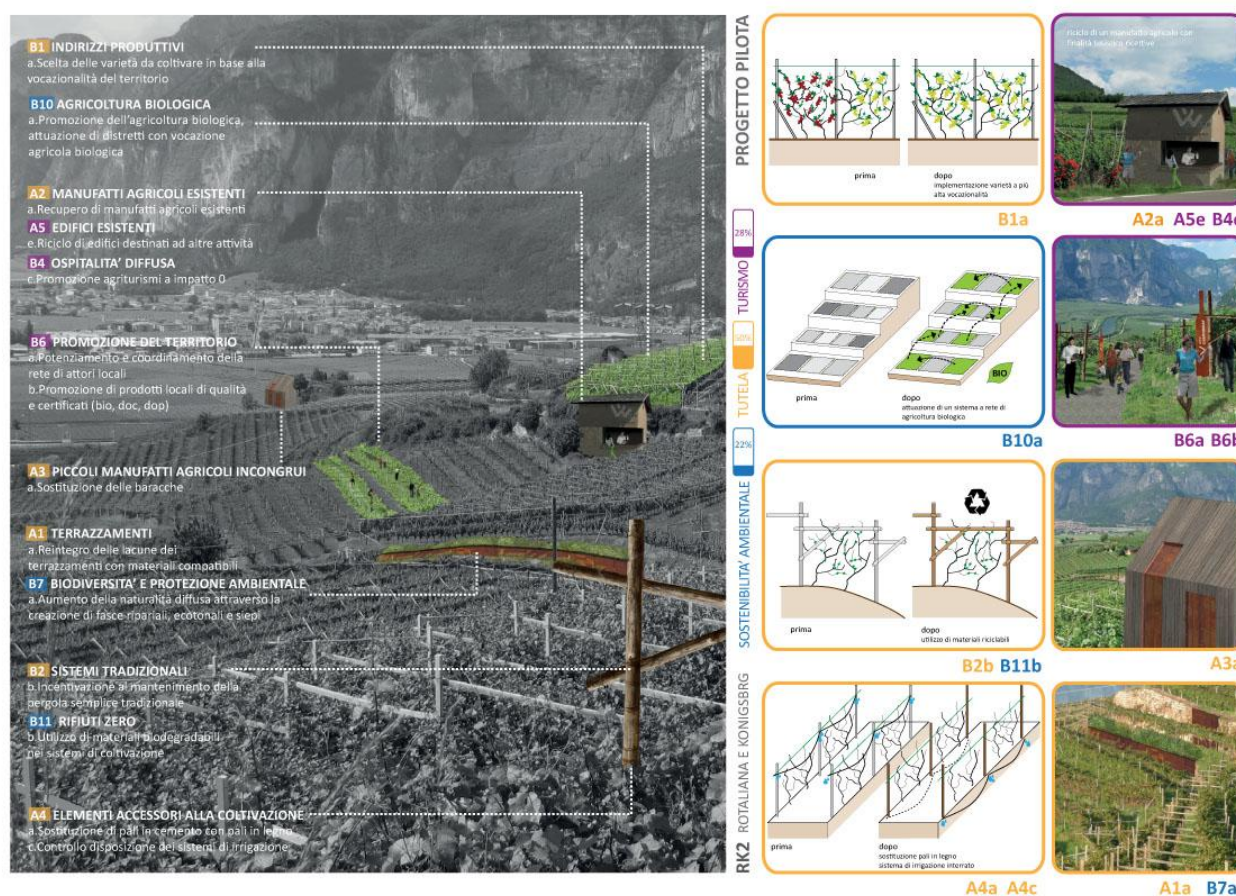
Le strategie specifiche vengono testate attraverso l'applicazione contestuale. Le tattiche locali, che esprimono gli interventi puntuali da attuare nei diversi contesti, vengono verificate attraverso cinque progetti pilota che interessano le aree sensibili individuate. Ciascun progetto prevede l'applicazione di una selezione di strategie specifiche le quali vengono successivamente tra loro integrate.


Fig. 5: Un esempio di scheda small

7   RIFLESSIONI CONCLUSIVE

Lo studio sulle AAV ha utilizzato il metodo Rischiopaesaggio per stabilire quali siano le aree maggiormente sensibili da destinare agli interventi prioritari. Le strategie, come obiettivi a lungo termine, e le tattiche, come risposte immediate alle questioni contingenti e alle peculiarità dei contesti, sono incentrate su una logica basata sulla premialità e sull'incentivazione, determinate in relazione al grado di rischio o di valore dell'area o a una combinazione di questi due fattori. A prescindere dalla futura scelta delle amministrazioni competenti in merito alle strategie da adottare per salvaguardare questi paesaggi, il contributo più significativo di questa ricerca consiste nella definizione della metodologia di individuazione e di classificazione delle aree. Il risultato principale dello studio è costituito dalle carte dei valori e dei rischi, che determinano l'importanza delle aree e stabiliscono la scala di priorità, considerando il paesaggio alla stregua di un bene culturale da conservare e valorizzare.[10]

1 ABSTRACT

Over recent decades, urbanization, industrialization, and floods have produced massive changes in the Zengwun River catchment in Tainan, Taiwan. Planners must reconcile at least three conflicting interests to facilitate the nation's rapid economic growth and to preserve the integrity of the catchment's water balance processes. Contributing to preexisting work done in integrated catchment management (ICM) and relying on the planner's triangle model to create a unique framework, this article proposes to encourage environment resilience in the urban, developing areas of the Zengwun catchment. The framework consists of two integrated models—water balance model and a geographic information system (GIS) to assess the conflicts among social, environmental, and economic interests. The empirical results obtained from our study of the Zengwun catchment's urban area have shown unequal regional spatial conservation and insufficient ICM strategies, both of which result in spatial mismatches and decrease urban environment resilience.

2 INTRODUCTION

The issue of integrated catchment management (ICM) has been investigated over the past several decades (Mitchell & Hollick, 1993; Batchelor, 1999; Verdonschot, 2000; Worrall et al., 2003; Wheater & Peach, 2004; Nunneri & Hofmann, 2005; Prato & Herath, 2007; Holzkämper, et al., 2012). More specifically, planning scholars have paid considerable attention to the conflicts that arise in ICM when individuals are unfamiliar with the three conflicting goals charted on the planner's triangle model—that is, economic development, environmental protection, and social justice—and the spatial mismatches that result from these divergent interests. In this article, these concerns are intimately linked. However, less attention has been paid to the role spatial analysis technology and the planner's triangle model can play in developing ICM policies. This paper proposes to enhance environmental resilience in urban, developing areas by using a modeling framework that contributes to preexisting work performed in ICM and on the planner's triangle.Arising as a result of divergent goals, the conflicts faced in catchment management are not superficial ones related to specific strategies.

From the point of view of climate and the hydrological cycle, room for the river linking spatial planning as an eco-regions zoning intervention, and by the resolve of environmental resilience and the environmental conflicts of the hydrological cycle, using incompatible land in order to reduce the damage to special ecological resources is a vital idea of practicing ecological urban planning thinking (Zhou, et al., 2003; Cook, 2007; Cesar et al., 2010; Galvan et al., 2010). The eco-regions zoning concept of imagination is not only the inspiration for disaster prevention and land use planning to prevent floods and control essential connotation of the exposition, but also makes us think carefully about responding to the city muscle and recognizing the unique natural and hydrological factors that could coordinate with one another in urgent need of ecological zoning to re-organize its system network.

The paper is organized as follows. It begins by reviewing pertinent literature about environmental resilience (ex. room for the river) in assessing water balance model, Eco-regions. Next, GIS is integrated into the research to enhance the effectiveness and precision of measurements Geographic information systems (GIS) is a new integrated modeling framework that contributes to the evaluation of water environment resilience based on the features of Eco-regions planning. To illustrate the entire process, Zengwun River basin, Tainan, Taiwan, is presented as an example in the case study. This combination enables researchers to fully attempting an overview of the Zengwun River basin water environment, through the analysis results of the water environment, spatial distribution, and finally with the establishing of the eco-regions program in order to understand the function and role of a regional water environment, such as assimilative central point (ACP), to identify the point of the runoff connection channel (RCC) and retention point (RP) of the water environment of the areas of urban development. Finally, the results will be helpful to the city planning

manager for the development of the water environment among urban development, drafting the management strategy of room for the river linking spatial planning.

3 ROOM FOR THE RIVER DEVELOPMENT IN TAINAN

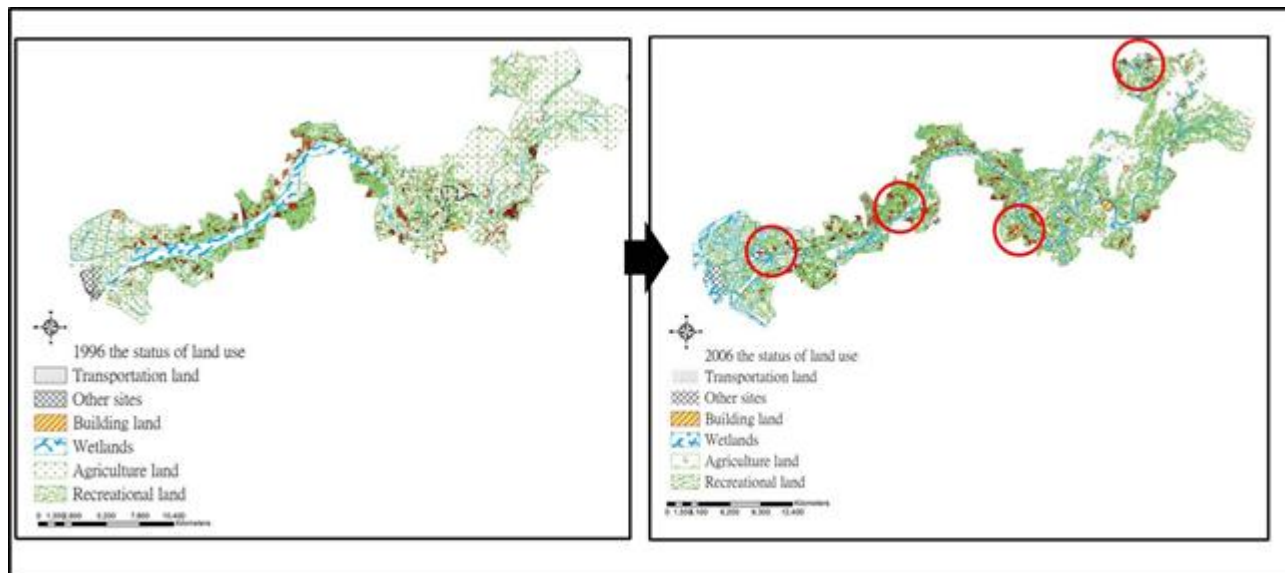
Room for the river had always been one of the central issues for the Taiwan Government. The government has always devoted high levels of research and development resources and management funds to implement water disaster management (Chiang et al., 2009). For example, the recently implemented 8-year NTD116 billion (approximately US$3,515.4 million) 'Flood-prone Region Water Disaster Management Platform Initiative' aims to systematically manage major rivers, drainage and seawalls on a nationwide basis, and to make improvements to land subsidence areas, low lying land areas and urbanized areas that face flooding problems. Due to Taiwan's unique geological conditions it is very susceptible to natural disasters such as floods, droughts, landslides and earthquakes every year. The occurrence of typhoons and floods is even more frequent, and the disaster reduction section of the World. According to the statistics provided by the Central Emergency Operation Center (CEOC) on 2009, Morakot killed 619 people, left 76 missing and 35 injured, damaged over 200 bridges, and caused more than 19.4 billion dollars of loss in agriculture. Therefore, dealing with the relationship between the catchment basin land development and the water environment and further drafting room for the river linking spatial planning strategy have become important issues. Assessment of urban water environment resilience not only represents benefits for both the economic and natural environment, but also means the improvement of management efficiency and competitive advantage of the urban water environment in an urban space unit by reducing the depletion of environmental resources for water and protecting resources of the ecological environment. Tainan City is located in southern Taiwan; it is the fourth largest city in Taiwan, after Taipei, Kaohsiung, and Taichung, with a population of almost 1,880,000. Tainan City proper covers 2,192 square kilometers of land, and statistics from 2010 show that each square kilometer of land is occupied by approximately 857 persons. Since the activities in the Tainan city are growing, people have converted the usage of land in order to meet the needs of urban economic development, and, although increasing the effectiveness of the economy, it has meant sacrificing the environment.


Fig. 1. The status Land use changes in Tainan's Zengwun River basin

Past settlement history and implementation policies have promoted the cultivation of agricultural produce and casual activities in the water catchment areas, enhancing the over-development of those areas without regulations. For the Zengwun River basin in Tainan, for the land use situation had the majority of the water environment as hinterland. Comparing 1996 and 2006, the pattern of land use change displays loss of function of land of more than 8 % water and agricultural land and culvert water, influencing the water environment for floods to occur, as shown in Figure 1. On the other hand, the damage caused by Typhoon Nari, and Typhoon Morakot can be found in the catchment areas within the watershed due to past settlement history of the evolution and implementation of the policy to promote planting settlements for the alpine agricultural needs of the economy and recreation booming of development, causing the river catchment to

have intensive reclamation areas, and most of them beyond the limits of over-exploitation of uncontrolled behavior, which can easily induce landslides of the hillsides and flooding in the middle and lower reaches. The interpretation of this concept on flood and water logging control will extensively interpret the concept of flood prevention and control and face the challenges of design with more delicate thinking about land usage for room for the river, and further propose functional suggestions for urban planning and urban flood prevention and control.

4 ROOM FOR THE RIVER LINKING SPATIAL PLANNING

4.1 Relationship between water environment and land use planning

There are a variety of discussions on the interaction between the urban hydrological cycle and the change of land use over the past decade (Niehoff et al., 2002). In natural science, the relationship between the urban hydrological cycle and land use that has been focused on is a very complex and dynamic process that includes closure, depression building, evapotranspiration, infiltration, seepage, surface runoff, etc. to consider different surface hydrological phenomena and analyze the hydrological cycle through long-term monitoring data, since the analyses of the hydrological cycle predicted and calibrated the basis of the fruitful results(Arnold & Gibbons,1996; Liu et al., 2007; Haase, 2009; Verbeeck et al., 2011). Such studies can be employed to explore the land-use impact on the hydrological cycle in the field of social sciences. In recent years, many studies have pointed out that the changes of land use have caused water environmental impacts, such as water resources, surface runoff, and micro-climate impact; from the above studies, in which emphasis is given to the phenomenon of exploration, those impacts without integrated planning control on land use and water environment must be further discussed (Haase and Nuissl, 2007; Lin et al., 2007; whitford et al., 2001). Regarding river management, exploring the relationship between the water environment and land use planning, there must be an integration of the upstream, midstream, and downstream parts of a coherent governance model, instead of segmentation of their governance, and the impact of the whole environment must be considered (van der Velde, 2006). For flood management in the international arena, such as the European Union's corresponding strategies, they have returned the room for rivers and implemented flood-preventing block strategies (Maltby, 2005). For a river water system that was originally within the land in the flood plain, there must be as many as possible land use governances and limitations to improve the integrated planning of land use and water and establish a hydrology land use management model. Goals for IUSM include (Chocat et al., 2001) 1.flood reduction—minimizing peak stormwater discharges from urban catchments; 2.Stormwater retention—harvest and beneficial reuse of rainwater and stormwater runoff within or near the urban catchment. 3. Urban landscape improvement—showing rather than hiding water by functionally incorporating stormwater into urban streetscapes and green areas. Looking abroad for flood management, successful stormwater runoff management and watershed management for water the environment management philosophy can be found in the minimum amount of impervious surface coverage, the minimum rainfall runoff, rainfall maximum time of concentration and water environmental impact assessment indicators as a basis for exploring the urban water environment and land use planning as an important strategy. Therefore, this article will transform those above factors into input indicators for important water environmental resources in the urban development process.

4.2 Measurement of the water balance

The resource conflict described in this article—that between the urban hydrological cycle and land use—involves a very complex and dynamic water balance process; for the purposes of examining different surface hydrological phenomena and analyzing the hydrological cycle through long-term monitoring, one must take account of groundwater, evapotranspiration, infiltration, seepage, surface runoff, etc (Arnold & Gibbons, 1996; Haase, 2009; Verbeeck et al., 2011). Thus, understanding of the changing impacts of land use on the catchment's surface run-off, urban impervious rate, and runoff time of concentration are of importance for the prediction and adjustment of flood hazards. Another model Arnold & Gibbons (1996) with an eye toward the urban impervious rate; numerous attempts have been made to develop suitable rainfall runoff indices by using land area and the runoff coefficient (Lin et al., 2007); empirical formulas developed by the Netherlands Institute for Inland Water Treatment and Waste Management (RIZA) and the California Department of Transportation have been proposed for estimating runoff time of concentration. Based on our prioritization of

research results, our water balance model calculates surface impervious rate, runoff time of concentration, land use, intensification of water balance, and surface runoff .

4.2.1 Impervious surface coverage

Impervious surface coverage is calculated according to the test of Arnold & Gibbons (1996). The purpose of using this formula and its parameters to calculate the impervious surface rate in urban areas is to understand how to improve the urban landscape and how to measure those improvements once they occur (see Table 2). The formula for estimating the surface impervious rate is as follows (Eq. 1):

$$I = \frac{A_P}{A} = \frac{\sum P_i \times A_i}{A} \quad (1)$$

Where I : Impervious surface coverage (%); A_P : Total impervious surface (ha); A : Land use area(ha); P_i : The imperviousness of surface coverage type (%); A_i : The area of surface coverage type (ha).

Table 2 Classification of land use by surface imperviousness

4.2.2 Rainfall runoff

The measurement of surface runoff on urbanized land will take three elements into consideration: rainfall intensity, runoff coefficients, and drainage area. Drainage area depends on the runoff coefficients pertinent to certain types of land use, as well as to the surface characteristics of the land. Studies about the calculation of runoff coefficients have been divided in their use of one of two methods: the first method obtains the runoff coefficient by estimating or directly measuring peak runoff and dividing it by the catchment's area; the second method takes into account how the area of a piece of land is used and calculates this type of use into the runoff coefficient. Numerous attempts have been made to develop suitable rainfall runoff indices for land used in particular ways. (Lin et al., 2007; Haase, & Nuissl, 2007). In the case of the second method, the runoff coefficient is arrived at by developing a ratio of land area by use and by including the rate of various types of impervious surfaces into the runoff formula. Hence, the formula for estimating surface flow is as follows (Eq. 2 and Eq. 3):

$$Q = 0.278CIA \quad (2)$$

$$I = \frac{500}{(t+5)^{0.413}} \quad (3)$$

Where Q is rainfall runoff; C is the runoff coefficient; I is rainfall intensity; A is land uses the type of drainage area; t is the rainfall duration.

4.2.3 Runoff time of concentration

Runoff time of concentration is defined as the time it takes rain water to travel from the remotest point in a water course to a gauging point in that same course; there are, however, some difficulties in determining its value in actual cases. Empirical formulas developed by the Netherlands Institute for Water Treatment and Waste Management (RIZA) and the California Department of Transportation have been proposed for estimating runoff time concentration. When the drainage area consists of different flow paths, the runoff time of concentration is the sum of the incremental travel times computed for each different reach of flow. The travel time in gutters, storm drains and channels is typically estimated using basic hydraulic data (t = distance/velocity). Thus, the formula for estimating surface runoff time of concentration in urban areas is as follows (Eq. 4):

$$t_c = t_1 + t_2$$
$$t_1 = l/v \quad (4)$$

where t_c is runoff time of concentration (min); l is overland flow length, m (ft); v is Manning's roughness coefficient; t_1 is time of surface rainfall runoff along the main storm drain to the main channel (min); t_2 is time on the watercourse from the basin outlet to the point nearest the basin centroid (min).

4.3Eco-regions planning in the application of the water environment

Eco-regions, a term first created in the mid-twentieth century, has now been used for more than 30 years; the partition of the eco-regions, however, has not yet had a common definition, but has long been widely used in different levels and areas, such as biology, hydrology, geology and natural environmental sciences（Bailey, 1983）. Some scientists believe that, to solve administrative problems and provide decision-makers with the information for managing environmental resources, the eco-regions principle is one method to consider for the assessment of productivity and environmental resource management units. In the United States as early as 1915, landscape planner, W. H. Manning, developed land-use planning aimed at the development of resource conservation and utilization strategies, and proposed land classification based on natural resources and the idea of natural systems. In 1950s, the rise of the green corridor movement, represented by ecological network planning and construction, had become the focus of the conservation of natural resources planning. For example, there are concepts of green corridors, ecological networks, and flood buffering regions etc. throughout the United States (Jongmana, 2004; von Haaren, 2006). On the other hand, in Taiwan, in the field of environmental planning, scientists have had discussions on different environmental physical properties of the partition characteristics of different natural ecosystems and energy flow trends, such as climate zones, catchment areas, topographic partitions, protected forest designated ecological energy partition, which have also had solid achievements. However, few of them have discussed land use planning from the point of view of land use in the face of ecological value, and the ecological function of different water environments should have a more extensive interpretation of land use in eco-regions to support eco-regions of the substructure or underlying foundation for a city or country continuing to grow on this basis. This article will define the application of ecological zones in land use planning, in the meaning of wanting to build a network of an interconnected water environment of their own water resource values and land use development planning and control, and lead to the creation of an open water environment of space distribution systems, as shown in Figure 2.
Fig 2. Eco-regions based on the water environment

First, the assimilative central point (ACP) of control on behalf of the surface runoff is still lower, representing the future of the region with the set assimilative as other high runoff of rain water in the village to guide the stranded buffer points with the setting of farmland, forests, regional parks, or water detention pond facilities. The runoff connection channel (RCC) is the bond of the water environment system integration, which will slow the runoff and maintain key biodiversity importance. Future assimilative control points can connect through the runoff to the channel identified, tried, through channels, tributary connections, so not only can existing parks, protected areas or natural detention ponds link up, the water environment of the corridor can connect the different ecosystems. The retention point (RP) is smaller than the control point, which is not necessarily connected to the overall network or regional protection system; different assimilative central points of control runoff connecting channels and water retention point scale create functional layouts of the overall water environmental network system. The analysis results will eventually be converted into the water environment relationship diagram, with which we can learn through the assessment of the spatial characteristics of the water provided in different environmental functions and in the future identify the center of runoff connection channel with the retention point to attempt to construct the prototype of a water environment.

5   ANALYSIS AND DISCUSSIONS

In addition to current data collection and the investigation of the two periods of land use in 1996 and 2006, we have built in this article the architecture required geographical database and socio-economic statistics, followed by the use of an assessment summarizing the resilience of the water environment analysis and DEA, such as integration, to estimate the resilience of the water environment profiles and assess the resilience of the water environment and its spatial difference characteristics.

5.1 Land use change analysis

For the Zengwun River basin in Tainan, for the land use situation in the 1996 survey of land use classification, we have categorized various land types of land use in Tainan's Zengwun basin, as shown in Figure 3 with the highest water conservancy land, followed by agricultural land. It has shown that the Zengwun River basin in Tainan had the majority of the water environment as hinterland. Comparing 1996 and 2006, the land use of the current status displays construction sites (1.16 %), transportation land (8.31 %), recreational land (0.12 %), other sites' (6.36 %) area ratio increased, while agricultural land (-28.6 %) and water conservancy land (-8.03 %) area ratio decreased. Zengwun watershed land use development has resulted in a loss of function of land of more than 8 % water and agricultural land and culvert water, influencing the water environment for floods to occur. In the future, land development should be strengthened to pay attention to preventing the loss of land resources of the water environment.

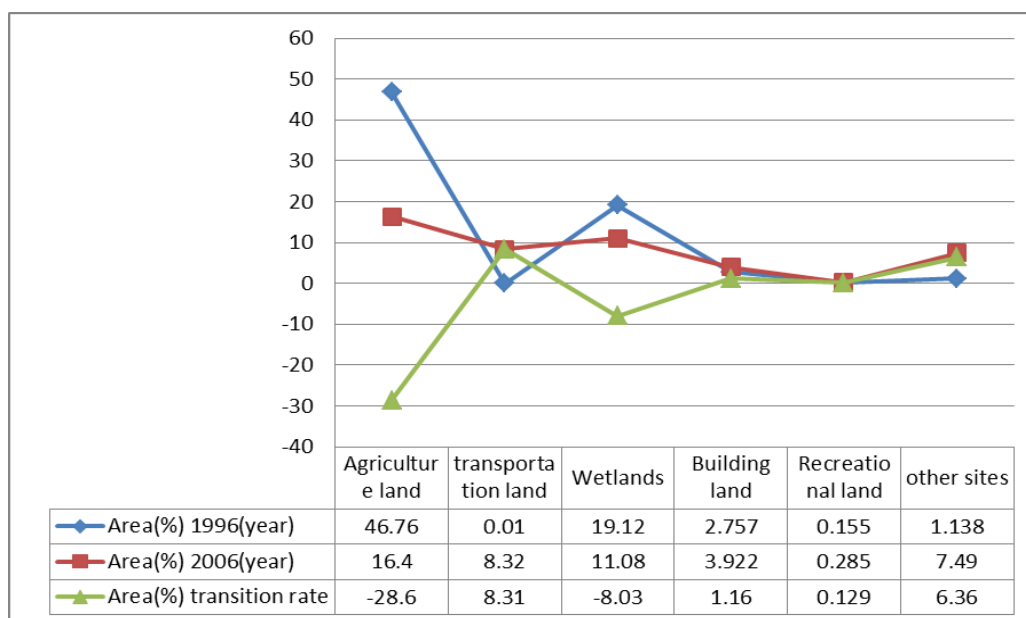
	Agriculture land	transportation land	Wetlands	Building land	Recreational land	other sites
Area(%) 1996(year)	46.76	0.01	19.12	2.757	0.155	1.138
Area(%) 2006(year)	16.4	8.32	11.08	3.922	0.285	7.49
Area(%) transition rate	-28.6	8.31	-8.03	1.16	0.129	6.36


Fig 3. The Analysis of Land use changes in Tainan's Zengwun River basin

5.2 Division of eco-regions in the water environment

An ideal eco-regions system of the water environment is controlled with the center of an assimilative central point (ACP), runoff connection channel (RCC) and Retention point (RP) is connected to the water environment, as shown in Figure 4. The geographical type space of self-correlation and the representatives of the WEI in the space generated by the spatial characteristics are designated as judges of the standard. First, we want to identify the current ACP that can still slow down the Zengwun River basin for protection. For example, if it shows up as LOW-LOW, it represents the clustering phenomenon of low rainfall runoff in the village, Da-Ne Township, Lake Village Shanhua Township, Jia-Bei Village, etc., which represents a future in the region with the set assimilative as other high rainfall runoff in the village to guide the stranded buffer point with the setup of farmland, forests, regional parks or wetlands, or detention pool facilities. The RCC is the bond of the water environment system integration, and these ties have important functions to slow down runoff and maintain key biodiversity. Space characteristics of the RCC through time of concentration index, showing the HIGH-HIGH cluster village with high time of concentration in An-Ding Township, Guan-Liu Village, Surin village, etc., have future ACP to connect through the RCC that will be identified by different villages, and they will go through the channels and tributary connections, which not only can connect existing parks, protection and/or detention ponds, but can also be used as the water environment of the

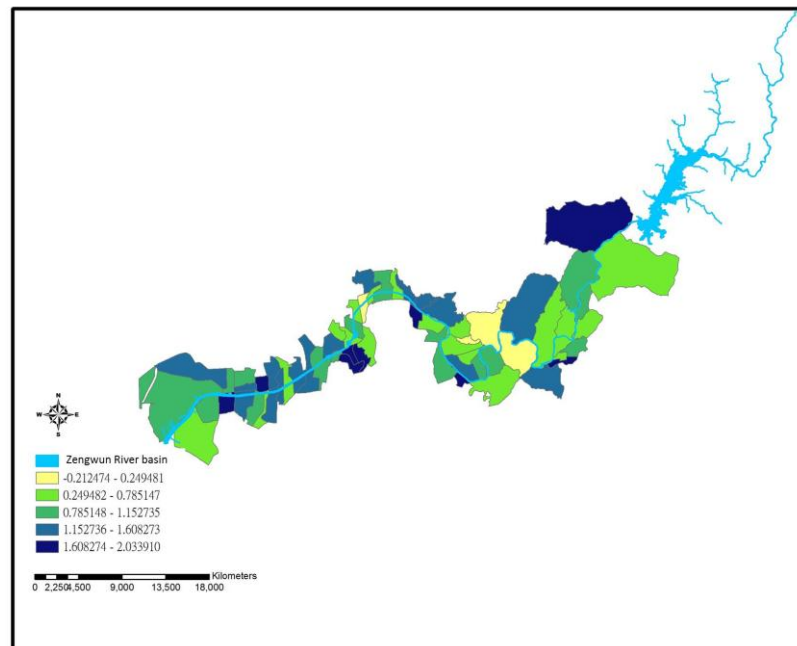
corridor to connect different ecosystems. RP of the central point of control will not necessarily be connected with the overall network or regional protection system. In this article, we connect them through the spatial characteristics of each impervious rate analysis, showing the HIGH-HIGH with the high rate of impervious surface coverage cluster in villages such as Da-Ne Township, Cu-Si Village, and Da-Ne Village, etc. They can be connected with different ACP, RCC and RP, with a functional layout of the overall water environment of network systems.
Figure 4. Spatial distribution map of eco-regions in Tainan's Zengwun River Basin in 2006.


Fig 5 Proposed scheme of Tainan's Zengwun River basin with water space planning in 2006.

5.3 Room for river linking spatial planning proposal

In this article, we have also further examined the villages in Zengwun River basin that are still available for planning proposal with water districts. The principle of screening has the LM value of rainfall runoff, LM value of time of concentration and LM value of impervious surface coverage. Then they are converted into the same unit standards (e.g. percentage) for spreadsheet processing; the higher value represents the water environment, marked as dark blue in line with the room for the river of the village with water, as shown in Figure 8; there are nine places, including Tainan Dong-Shan Township, Nanshih Village, Yutian Village, Yujing Village, the mountain villages of the mountain Township, the Shanhua Town Wing, Anding Township, Su Cuocun and Surin Village, Chiku Township, Zu-Cia Village, Annan District, and Sharon

Village, with the follow-up to strengthen the analysis of the appropriate assimilative control point, runoff channels and water retention points in the village to carry on the layout of the Zengwun watershed network of defense and spatial planning strategies to practice room for river.

6 CONCLUSIONS

In this paper, we have proposed a set new integrated modeling framework that contributes to the evaluation of water environment resilience for eco-regions in urban development. The framework consists of two integrated models—water balance model and a geographic information system (GIS) to assess the conflicts among social, environmental, and economic interests for measuring the relative water environment resilience on controlling the strategy of land utility via eco-regions. After using the case of the Zengwun River basin in Tainan, we propose these conclusions and suggestions.

This article is based on the case of the Zengwun River basin as the empirical region and the 1996-2006 land use changes. The Zengwun watershed land use development has resulted in a loss of function of the land of more than 8 % water and agricultural land and culvert water, but has also influenced the water environment, and it may cause floods to occur; in the future, the development of land should be strengthened to pay attention to the influence of loss of the water environment and land resources.

For design of the eco-regions system, this article has attempted to propose a new spatial planning of room for the river designated space evaluation of the characteristics and function of the water environment in different villages, to identify the assimilative central point (ACP), runoff connection channel (RCC) and Retention point (RP) in an attempt to construct the prototype of a water environment in line with urban development and the water development policy to guide water environment to change the future land use changes required to withstand the force of water environmental conditions, and thus reduce the losses caused by disasters and improve the water environment's natural healing ability.

This article has proposed a spatial planning strategy of room for the river, by an objective measurement of the difference in the development of comparative urban development and the resilience of the water environment, by the design of eco-regions for land use planning strategy of room for the river. By pointing out relatively inefficient areas of the water environment, we hope to provide future planners the basis to combine water-related areas and try to adjust for the development of future urban water environments in spaces through planning tools and planning analysis of the application. Moreover, the planners can employ the assessment framework proposed in this article to enhance the goal of the resilience of the water environment and propose appropriate spatial development strategies.

1 ABSTRACT

This paper reports, an experiment of 'article-finding behaviors (AFBs)' that are a typical shopping-around situation, under the following:

(1) incompleteness of mental-map, (2) loose time-constraints, (3) plural errands to be achieved, and (4) free walking in any remaining time.

Spatial behavior and cognition are measured by using an improved thinking-aloud-protocol method, GPS loggers, and video.

AFBs are often compared with 'way-finding behaviors' with a given goal point.

The findings are: (1) the layers of goal-subgoal of AFBs are fewer, (2) changes of the mental-map are observed, (3) walking speed is not different, and (4) walking routes are significantly different.

2 RESEARCH BACKGROUND AND OBJECTIVES

Modeling and simulation of downtown visitors' behavior is a great potential technique for supporting urban planning and design, thus one of the authors is recently tackling with research and development of a shop-around agent model. Recent research issues include agents' space cognition in their shopping-around situation.

A common factor of the typical shopping-around behavior observed in downtown is that (1) an actor's mental map of the district is incomplete, and the following can be observed: (2) under loose time-constraints; (3) they have plural tasks; and (4) they spend the remaining time strolling. It can be considered that complicated spatial cognition is involved in such spatial behavior; however, serious research has not been conducted yet.

Our research examines this kind of behavior as "article-finding behavior," and an experiment was conducted in the Osu district, Nagoya City; this research explores the characteristics of spatial cognition and behavior, through analyses employing the thinking-aloud-protocol method, and GPS loggers. In particular, this research clarifies the characteristics of article-finding behavior by comparing them to the experimental results of "way-finding behavior" with a focus on going to a given destination with an incomplete mental map.

3 EXISTING RESEARCHES AND FRAMEWORK OF THIS RESEARCH

This research focuses on shopping-around situations. As existing research on shopping-around behavior, questionnaire surveys by Takeuchi et al.(2011) and Oiwa et al.(2005) have been reported. In their research, to examine shopping-around behavior, in other words, typical behavior observed while shopping in a retail area, data for the shops visited or walking routes was collected by a questionnaire and analyzed; however, such research did not record or analyze the recognizing and thinking processes of a pedestrian while shopping, or the apparently insignificant behaviors that reveal these shopper's process. Therefore, this research defines general behavior while shopping, as the shopping-around situation, which includes not only walking-around behavior, but also cognitive behavior such as obtaining information by close observation or from studying a map. The methods described below are employed for analysis.

Section 4 describes the experiment, and Section 5.1 analyzes the spatial cognition that is seen when searching for articles, by employing the thinking-aloud-protocol method of Ericsson & Simon(1993). The section further conducts analysis by using the improved way-finding codes proposed by Hiiro et al.(1994) Then, by comparing the experimental results obtained this time with the results of the way-finding experiment previously conducted by Nakamura et al.(2011), the characteristics of article-finding behavior are clarified. Section 5.2 refers to the rough sketch maps to analyze spatial understanding used by Lynch (1960), and describes a map sketching exercise conducted to explore any relation between changes to the

before and after mental maps of each participant and their cognition level of the district (Funahashi, 1991a,1991b). In Section 6.1, with a focus on pedestrian insignificant behaviors, in a similar way to the analysis of finding behavior by Miura(2008), Mori & Oku(2002), and Suzuki et al.(2001), our research considers insignificant behaviors during the experiment, and examines the relation between spatial cognition and spatial behavior in article-finding behavior. Section 6.2 compares the walking route and walking distance of each participant, and from the viewpoint of route analysis, analyzes article-finding behavior in shopping-around situations.

4 ARTICLE-FINDING EXPERIMENT IN A SHOPPING-AROUND SITUATION

4.1 Classification of shopping-around behavior and selection of participants

In a large shopping street district, on a daily basis the structure and layout is daily changing its features; therefore, it is usual the visitor's memory, or their mental map would be incomplete. The experiment mainly focuses on the level of completeness of the visitors' mental map, in other words, the cognition level of the district (thereafter the cognition level). In the experiment, these levels were classified into three categories: High, Average, and Low.

To discover differences in visitors' cognition and behavior according to the cognition level, a questionnaire survey1) was first conducted among 21 university students to establish the cognition level, and a total of 8 students were selected as participants (3 High, 2 Average and 3 Low).
Fig. 1: Classification of article-finding behavior and its measurements

4.2 Experimental method of article-finding behavior

The experiment was conducted in the daytime on a non-rainy day in the Osu district, Nagoya City (Fig. 2). The Yabacho intersection was set as the starting point, and the following instructions were given to the participants: "Locate one example of each shop selling flowers, taiyaki pancake (fish-shaped pancakes filled with bean jam), or flashlights, (one shop per article). Return to the starting point within 60 minutes." Participants were given total freedom to decide the order of search for each article and how to allocate their time; they could also engage in free strolling at anytime. They were not allowed to carry a map of the district, but could refer to wall maps, signs, etc.

The thinking-aloud-protocol method was used to collect data. More specifically, participants were requested as much as possible to report out loud any thoughts that entered their minds; each participant was accompanied by an experimenter whose purpose was to encourage them to speak by asking appropriate questions. This spatial cognition process was collected as data by using a video camera to record speech and behaviors, and a GPS logger to track the actual walking route and speed. In addition, to explore any relation between their district cognition level and any changes of their mental map, before and after the experiment the participants drew a rough sketch map of the Osu district on a sheet of white paper.

4.3 Coding of thinking-aloud-protocols

The obtained thinking-aloud-protocols were segmentalized at each pause or at the end of a sentence, and then encoded as shown in Table 1. The codes employed were established by Nakamura et al.(2011), who added codes to the basic reference work of Hiiro et al.(1994), and moreover, in this research, to encode any remarks made by participants when they were unable to find their target store or article in a location where they had guessed they might find it, a new code "#: Awareness" was added.
Fig. 2: Osu district map and Shop locations sell the articles

	code	name	example
directions-information	V	view	visual information
	S	sign	check information (map,traffic-sign)
	M	memory	remember the place of the store
plan	Ap	plan A	go to the specific area
	Bp	plan B	do something for the time being
	Cp	plan C	go with feeling
	Dp	plan D	return
expressing emotion	?	lostness	"let me see..." "umm..." "I'm lost."
	!	finding	"I know!" "I see."
	#	awareness	"There's no it in the place which intended."
	code	thinking-aloud-protocol about lostness	
cause of lostness	α	failure of the movement to the destination	
	β	cannot grasp the current place	
resolution of lostness	α'	quick fix	
	β'	check information (map,traffic-sign)	

Table 1: Code system of thinking-aloud-protocols

5 ANALYSIS OF THE CHARACTERISTICS OF SPATIAL COGNITION IN THE ARTICLE-FINDING EXPERIMENT

5.1 Goal-subgoal analysis of article-finding behavior found by

A sub-goal refers to a partial goal condition that is formed to help fulfill a goal (fulfillment of goal conditions). Fig. 3 shows a typical case of analyzing the sub-goals and two goals of a participant, and Fig. 4 shows their walking route, and the spots where they made any remarks. As a method to organize the analysis, the process from each sub-goal formation through to fulfillment is represented by one box. Remarks that could be interpreted as being made during the process of achieving the sub-goal are given on the right side of the box. For example, the sub-goal of Remark No. 7, which was set to achieve the sub-goal set in Remark No. 6, is shown on the right side of the No. 6 box.

At Remark No. 2 in Fig. 3, the participant commented on a shop where they thought the article would be sold; however, they noticed that they were unable to find that particular shop (#), which indicates that the newly added code in this research enabled us to encode pedestrian behaviors more accurately. Moreover, in all district cognition levels, one particular result was observed: the participants found a shop which they thought was likely to sell a target article, but they were unable to find the article (#).

Next, the results of the article-finding experiment and the way-finding experiment were compared. The article-finding experiment gave "plural tasks" to examine "article-finding behavior," whereas the way-finding experiment gave "a single task" to examine "way-finding behavior."

Fig. 3: Goal-subgoal analysis of article-finding behavior, a typical case
Fig. 4: Walking route and the spots where he made any remarks, example

Fig. 5 shows a distinct difference between these two approaches: in the article-finding experiment fragmentary subgoals were created and only a small amount of the stacking of subgoal layers was found; on the other hand, in the way-finding experiment, sub-goals tended to stack up in several layers. This can be attributed to the following: since the specific destination spots in the article-finding experiment were not given, participants needed to immediately decide whether to change or fix a (sub-)goal in response to the on-the-spot situation.

The second difference involved the creation of subgoals based on sign information. In the wayfinding experiment fewer and 'longer-term' sub-goals were created. In the article-finding experiment, when many tasks were still left to be fulfilled, relatively 'shorter-term' subgoals were created, and when only a few tasks remained, 'longer-term' subgoals were created. These results could be attributed to the following factors: when many tasks were left, acquisition and organization of information was complicated; however, as the number of tasks decreased, acquisition and organization of information became simpler. In addition, in the article-finding experiment sub-goal creation based on visual information was often observed. It would seem

that in response to the changing situation, participants needed to obtain visual information from their immediate surroundings.

"Free strolling" was observed for all participants after they fulfilled all their tasks. Many of the participants at that time drew up subgoals to return to the starting point more or less straightaway, but often by chance, as they found other activities that interested them, they tended to engage in alternative temporary behaviors, and subgoal creation decreased.

Goal-subgoal analysis allowed us to clarify the characteristics of spatial cognition recognized during "free strolling," "article-finding behavior," and "the fulfillment of plural tasks."
Fig. 5: Comparison between article-finding behavior and the way-finding behavior

5.2 Article-finding behavior found by mental map analysis

To analyze any change to their mental maps, each participant drew a rough sketch map of the Osu district and its environs on a sheet of white paper before and after the experiment (Table 2).

Generally speaking, pre-experiment sketch maps showed that participants with a High district cognition level did not demonstrate any error concerning the locations of shops and streets, although there were differences between individual participants. Post-experiment maps of all three participants showed high accuracy of the overall picture of Osu, and also shops other than those inolved in task fulfillment were added along with those side routes seen during the experiment, but not explored. These results could be attributed to the following factors: since the initially-held mental map was highly accurate, the amount of information to be newly obtained was less, allowing for easier organization. It can be said that the participants with a High cognition level made additions to and improved their mental maps.

Pre-experiment sketch maps of participants with an Average district cognition level showed an ambiguous positional relationship with low accuracy concerning the places that they had visited and the immediate neighborhood. In the post-experiment maps, they were able to draw the whole Osu district, and showed improved accuracy of the positional relationship among shops and streets. When compared to the participants with the High level, apart from those shops involved in task fulfillment, overall they drew fewer shops, and the streets drawn were mostly those that they had walked along during the experiment, and few side routes were shown. From these results it can be said that although they had a mental map, there were

mistakes in important parts, and therefore, they tended to correct mental-map errors by using information obtained in the course of their behaviors.

Pre-experiment, participants with a Low district cognition level were hardly able to draw a map. On the post-experiment map, they only partially depicted the task shops and the streets they had walked, and errors were found in the linkage of fragmentary information. This could be attributed to the following factors: the information obtained was all new, and they were unable to completely process it. From this finding, it can be said that the participants with a Low cognition level created a slightly better mental map.

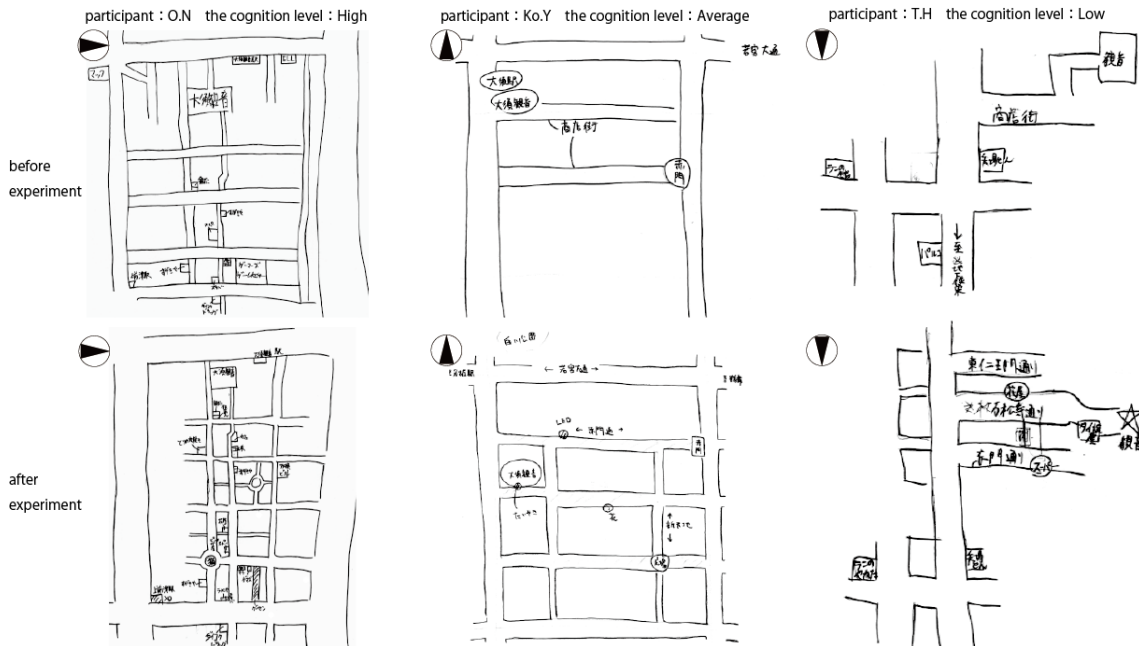
As mentioned above, the participants were requested to draw a mental map as an actual map, and according to the different cognition levels, corresponding changes to the mental maps were observed. From the results of the experiment, it can be inferred that the accuracy of a mental map is improved through the following stages: creation > revision > addition, and in the early creation stage a larger workload is undertaken.


Table 2: Sketch maps before and after the experiment

6 ANALYSIS OF THE CHARACTERISTICS OF SPATIAL BEHAVIOR IN THE ARTICLE-FINDING EXPERIMENT

6.1 Article-finding behavior found by walking speed analysis

Table 3 shows the results of all participants. Their walking speeds were collected at 2-second intervals by GPS loggers to analyze the characteristics of spatial behavior in the article-finding behavior. Firstly, 343 spots, where the walking speed decreased by 1km/h or more, were extracted, and then by comparing with video images, 56 spots, where the drop in speed was caused by a positioning error of the GPS logger, were removed. Consequently 287 spots were selected as data.

The data was analyzed and the main causes for any walking speed decrease were classified into the following 4 categories: 1) Traffic, e.g. waiting for traffic lights to change or vehicles to pass; 2) Pedestrian congestion; 3) Acquisition and confirmation of visual information, e.g. checking shops; and 4) Consideration, e.g. checking a map.

The cognition level		High			Average		Low		
Participants		K.N	O.N	N.T	Ko.Y	Ku.Y	A.H	T.H	K.H

	Consideration	2	3	4	6	2	4	3	3
	Traffic	11	9	2	8	3	8	21	13

Table 3: Result summary of the Experiment

Next, each point of time the walking speed decreased was recorded on a walking speed graph as shown in Fig. 6. In addition, the walking speed decrease spots of the participant and their route are shown in Fig. 7. As a result, once they entered into the shopping street, the frequency of "acquisition and confirmation of visual information" increased, along with a constant decrease in the speed of walking, compared to before the entering the shopping street. This could be attributed to the following factors: the participant, upon entering a shopping street, was bombarded by a large amount of information, and they maintained a slower walking pace while constantly obtaining and organizing this new information. It was also observed that they often stopped when they tried to obtain information actively.

After the fulfillment of all tasks, there was a drop in the frequency of walking speed decrease incidents due to "acquisition and confirmation of visual information" and "consideration." It can be inferred that since the participants had fulfilled their tasks, there was no need to actively obtain or search for information. In particular, those participants with a Low cognition level did not need to obtain information because they simply retraced their steps along their route (described in Section 6.2). Moreover, when the speed decreased due to "acquisition and confirmation of visual information," in most of these cases the participants had found something of interest to them.

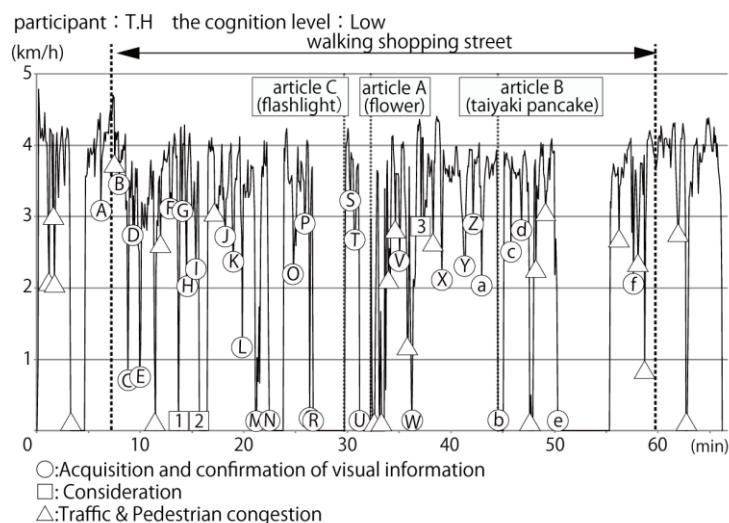
These results did not show clear differences according to the district cognition levels. It can be inferred that this was true even of those participants with a High cognition level, who knew the street map well, but did not know exactly the kinds of shops and their locations, and thus they too needed to constantly obtain and organize information. From this finding, it can be said that walking speeds in article-finding behavior are not affected by the level of completeness of a mental map.


Fig. 6: Walking speed analysis on article-finding behavior, example
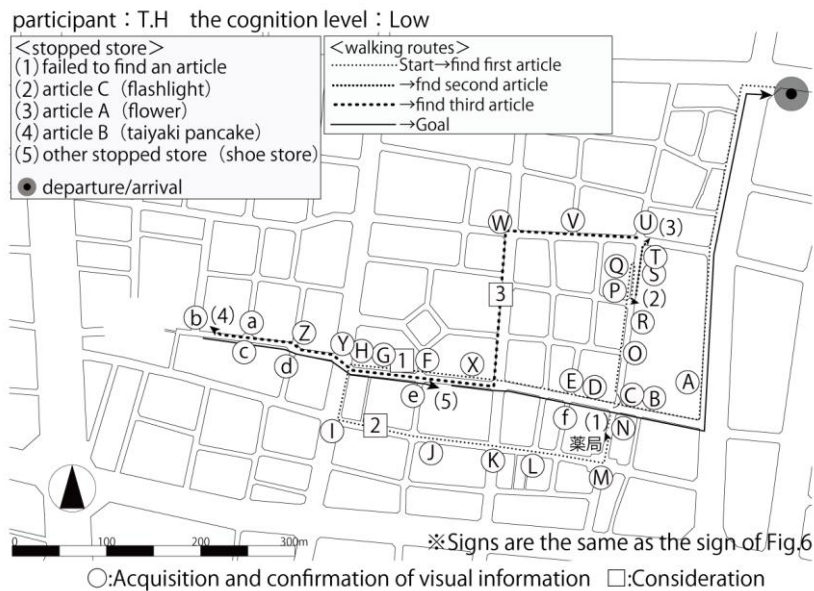

Fig. 7: Walking speed decrease spots of the participant and his route, example

6.2 Article-finding behavior found by route analysis

Table 3 shows the number of times the participants retraced their steps, which is a return behavior during article-finding, and the number of times they revisited any intersection. In both cases, the participants with a Low district cognition level tended to demonstrate higher scores. The main cause of retracing was that the shop or article was not found at a supposed location (8 out of 12 cases). The main reason for this can be considered as follows: being unable to find their target shop or article, and not knowing the way ahead, they started feeling uncertain, and turned back. Those participants with a High cognition level in the same situation were able to rely upon their mental map and move ahead, which resulted in a difference in the number of times of retracing.

Revisiting the same intersection due to retracing was observed in 7 out of 13 cases, and revisiting the same intersection from a different street was observed in the other 6 cases. It can be inferred that the participants with a Low level did not know how streets were connected, and thus retraced their steps.

Table 3 also shows analysis of walking routes and walking distances. The duplicated walking distance is the total of all the instances when participants walked along the same route, and the duplicated walking distance ratio indicates to what extent they walked the same street during searching and after searching.

On the whole the results indicate that the participants with a High cognition level showed a low value for the duplicated walking distance ratio during searching, whereas all participants with a Low cognition level showed a value around 10 %; this is caused by the retracing of the participants with a Low level. In addition, regarding the duplicated walking distance ratio after searching, the participants with a High level showed a low value, whereas the participants with a Low level showed high values with 72 % to 100 %. It can be said the participants with a Low level had a tendency to retrace their steps towards the final goal point without deviating. This could be attributed to the following factors: they held back from active strolling behavior so as to comply with the given final goal and time restriction.

7 CONCLUSION

The results obtained by this experiment are summarized as follows:

- From the goal-subgoal analysis employing the thinking-aloud-protocol method with the additional Awareness code, the cognition process that is characteristic of article-finding behavior was examined. When compared with way-finding behavior, it is characterized by a higher number of small sub-goals, and a lower number of planning layers.

- The experiment enabled the observation of the characteristics of mental maps and any changes. It can be considered that mental maps change through the stages of creation > revision > addition.

- In article-finding behavior, it is unlikely that walking speeds are affected by the level of completeness of the mental map.

- In terms of walking routes, differences among the district cognition levels were found in retracing and duplicated walking distances.

As shown by the above results, this article-finding experiment enabled the clarification of the characteristics of spatial cognition and spatial behavior in article-finding behavior.

Since the experiment was conducted under time constraints and the participants had limited time for exhibiting free strolling behavior, we were unable to conduct deeper analysis. Therefore, in the future, using several different kinds of analysis, there is a need to conduct an experiment focused on exploring the characteristics of free strolling behavior.

9 NOTES

To select participants, a questionnaire survey was conducted to establish the frequency of visits to the target district, and to ascertain the respondent's knowledge concerning 11 facilities in the district. Respondents chose one of five levels of answer, which ranged from: "I can give directions to this facility (1 point)" through to "I do not know the way to this facility (5 points)." In addition to the knowledge score of facilities in the district, the frequency of visits was also taken into account when the district cognition level of the respondents was classified into the following three levels: High: less than 30 points, and one or more visits per month; Average: less than 40 points, and one or more visits per year, but less than one visit per month; Low: respondents who did not qualify as High or Average.

1 ABSTRACT

The current pattern of urban development in the industrialized countries is growing of low-density, decentralized residential and commercial development. This form of development in urban and suburban areas is commonly known as "sprawl" that has caused fragmentation of the natural resource, declining water quality and traffic congestion. Urban development is a complex dynamic process which involves various factors with different patterns of behavior. Modeling urban development patterns is a prerequisite to understanding the process and lead to manage resources between communities and planning it. This research is going to introduce Cellular Automata (CA) as one kind of dynamic models to predict and simulate urban growth and also explain the necessities of using it and its parameters. In CA models space (it means place and its surrounding environment) should be represented as a grid of cells that can change state as the model iterates to simulate urban growth. Finally, Tehran simulation urban growth with cellular automata as a case study will be explained. In this case study, the applied CA model uses three historical images as the input data, and also a scenario is defined for the transition rules. After checking the precision of the simulation, the future of the urban growth in Tehran has been predicted with this scenario. At the end of simulation, finding of CA simulation was applied to planning. Such predicting will help municipalities to design the infrastructure plan, and apply a better management to handle the resources.

2 INTRODUCTION

With rapid urbanization in many countries, in addition to increasing the number of cities and their population, area of cities has expanded rapidly and this physical expansion was higher than population growth; this form of growth that is unplanned was called Urban sprawl (Bhatta, 2010). It was formed originally in developed countries, but today, urban sprawl can be seen in most countries in the world. In this type of development, land use patterns were changed and urban land capitation will be increased.While urbanization has occurred, natural resource lands, such as forest, wetlands and agriculture, have been replaced by land uses with more impervious surfaces (Javadian, 2012). Predicting future environmental consequences requires that we able to predict the spatial pattern of land use change. In recent years, spatially simulation models of urban growth patterns have emerged. The economic versions of these models estimate land use transition probabilities with using discrete choice methods based on the behavior of agents making land use decisions.

A relatively simple class of models, cellular automata (CA) has gained attention from researchers attempting to simulate and predict spatial patterns of urban development. CA models are not only conceptually elegant but also they have the potential to simulate the complex behavior of systems, such as city. CA models have been used to simulate different types of urban forms and development densities and to investigate the evolution of urban spatial structure over time.(Yang, 2003)

3 NECESSITY OF USING CA

To realize the dynamics of complex urban systems and to evaluate the impact of urban growth on the environment we require to procedures of modeling and simulation with innovative methodology and techniques. A number of analytical and static urban models have been developed that are based on different theories such as urban geometry, size relationship between cities, economic functions and social and ethnic patterns with respect to city structures. But these models were developed to explain urban expansion and to extract patterns rather than to predict future urban development. For understanding the spatial consequences of urban growth, a dynamic modeling approach is preferred (Alkheder; Batty, 1997; Fulong, 2002; Kiavarz, 2009). In recent years, dynamic modeling as a primary research field in geographical information science is rapidly gained popularity among geographers and urban planners as tools for urban and landscape

simulation. A variety of these models that are cell-based has been developed as either stand-alone packages or subcomponents that are linked with different software packages from GIS, visualization, or urban planning. They can be categorized incidentally, such as logit , Markov and cellular automata, or processes based, such as dynamic ecosystem model. These models have some common features such as the use of transition probabilities in a class transition matrix, cellular automata, and the GIS weighted overlay approach.

Among all the documented dynamic models, those based on cellular automata (CA) are the most effective in terms of their technological evolution in connection to urban applications. There are a number of reasons leading to the choice of this model for urban researches. The model is scale independent, dynamic, and future oriented, conforming to the essential requirement of urban growth simulation (Alkheder; Fulong, 2002; Kiavarz, 2009; Nuno, 2007). This may be valuable for producing reasonable growth prediction. The model can be verified through rigorous past to present calibration using historical land use/cover data and be used to simulate urban growth under different conditions by modifying some initial conditions and changing input data layers (Kiavarz, 2009; Nuno, 2007). This could be useful not only for guiding future urban planning practice but also for studying metropolitan dynamics. Last, in contrast to many existing models that were developed by different research teams with essentially no reuse, this model's design allows it to be applied to other regions with different datasets.

4 DEFINITION OF URBAN SPRAWL

The concept of sprawl-emergence of a situation of un authorized and unplanned development, normally at the fringe areas of cities especially haphazard and piecemeal construction of homesteads, commercial areas, industrial areas and other non-conforming land-uses, generally along the major lines of communications or roads adjacent to specified city limits, is observed which is often termed as the urban sprawl. (Bhatta, 2010: 7)

The area of urban sprawl is characterized by a situation where urban development adversely interferes with urban environment which is neither an acceptable urban situation nor suitable for an agricultural rural environment (Rahman et al.2008).

Much of the literature and debate on urban sprawl has been based upon experience in the United States (Galster et al., 2001; Peiser, 2001; Squires, 2002; for example). In this debate urban sprawl has been defined as:

„a pattern of land use in an urbanised area that exhibits low levels of some combination of eight distinct dimensions: density, continuity, concentration, clustering, centrality, nuclearity, mixed uses and proximity" (Galster et al., 2001, p. 685).

Or as Peiser (2001, p. 278) suggests:

„the term is used variously to mean the gluttonous use of land, uninterrupted monotonous development, leapfrog discontinuous development and inefficient use of land".

Urban sprawl has many features that can be identified by them, some of these features are occurred in the physical but others can be studied in other aspects such as social, economic and environmental realm. Part of these features that are physical aspects (because the Cellular Atumata models will predict based on physical characteristics) is proposed as fallow:

- Leapfrog Development
- Commercial Strip Development
- Low-Density Residential Areas
- Single Use Development
- larger separation of land pieces
- More useless spaces and abandoned spaces
- Loss of green space use and change to urban use (Javadian, 2012)

5 DEFINITIONS AND PARAMETERS OF CELLULAR AUTOMATA

Cellular automata are mathematical models for complex natural systems containing large numbers of simple components with local interactions; these models enable the examination of systems whose behavior at the global scale can be classified as complex, while at the local or individual level they are comprised of fundamentals simple components (Batty, 1997; Kiavarz, 2009; Nuno, 2007). CA models are cell-based that is a collection of "colored" cells on a grid of specified shape (Alkheder).

CA models are comprised of four individual components, all of which are required to be classified as a cellular automaton. Cell space, Local states, Transition rules, Neighborhood, in recent years other researchers have added an additional fifth component to CA, although it is naturally adherent to their nature Temporal space (time) (Alkheder; Batty, 1997; Nuno, 2007). Cells are Basic element of a CA and can be thought of as memory elements that store state information. All cells are updated simultaneously according to the transition rules, which are defined in more than 2 dimensions, but the 2-d form that makes them applicable to cities is the most usual (Alkheder; Nuno, 2007). Local states are the states that cells can take it in iteration process that can be change at the time to other states with transition rules such as 0, 1 in Boolean method or residential, commercial and green area in urban studies. The rules for transition from one cell state to another can be interpreted as the generators of growth or decline, such as the change from an undeveloped to a developed cell or vice versa. This change is a function of what is going on in the neighborhood of the cell (Alkheder; Batty, 1997; Nuno, 2007).

IF   something happens in the neighborhood of a cell

THEN   some-other-thing happens to the cell (Batty, 1997).

The neighbourhood usually being defined as immediately adjacent cells, or cells that "in some sense" are nearby. Urban growth and Specially in real city neighbourhoods provide excellent examples different type of neighborhoods are defined in CA that shown in Figure 1 .Von Neumann neighborhood Composed of the cells above, below, left and right and it has a radius of one. Moore neighborhood Composed of the same cells as the von Neumann neighbourhood, but also includes the diagonal cells and it has a radius of one. Extended Moore neighbourhood Composed of the same cells as the Moore neighbourhood but the radius of neighbourhood is increased and it has a radius of two (Alkheder; Batty, 1997; Kiavarz, 2009; Nuno, 2007).
Fig 1. Different type of neighborhoods that use in CA

6 MODEL PARAMETERS IN RELATED TO URBANIZATION TYPES OF GROWTH

A number of parameters must be defined by users before the model starts to run. There are five growth control parameters to be initiated, namely, diffusion coefficient, breed coefficient, spread coefficient, slope resistance, and road gravity. The diffusion coefficient controls the overall stagnancy of growth. The breed coefficient determines how likely a newly generated, detached or road influenced settlement is to begin its own growth cycle. The spread coefficient controls the amount of outward 'organic' expansion. The slope resistance influences the likelihood of settlement extending up steeper slopes. The road gravity encourages new settlements to develop near the transportation network. These parameters must be determined with intensive model calibration in which each coefficient combination needs to be tested individually and the modeled result is compared to historical urban and land use/cover data by using statistical methods. The coefficient combinations resulting in the best overall statistical scores are selected and the final values for these coefficients are then determined.

The urbanization is the sum of the four types of growth: spontaneous, diffusive, organic, and road-influenced. Spontaneous growth, models the development of urban settlements in undeveloped areas. Diffusive growth, permits isolated cells to be locations for new urban spreading centers, but these cells must

pass random tests for the diffusion coefficient and slope suitability. Organic growth promotes the expansion of established urban cells to their surroundings. Only undeveloped cells that have at least two urban neighbors and pass the spread coefficient and slope resistance tests become a new urban location. Last, road influenced growth promotes urbanization along the transportation network because of increased accessibility.

These newly urbanized cells must pass the random tests of breed coefficient, diffusion coefficient, slope resistance, and road gravity. During the urban growth computation, a second level of growth rules, termed self-modification, is invoked if the model's growth rate is larger or smaller than a critical number. In that case, the model will modify certain parameters to emphasize trend. This component is quite important to ensure reasonable results (Clarke, 1998).

7   CA SIMULATION IN TEHRAN CITY

One of study cases about application of CA is urban growth simulation in Tehran (Kiavarz, 2009). In this simulation process of a real city these process have done: data processing, CA algorithm design and implementation and finally evaluated of simulation result.

At data processing step, the data has been used, included three historical satellite images covering period of forty years, the images are geometrically rectified and registered spatially to each other, and then the images are classified to five classes: water, road, urban, green area and non urban area.
Fig 3. Tehran ground truth for 1975

In the implementation of CA algorithm, at the first, the oldest classified image 1975 was selected as an input for CA urban simulation. Ground truth images 1990 was used for training to calibrate the CA rules and growth step while ground truth images of 2001 was used for testing purposes only (because of not accessibility of newer photos). The different scenarios have been defined for CA algorithm. With these scenarios, the pixels of images were updated. Simulated images were compared with truth image 1990 and their precisions were calculated. The best precision scenario was selected for transition rules in a CA; the following scenario had the best fit with truth image of 1990.

Scenario:

1. IF tested pixel under consideration is water, THEN no growth is allowed at this pixel.

2. IF tested pixel under consideration is road, THEN no growth is allowed at this pixel.

3. IF tested pixel under consideration is residential OR commercial (Urban), THEN keep this pixel the same without any change.

4. IF center pixel under consideration is (Green Area) AND there are 3 Urban pixels in the neighborhood, THEN change center pixel to Urban

The achieved precision for CA calibration was acceptable about 88.82 %. The simulation of 2001 were calculated with following scenario, in order to test result, the simulated images for 2001 were compared with ground truth image for 2001; The achieved precision for predicted years 2001 was 85.90 % that it was reasonable.

Table 1, 2 summarizes the urban growth prediction evaluation results based on this scenario for years 1990 and 2001 and Fig. 3, 4 shows Tehran ground truth and CA simulated images based on this scenario.

Region	1990 Ground Truth (urban)	1990 simulated (urban)	error	Precision (%)
Tehran	95616	106301	24955	88.82

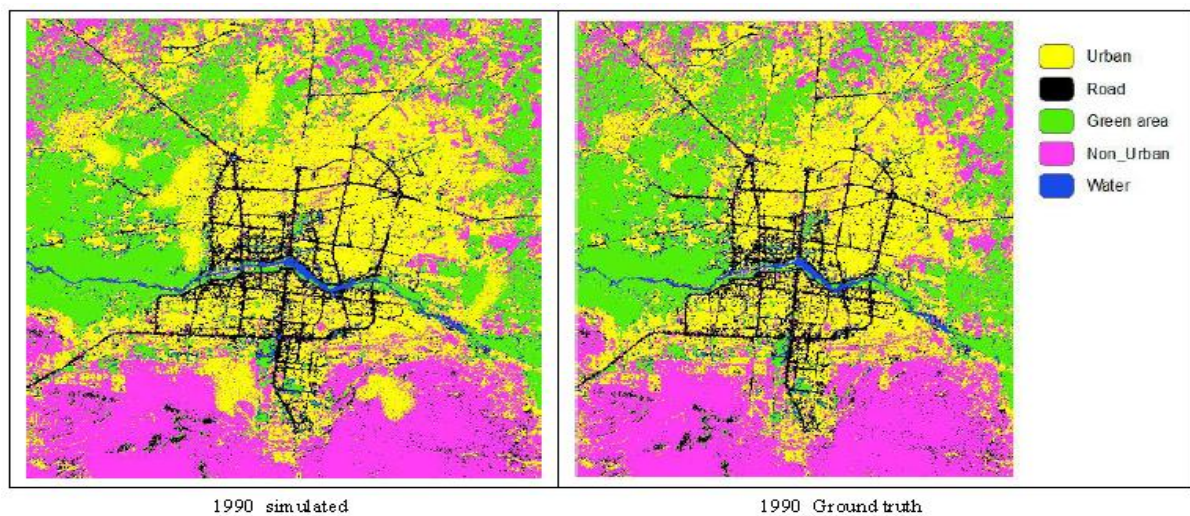
Region	2001 Ground Truth (urban)	2001 simulated (urban)	error	Precision (%)
Tehran	103070	117560	14490	85.90


Fig 3. Tehran ground truth and CA simulated images for 1990
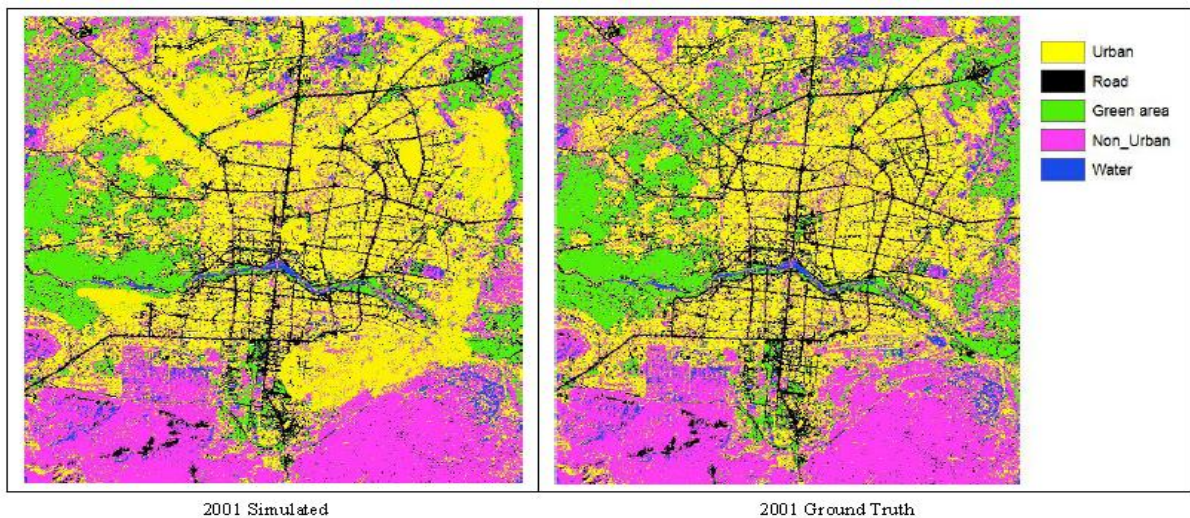

Fig 4. Tehran ground truth and CA simulated images for 2001

So based on the CA simulation strategy we used to predict 2001, future prediction of Tehran urban growth can be simulated (Kiavarz, 2009).

According to The results of simulations by using the scenarios defined during the years 1990 and 2001 which was acceptable and was matched with the fact, simulations for 2016 was done. The following result for the year 2016 is shown in Fig.5.
Fig 5. Tehran CA simulated image for 2016

8 ANALYSING OF CA SIMULATION

Based on the findings of the case study was seen that urban development in Tehran has dispersed and has spread to the West and Northwest, also this result shows that urban growth of Tehran lead to leapfrog discontinuous development. With this development seems to Tehran city are faced with the urban sprawl problem, this problem lead to Over-exploitation of land and the other hand, it made high potential land that is qualified for municipal services remain unused and disabled; while expanding the city limits, agricultural land and gardens are separated and thus a considerable amount of public investment is wasted and the consequence of environmental degradation is a consequence of urban sprawl. In other words, in Tehran city facilities and resources was shifted to around of the city because of lack of vacancy land and the higher cost of land in the central area of Tehran, migrating middle-income people to Tehran city who are not able to take possession of these expensive land and the occupants tendency to have larger land.

With this type of growth that simulated by CA models, urban manager in Tehran are faced to some problems in providing municipal services and facilities, and appropriate equipment to the urban sprawl areas. According to finding of these simulations and problems arising from this kind of urban development (sprawl development), urban management of Tehran ought to conduct facilities and resources to these region.

In order to treat or reduce the negative effects of urban sprawl, it seems necessary to understand to limit this phenomenon. So these strategies in physical and environmental realms offered to reduce or eliminated it (table 3).

physical	Development of public transport networks in order to increase access from urban sprawl region to other place of city and reduce their travel costs. (8th principle of Smart Growth Theory)
	Utilizing mixed land uses in order to allocate balance urban service in the city's area. (the first principle of Smart Growth Theory)
	Increasing access to urban facilities and equipment
Environmental	Preservation of agricultural land in the region to take advantage of green space. (6th principle of Smart Growth theory)
	Applying rules to increase density and control the horizontal spread of the urban and to prevent damage to the environment. (6th principle of Smart Growth theory)
	Creating green spaces for leisure use and equip existing green spaces in the area. (6th principle of Smart Growth theory)
	Prevent fragmentation or change in use of agricultural land to urban uses. (6th principle of Smart Growth theory)

Table 3: strategies in physical and environmental realms based on CA simulation result.

In addition by using simulation can be reviewed trend of development direction in Tehran that based on this can be predict utilities and infrastructure for responding occupant needs. In Tehran as it is extracted from the simulation − aspects of the development are the North and the North West region. Identifying spatial characteristics are necessary in order to plan so by using detailed plan in 2012 in Tehran, SWOT table in 7 realm such land use, Natural disaster, urban Infrastructure, transportation, environment, Social-economic-population, Housing and density These areas are provided (table 4):

Realms	SWOT	Description
Land use	S	Possibility of using appropriate arid land for constructing needed land uses Existence of land uses related to tourism in city
	W	Shortage of facilities and welfare services at resorts area
	O	Tendency to investment in the region and conducting them to tourism, Recreational and Cultural land uses according to Properties of region.
	T	construction without a license and lack of supervising on the construction in marginal zone Changing green spaces land use to residential land use.
Natural disaster	S	Existence of Open Spaces in order to disaster Relief
	W	Non-concurrence of construction with high potential Density of seismic in Tehran High housing density in the region, especially in old buildings
	T	Lack of efficient organization of disaster management in the region (and Tehran) Existence of Tehran North fault, and the threat of earthquake
Urban Infrastructure	S	Implementation of the sewer project in some areas.
	W	Vulnerability due to old water supply pipes due to decay The lack of a modern and extensive network of waste system
Transportation	S	Existence of snag in Transportation network
	W	Not applicable of the detailed plan for transportation network high sloping pathways and pavement performance problems
	O	Extension of metro networks in region
	T	Lack of streets proper servicing
Environment	S	Appropriate environmental and climatic conditions of the region
	W	Offensive to rivers domains Environmental pollution is the release of sewage in rivers and canals
	T	Destroy of gardens and rich vegetation of the area due to construction
Social-economic-population	S	Higher levels of education, profession and income of people living in the region than in Tehran Willingness to residents to participate and collaborate in urban issues
	W	Heterogeneity of social, cultural and economic sectors of the region
	O	Settlement of political, social and economic national and international leaders in the region Willingness to invest in the region because of the economic benefits
	T	High growth rates than the general population in Tehran The overflow of capital into the housing and construction sector in the region in recent years
Housing and density	S	Desired Status indicators density (family in dwelling unit and person in the room) than in Tehran
	W	Existence of high density residential area in the historic core Low-quality housing in the peripheral areas and non-regulated renovation of them high-rise building in inappropriate topography, locations and access to public services
	O	Willingness to renovation according to economic benefits The possibility of regulated revenue during demolition & Renovation of high-rise building in the area
	T	Construction of the residential units in the boundary of faults and watercourse

Table 4: Swot analyses of the new development region based on CA simulation.

By using information extracted from swot which is provided for the future development, some strategies in seven realms to improve the region capacity for dealing with development are presented in the following table (table 5):

9 CONCLUSION

The increasing urban growth through the world has effected over the degradation of our environmental and ecological health. Understanding the dynamics of complex urban systems and evaluating the impact of urban growth upon the environment involve procedures of modeling and simulation, which require robust methodology and techniques. In recent years, dynamic modeling was rapidly gaining popularity among geographers and urban planners as a tool for urban and landscape simulation. Cellular modeling as a popular dynamic modeling method has witnessed much technological advancement in the past ten years, enabling it to grow out of an earlier game-like simulator and evolve into a promising tool for the exploration of complex

urban systems. These predictions can be help to the Tehran urban management to prepare urban development plan such as detailed plan and structural plan. Hence urban planner can decide more appropriate decision based on the results of such predictions for land use planning for the future development of land in these areas.

Realms	Strategies
Land use	Suit distribution of urban land uses and their special spaces
Natural disaster	Attention To capacity of the land, especially in vulnerability and disaster issues
Urban Infrastructure	Synchronization of urban infrastructure in related to increase of the population
Transportation	Prioritize to public transportation
Environment	Maintain and enhance structural and functional sustainability through restoration and completion of the green spaces network
	Improve and develop green spaces with recreational and Renovation environmental quality
Social-economic-population	Prioritize to land uses in related to public facilities and services
	Synchronization of urban services in related to increase of the population
Housing and density	preventing illegal constructions in the area
	Controlling the construction and building density in the area

Table 5: strategies of the new development region based on CA simulation.

As in the study was shown by using CA simulation, Tehran growth was reviewed and analyzed. Based on finding of reviewing growth, was determined that Tehran growth trend is likelihood to urban sprawl; so in order to reduce or eliminate this phenomena some strategies was presented in physical and environmental in two realms . It should be noted that these strategies is according to the principles of smart growth strategies that is a one of important strategies for reduci ng or eliminating effects of urban sprawl . In addition by this simulation can be predicted development aspect s in Tehran and based on some preparation was recognized for dealing with such development in process of spatial planning in Tehran. However, it is considered urban and regional planner should not rely on these simulations and all their planning is based on them, but these models can be used as a tool to assist better decision-making, because urbanization and urban development is a multi-dimensional phenomena, thus was not considered on physical realm, and also it is necessary to attend social, economic, environmental dimensions for planning.

Approach to Spatial Data Infrastructure Development for Spatial Planning in Serbia

Ljiljana Živković

(Ljiljana Živković, PhD, MBA, Republic Agency for Spatial Planning, Kralja Milutina 10a, Belgrade, Serbia, liliana.zivkovic@gmail.com)

1 ABSTRACT

Spatial data infrastructure (SDI) represents a socio-tehnical concept that aims to create a context for cooperation and exchange of data and information between a certain spatial data community's stakeholders. Thus, the aim of SDI concept development is to establish a common and spatially supported platform of organized information needed for making right decisions relevant for economic progress, good governance and sustainable development in general within a certain domain or jurisdiction. Today, the majority of launched SDI initiatives are on the national level that is by some authors identified as the crucial one for evolution of this concept in general. Additionally, recent research has proven that SDI developments have become prevailingly social phenomena since interactions between community stakeholders appeared to be critical for achieving purpose of SDI concept and vision in general.

Recent socio-economic issues in Serbia and existing practice in domain of spatial planning have proven strong need for new, systematic approach and efficient mechanisms towards sustainable development of its territory. In a narrow sense, this systematic approach should include clear responsibilities and participation among spatial planning stakeholders within spatial development monitoring and evaluation process and identification of sustainable development alternatives, where the whole process should be supported by appropriate GIS-based information platform. On the other side, this new approach along information platform should support consequently mechanisms and tools for efficient and continual sustainable development alternatives and decision-making on resources and existing capacities development in Serbia. Finally, in a broader sense, this new system should provide basis for realistic and sustainable spatial development policy definition and, along it, conditions for its optimal implementation strategy identification.

Therefore, recent activities in the Republic Agency for Spatial Planning (RASP) have been oriented towards building basic database model for projected information system that would be followed up by spatial planning SDI in future. This latter should become platform for efficient and effective communication and coordination among spatial planning SDI stakeholders in Serbia. However, it would be also expected to provide input for translation of spatial data and information into knowledge that support continuous, informed and timely sustainable decisions making and development alternatives creation and management employing planning support systems (PSS) and decision support systems (DSS) technologies.

Thus, aim of this article is to propose an appropriate approach, i.e. model for spatial planning SDI development in Serbia based on present database model and its development concept, as well as to describe recent activities on the same and discuss expectations for PSSs and DSSs.

2 INTRODUCTION

The well-known Bruntal Report's definition of sustainable development assumes development that meets present generation needs without jeopardizing capabilities of future generations to satisfy their own needs as well. This means that sustainable development encompasses sustainable management of all three main spatial systems, namely social, economic and environmental/ecological ones, as well as their relationships. Besides spatial dimension, sustainable development definition above assumes, also, dynamic dimension of those three systems. This includes need for monitoring of three systems and their relationships through time, i.e. during generations, and collecting and storage of information series on systems' statuses as well as taken management actions. (Shcherbina et al, 2010; Feeney et al, 2001)

Today sustainable development presents dominant governance approach to resources management. Thus, modern societies are build different information and communication management capacities –namely, tools, instruments, models, etc.- for spatial development status monitoring and evaluation, on one side, and for making sustainable development decisions, policies and strategies based on dynamic relationships among social, economic and environmental phenomena, on the other. (Williamson et al, 2006) Therefore, it could be claimed that data and information have critical role for management towards sustainable development goals

achievement: economic progress, good governance and environmental responsibility. (Shcherbina et al, 2010)

On the other side, data and information and their organization is main focus of the SDI paradigm, which is a part of Al Gore's (1998) Digital Earth (DE) vision of „a multi-resolution and three-dimensional presentation that…enable discovering, visualisation and true understanding of an enormous quantity of geo-referenced data and information about social phenomena and environment on our planet". (Craglia et al, 2008) After 15 years of DE vision launching, SDI concept today is developing and evolving its paradigm within different domains and levels of public sector, both in developed and developing countries, where national level is found to be of critical importance for SDI paradigm development in general. (Rajabifard et al, 2000) From the early development, SDI concept was considered as prevailingly public policy analysts' tool, needed for informing different public policies and sustainable development decision-making, and which was generally implemented by legal mechanisms. (Craglia et al, 2008) However, some recent analysis has decline SDI firstly claimed decision-making functionality (Feeney et al, 2001), and instead they positioned SDI as important facilitation tool, i.e. supporting information platform for various models and infrastructures for professional judgment, like PSSs, and policies decision-making, like DSSs.

In domain of spatial planning in Serbia today notable efforts are investing in building GIS-based tool that would a) support identification, planning and monitoring of sustainable development alternatives; and b) provide platform for making informed decisions, strategies and policies that would contribute to sustainable development scenario achievement. (Živković, 2012) Clearly, this tool in future should include implementation of PSS and DSS solutions adapted to spatial planning system and its jurisdiction's needs in Serbia. However, since both PPS and DSS functionalities and usefulness depend on available data and information quality and quantity, spatial planning SDI and its integrability and interoperability would be thus of crucial importance for future sustainable decision-making and development in Serbia in general. In other words, this implies that spatial planning SDI would have significant effects on emerging PSS and DSS infrastructures in Serbia, and that tackling of different technical and non-technical SDI implementing issues today could have direct impact on sustainable spatial development decisions and actions in future.

Therefore, this article aims to identify and propose SDI development approach or model that would be appropriate for spatial planning system establishment in Serbia. First, basic introduction to SDI paradigm and its development and evolution are going to be presented. After that, in Chapter 4, new methodological approach to sustainable spatial development in Serbia will be explained, and general description and objectives of initial model for spatial planning database (SPACE) and information platform (ISSPace) will be identified. In following Chapter 5 model for SDI development for spatial planning domain in Serbia is going to be proposed, along general assumptions on how proposed model would reflect on latter PSS and DSS technologies implementation.

3 SPATIAL DATA INRASTRUCTURE

3.1 SDI: Definition, components, structure, national SDI and development models

The SDI concept is usually defined as a set of policies, technologies and standards necessary for efficient collection, management, access, exchange and usage of geospatial data and knowledge within geospatial data communities –consisting of stakeholders, that is, users and producers- on global, regional, national and local levels. (Rajabifard et al, 2002) Therefore, SDI is usually described as a constellation of five basic components and their relations: people, access networks, policies, standards, and data. (Rajabifard et al, 2001; Mohammadi et al, 2008)

Since the first initiatives were launched, relationships between SDI components have been changing. (Craglia et al, 2008) At the beginning, the focus of SDI concept development was on creation of concrete products and/or services within single jurisdiction. Later, relationships between people, i.e. social component and data component have become critical for the SDI concept development in general. Therefore, today the focus of SDI development is on management of different stakeholders' rights, restrictions and responsibilities against data through the different cross-jurisdictional partnerships. (Feeney et al, 2001; Rajabifard and Williamson, 2002)

Thus, the originally dominant short-term product-based approach to SDI development, oriented towards content building, has been later complemented and dominanted by a process-based approach to

establishment of communication conduit that needs to secure long-term commitment of all SDI stakeholders to collaborate and exchange data between included jurisdictions. (Rajabifard and Williamson, 2002)

A) Product-based model

B) Process-based model
Figure 1: Approaches to SDI development. Product- and process- based models for SDI development (Rajabifard et al, 2002)

Adoption of either one of two SDI development approaches depends directly on a mandate that particular jurisdiction needs to establish. (Feeney et al, 2001) However, it is also possible to implement a composite product-process approach that secures advantages of both models, making thus development and evolution of particular jurisdiction more flexible as a whole. This is due to the initial raising of social commitment to SDI concept building, securing a common leadership and trust necessary for data sharing.
Figure 2: SDI spatial pyramid. SDI global hierarchical structure is the result of different mandates of the SDIs' jurisdictions on different levels, as well as within the same level (adapted: Rajabifard et al. 2002).

According to Rajabifard et al (2000), SDI components on national level have the greatest and direct impacts on development of the same components on the other levels in SDI spatial hierarchy, i.e. pyramid, national SDI initiatives have been identified to posses decisive role for the development of the global SDI concept in general. (Rajabifard et al. 2000) However, Carrera and Ferreira (2007), Nedović-Budić et al (2007) and Živković (2012,b) claim that future of SDI should confirmed and highlight significance of local and regional GIS-based information platforms, i.e. municipal and regional SDIs, for producing fine-grained and up-dated (re)usable spatial data and information in and for public, private and non-profite sectors. Also, these authors claim that this would be the most efficient and effective way of developing, maintaining and integrating national datasets in future.

Latest development and fast spreading of different Geo-Web services and Web applications in general, point to a vision of SDI development in future as an infrastructure or network of infrastructures build up of loosley coupled Web-GIS systems, which would be shared within a different hierarchical levels (vertically) and

areas (horizontally). (Carrera and Ferreira, 2007; Mohammadi et al, 2008) However, in order for promised advantages of information infrastructures, i.e. smooth flow and easy exchange of data via Geo-Web services through integration of distributed local/regional GIS/SDI to be achieved, number of technical and non-technical issues should be implemented today by social component of SDI. This fact confirms critical role of social component and social character of SDI paradigm development in general, which is already stressed at the beginning of this article.

Technical issues	Non-technical issues			
	Institutional issues	Policy issues	Legal issues	Social issues
– Computational heterogeneity (inconsistent standards) – Poor/no metadata – Format – Semantic heterogeneity – Data Quality – Reference system and scale	– Inconsistent collaboration models – Differences in funding models – Lack of linkage between data management units – Lack of awareness of data integration needs	– Lack of awareness of data existence – Lack of legislation – Political stability – Inconsistency in policy drivers and priorities (sustainable development)	– Rights, restrictions and responsibilities to be defined – Copyright and IPR differences – Difference in data access and privacy – Licensing	– Cultural issues – different background of stakeholders – Capacity building – weak activities – Equity

Table 1: SDI implementation issues. Technical and non-technical issues associated with spatial data integrability and interoperability (Mohammadi et al, 2008; Williamson et al, 2006)

3.2 Spatial planning infrastructure and planning and decision support systems infrastructure

Sustainable development requires continual and integrated consideration and analysis of social, environmental and economic issues, as well as their evaluation and prioritization against current and planned land uses in order for potential development conflicts among those three systems to be minimized. (Feeney et al, 2001) Therefore, planning of sustainable development alternatives and making decisions adjusted to sustainable development strategies and policies require technologies with capabilities for modelling and handling complex spatio-temporal phenomena, like PSS and DSS combined with GIS advantages. (Shcherbina et al, 2010; Boerboom, under review)

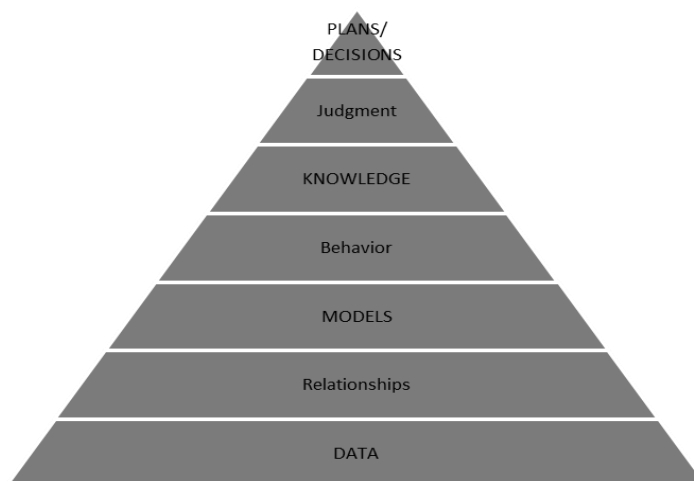
Since both PSS and DSS outputs' quality highly depend on available data and information, both Feeney et al (2001) and Boerboom (under review) have identified reliable SDIs, meaning fully integrable and interoperable, as critical for collecting and storing of needed data on environmental, economic and social rights, responsibilities and restrictions. This means that SDI in future should provide comprehensive spatial and non-spatial data sets, and thus facilitate and optimize utilisation of different planning (PSS) and decision-making (DSS) technologies.


Figure 3: PSS and DSS. Value of data is increasing to judgement and decisions, where DBs and SDIs contribute with organized data on economic, social and environmental elements, their relationships and related rigths, responsibilities and restrictions (Boerboom, under review)

Finally, Boerboom (under review) goes even further claiming that in near future focus would be on development of spatial planning and decision support systems infrastructure (SPDSS-I) concept. This paradigm should emerge from loosely coupling of different PSSs and DSSs systems in infrastructures that would be relying on comprehensive and reliable spatial planning SDIs. And, unlike the spatial planning SDI general purpose to exchange data, SPDSS-I purpose would be exchange of relevant spatial planning knowledge and judgement. Thus, supporting the online creation and exchange of knowledge and judgement, SPDSS-I keeps a promise of creating conditions for transforming today spatial development planning and management procedures into continual real time process of sustainability status monitoring and evaluation in future.

4 SPATIAL PLANNING IN SERBIA

4.1 New approach to spatial planning and development implementation

Number, dynamics and complexity of prolonged transitional economy events within the territory of the Republic of Serbia require today different approach to their management, in order for sustainable character of spatial development to be preserved or (re)gained in future. Therefore, the latest Law on planning and construction (Law) (Official Gazette of the Republic of Serbia 72/09, 81/09, 64/10, 24/11), along the current Spatial Plan of the Republic of Serbia 2010-2020 (SPRS) and its Implementation programme for 2011-2015 (2011), have prescribed new approach, methodology for spatial development planning and, especially, implementation. This new methodology includes:

- Organizational model for early involvement, and continual, clear and direct responsibilities of relevant spatial development stakeholders in Serbia for identification and implementation of development alternatives, namely strategic priorities or projects (SP). These stakeholders would be also members of Serbian spatial planning SDI community in future; and

- System of social, economic and environmental spatial development indicators (DI) for territorial development status monitoring and evaluation. This system of DIs interrelated with SPs should form information platform for revision of existing and preparation of new spatial plans and other planning documents in Serbia.

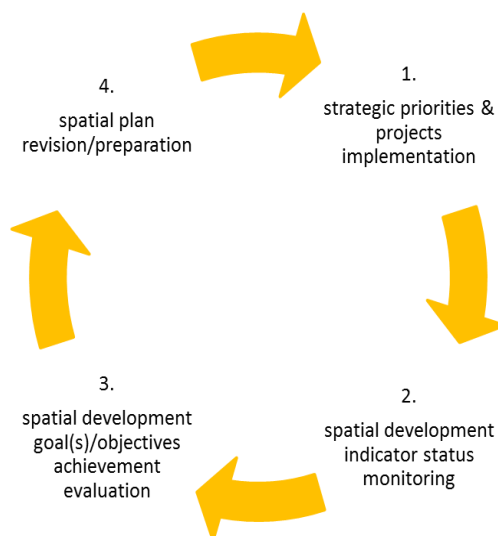
Basic hypothesis behind applied methodology assumes that implementation of identified SPs should affect DIs' values, i.e. statuses, and thus generate or trigger planned development and identified sustainability goals achievement within certain territory. (Figure 5) Also, planned time framework for SPs implementation should be monitored, since the absence or presence of planned results and/or expected development progress should impose changes and/or adjustments of development alternatives both in sectoral as well as spatial plans and programmes in return. (Živković, 2012c)


Figure 4: Territorial monitoring and evaluation concept. Integration of spatial planning cycle with territorial monitoring and evaluation elements, DIs and SPs, for spatial development implementation and planned goals achievement

4.2 Information platform for spatial planning

In accordance with the mentioned Law, within a year after SPRS was enacted, the Republic Agency for Spatial Planning (RASP) has prepared its (SPRS) first (ever) Implementation Programme for period 2011-2015. (2011) Besides porposing the action plan for monitoring and evaluation of SPRS implementation using DIs and SPs, as well as recommendations for annual report preparation, Implementation Programme has described general concept and framework for establishment of information platform for spatial planning activities in Serbia.

Thus, this first Implementation Programme has identified aim, objectives and preconditions for establishment of spatial planning information platform to be modern GIS-based tool that would simultaneously (Živković, 2012a):

- Provide monitoring functionality for spatial plans and other planning documents implementation in jurisdiction of RASP in order to support revision and preparation of new spatial plans and planning documents; and

- Support data and information collection needed to RASP to annually monitore and evaluate spatial development status in Republic, and to communicate it to the Government and public in form of report now and in future on-line via Web portal using shared Web services.

Aim	Objectives	Preconditions
Simple and efficient management of data and information needed for making timely and informed decisions and policies for balanced and sustainable development of socio-economic-environmetal resources within the Republic of Serbia territory	- Build instrument to support preparation, adjustment, monitoring, evaluation and revision of spatial plans and other planning documents; - Implement standards into domain of planned sustainable development, in respect to applied technologiess as well as content of plans and planning documents; - Create preconditions for simulation and scenario methodologies implementation, as well as for automatization of other methods and techniques needed to spatial and urban planners; - Support creation of policies for planned development and sustainable management in Serbia; and - Develop capacity of spatial planning system, that is, its institutional and organizational frameworks, and especially human resources.	**Technical framework** - standards ISO/TC 211, OGC, W3C and others; - recommendations of INSPIRE Directive and Programme, Plan4all Project; - Serbian NSDI 'GeoSrbija' recommendations; - standards of sectoral ISs in Serbia; **Organisational and institutional framework** Development of appropriate institutional and organizational framework for ISSpace by implementing internationally and nationally adopted documents and best practices, as well as by development of local solutions, which would together contirbute to more efficient operation and management of spatial planning system in Serbia **Significant financial means** **Educated and skilled human resources**

Table 2: Towards comprehensive information platform for spatial planning in Serbia. Aim, objectives and preconditions for establishment of SPACE database and ISSPace (Živković, 2012a)

4.3 Information system for sustainable spatial development, phased approach

As a first step towards spatial planning SDI establishment in Serbia, RASP has planned in the mentioned Implementation Programme to firstly establish GIS-supported information system for spatial planning, ISSPace with database SPACE.

Due to the Serbian Government aspirations to join EU, both social and technical components of ISSPace and latter SDI would be accommodated to the needs and demands of INSPIRE, as European multinational SDI initiative.

Structures and elements of SPACE and ISPPace are planned to be scalable, flexible and adjusted to future smooth data and information usage and exchange between same or similar systems and infrastructures in Serbia and Europe (following INSPIRE Directive and Plan4all recommendations), and wider (through implementation of ISO and other internationally adopted technical standards). Also, recommendations of Serbian NSDI initiative GeoSrbija would be included. (http://www.geosrbija.rs; Živković, 2012b)

Database SPACE itself is projected to record and store, in the first phase, three basic types of data and information for spatial development planning: 1) plans' and datasets' metadata, 2) spatial planning data (including DIs and SPs) and 3) sectoral data. Metadata package (blue coloured box) would support development of spatial plans and planning documents register in Serbia and, thus, their identification and fitness for use assessment using basic information, like name and type of plan or document, its scope and scale, lineage information, responsible organization, reference dates, etc. Planning data package (yellow coloured box) would provide administrative information for each type of plan and planning documents in Serbia, as well as store contents for national, regional, special purpose area as well as municipal spatial plans, with capabilities for urban plans' content to be added latter as well. Besides administrative information and planning content, this package would also provide data on MEGAs and functional urban areas (according to ESPON definition), as well as store definitions and status values for relevant DIs and SPs within monitoring and evaluation module. Finally, sectoral data packages (grey coloured boxes) needed for some SPs implementation follow-up as well as for revision and/or new spatial plans and other planning documents preparation, would be stored in 23 separate packages. And, once the relevant sectoral ISs would be established, data from these 23 packages would be gradually substitute, that is, (re)used via certain Geo-Web services that would be shared within ISSPace and, latter, spatial planning SDI environment as well. This should be seen as second phase of ISSPace development.

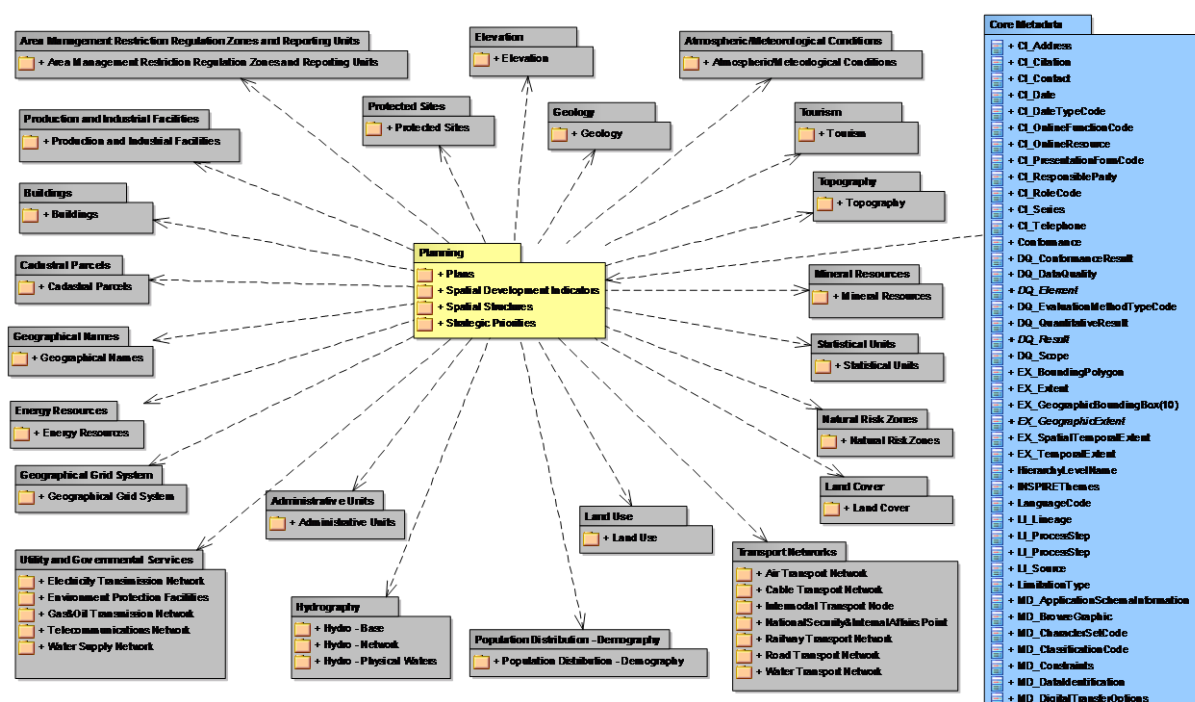
Finally, the same approach is assumed for the other lower-than-national planning level and their data: once regional and municipal ISs and SDIs for planning would be established, plans and planning documents data would be (re)used and exchanged between those hierarchically coupled shared GIS systems and infrastructures via different Geo-Web services.


Figure 5: Basis for spatial planning SDI development. SPACE database structure (adapted: Implementation Programme of the SPRS 2011-2015)

In order for described planned technological supports and their advantages to take place in future, and for successful establishment of ISSPace and database SPACE in the first place, standardisation of the spatial plans'contents and other planning documents in Serbia has been identified as a critical initial precondition. These standards would ensure simple exchange and use of data and information stored within the other for spatial planning relevant information infrastructures, systems and databases, securing thus timely and informed approach to spatial development planning in Serbia in future. But, on the side of social component, for planned IS establishment and latter emerging SDI advantages development, improved capacity of human resources would be of key importance. (Živković, 2012a)

In addition, establishment of ISSPace and latter spatial planning SDI would support conditions for real-time continuity in monitoring and evaluation of spatial resources status and development trends in Serbia, and

thus transform set of today's discrete spatial planning procedures into process of planned and sustainable management of socio-economic and environmental capacities in the Republic.

5 APPROACH TO SPATIAL PLANNING SDI DEVELOPMENT IN SERBIA

5.1 Spatial planning SDI development model

Developing countries, like Serbia, are facing today the challenge to institute the SDI concept faster, more efficient and at lower cost. (Williamson, 2004) Therefore, spatial planning domain in Serbia should consider solutions and experiences found to be best practices in SDI establishment, and follow those lessons learnt in spatial planning SDI implementation.

Today in Serbia there is a general lack of fundamental and other datasets, and awareness and knowledge on SDI concept is generally low. (Nedović-Budić et al, 2007; Živković, 2012a, 2012b) Also, installed base and general infrastructure, both treated today as conditions for SDI paradigm establishment, are still in development in Serbia. (Nedović-Budić et al, 2007) Therefore, spatial planning domain should adopt approach that would facilitate simultaneous and coordinated development of all 5 basic SDI components (people, data, policies, standards and access networks) almost from scratch.

Therefore, spatial planning SDI initiative in Serbia should follow today favoured composite product-process development approach. This means that spatial planners in Serbia should initially focus their efforts on establishment of appropriate SDI community (people component), on one side, and establishment of communication channels needed for relevant knowledge dissemination and capacity building among stakeholders, which is prerequisite for development of other SDI components (like, data, policies, standards, access network), on the other (Figure 1.). This approach is, also, in line with and confirms today prevailing opinion on SDI paradigm as social phenomenon.

Additionally, framework for spatial planning SDI components and concept development in general in Serbia should include newly adopted systematic/methodological approach to spatial plans and other planning documents preparation and implementation; also, this framework must be outlined around expected functionalities as well as identified development aim, objectives, preconditions and content of database SPACE and ISSPace system (Table 2.). By this approach, development framework for spatial planning SDI would support both building necessary organizational and human resources' capacities for SDI, as well as solid socio-technical preconditions establishment for its consequent upgrading with DSS and PSS functionalities once SDI is established.

In other words, from proposed composite development approach perspective, spatial planning SDI community in Serbia should be initiated and evolve around those spatial development stakeholders' that are already involved within the spatial planning cycle. Consequently, relying on this initial SDI community, first communication channels for SDI development process-approach should be initiated around its database SPACE module for territorial development monitoring and evaluation (conceptualized in Figure 4.), and latter diversified following expected database SPACE and ISSPace functionalities, benefits and needed conditions and capacities acquisition (Table 2.). Finally, SDI development product-approach should be employed within different work groups that would be established around communication channels and composed of various spatial planning SDI stakeholders to produce particular product/service for mutually agreed non-technical and technical standards (Table 1.). Besides these tasks, some of those work groups would be working on establishment of preconditions for spatial planning SDI further enhancement by employment of DSS and PSS technologies for making knowledge, judgements and decisions on sustainable development alternatives and policies.

Finally, having the seeds of information society and NSDI still in the ground in Serbia (Nedović-Budić et al, 2007), and following principle of the national level SDI's components greatest impact on the other SDI levels' components within the spatial pyramid (Figure 2.), where regional and municipal spatial planning SDIs are yet expected to play significant role, RASP should take leadership role now and prepare preconditions for optimal Serbian spatial planning SDI pyramid evolution in future. Concretely, RASP should provide directions for domination of process-based development model on national –i.e. Republic-, regional and municipal levels, where product-based development model should dominate among various work-groups established within each of those levels and SDI initiatives with aim to develop particular

contents, like legal and technical standards framework, access and exchange policies preparation and maintenance, and other SDI and latter PSS/DSS -relevant conditions, products and/or services.

5.2 Approach to SDI development and its implication for spatial development decision-making and policy management in future

Previous attempts to use SDIs for making decisions or creating policies and strategies have failed. (Feeney et al, 2001; Boerboom, under review) Since SDI main role is to organize spatial and non-spatial data, making of sustainable development decisions and definition of relevant policies and strategies in Serbia would require PSS and DSS tools to be implemented. However, the question is how proposed composite product-process approach to spatial planning SDI development in Serbia would reflect on utilisation of planning and decision-making technologies, as well as ultimate concept of SPDSS-I? Even being too early for exact predictions and impacts estimation, some assumptions on this issue are proposed in next lines.

Since PSSs and DSSs outputs' quality highly depend on available data and information, that is, on underlying SDIs' capacities to store and exchange various environmental, economic and social data, which are usually coming from different sources, proposed composite approach should have at least two advantages for building decision- and policy- making capacities in Serbia in future.

The first generally assumed advantage of proposed composite model refers to its dominant process-based approach and prioritization of spatial planning SDI community and communication components building. This means opportunity to involve knowledge workers and other experts -responsible for PSS and DSS tools development- among SDI stakeholders' community for the very beginning of concept development. Using their knowledge and expertise, these SDI stakeholders could immediately impact and optimize database SPACE, ISSPace and future spatial planning SDI solutions for PSS and DSS technologies implementation, and avoid thus maybe some future expenses for platform adaption. Also, as a second generally assumed advantage of proposed composite SDI development model for spatial planning domain in Serbia, where process-based approach dominante, knowledge workers and experts could -along the other work groups that perform on product-based approach- establish their own groups that would work on upgrading of mentioned SPACE's territorial monitoring and evaluation module from the beginning. On this way, they could further enhance preconditions for creating added values of prospective sustainable development models, simulations, PSS and DSS employment towards creating knowledge for right decision-making on development alternatives as well as forming judgement for policies and strategies creation (Figure 3.).

Finally, since predicted SPDSS-I concept assumes exchange of knowledge and judgement between PSS and DSS infrastructures, proposed composite development approach for spatial planning SDI in Serbia seems for time being to be irrelevant for the same.

6 CONCLUSION WITH DISCUSSION

Sustainability has become today leading governance principle for creating judgement and decision-making on spatial development alternatives. Thus, since sustainable development concept includes all 3 major spatial systems, namely environmental, economic and social, as well as their complex and dynamic spatio-temporal relations, modern societies are investing significant efforts in building tools to understand, predict and manage them.

On one side, sustainable development principles implementation assumes collection, processing, management, usage and exchange of significant number of various spatial and related data in an organized way, what is the actually purpose of SDI paradigm. On the other side, avoidance or minimization of conflicts among environment, economic and social systems for sustainability development character preservation, requires employment of different spatio-temporal modelling, decision and knowledge creation tools, like PSSs and DSSs technologies are. These tools have advantages to support mutlicriteria spatial analysis as well as dynamics of real-time development events, both features underlying sustainable development today.

Following need to develop further living and working conditions in Serbia, spatial planning domain works on establishment of information platform that should in short-run support systematic monitoring of planned development alternatives implementation, on one side, and evaluat their effects on identified sustainable development goals, on the other side. This first GIS-oriented solution for ISSPace with database SPACE as core should provide in the long-run basis for establishment of spatial planning SDI in Serbia by using today

favoured composite product-process development approach. This approach is suitable for Serbian still developing socio-technical and data capacities, since it provides advantage of overcoming locally existing development deficiencies by building strong human resources claimed to be of critical importance for building SDI concept today.

Also, relying on flexibility of composite SDI development model, which stresses importance of communication, facilitation, coordination and capacity building, this model seems generally more appropriate for establishment of fully interoperable and integrable spatial planning SDI, as prerequisite for latter optimal employment of PSS and DSS technologies' advantages. On the other side, pure product-based or process-based approach to spatial planning SDI development in Serbia would limit in the former case its future options to employment either PSS or DSS for single development purpose, while in the latter case employment of PSS and DSS would be restricted to mere exchange of knowledge and discussion of potentials rather than having some exact applications or results.

1 ABSTRACT

Security and reduction of vulnerability of the city, as a place of conflict, disorder and terrorism have been considered by various countries since the past up to now. In this regard, the militarization of urban spaces is not always an effective option in establishing security firstly because of high costs of security establishment and then revelation of the strategic spaces. Nowadays, planners have started to think more creatively about how they can hide security behind planning and design features.

With emphasis on passive defense concept all around the world, defining new spatial logics and including related policies in urban spatial development plans have been cited in planning agenda. The importance of Tehran metropolitan area, as political and economic capital due to accumulation of power, population, activities and wealth, has made application of passive defense policies necessary. So the goal of this research is to assess impact of interventions resulting from application of principles and policies of passive defense on Tehran metropolis spatial logic and to formulate appropriate framework of spatial development policy making for vulnerability reduction.

2 PREFACE

In the present preface, necessity for dealing with research issue is elaborated and history of research in the world and Iran is explained and goal and method of research are mentioned in order to achieve the goal.

2.1 Elaborating Role of Urban Spatial Structure of City in Reduction of Vulnerability and Increase of Security

Subject of security and reduction of vulnerability of city (as place of conflict, crime, disorder and terrorism) and continuation of development in different military and nonmilitary methods have been considered by different countries in the world since the past. In this regard, militarization of urban spaces is not regarded as a suitable option for establishing security due to necessity for establishing balance between costs and benefits of security and revelation of strategic spaces. This subject led the planners to think about other unobservable methods of security establishment in covering features of planning and design. Unobservable methods male cities more beautiful and convert them to more pleasant places for spending leisure time while realizing goal of establishing security (Briggs, 2005). In this regard, importance of passive defense is regarded as the third layer of response to threat.

2.2 Elaborating History of Passive Defense Principles Application

Idea of passive defense is regarded as important element in thought of strategic planning of America and other threatened countries (Pedatzur, 2007). Passive defense is defined as set of actions which and seek to limit damages resulting from war, improve capabilities of space in order to protect life of the citizens and minimize life losses resulting from war without any need for application of military equipments and firearms and only based on planning of urban spatial structure from two perspectives of form and function (Lacina, 2006). Goal of application of passive defense is to increase continuation of vital operations and activities and to give service to vital, critical and important centers at time of threat and crisis. Now, the planners have found that the built environments and form of the city play important role in increase of urban security (Liesette, Frances & William, 2001). Elaboration of this relation has led the researchers and professionals of different disciplines to search for suitable forms of urban places of residence for establishing sustainability and urban security (Jabareen,?). This effort can be manifested in emergence of defensible Space (DS) theory[1] as well as effort to study role of counter-terrorism policies in internal form and structure of metropolises in order to achieve more sustainable urban form especially after event of 11 September

---

[1] Defensible Space (DS) theory of Oscar Newman –urban architect and planner –includes thoughts about prevention of crime and establishment of security in urban districts which was extended in early 1970s and a book was written about it in 1972.

(Marcuse, 2002) not only in New York but also in most developed countries in the world. In Iran, passive defense principles have been considered in design of spatial structure of cities since the past up to now. Spatial structure of material city including a central powerful core with impenetrable strengths, construction of Persian city affected by defensive strategies of Achaemenid Empire in strategic and border points, circular structure of Parthian cities for establishing enough security in Parthian lands which are subject to internal and external insurrections, attention of the Sassanid to selection of a place for establishing city using factors or natural barrier for making access to city difficult, defensive elements of city in Islamic periods including castle, bulwark, and trench, centrality of Feudal castles and fortifications in Safavid period all are indicative of importance of defense in Ira since the past up to now(Mir Ahmadi and Yadegar Zendeh, 2011).

2.3 Explaining Goal and Method of Research

Governing conditions of global society, hostility of the western autocratic states and USA and Israeli against Iran as well as special position of the land in critical zone of Persian Gulf and Middle East made defensive preparedness necessary in all fields. In modern wars, goal of the enemy is to remove strategic centers and activities not people and in gravity center destruction strategy which is known as Five Strategic Rings of Warden,[2] the attacked country is regarded as an organic system and the most important duty in war planning is to identify gravity center of the attacked countries (Movahedi Nia, 2007). Centralization of five strategic rings in Tehran as the political and economic capital of Iran necessitates importance of this metropolitan area due to accumulation of power, population, activity and evident wealth and application of passive defense policies for reducing vulnerability. In this regard, goal of the present research is to evaluate effect of policies and principles execution interventions on spatial logic of Tehran metropolis and formulate suitable spatial development policy making framework in order to reduce its vulnerability. In order to achieve the mentioned goal, the selected process and method applied in each stage include the following steps:

- Elaborating passive defense principles and criteria by archival study and history of this field
  - Identifying and understanding effects of application of passive defense principles and criteria on urban spatial structure generally /deducing spatial representation of principles and criteria of passive defense.
  - Recognizing the status quo of Tehran metropolis based on circumstances of passive defense
- Measuring vulnerability of spatial structure of Tehran metropolis by adapting elements of urban spatial structure to spatial representation of passive defense principles and criteria
- Formulating suitable spatial development policy making framework and presenting vulnerability reduction strategies.

3 IDENTIFYING AND UNDERSTANDING EFFECTS OF PASSIVE DEFENSE PRINCIPLES AND CRITERIA APPLICATION ON URBAN SPATIAL STRUCTURE GENERALLY/ DEDUCING SPATIAL REPRESENTATION OF PRINCIPLES AND CRITERIA OF PASSIVE DEFENSE

It was mentioned before than urban spatial structure plays important role in reduction of vulnerability and increase of security and sustainability of the city against potential attacks. One of the key branches which plays major role in completion of passive defense goals is use of spatial development planning (Maleki and Brandkam, 2011). In this regard, different countries have included new spatial logics in agencies of urban spatial development agendas in order to achieve security and sustainability based on subjects of passive

---

[2] In theory of Five Strategic Rings of Warden which was mentioned by an American retired colonel in 1988, gravity centers of a country were regarded as organs of a body which will be crippled in case of destruction of each part of the country and will not be able to continue working. These gravity centers can be classified as five strategic rings : the first ring –national leadership includes political leadership, main centers of political and military decision making (ministries, command post , telecommunication , Broadcasting Organization) as brain and neural system of the country , the second ring –key precuts including power plants , raw material production heavy industries and centers, military equipment production industries , water supply network etc as digestion and blood flow system , the third ring as communication infrastructures including airports , railway , roads and bridges as motor organs , the fourth ring –the public and the fifth ring –operational forces as defensive cells.

defense. Determination of special spatial logic in Iran resulting from execution of passive defense policies requires the following steps:

- Identifying passive defense principles and criteria.

- Explaining elements of urban spatial structure.

- deducing representation of passive defense principles and criteria in elements of urban spatial structure.

3.1 Identifying passive defense principles and criteria

Achieving goal of sustainability and reducing vulnerability of city from the viewpoint of passive defense subjects first require identification of passive defense principles and criteria which are related to urban spatial structure.[3] These principles are studied in some general classes including camouflage, concealment & cover, deception, separation, dispersion, multi-functionality of urban elements and access (Movahedi Nia, 2007).

Principle of camouflage

The main factors which facilitate identification of a strategic goal include form, shadow, texture &shine. Therefore, making texture and form of installations, equipments and forces equal to the surrounding environment makes identification difficult (Movahedi Nia, 2007). Concealment means utilization of equipments and methods for concealing, homogenizing, transforming and simulating, creating deceptive goals and deleting regular geometrical shape in order to prevent the detectors and sensors of enemy from discovering and identifying forces, equipments, installations and activities (Maleki and Zarifi, 2011). Methods of concealment are different in lifestyle of the system (Ghanbari, 2011) and (Movahedi Nia, 2005 and 2007):

- Surface treatments which are applied for design of new systems and along with them are a part of the performed camouflage on goal and a part of system design and are accompanied by it and there is no need for any action of military forces for applying it. The systems which are in the first stages of design have the best conditions for adopting surface treatments strategies. Geometrical forming is one of the most important methods of surface treatments which is achieved with the following criteria (table 1);

Remarks	index	Criterion
The larger the cross section the more the radiant radar energy toward the reflected signal place and the easier the identification of goal	Downsizing and reducing radar cross section	Target dimensions control
-	Low height	
Preventing application of electrically conductive surfaces such as metals and glasses with radar reflection, flat surfaces and surfaces with perpendicular sides prevent scattering of radar waves.	Radar waves scattering and deleting radiations of systems against sensor	Target form
-	Considering target less important (face transformation)	
Showing large goal as some small goals /dispersion		
It means separation or transformation of building, prevention of equal repetition of buildings and construction of uniform buildings because order is a sign of manmade objects and disorder is a sign of nature.	Creating failure and deletion of geometrical regular forms and reduction of other signs	
Homogenization is made possible by similarity to the surrounding environment.	Homogenization with environment	

Table 1: strategies of geometrical forming as one of the surface treatments methods

- Add – On Camouflage is used for the systems which have existed before. This is done by two kinds of substance:

---

[3] One of the principles of passive defense in different texts is principle of hardening the vital structures which has not been mentioned in this research due to the absence of representation in urban spatial structure.

- o Natural substances of camouflage include plants and soil (plant vegetation) : green space causes to reduce vision and enemy identification and attack factors and adjust explosion wave and vulnerability (Saeedi and Iran Doost, 2011).
- o Synthetic substances of camouflage include artificial and semi-natural supplements, isogam and sound and electromagnetic insulation .

Principle of concealment

Concealment means being hidden from the vision of enemy and is a location based on passive defense of which basis is correct settlement in natural and built environments. Concealment methods include (Movahedi Nia, 2005) and (Boozari, 2009):

- Use of morphologic factor for making the target buries or semi-buried; it will be easily possible to identify installations in extensive plains and zones without geographic feature because they lack passive defense considerations (unsuitability of zones without natural reliefs for establishment of equipments, construction of installations and construction of shelters and safe places). Therefore, this will be possible by using natural valleys and earth cracks inside the internal tunnels, grooves, in shelter of highlands, natural reliefs and   hiding surfaces difference. In passive defense considerations especially in concealment or secretiveness, it is common to use fault cliffs and fault valleys because these structures prevent from targeting equipments. For example, in Korea, museums have been constructed inside the mountains in order to protect cultural monuments. In European countries, serious efforts have been made to hide infrastructural installations such as power plants.
- Creating visual barriers and concealing them in natural and built shades as factor of light reflection reduction and difficulty of tracking.

Principle of deception

Identification of strategic goal difficult. Theory of deception is based on the fact that vital part of the set should be transferred to another part or appropriated to open space (Hashemi Fesharaki and Araghi Zadeh, 2011).

 Principle of separation and prevention of vital systems interdependence

Separation of the vital systems from each other guarantees survival of city in case of failure of its part. This is possible by parallelizing and predicting the alternative systems (Movahedi Nia, 2007).

Principle of dispersion

Among principles of passive defense, dispersion is more related to urban spatial structure. Dispersion of important urban activities in this field has two main applications (Mir Ahmadi and Yadegar Zadeh, 2011):

- Reducing ability of enemy to recognize, target and penetrate into key, important and critical points at critical times; abundance and dispersion of urban centers cause to use more defensive forces.
- Guaranteeing survival of city in case of failure of its part due to dispersion of urban elements and infrastructures ; in old Iran,   of the defensive strategies for reducing vulnerability are dispersion of services by creating servicing hierarchy in district, regional and urban scale and self sufficiency of the districts.
- Multi-functionality of urban elements

Creation of dual purpose structures which can have defensive function in addition to ordinary function is one of the principles of passive defense. By making dual purpose structures, construction cost of public shelters will be saved and shelters will not be deserted (Movahedi Nia, 2007). Of the strategies used for this purpose in different countries are use of urban subway as public shelter[4] and development of green and open spaces which help conceal the region in addition to role of shelter at critical times.

Principle of access and penetrability

---

[4] Shelter is the place which is more secure against different effects of weapons on ordinary buildings or open space (Movahedi Nia, 2005).

Transportation networks should be designed and reinforced such that it is possible for the public to exit and have access to relief in emergency.

3.2 Explaining elements of urban spatial structure

Organizing the urban spatial structure based on principles and strategies of passive defense in order to reduce vulnerability and increase sustainability is very important in issues of urban planning. Access to sustainable spatial structure requires identification of different elements of urban spatial structure. In this research, the studied elements of urban spatial structure were identified as follows:

- urban spatial development pattern

- spatial dispersion and layout of urban elements in the entire set (principles of strategies performances)

- juxtaposition and combination of different urban activities and performances (use of space, compatibly and proximity)

- accumulation, population density and activity at one place

- relationship between elements and performances (condition of communication network)

- space morphological subjects

- Organizing the urban spatial structure based on principles of passive defense requires identification of effects of passive defense principles and criteria on elements of urban spatial structure.

3.3 deducing spatial representation of passive defense principles and criteria in elements of urban spatial structure

Deducing spatial representation of passive defense principles and criteria is the final step in formulation of spatial logic of urban development based on defensive considerations. In this regard, effort is made to search for spatial representation of each passive defense principle in urban spatial structure which comprises of elements elaborated in the previous chapter. Result of the performed search is shown in table 2. This table is also regarded as a framework for measuring vulnerability of spatial structure of Tehran metropolis from the viewpoint of passive defense principles and criteria by giving arbitration tools.

4 MEASURING VULNERABILITY OF SPATIAL STRUCTURE OF TEHRAN METROPOLIS BASED ON CIRCUMSTANCES OF PASSIVE DEFENSE

Measuring vulnerability of spatial structure of Tehran metropolis in the first step requires identification of status quo of Tehran metropolis based on circumstances and principles of passive defense. At the end, conformity of urban spatial structure with spatial representation of passive defense principles and criteria which was explained in table 3 indicates vulnerability of spatial structure of Tehran metropolis.

4.1 Measuring Vulnerability Of Tehran metropolis based on principle of camouflage

Generally, Tehran metropolis with only 2 % of buildings with more than 9 stories and average compaction of two stories is the shortest capital in the world. However, Tehran city recently has seen construction of long building without planning and without observance of many passive defense requirements especially for vital and important governmental and public activities which has converted high rise building to an element contrary to sustainable development in urban development. Although it is cost effective to construct distinguished high buildings in globalization era and due to expensiveness of land in large cities, this case is not justifiable in the militarily threatened cities (Briggs, 2005). Generally, most of the governmental and public buildings in Tehran are relatively higher than their surrounding environment and this makes the target more important and facilitates its identification. One of the other weaknesses of Tehran metropolis is to expand large public and governmental buildings. National Iranian Library with approximate area of 9.7 hectares which has been constructed on hill in addition to its large scale is one of these examples. Another example is Tehran Mosalla complex located in southern side of Abbas Abad lands, although expansion of green space of Abbas Abad lands around these spaces is a potential for camouflaging them(figure 1).

Figure 1: a view of National Iranian Library building (derived from Google Earth software)

Use of uniform repetition of buildings (construction of uniform buildings) is one of the other subjects studied in this field. Residential and modern and future high buildings beside Evin Hotel (figure 2) and Ekbatan Residential Complex as the fourth Strategic Rings are of these class. Construction of spaces with geometrical and regular shapes facilitates identification of target from the surrounding environment.

Figure 2: a view of future buildings (derived from Google Earth software)

In morphological terms, weakness of Tehran metropolis is expansion of use of glass and aluminum view of office and governmental buildings due to easy installation and low cost price and this facilitates scattering of radar waves and identification of target. The known glass building of Ministry of Agricultural Jihad located in Keshavarz Blvd. as one of the first strategic rings and building of Bank Markazi (figure 3) have this feature.

Figure 3: a view of Bank Markazi building

Morphological subjects	Accumulation and density of population and activity in one place	Juxtaposition and combination of different activities and performances	spatial layout and scattering of performances in the complex (principles of strategic performances settlement)	Urban spatial development pattern	Index	Criterion	Principle
• Preventing expansion of vital and critical large-scale centers • Small grading of uses	• Determining optimal scale of population settlement and activity in space • Reducing the price and downsizing residential units	-	-	-	Downsizing and reducing radar cross section	Target dimensions control	Surface treatment / camouflage
-	• Preventing high rise building of vital and important installations			• Emphasis on urban sprawl	Low height		
• Preventing application of electrically conductive surfaces such as metals and glasses with radar reflection in view of strategic buildings, • Preventing application of flat surfaces or the surfaces with perpendicular sides	-	-	-	-	Radar waves scattering and deleting radiations of systems against sensor	Target form	
• equality and harmony of form of relief and environment	-	-	-	-	Considering target less important (face transformation)		
• preventing uniform repetition of buildings and construction of uniform buildings	-	-	-	-	Creating failure and deletion of geometrical regular forms and reduction of other signs		
-	-	-	-	-	Homogenization with environment		
-	-	-	• layout of critical and vital activities in green space	-	Add - On Camouflage		
• Preventing construction of symbols, signs and indexing		• Separation of vita activities from signs such as installations,main communication networks	• Preventing layout of important structures in large plains and zones without relief • Settlement of important activities in tunnels, grooves, highlands, natural reliefs	• Making structure of city uniform with the surrounding areas and making determination of urban border difficult	Concealment		
• Necessity for avoiding difference of physical organization of vital activities of the surrounding texture	• Reinforcing surrounding residential places of large cities as deception and delay barriers	-	-	• Decentralizing and accepting polycentric development	Deception		

	spatial representation of passive defense principles and criteria in urban spatial structure				assive defense principles and criteria		
	elements of urban spatial structure						
Morphological subjects	Accumulation and density of population and activity in one place	Juxtaposition and combination of different activities and performances	spatial layout and scattering of performances in the complex (principles of strategic performances settlement)	Urban spatial development pattern	Index	Criterion	Principle
-	• Reducing interdependence of different districts by establishing required services in the district (districts independence potential) • Preventing population increase and emphasis on dispersion approach	• Establishment of compatible uses in space • Relative separation of business centers from residential centers • Farness from hazardous production centers	• Creating hierarchical structure and centrality (district, local and regional centrality) of urban services	• Focus on suburban sprawl pattern; • Avoiding application of linear development pattern and disruption of relationship between different parts of the city			separation
-	• Decentralizing and transferring strategic centers to urban suburbs and appropriation of Central Business Districts to less strategically important activities • Reducing charismas of central and critical business districts for establishing residential texture and encouraging to transfer them to suburbs of cities • Necessity of uses distribution in urban structure such that it prevents centralization in gravity points of the city.	-	• Creating servicing hierarchy with emphasis on neighborhood units patterns				_Dispersion
-	• Increasing open space in the entire surface of residential sections as the factor increasing efficiency of the texture at time of accident	• Making dual -purpose public spaces for building shelters • Building common tunnel of underground installations	-				Dual purposes of space /multifunctional urban elements

	spatial representation of passive defense principles and criteria in urban spatial structure				assive defense principles and criteria		
	elements of urban spatial structure						
Morphological subjects	Accumulation and density of population and activity in one place	Juxtaposition and combination of different activities and performances	spatial layout and scattering of performances in the complex (principles of strategic performances settlement)	Urban spatial development pattern	Index	Criterion	Principle
• Increasing the barren and green lands and plant vegetation in city • City fortification	• Closeness of collective spaces to open spaces with low confinement • Urban density distribution in resistant and accessible districts	• Closeness to green and open environments, therapeutic and hospitals centers, firefighting centers and police stations for establishing security • Farness of residential centers from fuel tanks, military bases, the desired targets of enemy including management and governmental centers	• The presence of suitable and homogenous communication network by creating a network of equivalent ways relating to other districts of the city • Establishing vital activities in main communication routes • Hierarchical structure of communication network and limiting easy access to residential places	• Preventing acceptance of galaxy development pattern5 • Accepting chess development instead of organic development in design of communication network • Increasing entrances and exits of the city			Access and penetrability

Table 2: spatial representation of passive defense principles and criteria in urban spatial structure –writer

[5] Galaxy development is defined as development between expanded and centralized city in open and relatively small units and density is maximal in centers. In this kind of development, penetration into the city is easily done due to abundant open and green spaces between urban knots

In addition to these weaknesses, one of the weaknesses of spatial structure of this metropolis is development of city with average density of two stories.

4.2 Measuring Vulnerability of Tehran Metropolis based on Principle of Concealment

Attribution of bleak city to Tehran as 700-cubic km capital of Iran with all disadvantages from the viewpoint of city development management and planning has some advantages from the defensive viewpoint. Tehran is attached to Shemiranat and Rey under the best condition but a more careful look shows this urban giant geographically in touch with adjacent cities, estate and counties. Robat Karim, Eslam Shahr and Shahre Ghods have been separated from Tehran only with streets and highways which indicate a part of this borderless metropolis. Recently established Alborz Province is adjacent to Tehran only with a short road and border of Tehran metropolis is not easily distinguished from the surrounding districts.

One of the weaknesses of Tehran relating to principle of concealment is widespread tendency to indexing and construction of symbols and signs (figure 4). After attack of twin high buildings in 11 September, it seems that skyscrapers have lost their attraction in developed countries because terrorist is aware of power symbols (Briggs, 2005).

Figure 4: tendency to indexing in Tehran metropolis (derived from Google Earth software))

Layout of important and vital installations in large plains without relief is one of the other weaknesses of Tehran metropolis in this field. In this regard, one can refer to location of Milad telecommunication tower or Bagher Shahr power plant in southern plains of Tehran.

4.3 Measuring Vulnerability of Tehran Metropolis Based On Principle of Deception

Tehran as capital is highly vulnerable as industrial –administrative pole of the country due to centralization of main industries and ministries and important administrative centers. On the other hand, major economic activities of the city are located in its central zone.[5] Generally, contemporary spatial structure of Tehran can be typologically imagined in "centralistic, single centric and dispersed radial "framework (figure 5). In recent decades, centralistic trends have led to intensification of single centric system of Tehran city. This trend led to more domination of main center of Tehran which is slipping and creeping toward north (Boom Sazgan Consulting Engineers, 2006). While there is principle of being outstanding in central development pattern which facilitates recognition of strategic business centers due to the growth pole. Therefore, one should transfer the complex to another part using theory of deception or appropriate it to open space (Hashemi Fesharaki and Araghi Zadeh, 2011).

Figure 5: centralization of the most important urban settlement centers in northern-southern axis direction (Boom Sazegan Consulting Engineers, 2006, Tehran master plan)

---

[5] Central zone is defined as distance between Valiasr , South Karegar Streets and Shahid Rajaei Highway from the west and Shariati , 17 Shahrivar and Shahrzad Streets from the east.

Another issue in this regard is economic, administrative and servicing weakness of the surrounding residential places around Tehran and their use as barriers makes deception and delay impossible. However, abundance of equal urban centers makes enemy's deception possible.

4.4 Measuring Vulnerability of Tehran Metropolis Based on Principle of Separation

Chaotic mixture of critical business centers in residential textures and zones is one of the weaknesses of spatial structure of Tehran metropolis. In this field, several cases are explained:

- Preventing observance of industries and residential texture proximity (industrial zone of district 21, industrial zone of eastern District 4, business centers around Khavaran Road etc).

- Proximity of political activities of the country such as Beit Rahbari and parliament to residential texture

- Proximity of Milad therapeutic center as one of the largest therapeutic centers of the country to Milad Telecommunication tower which makes its identification easier.

- Location of military region in east and its proximity to residential texture.

- Location of gas stations to residential zones.

- Location of power plants such as Bagher Shahr adjacent to residential texture.

- Others

Of the other weaknesses of Tehran metropolis are location of business-service centers on arterial axes generally and expansion of the most important business centers in national scale across main northern-southern axis because linear development doesn't cause to enjoy districts independence potential though which other parts continue functioning in case of failure of one part and efficiency of the dependent performances is reduced in case of failure of some main axis of the city. This will be aggravated by continuation of radial structure of Tehran metropolis. Other challenging issues in principle of separation in Tehran metropolis are interdependence of different districts despite history of self sufficient districts and failure to observe minimal safe distance between the residential buildings.

4.5 Measuring Vulnerability of Tehran Metropolis Based On Principle of Dispersion

Dispersion of important urban activities causes increase of security and sustainability of city despite increase of servicing costs due to reduction of enemy's ability to recognize, target and penetrate into important points, necessity of use of more defensive force due to abundance and dispersion of urban cities and guarantee of survival of city in case one part fails. Galaxy development and urban sprawl patterns are preferred over other urban physical development patterns. Centralistic spatial structure of Tehran city is vulnerable from this viewpoint.

4.6 Measuring Vulnerability of Tehran Metropolis Based On Principle of Multifunctional Urban Elements

One of the defensive strategies applied in old Iran in order to reduce vulnerability of city is the presence of multifunctional urban elements such as aqueduct which has played role of shelter as underground communication way between districts in addition to its main role at time of enemy attack. Hosseinies played role as district defense centers at any place at critical times (Mir Ahmadi and Yadgar Zadeh, 2011). In other parts of the world, Russians take action regarding creation of the required shelter as masters of passive defense and multipurpose designers of spaces redundancy when length of metro lines increases. Safe Swiss Metro with suitable depth, Pyongyang dual-purpose Metro in North Korea with depth of 90-105 m are the good examples (Maleki and Zarifi, 2011). Of the weaknesses of Tehran metropolis are insufficient coverage of metro lines and avoidance of its settlement in suitable depth for playing role of shelter (figure 6).

Figure 6-the present and future rail lined of Tehran city (Boom Sazgan Consulting Engineers, 2006).

One of the other strategies in this field is use of open and green space in the city (figure 7) which is not available in Tehran metropolis.

Figure 7: layout of large-scale green space among Moscow urban texture

4.7 Measuring Vulnerability of Tehran Metropolis Based on Principle of Access and Penetrability

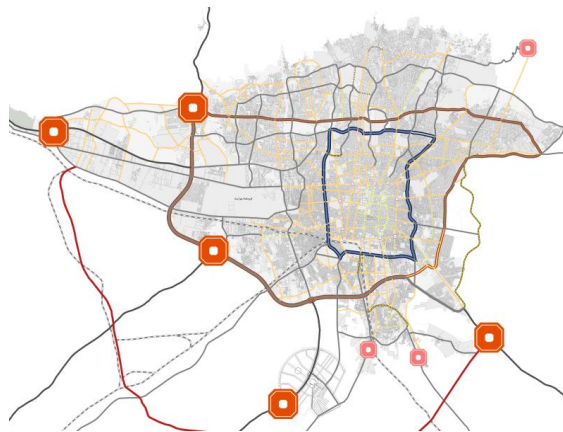
Incomplete communication network and especially Tehran metropolis highway network and discontinuous performance of the network, unsuitable access in some parts of the city especially the decays as well as important business centers of the city make servicing difficult at time of threat. Of the other weaknesses of spatial structure of Tehran metropolis is layout of high buildings in low penetrable regions. Establishment of the most important business centers across main arteries facilitates access and relief despite some disadvantages. Abundance of entrances and exits of Tehran metropolis is one of the strengths which allow the population to immediately exit (figure 8).


Figure 8: dispersion of exits and entrances of Tehran metropolis (Boom Sazan Consulting Engineers, 2006)

5 FORMULATING SUITABLE SPATIAL DEVELOPMENT POLICYMAKING FRAMEWORK AND PRESENTING VULNERABILITY REDUCTION WAYS

Result of the performed studies, vulnerability of spatial structure of Tehran metropolis is summarized in table 3. The hachured cells indicate vulnerability grounds and grey cells indicate sustainability grounds.

Spatial representation of defensive principles and criteria in spatial structure					Passive defense principles and criteria		
Elements of urban spatial structure							
Morphological issues	Accumulation and density of population and activity	Juxtaposition of activities and performances	Layout and distribution of performances in complex	Urban spatial development patterns	Index	Criterion	Principle
					Downsizing and reducing radar cross section	Target dimensions control	Surface treatment / camouflage
					Low height		
					Radar waves scattering and deleting radiations of systems against sensor	Target form	
					Considering target less important (face transformation)		
					Creating failure and deletion of geometrical regular forms and reduction of other signs		
					Homogenization with environment		
					Add - On Camouflage		
					Concealment		
					Deception		
					separation		
					Dispersion		
					Dual purposes of space /multifunctional urban elements		
					Access and penetrability		
Sustainable	Vulnerable	Without proof			Table guide		

Table 3: measuring vulnerability of spatial structure of Tehran metropolis based on defensive circumstances-writer

High vulnerability of Tehran metropolis to threats clarifies necessity of formulating suitable policymaking framework . In this regard, vulnerability reduction strategies have been suggested in each one of the studied axes:

- Strategies of fulfilling principle of camouflage
  - Constructing vital underground centers and installations; in Sweden, power generation, fuel reserves and necessary procurement centers have been laid out in the underground (Maleki and Zarifi, 2011).

- Strategies of fulfilling principle of concealment
  - Using river five northern –southern valleys of Tehran city in order to decentralize nonresidential performances in zone of northern –southern continuous axes and using their privacies as protective green space; in wrinkled regions , erosive performance of synclines causes formation of broad valleys or confirmed plains of which abundance facilitates dealing with principle of dispersion in passive defense(Boozari, 2009).
  - Preventing construction of symbols, signs and indexing –using few high symbols

- Strategies of fulfilling principle of deception
  - Accepting urban dispersal strategies, Tehran center refinery and promoting its functional level and quality for cultural, touristic and recreational performances; in Tehran, most of large enterprises are governmental and strategy of decentralization and transfer of important centers to suburb districts and appropriation of central spaces to the activities which are of less strategic importance (such as coffee shops and galleries) is the best strategy.
  - Reinforcing polycentric pattern and equivalent urban centers in urban spatial structure by prioritizing equipment of peri-urban centers of Tehran and new satellite towns and

transferring administrative and political centers to peri-urban centers ; concurrently with start of Tehran Regulatory Plan enacted in 1991, chaotic condition of Tehran led some authorities to think about transfer of capital and some studies started in this field resulting in long time (15 to 25 years) and heavy expenses of transfer which dissuaded the authorities to do so(Boom Sazgan Consulting Engineers, 2006). Now, policy of transferring administrative capital to Parand seems to be a suitable strategy in this regard.

o Accepting decentralizing patterns in spatial structure of Tehran metropolis; among different urban development patterns, centralistic forms due to easy identification and failure of main functions of city are the most vulnerable and on the contrary, decentralist forms are the least vulnerable due to difficult identification of business centers (Mir Ahmadi and Yadegar Zadeh, 2011).

- Strategies of fulfilling principle of separation

    o Emphasis on neighborhood units approach and independency and self sufficiency of districts

    o Relative separation of business centers from residential zones and observance of compatibility principle in layout of activities and prevention of creation of hazardous installations in public centers and transfer of these installations to outside the city

    o Observance of minimal distance between residential buildings and coverage of open space by green land use

- Strategies of fulfilling principle of dispersion

    o Emphasis on urban sprawl pattern ; less density of population reduces vulnerability and increases attack cost(Ebrahimi, Mobin Rahni, 2010), though increase of density will not be effective on vulnerability dependent on place(Saeidi and Iran Doost, 2011). Authorities of this field believe that recent terroristic attacks on urban centers of America facilitate urban scattering toward the margin such that this country will see intensive increase of life rate around the city and decentralization of business centers (Ziegler, 2005). Suitable scattering of masses by changing to polycentric, multiplex and network[6] development patterns; polycentric systems are more sustainable due to variety because there is substitute for it in case of failure of one of these centers (Marcuse, 2002).

    o Refining the present business zones and expanding fields of activity in domain of Tehran city and peri-urban development; edge cities form the future spatial development pattern due to benefits of passive defense (Ziegler, 2005). Tehran will be forced to move toward a regional multi-centered business environment in order to fulfill principle of sustainability and security. In this way, more independent vital enterprises in urban centers which have internalized large part of their external benefits move toward less dense urban fringes and the activities which are not dependent on communication media and modern transportation technologies remain in center. After 11 September, many main enterprises in New York possessed large satellite departments in urban fringes (Marcuse, 2002).

- Strategies of fulfilling principle of multifunctional urban elements

    o Increasing flexibility, variety and efficiency of urban spaces

    o Increasing length and depth of metro lines and equipping it as shelter, including shelter for a city with population of 4000 and area of 600,000 cubic meters and one can construct 150-km tunnel in underground depth which is accessible to the public. By designing safe

---

[6] Typologically, this structural change can be regarded as movement toward network pattern. In this pattern, hierarchy is not only regarded as key and critical concept but also attempt is made to give any part of city identity by distributing centrality and density in large scale and by covering the metropolis resulting in its special and suitable performance without it is regarded less important or more important than other parts. Therefore, abundance of the related, complementary and distributed centers in the city level, formation of abundant functional and physical barriers, varied and balanced transportation system and finally functional and multilayer balance can be regarded as main features of network spatial structure.

REAL CORP

multipurpose structures such as metro, underground shops, construction cost of public shelters will be saved and shelters will not be deserted (Movahedi Nia, 2005).

- Strategies of fulfilling principle of access and penetrability

    o Observing hierarchy in structure of residential place and communication network ; in the past, observance of hierarchy of access, organic structure and narrow passageways, dense urban texture have made penetration of immigrants impossible (Mir Ahmadi and Yadegar Zadeh, 2011).

    o Reinforcing transportation network based on astral and radial patterns in order to facilitate exit of the population.

    o Layout of squares and local gathering spaces in urban texture with rapid accessibility to residents; proximity of collective spaces to open spaces with low confinement reduces resistance of space against war injuries (Saeidi and Iran Doost, 2011).

    o Fortification of city and public places: public places should be less public and their free access and use should be limited. Instead, controlled spaces such as large shops have increased their attraction in this regard (Marcuse, 2002).

    o Easy access to business centers by arranging activities as abundant and integrated centers.

    o Attention to principle of easy access in location of high buildings.

(Mag.FH Mag. Peter Sittler, Institute of Real Estate, University of Applied Sciences Vienna, Währinger Gürtel 97, 1180 Vienna, peter@sittler.at)

1 ABSTRACT

Our research focuses on the appliance of real estate applications (RE-apps) especially on the unchartered topic of the use of augmented reality (AR) and in special cases for virtual reality (VR) in the field of real estate. Apps are small programmes on smartphones and tablets. These apps will be classified by their usage for a modern city. A sub-classification is made for the ability of AR functions.

Augmented reality means that the reality of the camera is enhanced with additional information through GPS and compass information, data from external knowledgebases, social media networks or real estate search engines. So a value for the user could be created that turns the real and the virtual objects in a multi-dimensional relationship to each another.

The paper analyses the usage und functionalities of the offered real estate applications concerning architecture, buildings, refurbishment and housing renewal. First results have been shown at the Pacific RIM Real Estate Society (PRRES) conference 2012 in Adelaide, Australia.

The work is based on extensive literature research providing a methodical comparison of applications available. Based on the results, the project covers the structural, technological and user related factors that facilitate or impede dissemination of AR-apps. As a result it is given a smart overview of the existing AR- and VR-applications and the market potential for real estate with a visionary conclusion of expected future developments.

2 INTRODUCTION

Apps are small programmes on smartphones or tablets which are characterized by simple usage and a flat training curve in usage in a short life cycle. They are often cheap products, created for consumers and distributed via virtual markets. (LANG; SITTLER 2011, p. 1) But technically seen apps are no new phaenomenon. (MAYER 2012, p. 13)

Though the worldwide sales of mobile phones to end users have reached a peak with 428 million units in the third quarter of 2012, this means a 3 percent decline from the third quarter of 2011. But the smartphone sales increased by nearly 47 percent. (GARTNER 2012a) Additionally the use of Non-Computer devices like smartphones and tablets increases rapidly. (COMSCORE 2012, p. 50) In this enviroment it is not surprising that an older whitepaper points out that mobile applications are achieving unprecedented download levels driven by the success of the Apple App Store. So the opportunities for mobile applications with AR are strongly increasing. (JUNIPER RESEARCH 2009, p. 1)

We began our research in 2010 with apps for finding property via smartphones. We early noticed that several categories of apps can be used in the field of real estate. (LANG; SITTLER 2011, p. 3) Further on we additionally classified the real estate apps by their usage of augmented reality (AR) functions. (LANG; SITTLER 2012a, p. 4). In addition to this paper some of the apps changed and many new came into range.

"Augmented reality (AR) is a term for a live direct or an indirect view of a physical, real world enviroment whose elements are augmented by computer-generated sensory input, such as sound or graphics." (KENT 2011, p. 1)

Following the definition of AZUMA (1997) an AR system has to fulfill following three requirements:

(1) Combines real and virtual

(2) Interactive in real time

(3) Registered in 3-D

According to the Milgram continuum of reality and virtuality AR is one of the possible states of mixed reality (MR), which begins with the real enviroment and is continously enhanced by additional data and external information. So as it can be seen in Fig. 1 AR is the picture of the real world enhanced eg. with data

of the Pisa tower. AR is based on the real world with a limited set of virtual objects mixed in. When only the virtual reality is enhanced with some real views it is called augmented virtuality (AV). It is pointed out that the virtuality continuum juxtaposes AR and AV (WAGNER 2007, p. 2) While AR shows the real world, AV shows a virtual reality based on a computer-generated world. The boundary between AR and AV is not strictly defined. (LANG; SITTLER 2012a, p. 2)
Fig. 1: Milgram continuum of reality and virtuality (SIEGLER; WIETZEL 2009, p. 90)

3 FIELDS OF AUGMENTED REALITY APPS FOR REAL ESTATE

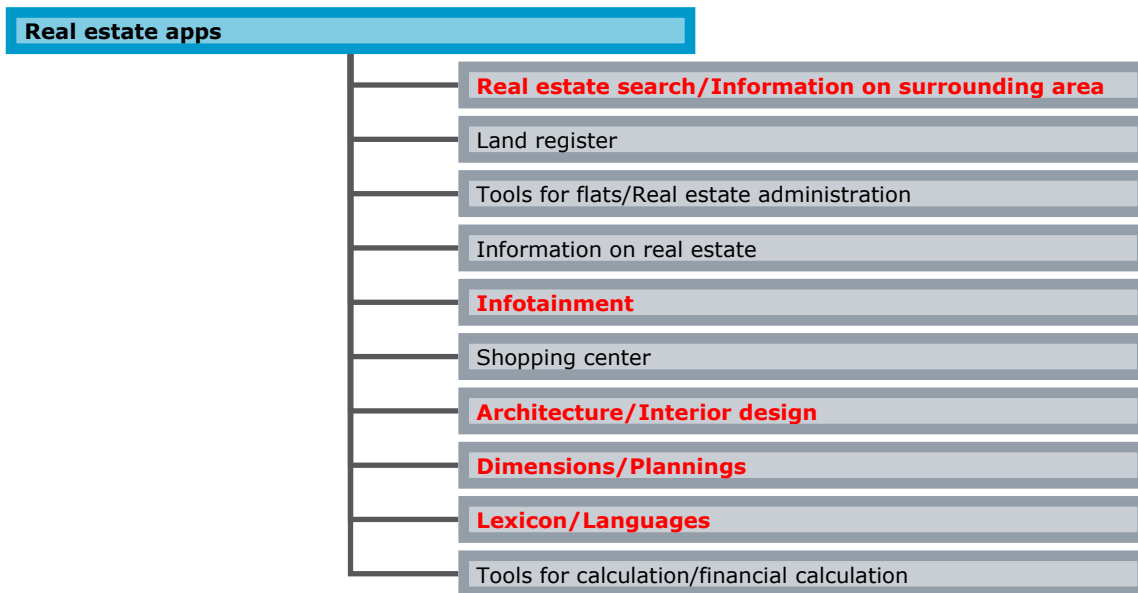
The real estate sector even noticed that the development of apps is an important criteron of marketing for the customer. In early times AR-apps for the iPad have not been developed due to the lack of camera in the first generation. (CARMIGNIANI; FURTH 2011, p. 36) Only a few companies offer RE-apps. The number of AR-apps is even smaller. We pointed out that there is only few literature concerning AR in the field of real estate.There can be additionally mentioned (ALLBACH; MEMMEL; ZEILE; STREICH 2011), (GAWLITTA 2012), (KIPPER; RAMPOLLA 2013, p. 16) and (MEHLER-BICHER; REISS; STEIGER 2011).


Fig. 2: Classification of the real estate apps (LANG; SITTLER 2012b, p. 5)

We made an extensive internet and literature research to find some apps in several publications, but AR applications for real estate are only partially mentioned. A whitepaper concerning several business models of AR describes the AR search of property regarding the app of the German real estate search engine Immonet. (JÁNSZKY; SCHILDHAUER 2010, p. 26) The search of property is the best known and most distributed AR application in the field of real estate. Additionally MEHLER-BICHER; REISS; STEIGER (2011) try to classify the fields of applications of AR with education, presentation/visualization, collaboration, configuration/simulation and navigation/orientation. (MEHLER-BICHER; REISS; STEIGER 2011, pp. 73

77) It is often seen that in the literature real estate applications are mixed with architecture and other fields of applications. But real estate seems to be an enormous factor for the economy, so several fields are concerned. (LANG; SITTLER 2012a, p. 3)

We made a classification with the several fields of applications that are concerned with RE-apps with a sub-classification for the ability of augmented reality (AR) functions (in bold red). (LANG; SITTLER 2012b, p. 5)

The AR applications are a subset of RE-apps. As a field of research we collected a number of RE-apps for smartphones. This applications are mostly focused on the Austrian market, but some of them are international while there are no apps concerning a digital city (JAEKEL; BRONNERT 2013, pp. 35-63). (LANG; SITTLER 2012a, p. 4)

4 AR-APPS FOR REAL ESTATE

The following individual areas of applications are shown with examples and discussed with respect to AR-apps for real estate.

4.1 Real estate search/Information on surrounding area

We made a research on the main searching-apps in the field of real estate in the German speaking region and noticed that the first application was the app of www.immobilien.net, which took back their app from the Apple iTunes store meanwhile. So only the German RE-app www.immonet.de offers an AR-search through an own RE-app. (MAYER 2012, p. 13) The main reason why immobilien.net gave up their AR strategy was that the amount of findable objects within the app was very small, while flats could only be exact positioned when full data of the object is registered by the real estate agents. This is a problem in Austria, because only 10 % of all real estate on offer are currently geo-coded. In practice (even without AR) geo-coded objects that display full address information are 40 % shorter on the market. (LANG; SITTLER 2011, pp. 5-6)

In order to show how the app was running there are some screenshots shown below in Fig. 3.
Fig. 3: Real estate search application Immobilien.net (LANG; SITTLER 2012a, p. 5)
Fig. 4: RE/MAX real estate search with Layar, Wikitude and Junaio

Another field of application for AR-apps in the city is information on surrounding areas. The main apps are Layar, Wikitude and Junaio which show information on the surrounding offices, restaurants, educational infrastructure, etc. on the screen of the smartphone or tablet. The mentioned apps are partly described in AR-

literature: Layar (MADDEN 2011, pp. 36-39), Wikitude (KENT 2011, pp. 41-42), Junaio (KENT 2011, p. 37).

There are some real estate agents which use layers to show their property with an AR functionality. In Austria the company RE/MAX[1] uses the apps Layar, Wikitude and Junaio for this purpose.

4.2 Infotainment

A wide range of smartphone concerns entertainment and infotainment to prospective customers. In the field of real estate the Australian Commonwealth Bank uses AR in their app. The aim of this app was to show non technical users how to use AR functionalities for their AR-search app. With this app you use a marker to start the real estate market in the virtual city Cherryford Hill. A virtual person named Paul explains with voice guidance terms, transactions and purchase prices. (BROUGHALL 2011)

Fig. 5: CommBank 3D Reader

4.3 Architecture/Interior design

Another extensive use of RE-apps is architecture and interior design. In the last years there are aditionally several applications that use AR. Some of the first experiments were made by the company Ikea. (MEHLER-BICHER; REISS; STEIGER 2011, pp. 103-108) Today they offer their catalogue as an interactive AR featured one, but the AR functionalities are only for showing further information or videos, not for showing virtual furniture. (TRAK 2012)

In this field of interior design the Viennese company Meixner IT-Solutions[2] offers an AR-app called ViewAR that is able to place virtual interior in an real enviroment. Some other firms use their technology with white lable apps . Within this app you can place a virtual piece of furniture in your flat by using a marker. A marker is needed for showing the AR-app the position of the model.

Fig. 6: ViewAR

---

[1] www.remax.at

[2] www.meixner.at

Using the orientation features of a smartphone or tablet like GPS,[3] compass, accelerometer and gyroscope it is possible to interact with the real enviroment. So a prototype application for architectural on-site visualisation could be build to simulate a bridge beetween two existing buildings (NIEDERMAIR 2012, pp. 20-21, 64).

Fig. 7: Prototype AR-app for showing a bridge (NIEDERMAIR 2012, p. 62)

What is used above as a prototype is in other projects already in use. The app 3Don ARchitecture[4] is a 3D viewer for architectural models integrating a geo-tagged ability. (NIEDERMAIR 2012, p. 17) Vienna was one of the first cities that implemented the AR technology for visualization of a development in urban areas. The construction site is in the north of the city and called "Seestadt Aspern" and will be be developed in the next years. The Austrian company Ovos[5] set up a special layer using the app Layar (compare to chapter 4.1) for prospective customers. So you can see future buildings and architecture live on the construction site. (OVOS 2011) (LANG; SITTLER 2012a, p. 8)

Fig. 8: AR app for large development area – Vienna Seestadt Aspern (OVOS 2011)

Fig. 9: Wohntraum am Olympiapark

---

[3] Global Positioning System

[4] www.3don.co.uk

[5] www.ovos.at

Without using a third-part AR-app there are several projects that already use AR technologies. But these projects are located in Germany. The first app was "Wohntraum am Olympiapark" which is situated in the city of Munich. The title page of the project catalogue is used as a marker for the app. Beside additional information of the project the AR mode can be reached with the "3D view" button. So the whole project is shown on the display. The app was also programmed by the company Meixner IT-Solutions.

The second project is "AR Winterhuder Wohnkultur" which also offers additional information on the project and two ways of visualizing the site. The first way is a classical AR approach with a special logo in the prospect using a marker for getting the project shown as virtual model (using button pages 1-9). The second way is non-AR, but shows the architectural objects interactive by holding the camera around (using button pages 10-16). Knowing the position the app guides you through the 3D model. Strictly speaking this is not AR, is is virtual reality (VR) instead.

Fig. 10: Winterhuder Wohnkultur (AR view)

Fig. 11: Winterhuder Wohnkultur (3D model)

Fig. 12: BIMx (Reconstructed 3D model of synagogue 1190 Vienna, Dollinergasse)

Other apps using this method of orientating in the building or interactive showing the 3D model are BIMx and iVisit 3D. All these apps can be used as an innovative method for 3D presentation of architecture setting

new standards. In Vienna there was a project which rebuilt the destroyed synagogues in the city with virtual models. (MARTENS; PETER 2009) The Austrian company A-Null Bausoftware[6] made it possible that these buildings are in a BIMx virtual environment. In this app you can virtually move inside the objects.

With the iVisit app architects can upload their own projects. It is developed for architects and designers, to allow users to view panorama renderings. In the navigation mode you can look around in your model by moving the smartphone or tablet. The views are genrated by rendering only images. This property is not in Vienna. But again this is also Virtual Reality, even a smart way to present property.

Fig. 13: iVisit 3D

4.4 Dimensions/Plannings

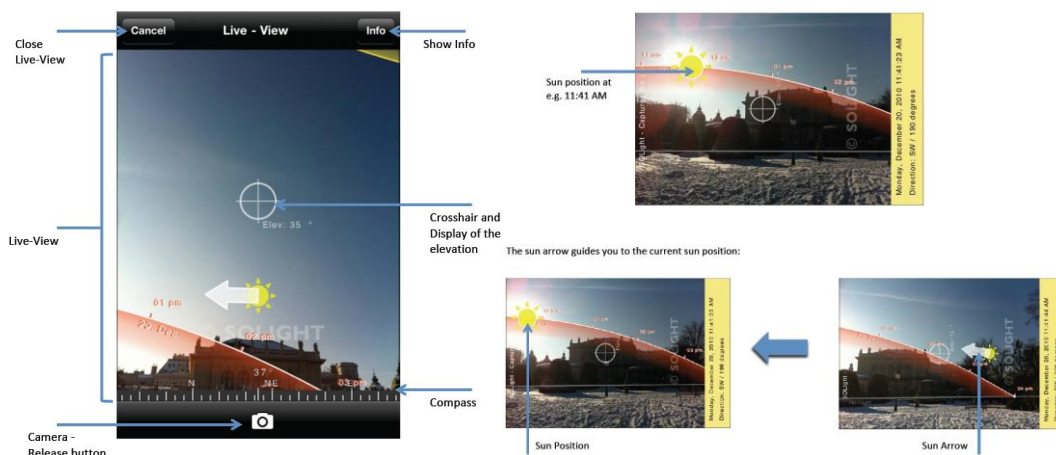
As a planning tool the app SOLight from the Austrian company Anvartec[7] is used to show the sun path throughout the whole year. The app calculates the exact sun path for the current GPS position and overlays the live picture with the sun path in front of the surrounding area (houses, trees, mountains, etc.). The difference between the summer and the winter sun positions could be helpful for visiting an object and detecting several lightning problems e.g. with new or prospective condominiums. (LANG; SITTLER 2012a, p. 9)


Fig. 14: SOLight (ANVARTEC 2010, p. 2, 4)

4.5 Lexicon/Languages

Tourism is one of the most wanted categories for apps, while the use of smartphone features is applicable for AR use. In this field the app Word Lens was developed. It is an entirely new tool for live translations using the camera image to immediately translate the appropriate language. The result is simultaneously displayed in the desired language. Currently the translation of Spanish, French, Italian and German into English (and vice versa) is supported. With this application every language challenge or sign reading on a construction site will be no problem any more. (LANG; SITTLER 2012a, p. 9)

Fig. 15: Word Lens

5 CONCLUSION

"AR is still in infancy state, and as such, future possible applications are infinite" (CARMIGNIANI; FURTH 2011, p. 38)

The above mentioned classifications in the use of AR have different relevance in terms of their capabilities in use and their benefits for the user. The size of the circles indicates the estimated market share. In comparison to the results of 2012 there is a a sharp shift towards architecture and interior design at the expense of real estate search. (LANG; SITTLER 2012a, p. 10)
Fig. 16: Capabilities in use and benefits for the user of AR RE- apps (first graphic LANG; SITTLER 2012a, p. 10)

The focus of AR and VR is located on presentation and visualization. AR is predicted to be increasingly used in a major number of areas and it is a question of time when AR-apps will become a familiar technology. (BIESZKE 2011, p. 41-42) AR is a revolutionary technology, which is more and more used in real estate. Even the augmented view of a construction site with the virtual building is possible. The site notice board can be as anchor of the marker for the virtual sightseeing. The broker could stand in front of the desired site showing the customers house by AR animation and virtual tours before construction begins. (GAWLITTA 2012, p. 67 70) In addition VR-apps give well known visualization for prospective customers and are easier to create. With the new standard of Building Information Modeling (BIM) an intelligent model-based design process gives added value to the entire lifecycle of a building and infrastructure project. (AUTODESK 2011)

Apps enhance the perspective of customers with showing how his future home looks like. Also location based services with GPS will influence the customer use. (TÖNNIS 2010, p. 166) Especially the field of real estate should benefit from the increasing AR market. (LANG; SITTLER 2012a, p. 11)

6 SUMMARY OF USED AR-APPS

The following table (in two parts with Fig. 17 and 18) shows all mentioned app available in any of the main app stores.

Name of the App	Layar	Wikitude	Junaio	CommBank 3D Reader	ViewAR	aspern Die Seestadt Wiens
Vendor	Layar HQ	Wikitude GmbH	metaio Inc.	Commonwealth Bank of Australia	Meixner IT-Solutions GmbH	ovos media consulting gmbh ovos realtime 3D gmbh
Category	Information on surrounding area			Infotainment	Architecture/ Interior design	Architecture/ Interior design
Description		Augmented Reality browsers for live views of the surrounding information of the desired object. Hotspots, pubs, premises around the location are shown in the live view of the camera of the smartphone. Individual layers for own purposes can be viewed.		With this app (and the concerning marker) the real estate market in the virtual city Cherryford Hill can be visited. Terms as transactions and purchase prices are shown. This fun app is used for explaining AR.	App for visualizing furniture, interior design, kitchens and even whole architectural buildings. With a marker the object could be viewed in the display of the smartphone or tablet.	Using the Layar AR-browser the building site named "Seestadt Aspern" can be viewed through the camera of the smartphone. With 3D-objects the future buildings are shown schematically from special viewing points onsite. The virtual city is contributed by additional texts, pictures and videos.
Operating System	iOS, Android	iOS, Android, Blackberry, Windows Phone	iOS, Android	iOS	iOS	iOS, Android

Fig. 17: Summary of used AR-apps (part1)

Name of the App	Wohntraum am Olympiapark	AR Winterhuder Wohnkultur	BIMx	iVisit 3D	SOLight	WordLens
Vendor	HI Wohnbau GmbH Meixner - IT5	Wulff Hanseatische Bauträger GmbH	Graphisoft SE	Abvent R&D	Anvartec Dipl.-Ing. Bernd Rene Ruprechter	Quest Visual Inc.
Category	Architecture/ Interior design	Architecture/ Interior design	Architecture/ Interior design	Architecture/ Interior design	Dimensions/Plannings	Lexicon/Languages
Description	The app uses AR-technology to show the project "Wohntraum" in Munich (Germany) by a virtual and 3-dimensional object. The title of the project-folder is used as an anchor to see the object from several angles.	The app uses AR and 3D modeling technology to present the project "Winterhuder Wohnkultur" in Hamburg (Germany). A special logo in the project-folder is used as an anchor to see the object from several angles or navigate throug the virtual property.	Virtual reality app which shows virtual objects which can be walked through like in a jum-and-run game. Architecture is simply imported and shown to the customer.	The app is available in two versions. The Lite version is free, but only shows one panorama each day. For heavy users the Pro app with the same functions shows views of buildings and architecture, which you can move throug ba handling the smartphone or tablet.	With this AR-app you can see detailed information concerning all sun paths with highest and lowest positions of the sun. To determine the solar time of an apartment you can check the light intensity with this app.	With this app short words an sentences could be translated live within the camera view of the smartphone. Currently the translation of Spanish, French, Italian and German into English (and vice versa) is supported
Operating System	iOS	iOS	iOS, Android	iOS	iOS	iOS, Android
Price	free	free	free	free / 17,99 EUR	2,99 EUR	4,49 EUR [1]

1 ABSTRACT

One of the main parts in planning is the communication of planninginformation. Not only the decision maker, but also the inhabitants have to be informed on the planned actions, no matter if they are affected directly or indirectly by the planning . The classical two-dimensional visualizations do not offer the required range to present the contents of the planned changes, and lay people do not have the same base knowledge to understand the three-dimensional extent to what is shown in the plan.

3D models are one possible solution to this problem, based on the fact, that e.g. a new planned building or area can be viewed from different angles and also allow a direct judgement.The down side of these models is the creation. It is complicated and expensive to create the three-dimensional surroundings. What if the virtual model could be combined with the existing reality? Would that make things easier?

With the use of Augmented Reality various techniques are available which have to be tested.

Using these methods real-world situations can be overlayed with digital content which allows an extension of information of reality. Based on practical examples, these new methods and techniques are explained in detail.

2 INTRODUCTION

Urban planning is an extremely complex subject that is often difficult to understand for lay people. Especially if the individual is affected by the planning process, the possibility must be given to express his dismay in the participation process. But how can citizens express their opinion if their basic knowledge is not the same? What can help these people to understand the three-dimensional effect of a plan based on the classical two-dimensional visualization. How can this be made more transparent and understandable?

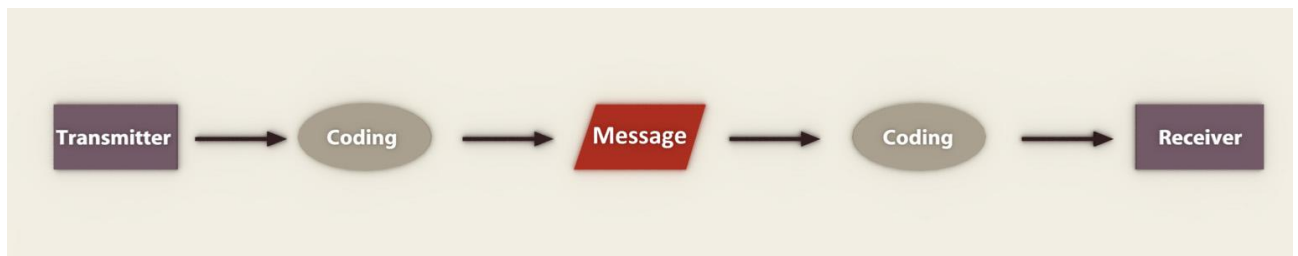
Regardless to the chosen (visualization) method, factors of the communication theory must also be taken into account. The general view on the continuous communication between planners and the addressee in the whole planning process, shows that the analytical categories of communication theory can be applied (Fürst & Scholles 2008:198).


Fig. 1: Communication in planning processes, based on transmitter-receiver model (Zeile 2010, according to Fürst & Scholles 2008:198)

The vocabulary that planners use to define a problem in planning is very fixed and defined by law. They encode their core message, which then must be decoded by the receiver. This can result in transmission errors, since the receiving side remains within its own interpretation range. It attempts to translate the information to his language. Here emotions, such as a distrust of the stakeholders, or a defensive position due to personal fears, or the own idea of a "good" plan, can falsify the actual statement. (Fürst & Scholles 2008:198).

In this content Smartphones or tablets with Augmented Reality Browsers offer a possible solution for a better exchange of information as they are more understandable and transparent. Augmented Reality is conciderd to be "the extension of reality with additional content". Two different methods can be differentiated: On the one hand the use of Augmented Reality in situ, meaning that in the case of a planning project, fotos or 3D models can be blended in to the built reality. On the other hand, a printed 2D plan can be extended with additional

information or models, with the use of Augmented Reality markers. These methods can be seen as a type of translation, as it enables a lay person to understand the previously complex two-dimensional presentation.

In the follwing current methods and techniques are to be discussed.

3 STATE OF RESEARCH

3D-city models have gained more and more popularity in the last years. This is especially based on the continously simplified development. If the new design of a building or situation is integrated in a city model, it can be viewed from all perspectives and alternatives can be discussed and rated.

On the other hand it is criticized that the effort and the costs to create the surroundings is too high. Can the new design be combined with the built reality (Zeile 2012) ?

3.1 Augmented Reality

This question constitutes the approach of the technology of augmented reality. Instead of using a virtual environment to show the content, it is projected into the reality. To achieve this 4 elements are needed: a computer with the required software, which serves as rendering unit, overlaying real pictures with virtual pictures, a tracking system, which locates the position of the user, a recording device in form of a camera and also a display.

If all these requirements are fulfilled, 4 different methods of Augmendet Reality can be differentiated (Höhl 2008):

- The Projective Augmented Reality (PAR) uses a projector to show digital information on a real object.

- With the method of Video See-Through (VST) enclosed projection glasses are used.

- The Optical See-Through (OST)-method works with an optical unit to combine the signals, a semi-transparent mirror, which allows the perception of the environment.

- The Monitor Augmented Reality (MAR) displays digital contents on a Monitor. This technique is concidered the easiest solution.

A few years ago this method was only possible from a stationary computer, or the User hat to transport about 20 kilos of equipment. Today the same technical effort can be given to the User as a handheld device in form of a smartphone (Zeile 2011). The Augmented Reality technique implemented in smartphones shows a whole new form of Augmented Reality. It is basically an advanced form of the Monitor Augmented Reality, only that the User is not fixed to one spot, but can move freely in reality. This makes it possible to use the system nearly everywhere, as long as a mobile internet connection is assured and the required App (a so called Augmented Reality-Browser) is installed. The tracking system to determine the perspective is included in practically all newer smartphones in form of a GPS-module and also a compass (Allbach et al. 2011).

3.2 Geolocalisation or Marker Based Technics

With the current MAR-techniques two procedures are differentiated: On the one hand, using the integrated GPS-module, the geolocalisation techniques and on the other hand the so called marker-based techniques. In the case of the geolocalisation the content, which is to be displayed is linked to the geoposition, allowing the user to view it at the point of interest. This method is restricted though because the GPS-localisation is not always as exact. If there is a high density of buildings or trees, the GPS-signal and the deposited AR-content starts to "jump".

A new approach to solve this problem is found in the marker-based tracking systems, which do not need a GPS-signal. The setting, in which the content is supposed to be overlayed is found on a server as a marker. All that is needed is a foto of the setting. Originally set up for print media, this application can be extended to the built reality with simple tricks: disturbing elements that complicate the recognition, such as reflecting windows or weather-related changes in the sky, have to be cut out with image editing programs, e.g. Adobe Photoshop. Distinctive structural elements in the face of the building are adequate to recognise the according setting to then overlay the content (Zeile 2012). The technical restrictions to create such an Augmented Reality projection are reduced to a minimum. Years ago it was limited to people with the needed know-how

to set up such a server and deposit certain contents, whereas now there are platforms that offer a graphical user interface and drag&drop functions. Therefore Hoppala augmentations (Gadeya 2013) or the RADAR-platform of the DFKI Kaiserslautern (Memmel 2013) can be used for the accomplishment of geolocalized AR-visualizations. This development is continued by the new platform "LayAR-Creator" (Layar 2012) relating to the current AR-application LayAR. Centre of attention is the user-friendliness.

4 METHODS FOR AUGMENTED VISUALISATION OF URBAN PLANNING

In the presented projects three different methods, meaning also three different applications were used: LayAR (Layer 2009) as a representative of the location based service as well as LayAR Vision (Layar 2012) and AR Media (Inglobe Technologies 2011) as marker-based techniques. LayAR is concidered to be the most common Augmented Reality-Browser on smartphones. The georeferenced contents can be stored on a server for a later presentation when a GPS-localisation is possible and the smartphone only has to be aligned on-site to show the contents on the display. This allows an import of pictures, 3D-objects, audio- and video data in to reality.

LayAR Vision is the marker-based version of LayAR. Both versions are combined in the same App. Since the introduction of LayAR Vision the App LayAR directly starts in a "Scan"-mode. If a photo is taken in this mode the App compares this situation with all the markers filed on the server. If it finds this situation on the server it leads the user to the according info-layer within the App.

Manual navigating to the LayAR-channel, which is still necessary with geo-referring layers is not applied in this option. With LayAR Vision it is not yet possible to visualize three-dimensional contents.

A marker based AR-technique to present three-dimensional information is AR Media. This application can be used as a plugin for any current softwareprogramm for three-dimensional modelling (SketchUp, Vectorworks, 3D Max,…). The program is then extended with the AR-function. With the help of this, 3D models can be placed on such a marker, which resembles to the famous QR-codes. This marker can be printed out at home by everyone, the matching 3D-model can be downloaded as well as the free AR Media Viewer (Inglobe Technologies 2011). By adjusting the webcam to the marker an AR visualization can be generated on the monitor. For Apple's iOS systems there is the so called AR Media Viewer, a free App which enables a visualization with a smartphone or a tablet.

AR Media shows tremendous functions, such as the scaling of the 3D-model, the ability to show different versions and different angles by turning the marker or by using the common form of wiping over the touchscreen. A high level of detail can be displayed, as the model is saved locally on the device and does not have to be streamed over the internet. Therefore the only restrictions result in the hardware of the used smartphone or tablet.

5 USE CASES AUGMENTED REALITY

The presented methods were tested within cooperation projects with cities and communities, adjusted to their objectives and presented in the following.

5.1 Smartwalk Saarbrücken „Stadtmitte am Fluss"

In the summer of 2012 the research team of the department CPE worked with the mentioned visualization methods on the example of the major project "Stadtmitte am Fluss" in Saarbrücken. This major project dealt with the revaluation and creation of a better quality of ambience along the river Saar, which runs directly through the city.
Fig. 2: Track oft he smartwalk through the area „Stadtmitte am Fluss" in Saarbrücken (Research group CPE, based on the master plan of Saarbrücken)

Especially building projects to reduce the traffic pollution, such as noise and emissions were intended. A focal point of this planning was the tunnelling of the urban motorway which runs alongside of the Saar.The emerging free space on the top of the tunnel is supposed to be used by the people as an attractive park and recreation space. Also the boulevard on opposite side of the river is to be upgraded and integrated in the urban pattern. Key aspect of the research was on the one hand to communicate with the inhabitants on the planning, on the other hand to reach and fascinate young adults with the help of innovative visualization methods. The second aspect should work by the principle of the "Homo ludens" (Streich 2011) with a "playful contact" of the subject of planning and town developments.

Fig. 3: Use of Augmented Reality to overlay the new virtual design of a pedestrian bridge over the real picture- (Research Group CPE)

The main focus was set on the development of the so called "Smartwalk", a kind of virtual tour through nine stations without a fixed order. The walk extends to the planning area of the project "Stadtmitte am Fluss" and uses various digital contents configured for smartphones or tablet pcs.

If the observer is for instance at a station where he can see an empty site the new planning can be experienced with a video fitted to the gap. At a different station the new planned pedestrian bridge is blended in as a 3D-model and at yet another station viewers can get a brief overview of the whole area with some basic textual information as well as information on the project.

At a different spot a 3D-model of the entire area including noise pollution and flooding simulations can be viewed. To offer a better understanding of the new planning the presentation was not only made for future planning but also shows a comparison to the historical development and the current situation.

The associated information of the project can be accessed at every station, either through a mobile website or in form of an available audio-stream. To reach as many people as possible a simplified version of the walk is offered based on QR-codes and mobile websites. The purpose of the Smartwalk is not only to inform, but the city of Saarbrücken is hoping to get feedback of the viewers. To allow this, every station offers the possibilty of a rating- and commenting system (Becker et al. 2012).

Fig. 4: Visualization if a new design in AR Media, (left) Visualization over Webcam and Notebook, (right) iPad (Research Group CPE)

AR Media was also used so that citizens had the opportunity to look at the new planning from home, by using the augmented 3D-models. In the end not everyone interested in the project has the chance to take a tour of the area to get more information.

5.2 Conversion area Trier Bobinet

Often the area affected by building projects is spread over such a large range that the whole extent of the project can not be taken in by the viewer straight away. The use of AR Media opens further potential since a 3D model does not have to be placed on one single marker. Shown in the example of the conversion area Trier Bobinet the 3D-model of the entire planning area was set on various markers arranged in a grid. AR Media supports a maximum spreading of 7x7 markers. This way the display of the 3D-model in the Augmented Reality view can be increased. Depending on which marker the webcam (or the camera of the iOS-device) is directed the matching section of the 3D-model is shown. The transition from one marker to another is smooth which allows a scan of the entire area (Noll 2012).
Fig. 5: Placement of a new design with the help over several markers in AR Media (Noll 2012)

5.3 Added value for urban planning

After selecting technical capabilities for the use of AR-presentations in planning, it has to be figured out if the new repertoire of methods can help a lay person to judge the planning project and form an opinion. To fathom out the question the new methods were compared in another final paper and the value for the interested citizen was determined based on a questionnaire. This was applied in the example of the Landesgartenschau in Schwäbisch Gmünd. Here Henn architects are planning a research centre and a trainee center, that is going to be a combination of 35 ship containers. By stacking containers of different sizes an abstract construction is created (Henn 2012).

Fig. 6: Evaluation at the construction site in Schwäbisch Gmünd (Dübner 2012)

To find out if the people passing by the planning area can imagine how it will look the evaluation takes place at this point, devided in different stations. The first evaluation took place after looking at the two-dimensional plan. In the following steps the various AR-methods were added, repeating the evaluation after every method. The interested people viewed the building project as a marker-based visualization in AR Media, as a two-dimensional overlay with LayAR and finally as a three-dimensional model over a LayAR-geo-channel. Regardless to their age or previous experience with smartphones and Augmented Reality every person could handle the techniques. The presented AR-methods were consistently seen positive and helped the test person to imagine the building (Dübner 2012).

5.4 Augmented Reality as a communication instrument for landuse planning

Besides the pure presentation of the planned construction of a building project, the legal regulations of a development plan also have a spatial impact. Therefore, also the classical two-dimensional plans require a translation. Can the presented mobile Augmented Reality methods enable this translation for citizens? Since not every citizen has the same spatial perception the question arises, if the complex contents of a development plan can be shown in a three-dimensional visualization, including the extent the planning will have on the area. Within another research project, the contents of the development plan were created as a three-dimensional alternative. After an existing development plan was recreated on a three-dimensional level and presented in Google Earth, the next step was to find out how Augmented Reality methods can offer a higher value for citizens. In the first possibility, the models were transformed and located on a geo-channel in LayAR. This allowed an inspection of the development plan "in situ". Particular regulations, which are in their selves complicated enough, were extended with additional textual information. This offers a combination of the visualization of the set regulations with the translation for the interested layperson. The handling of this method though, turned out to be difficult, as the restriction of the exact location was set because of an insufficient GPS-signal. In addition, the level of detail that influences the data volume of the model was limited through the quality of the mobile internet connection (Broschart 2011).
Fig. 7: Threedimensional examples of the content of building codes (above: open design; below: perimeter and fixing building limiting line) Augmented Reality Visualization of a development plan (Broschart 2011)

In the second version, the attempt was started to explain the contents of the development plan with the help of mobile Augmented Reality methods directly on the plan. Again, LayAR Vision was used for this approach. The actual development plan is then set as the marker and additional contents can be "placed" on this surface. On the other hand, LayAR Vision does not offer the presentation of three-dimensional contents, so the explanations to the single regulations are pictorial. The contents with various degrees of information are basically supposed to be decoded through the smartphone to enable the understanding of the different regulations. With this technique, the legally valid development plan can be used as the base without changing the plan. This means that the smartphone would function as an informal translation device for the formal plan, which could be used for the mandatory presentation (Zeile 2011).

Fig. 8: Marker-based AR-Visualization of a developement plan with buliding codes (Zeile 2011)

6   CONCLUSION

The presented Augmented-Reality methods can already be used in various parts of planning. The methods repertoire of a planner is being extended in its function of "translating" for lay people who are interested in planning. First evaluation results turned out positive: For inhabitants an additional benefit is assured, as they are assisted in their spatial perception, but also there is the possibility of making planning activities more attractive with the playful and interactive handling.

Currently there are certain restrictions to these techniques, such as an insufficient mobile internet connection or the vague GPS-signals which are needed for the geolocalizing AR-techniques like LayAR.

The newly provided LayAR Vision, a marker-based technique can compensate these problems, nevertheless the assistance for 3-dimensional contents is (still) missing. However it is expected to proceed in a continuous development, which will enable further possibilities for the supply of information.

Also in the area of the handling there is some potential, possibly Google's Glasses Project shows the next step to make Augmented Reality more intuitive.

The shown Augmented-Reality methods do offer an enrichment, but their use must me considered, as it should only be seen as an extention to the already existing methods of participation. Non of the forms of information processing should be used on it's own. The Augmented-Reality methods can only show their full effect if they are used as an addition to the participation process.

All in all it can be said that planning is based on the communication between all people involved and this works best in the direct conversation. "Online does not work without offline!"

1 ABSTRACT

This paper reviews experiences of a partner involved for nearly a decade in promotion of Brownfields reuse, Brownfields awareness raising and Brownfields education and know-how transfer to the Central and the East European Countries. These experiences were gained from involvement in various projects such as Brownfields project for the Czech Ministery of Regional Development, Brownfields inventory projects for CzechInvest, BROWNTRANS, LEPOB, BRIBAST, CABERNET, CobraMan, CircUse and others, and they serve as a background for considering the effectiveness of various know-how transfer approaches. Different focus of individual projects, their partners´ profiles and project outputs are also reviewed. Project impacts and sustainability and transferibility of project results are examined. The effectiveness of Brownfield know-how transfer for different type of partners and stakeholders is also considered. For some projects, details of their local impact are compared and potential benefits to their participants and to local stakeholders are described. Finally, a recommendation is given for an approach to Brownfield know-how transfer to countries, which are yet to grasp the Brownfield nettle and need to integrate their Brownfields reuse into their national, regional and local systems.

2 EMERGENCE OF THE BROWNFIELD ISSUE

2.1 Introduction

Societal and production changes of the 1990's in the Central and the Eastern European states have generated large amounts of underused Brownfield land. These changes [1] required a spectrum of know-how, skills and tools, which would help them and their citizens to cope with new issues and emerging free markets. In some fields such know-how became avaliable, in other fields it was missing. An absence of know-how, skills and suitable tools particularly affected the urban development domain and actually it is affecting it until today. Here, local spatial planning was (and still is) failing to cope with the forcoming situation, turbulent market forces and the subsidiarity principles drive for community based leadership, which substituted the centraly planned and driven economy. All this was (and still is) simultaneously contributing to a worsening land use economy, Brownfields emergence and to a deregulation of large amount of Greenfield land, which is seldomly linked to any real population increases. The consequences are the increased costs of local development externalities and sharply developing differeces, between the "rising" and "failing" urban locations. Where as the "rising" locations are attracting development on Greenfield sites and exeptionally also on Brownfields land, the failing locations are experiencing ever increasing dilapidation, which is weakening local communities and deterring even further any potential investors. At the beginning of this milenium, such development dynamics were still not really fully perceived or understood by these countries politicians, academics or practitioners, nor they were clearly understood by various teams of international advisors, which in those days traveled these countries.

2.2 Problem identification and recognition

Nobody initially perceived (in policy or practice) that these sprouting dilapidated industrial, institutional or agricultural sites were "the same thing", which needed a common label! At the early days no external technical assistance was available for planning and development, but it was being available for environmental and economic issues. One of such US EPA external technical assistances has in the Czech Republic in the late 1990 labeled as Brownfields the environmentally polluted and dilapidated industrial sites and similar labeling have occurred also in another Central and Eastern European countries. The different

---

[1] GAVRILIDIS A., IOJA C., SAGHIN I.:Urban Regeneration through Industrial Restructuring of Brownfields   47th ISOCARP Congress 2011

nature and origin of Brownfield sites, their varied development potential and their spatial aspects were started to be recognized in the Czech Republic after the year 2002 and the local planning system in the Czech Republic acknowledges Brownfields only since 2007. However, most of the other Central and Eastern European countries´ local planning systems have not perceived Brownfields as a land use and planning issue [2] until now. It is Brownfields multi-sector and cross-professional reach, which makes their problem recognition and solutions difficult. In the Czech Republic during the years 2002-2004, it was the external experts and the NGOs who helped the Czech Brownfields issue perception and recognition. This was achieved by estimating and sizing the magnitude of Czech Brownfields, by promoting Brownfields typologies and by identifying the need for an overall institutional responsibility for the land use. When finance was attracted into Brownfield research, the awareness of the issue among academics has improved. Increased knowledge and subject publicity have then helped lobbying Brownfields into the key national policies. In most of the other New Member States, such recognition has emerged five or more years later. For example until recently, some of Latvian, Bulgarian and Romanian, academics and practitioners still perceive Brownfields as an environmental and not as a land use and development issue [3]. For brownfield solutions to be successful, awareness and know-how improvements have to reach the national as well as the regional and the local levels. The regional and the local levels however, have serious language barriers, which prevent them from benefiting from international resources and literature, foreign experts´ produced reports and web-based information on Brownfields. Also, the local and the regional levels were not (and until today are often not) able to cope with the EU urban regeneration and management expertise transfers. This is because there are large areas of development and economic related know-how still missing in these local systems – and this effect the ability at the local level to absorb state-of-the-art urban development and Brownfield know-how. Simply, it takes time to build it up.

BOX 1 – Emerging brownfield know-how

Slovakia and the Czech Republic have similar political and development conditions and legal frameworks, but in terms of Brownfield regeneration the Czech Republic became the know-how transfer partner for Slovakia (see various papers by the authors dealing with the Czech Brownfields). In 2004, the Slovak Chamber of Charted Engineers and one of the educational institutions became a partner in the Czech initiated LEPOB project, focused on Brownfields education in local languages, targeted mainly to local practising construction and development professionals. At that time, understanding of the Brownfield issue in the Czech Republic was relatively well developed, whereas in Slovakia, the issue was so new, that it became difficult during this project to access experts, which could convert the generic Brownfields handbook into a Slovak country-specific version. Since this time, further Brownfield know-how transfers reached Slovakia from the Czech Republic. For example the Czech national investment support agency, CzechInvest, has in 2009 shared with the Slovakia´s investment agency SARIO expertise on Czech industrial Brownfield support programs and Brownfield inventory making. Meanwhile, Slovakia´s partners have also participated in other European Brownfields focused projects. By the year 2011, the awareness of Brownfields issue in Slovakia developed to such an extent that Slovakia´s stakeholders were themselves seeking means, how to improve and update their local Brownfield know-how. To fulfil these objectives they prepared the project BROWNTRANS financed from the EU Livelong Learning Programme. But the BROWNTRANS project aims not only to develop the Slovak professionals and academics Brownfield know-how, it is also reaching further East, to initiate and to open up Brownfield know-how transfer to Bulgarian and Romanian partners [4].

Whereas in the Czech Republic the national policy has responded to Brownfields since 2001, the Czech regional and the local levels, were responding later, partially from 2005, but on a larger scale after 2006, when Structural funding for urban and industrial regeneration became broadly available. In the other Central and the Eastern European states, such a policy and programme recognition of urban regeneration and Brownfield issues occurred a few years later. Hence the full impact on urban land use, which was possible in

the Czech Republic by the application of 2007-2013 Structural funding, is in these countries yet to come. But time moves on and also in Bulgaria and Romania various successful Brownfield projects are now springing up. They are mostly privately financed, but there are also emerging various publicly financed urban regeneration projects, some of which can be classified as projects on Brownfields [5].

BOX 2 – Brownfields in Romania and Bulgaria

There are several similarities of Brownfield perception in Romania and Bulgaria [6].

- In both countries until now Brownfields are perceived nearly exclusively as a contaminated land issue.

- In both countries there exist databanks of contaminated land but no databanks or inventories concerning dilapidated or underused urban land (Brownfields).

- In both countries, dilapidated or under-used urban land (Brownfields) is not recognised as a local urban, spatial, an economic or a social issue by the national legal framework and policies.

- Spatial planning in both countries does not "see" dilapidated or under-used urban land (Brownfields) as land use, planning and development issue.

- In both countries dilapidated or underused urban land (Brownfields) does actually represent a considerable amount of local urban fabric and because this issue is not correctly labelled, recognised or sized, Brownfields continue to be excluded from local urban policies and local urban plans, and financial resources, which could aid their remediation, are therefore not being provided.

Where the approach to Brownfields differs between the Bulgaria and the Romania is in their academic spheres. Whereas from the year 2007 there now are several scientific papers written by Romanian academics recognizing the economic, the social and the spatial context of Romanian Brownfields, there seem to be no such papers produced by the Bulgarian academia, which publishes only numerous scientific papers related to soil contamination and environmental aspects of Brownfield land.

Estimating and sizing the seriousness of the Brownfield issue was attempted for the first time in the Czech Republic by external experts in 2003 [7]. But for this now very outdated estimate, until today no other actual Czech Brownfields volumes figures exist. Brownfield data are also missing, or are incomplete and incompatible in most of the other Central and the East European states. Gathering qualitative data (achieved by an expert judgement stigmatising a property as a Brownfield) is an expensive pursuit and, if it is to be of any use, it requires a common approach to such data collection. This is still missing, even in the Czech Republic. Up to date Brownfields data are unavailable in the Czech Republic despite that since the year 2007 the Czech law enables signifying and publicizing properties as Brownfields for purposes of planning support information gathering. Because in the Czech Republic such an indication on a property usually has allowed its owners access to the Structural funding, property owners were in general not objecting to this very much. In the other Central and the Eastern European countries such a legal framework does not exist, which leads to difficulties with Brownfields surveys legitimacy and it also causes difficulties with Brownfield data publicity. Without at least estimating the amount of Brownfield land, and without analysing gathered data to understand what type of problems local Brownfields represent, it is very difficult to include Brownfields into the national/regional/local policies, channel research into them, or prepare programs and focus public finance and mainly soft intervention to Brownfields.

BOX 3 – Private sector – a leader in Brownfield reuse know-how

Despite the public sector failing in providing suitable policies or legal frameworks and despite an absence of suitable programs focused to aiding Brownfield regeneration, in the Central and Eastern Europe countries, the private sector is taking a lead on viable and well-located Brownfield sites. Such Brownfields are redeveloped by 100 % private funding for various commercial activities. Examples can be quoted not only from Czech Republic, Poland or Slovakia, but also from Romania[8] and Bulgaria.

3   LEARNING THROUGH PROJECTS

3.1 History of participation on international Brownfield projects

One of the first international Brownfield projects where the Central and the Eastern European countries have participated was the CABERNET [9] network. This network was conceived and lead by the Western academia and this was why, in 2003, the Central and Eastern European countries partners invited to participate on this project, were not from the policy of professional backgrounds, but were from the academic backgrounds, often quite removed from the Brownfields issue. This has presented problems with the project results dissemination, if there was not a strong backing from another national organization, with a keen interest in promoting Brownfield issue. One of the spin-offs from the CABERNET project for the Central and the East European states was in the year 2004 the project LEPOB. The CABERNET project outputs were all in English and were presenting relatively sophisticated concepts, which were in general preceding in time the general European professional perceptions of the issue. This was why these outputs became not too easily accessible for the Central and Eastern European audience. This was partly because of language barriers, but also because of a high level of background property, economic development and other knowledge, which the CABERNET outputs presupposed from any potential reader. The LEPOB project lead by a Czech partner and its later clones, the BRIBAST and BROWNTRANS projects have adapted and interpreted the CABERNET message to the Central and the Eastern European audiences. Parallelly, there were a number of other Brownfield projects [10], where the Central and Eastern European partners have also taken part, but in these projects the Central and Eastern European partners were usually in passengers and not the drivers´ seats. This was why a full impact of such projects was usually limited to projects partners´ participation and there was a little impact reaching the national, regional or local levels. Not until the CobraMan or CircUse – Brownfield and land used focused projects, initiated from 2009 by the Central European programme (which however limits participation only to the Central European states), similar approaches were adopted. That is, the training materials and selected outputs which were focused onto local stakeholders were adapted into country specific versions and were translated into local languages.

3.2 Partners profiles and beneficiaries

The partners in the Lifelong Educational Program projects (LEPOB, BRIBAST, BROWNTRANS) were mainly experts, educational providers and dissemination bodies such as professional chambers. These projects´ main beneficiaries were practising professionals, but also academics and students benefited. As a spin-off of these projects, Brownfield courses started in several of the Central European universities. On the other hand, the partner mix in Central European Program projects (CobraMan, Urban SMS, ReNewTown, CircUse) were focused on cooperation of local or regional authorities and research or academic bodies. Their main beneficiaries here were local and regional administrations. The partners in the URBACT Program Brownfield project project BRING UP were public bodies supported by a delegated expert and beneficiaries of this project were the local authorities. Partnership in the INTERREG III C program project the B Team was a large one, consisting mainly of public bodies and institutes, where the beneficiaries here were the local and regional administrations.

3.3 Sharable projects outputs

There is a transnational value in these various Brownfield and urban land development focused projects´ outputs. Especially for countries, where the Brownfield subject is a new one or a rising issue, which is not sufficiently supported by local resources. In such cases, local language resources are usually very limited and all resources which are adapted to country-specific versions and are in local languages are of a great value. But for a non-academic newcomer to Brownfields, reaching all these international or even the local language outputs may not be easy. Various EU Programmes may harbour Brownfields and urban land development related projects, but they do not enable cross programme subjects search. Also projects web life after projects´ completion is limited. The EUKN network [11] so far posts mostly outdated information and the

[11] EUKN – European Urban Knowledge Network, http://www.eukn.org/ (last accessed 15.1.2013)

EURO Soil [12] portal is focused only on soil issues, not on the spatial and the urban development ones. The outputs produced in national languages are even more difficult to identify, as they may not always be on the public side of projects´ web pages and a search on the local partners´ webs may be needed. So far, the Local Contact Points of various programs do not have any duty to provide web sites for their projects outputs, which can be sourced in local languages. The other issue is, that the outputs and information in respects of Brownfields and urban land development ages quickly, but unfortunately they do not age all in the same rate. A new comer to this field may not to realise that for example, the CABERNET project findings from the year 2006 are nearly all relevant and valid until today, where as the outputs of some other or later Brownfield projects, do not age so well and may be outdated even on the day they are posted on the web.

4 THE EXPERIENCE OF HINDSIGHT

Experience shows that the structure of the project partnership is important. When the lead partner has sufficient experience and partners know each other from the past, the matters usually run much smoother. Firstly, the project is conceived on a more balanced way, where all partners contribute, and not on bases that partners are being invited to a more or less "baked cake". Secondly, individual partners can more influence outputs which would be advantageous to be produced in their national languages and have more time to approach suitable local associated partners for projects outputs dissemination. But large partnerships (above 12 partners) also limit partners direct input into the scope of a project. The aim of any partnership should be to work together to the contracted goals, share knowledge and findings and add transnational value to such cooperation. But sometimes it is difficult to balance contributions from various partners, especially, when considering partners (and also countries) levels of subject expertise, technological standards or limits of local legal frameworks, policy, institutional capacity and modes of operation. Partners which are new comers to the subject, may feel lost, whereas the expert partners, especially when participating on non-research focused programs, may feel frustrated, because in these non-research programs, the experts position offers relatively a low value to such partner own expertise expansion. It is often much better for an expert partner to enter a project with a subject, which only relates to the partner´s key expertise, because in such a case his benefits from project participation are much more substantial (this applies not only to Brownfield projects). Some motivation from programmes to encourage top expertise partners in non-research projects is needed.

5 RECOMMENDATION HOW TO START ADDRESSING THE BROWNFIELD ISSUE

In Central and the Eastern European countries, the spatial and urban context of Brownfields has to be acknowledged at all governance levels. This is in order to drive and improve Brownfields´ regeneration chances and aim for more sustainable land use practices. Channelling public funding into Brownfield research and education drives such country knowledge and helps to develop understanding for necessary changes in national policy and legal framework. Defining, identifying and mapping Brownfield sites attracts stakeholders, investors and public interest to Brownfield regeneration and allows for integrating Brownfields into the existing urban context and local spatial and development planning. Data availability also helps to understand and identify likely development potential of local Brownfields and their realistic chances for any meaningful reuse. Understanding of Brownfield sites volumes, typologies and their redevelopment potential enables governments, regions and municipalities to formulate public programme interventions (perhaps also dedicate some soft and hard funding) which can help Brownfield regeneration, or can mitigate the impact of undevelopable Brownfields. Balancing the use of Brownfields and the Greenfields, creating job opportunities, strengthening local communities and preservation of historical heritage are just few examples how Brownfields can be integrated and reflected into local or regional policy and planning regimes.

Cadastral Feedback on Spatial Planning

Gerhard Navratil, Paolo Fogliaroni

(Dr. Paolo Fogliaroni, Vienna University or Technology, Department for Geodesy and Geoinformation, Gusshausstr. 27-29, A-1040 Vienna, Austria, paolo@geoinfo.tuwien.ac.at)

1 ABSTRACT

Spatial planning shall guarantee that the limited resource land is used efficiently. One problem connected to such a task is the control of the result's quality. In case of spatial planning the question is, whether the proposed usage and the legal framework requirements actually fit the needs of the society. A problem in such an assessment is the time frame. Planning of concrete situations, e.g., of a large bus stop, is implemented quickly and thus feedback can be collected by the people who were doing the planning. The results on strategic development plans, however, may take decades to become visible and thus it is difficult to learn from mistakes or find examples where the planning was successfully implemented.

In this paper we propose using the cadastre as a source for feedback on spatial planning. The idea is that the cadastre contains all data to show the effects of spatial planning. However, it does so in a way that is not supporting any feedback. The cadastral data must be rearranged in order to extract the effects of spatial planning. We discuss the information hidden in the cadastral data sets and show some directions for implementation issues.

2 INTRODUCION

Land is a limited resource and as such has to be used efficiently and sustainably. The goal of spatial planning is to optimize the utilization of land. This requires a balance between two contradicting goals: To guarantee the prosperity of society and to preserve the beauty of the natural environment for future generations. However, achieving this goal is not simple (compare Laistner & Laistner, 2012) and feedback is necessary to improve the planning procedures. In order to assess the quality of spatial planning, different measures can be taken. Faludi, for example, only discusses strategic plans, which he sees as coordination efforts between project plans. He argues that the quality of strategic plans can only be measured by their performance in subsequent communication processes and not by the conformity of the outcome with the intentions (Faludi, 2000). The difficulties of such an approach are visible when trying to define concepts, e.g., the notion of the "quality of life" (Ryser, 2011). Receiving feedback directly is essential and although the evaluation of Internet questionnaires can produce interesting insights (compare Pešek, Fialová, & Špačková, 2012), the process of questionnaire development is not trivial, the methodology only works if Internet access is available and will not produce an unbiased sample. Thus a different method to obtain feedback is necessary. The main idea is that the effects of spatial planning will lead to changes in the spatial structure of rights. Observation of these changes is possible if adequate land administration is in place. In the paper we discuss the use of the cadastral maps and explore the boundaries of such an approach.

The goal of spatial planning can be split into two different categories: (i) determining the spatial distribution of different processes and (ii) analyzing the spatial distribution of objects to enable such processes (compare Navratil, 2006). The result of the first category is usually a map showing the intended use of land. Depending on the planning scale, this may be an overview to identify large regions, e.g., national parks, or large-scale maps representing detailed parameters, e.g., for new buildings. The result of the second category is an implementation—or at least guidelines for an implementation—to solve a practical problem.

3 LAND MANAGEMENT AND LAND ADMINISTRATION

Since land is a limited resource, its utilization has to be organized. Resource utilization is typically a part of management, which can be defined as the "organization and coordination of the activities of a business in order to achieve defined objectives" ("management," 2013). Land management is management of the resource land. It comprises various processes including land planning, land reform, land market control, etc. and defines land-related policies and strategies. The implementation of these policies and strategies requires base data on land. These data are provided by various organizations, which together establish land administration (Williamson, Enemark, Wallace, & Rajabifard, 2010, p. 5). The organizations involved in

land administrations may vary between countries, but the types of data are similar. The data describe geometrical, physical, and legal attributes of land. The types of data necessary are mainly defined by the key tasks of a cadastre. These tasks are (Creuzer, 2002, 2007)

- the registration of all real estate,
- the maintenance of base information, and
- the provision of secure land markets and property transactions.

Modern land administration systems have to adopt a multi-functional approach to meet the demands of society. Although differences are clearly visible between different countries, e.g., between Austria and Serbia (Mansberger et al., 2011), the society needs are similar worldwide. A separation between geometrical, legal, and economic description of pieces of land (usually called "parcels") is not compulsory but often visible. In Austria, for example, the cadastre provides the geometrical description, the land register ("Grundbuch") provides the legal description, and the economic description (the value of land) is missing. The reason in Austria is the difference between private land public law and the differences in the legal processes attached to these types of law. Dealing with both types in a single organization is more difficult than to have two organizations.

One of the problems of land administration is the changing needs of society. The original task of land administration was simply the documentation of the current status of land to support land taxation and land ownership protection. Today, land administration supports a wide variety of different tasks including agro-subsidies, environmental protection, and financial services (Muggenhuber, Navratil, Twaroch, & Mansberger, 2011). This requires more data on land than the original tasks. Each new task may require additional data sets leading to extensive data collection campaigns. A simple example would be a visibility analysis for new constructions (What is the area from which a new construction can be seen?) because it requires 3D data which is usually not included in 2D cadastral systems because it is not necessary (Navratil & Hackl, 2007). However, new demands of society may always lead to new elements in the cadastre, if the demands justify the additional expenses. In Austria, for example, the need of improved boundary reliability led to the implementation of a coordinate-based boundary cadastre.

4 ELEMENTS OF A CADASTRE

As mentioned before, a cadastre maintains administrative, legal, ownership, usage, and geometric information about land. Thus in a first step, pieces of land have to be defined such that the data can be attached to these pieces. The smallest spatial unit is typically the parcel and the data are either related to one parcel or a group of parcels. The cadastre defines the spatial extent for each parcel and assigns a unique identifier to each parcel. The cadastral processes must also guarantee that the parcels do not overlap and completely cover the area of the country, i.e., they do not allow for areas that are not part of any parcel. Ownership of land and other private rights on land are registered in Austria at the land register. The rights are registered for a specific land registration item. A list of parcels is connected to each item. Thus the rights have a defined spatial extent even if the pieces are not necessarily connected.

The cadastre maintains the cadastral map, a graphical representation of the parcel boundaries and some additional information. Additional information is, for example, the area and the postal address. The graphical representation is a set of lines representing the boundaries between the parcels. Depending on the jurisdiction, the quality of these lines and their legal status may differ but mapping proved to be a simple method to avoid inconsistencies in parcel boundary definitions. The graphical representation guarantees that overlapping parcels or gaps between parcels would be easily detected. The quality of the boundaries varies since the sources range from digitization of old maps to modern surveys and different surveying methods also result in different quality. The parcel boundaries are then used to determine the parcels. A parcel is the area surrounded by boundary lines. Each parcel is assigned a unique identifier. Austria, which is a rather small country, currently consists of approx. 12 Mill. parcels (Abart, Ernst, & Twaroch, 2011, p. 105). In order to avoid huge parcel identifiers in local processes, the cadastre is organized in almost 8000 small administrative units. Each of these administrative units has a unique identifier and the identifiers of the parcels only have to be unique within the administrative unit. Additional data shown in the cadastral maps are land use and some data for orientation. Names of important roads, for example, can be placed on the map. The same is true for major water bodies. In addition, the direction in which rivers and rivulets flow can

be indicated with an arrow. However, only the information on land use is compulsory. Land use may not be unique on a parcel. A parcel may, for example, consist of a house and the adjacent garden. These are two different land uses and thus the cadastre in Austria can separate different uses of land with a specific type of line, a land use separation. These allow for, for example, identifying buildings and their geometry even if the building is not a separate parcel.

Figure 1 shows an example of an Austrian cadastral map. It shows the parcels boundaries and the parcel identifiers. It also shows symbols representing the current land use and the outlines of buildings. However, neither correctness nor completeness is guaranteed for the buildings. The buildings do not have separate parcel numbers. Thus they are not parcels themselves but areas of the parcels with a different type of use.

Fig. 1: Sample from the Austrian cadastral map (data © BEV)

Since a cadastre shall reflect the real situation, the cadastre must be constantly adapted to the real situation. The geometry of the parcel may prohibit a special use of the land. If a parcel is too small, for example, the owner of the parcel has to buy adjacent land to place a building. Since buildings are not allowed to cross parcel boundaries, the owner must adjust the boundary or merge the parcels. A parcel may be split into two or more parcels, if the owner wants to sell a part of it. Thus, frequently, parcels are split up and merged and parcels boundaries are changed. All these changes must be documented in the cadastre. The principle of private-public-partnership was introduced in Austria and many other countries to fulfil this task, i.e., private surveyors perform the surveys and the public authority inserts the changes into the cadastral map. The communication between these two groups requires survey documents specifying the change. These documents contain the old and the new situation including some administrative information, e.g., the new areas of the changed parcels.

These survey documents are used to update the cadastral map whenever a change occurs. However, various errors may occur in the whole process of map update: Misplaced lines in the old or new situation of the survey document, misinterpretation of the land owner's intention by the surveyor, misinterpretation of the survey document by the cadastral authority, etc. Additionally, manual revisions of the cadastral maps were necessary when the maps were maintained in analog form because the carrier (paper or transparencies) were worn out by use. This created additional problems and resulted in a mismatch between the original measures taken in the field and the distances observed in the cadastral maps (compare Navratil, Hafner, & Jilin, 2010).

Thus it is essential to keep a register of all survey documents to be able to correct these errors. The survey documents are time stamped. These time stamps can be used to filter changes that occurred in a specific region since an arbitrary date. Assuming that all changes are documented and implemented correctly, this allows restoring the geometry of the cadastral map for any point in time since the first survey. A cadastral database that supports this type of query could be called a temporal cadastre.

Some data in the cadastre are easily observable, e.g., the outline of a building. Other data are difficult to observe. Land use is an example for this. Land use is a process but only a status is easy to be observed, e.g., the extent of a lake, the area where trees exist, or the position of a fence protecting grassland. However, this is only land cover and the boundaries between different types of land cover. Although there is a high correlation between specific types of land cover and land use (Ippoliti, Clementini, & Natali, 2012), difficulties will arise on a number of occasions. Grassland protected by a fence may be used as a garden, as a playground of a kindergarten, as a sports field (e.g., a golf course) or as a military training area. In order to determine the exact use, these processes have to be observed. This may be difficult because the processes will not take place constantly. Some evidence may be visible, though. Shape and extent of areas used as gardens are usually different from that of a golf course and military training areas are usually connected to a complex owned by the military. Thus in combination with land cover information, shape, size, and context can provide evidence for land use.

5 DETERMINATION OF LAND USE FROM THE SHAPE OF PARCELS

Changes in cadastral data are interrelated with spatial planning inasmuch changing the planned land use for a set of parcels can affect parcel boundaries: For example, areas fit for agricultural use have a different size than areas for industrial or residential use. A parcel with an area of 500m2 can be sufficiently large for residential areas because it allows the creation of a small building and still leaves some room for a garden. 500m2, however, are much too small for modern agricultural use because the advantages of modern machinery cannot be utilized. Changes in the spatial planning, thus, must have an effect on the cadastral geometry. However, spatial planning is an authoritative process initiated by the local administration whereas the change of cadastral boundaries is a privately organized process managed by the respective land owners. The land owners will react promptly to any change in spatial planning, if the change is in their advantage. Farmers, for example, can sell land profitably if

- the land lies in areas intended for residential use,
- their loss in productivity is small, and
- there are sufficient potential buyers to spike the prices.

This will become visible in the cadastral maps because a number of small parcels will be created. However, the farmers will not sell, if above conditions are not met and thus the geometry in shown in the cadastral map remains unchanged. Thus, the effect of spatial planning on the cadastral geometry reflects the concord between concepts developed by the administration and needs of land owners and the local society. The delay between change of spatial planning and changes in the cadastre can serve as a measure for concord.
Fig. 2: Parcel patterns of four different types of land use: (a) residential area (b) agricultural area (c) forest (d) intersection between highway on-ramp (examples from DORIS, the Upper Austrian land information system)

Figure 2 shows different types of land use and how the land use affects the shape of the parcels. Residential areas (Figure 2a) are composed of small, parcels of similar size. Rectangular shape simplifies the construction of buildings and thus rectangular parcels are predominant. In city centers, the pattern may vary because high buildings require larger area and old road networks are rarely orthogonal. However, the land use in old city centers typically does not change much. Since all parcels must have access to the public road network, there is a dense network of roads in residential areas. Most of these roads will be quite narrow to restrict through traffic. Typical parcel width for these roads is in Austria 8m. Agricultural areas (Figure 2b) have a similar pattern than residential areas. However, the parcels are typically much larger and there are often rectangles with a large difference between length and width. In addition, the access to the agricultural areas is granted by narrow paths with a width between 3 and 4m in Austria. Therefore, the ratio between productive area and roads is different from that in residential areas. Forests (Figure 2c) may have parcels of similar size than agricultural areas. However, forests parcels have to consider topographical elements like ridges more than agricultural areas. The last example is constituted by traffic areas (Figure 2d), which consist of long, narrow parcels.

The development of a temporal cadastre to provide feedback for spatial planning requires different steps. The first step is providing the technical basis for such a system. This requires digitizing all survey documents, storing them in a computer system, and connecting them such that all necessary evaluations become possible. In a second step, it is necessary to be able to detect patterns related to spatial planning. It must be possible to automatically detect, for example, agricultural areas based on the geometrical characteristics. This step is more complicated than the first one because the characteristics will vary between countries and probably

even regions of the same country. There may also be a temporal component. Agricultural areas, for example, became much larger with the development of efficient machines because one farmer could handle much larger areas if they were arranged in pieces of suitable size. The third step is then to identify the lag between a change in the spatial planning documentation and its effect on the cadastral geometry. How long, for example, does it take for a new residential area to be used for living? The answer may vary for different areas and research can then concentrate on areas where concepts of spatial planning were implemented slower than average.

6 DATABASE ISSUES

In this section we present an overview of database issues that have to be addressed in order to enable the type of cadastral feedback for spatial planning we discussed above. More specifically, main challenges raised by the suggested approach are made explicit and an overall analysis of today's technologies that are better suited to tackle such challenges is carried out.

Any kind of spatial information system, including cadastre and spatial planning applications, typically relies on spatial database management systems (DBMS) in order to optimize data storage and retrieval. Any DBMS, in turn, implements one of a variety of theoretical data models, as well as a series of data access methods. Each data model is better suited for the treatment of a certain type of information (e.g., scalar, multi-dimensional, hierarchical) whereas requires cumbersome adaptations for the treatment of other types. Thus, it would be reasonable to think that, according to the type of information to treat, each application relies on the most appropriate data model. Unfortunately, because of historical reasons, this is not the case. Conversely, only one data model is predominantly used today: the relational data model (Codd, 1970). That is, the majority of cadastres and spatial planning applications relies on relational DBMS.

According to our previous analysis, two central features required to exploit cadastral feedback are: document storage and temporal support. Relational databases are not very well suited to implement these features. The documents that have to be treated can possibly be in either a paper-based or an electronic format. Moreover, since they come from different sources or authorities (or even from different time periods), they do not posses, in general, a common structure. This raises the following two issues: (i) as a first step, paper-based documents have to be digitized. But according to which structure? (ii) The second issue is related to the inefficiency of the relational data model to treat structureless data: relational databases usually store structureless data in a raw format as a so-called binary large object (BLOB). This is greatly inefficient in terms of both, storage space and retrieval time. Indeed, it is very hard to find and eliminate redundancies within this kind of data (storage inefficiency). Moreover, it is not possible to index (retrieval inefficiency) BLOBs in a meaningful way (i.e., according to the pieces of information they contain) because of the unpredictability of their content.

Temporal support is also not provided natively by relational DBMS. A possibility in this case would be to resort to data warehousing: a design technique for relational databases that allows for designing the schema of the database in such a way that historical data can be maintained and analyzed efficiently.

An interesting alternative to the relational model is provided by document-oriented databases (Strauch, Sites, & Kriha, 2011, Chap. 5): non-relational databases whose functionalities are developed around an abstract definition of document. Such kind of database natively supports the management of unstructured or semi-structured data, allowing for optimality in data storage and retrieval. Two representative document-oriented databases are CouchDB (http://couchdb.apache.org/) and MongoDB (http://www.mongodb.org/). They both natively provides the requested temporal support: every time a document insertion, update, or deletion occurs, the database system does not change its state; rather a new state is created according to the issued action while the previous one is marked as obsolete (but not deleted). Because of their features, CouchDB and MongoDB are excellent candidates to keep trace of and analyze temporal changes.

7 CONCLUSIONS

It will not be possible to use this kind of feedback for all kinds of spatial planning activities. Nature protection areas, for example, will not show on cadastral maps because nature protection prohibits a wide range of activities. Most of the allowed activities do not produce much revenue for the land owner. This restricts the resources put into the development of land and optimizing the parcel shape is one of the development activities. Of course, this should not come as a surprise because it is the basic idea of nature

protection to restrict development activities. On the other hand, parcel boundaries may adapt to the shape of the nature protection zone and the zone itself may become visible.

An automatic system to detect land use can present areas where the changed land use is not implemented. This provides one source of feedback that spatial planners can use to optimize the utilization of land. It can also provide feedback in the opposite direction. Sometimes the assumptions under which spatial planning was working are not adequate. The economic and social situation of the regions next to Czechoslovakia, for example, changes significantly with the opening of the borders in 1989. Concepts of spatial planning had to be adapted to these changes and old concepts were maybe not optimal in the new context. However, if some of these outdated concepts were already implemented, how long does it take to correct these problems? A temporal cadastre could help addressing questions like that.

An automatic system can also be used as the bases for even more advanced analysis. Changes in spatial planning typically have an effect on land market. The classification of land as residential land, agricultural land etc. has a dramatic impact on the value of land. Thus, the land owners in some areas will benefit from the change, the owners in other areas will not. This leads to new questions, e.g., about compensation payments. However, a different question could also be who the persons are that profit most from a change in spatial planning. In general we can assume that from a statistical view all land owners will benefit equally from spatial planning. However, what happens if always a specific class of land owners profits? Such statistics can be produced automatically if sufficient data is available and the historic development can be modeled. The effect would be a more transparent system of spatial planning where (at least some) hidden agendas could become visible.

1 ABSTRACT

We show how small to medium sized cities can make use of the Cellular Automata (CA) approach to integrate land use data and other GIS based data with inter-active long-term scenario evaluation. Our CA model illustrates the interdependency between transport infrastructure supply and population density. It can be used to generate maps of future land use patterns for potential future scenarios. It provides a fast and economical way to compare alternative strategic plans and development rules for a small to medium sized city. For our sample town, Austria's second largest city Graz, we develop three different long-term scenarios (fast population growth, slow population growth, and urban sprawl scenario in which population growth is concentrated in the suburban areas). The model output for each scenario can then be used as input for infrastructure planning procedures. We illustrate some examples: the graphic representation of the spatially differentiated structure of the population, ex-ante public transport infrastructure evaluation, evaluation of existing zoning rules, and the evaluation of infrastructure capacities by combining the model outcomes with capacity calculations for the public sewage system.

2 INTRODUCTION

The starting point of our Cellular Automata model is the Corine Land Cover (CLC) Project (2006) which is used to represent the current situation of land use within the city limits of Graz and also provides us with the cells of the dimension 100m x 100m that serve as the individual building blocks of our Cellular Automata model. Using this structure we develop a Cellular Automata model that illustrates settlement activity within the city limits of Graz for each year until 2050. This is done for three different scenarios which illustrate a broad spectrum of possible future developments of the city until 2050. We feed each of these alternative scenarios into the model, combine it with future population predictions, and let it run for 44 periods, where each period represents one year. The model output then illustrates settlement activity within the city limits of Graz until 2050 in the case this particular scenario occurred.

We choose a broad variety of different scenarios to illustrate the scope of our model's possibilities. The first two of these scenarios are based on extrapolations of current trends of population growth (one illustrating a fast growth scenario and the other one a slow growth scenario). The third scenario deals with the issue of urban sprawl.

The model output for each scenario can then be combined with a variety of infrastructure applications to estimate likely future needs and to check in which way capacities of the current (public) infrastructure would need to be expanded. For example we look at where new public transport routes would be necessary, we check whether the current sewage pipe system would be adequate for the city of Graz under each of the three scenarios. By comparing the model output with actual zoning rules we can pinpoint areas that experience too much population pressure as well as those areas that have free capacities for densification. By highlighting areas with potential for further improvement the model can help city planners to locate areas that would benefit from an improvement in public infrastructure (which in turn would increase their attractiveness for development in the model and in reality). The model could also be used to find the optimal future locations for kindergartens, schools, shopping facilities and other infrastructure needs.

In this paper we show how our CA model can be used by city planners to better understand the structure and dynamics of their city as well as its infrastructure limitations. This should be helpful for long term planning of zoning regulations, public infrastructure such as public transport services, the dimensions of sewage systems to name but a few.

3 MODEL

3.1 Model Structure

The basic structure of our model consists of four parts: the cells, their states, their neighbourhoods, and the transition rules that regulate how cells can change their state through influence of their neighbourhood.

We choose the model's cell structure to coincide with the grid structure of the Corine Land Cover Plan 2006 (European Environment Agency, 2010). This provides us with a two dimensional representation of Graz that consists of 12,762 grid cells with dimension 100 by 100 meters. The possible states of the model were defined by us and are based on the Corine land use classes which were combined with population data. The Corine Land Cover Project allocates to each cell one of potentially 42 different land cover classifications. 12 of these land cover types are represented within the city limits of Graz. The actual population data for Graz is available at census district level ("Zählsprengel") of which there are 259 within the city limits of Graz. We define the neighbourhood of a cell as the 8 cells surrounding the cell itself. The transition rules are more complicated as they depend on more than one factor. We concentrate on the transition of unpopulated cells into populated ones. For an agriculturally classified cell to be converted into building land it has to be surrounded by at least 4 populated cells. The likelihood with which a cell attracts population is then dependent on two factors: one is the proximity to the city centre, the other is the distance to public transport stops.

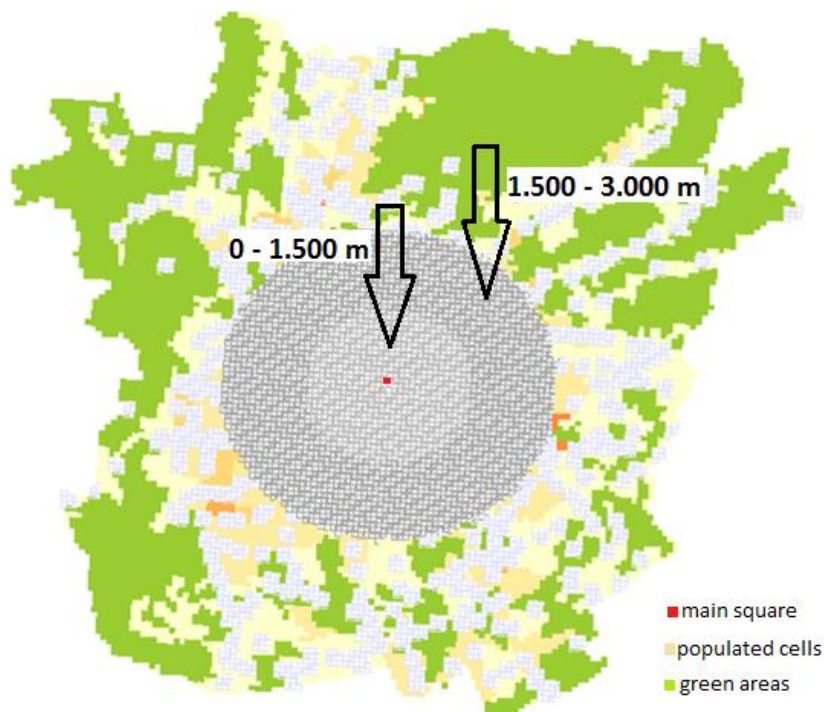
The distance to the city centre is important as Graz is a traditional city that is structured in a way similar to the monocentric city model (Alonso (1960, 1964), Mills (1967) and Muth (1969)). Most jobs are located in the central part of Graz and there is a central transit place in the city center ("Jakominiplatz") where all public transport routes of the city meet. To illustrate this situation we divide the city into three distinct areas by introducing two concentric circles around city centre (with a 1500m and 3000m radius). For the cells in these areas we assume different possibilities of development (transition probabilities). The levels of these relative probabilities are found by solving a linear optimization problem. A graphic illustration is given in Figure 1.


Fig. 1: Graz divided into three main areas.

3.2 Data

The following data inputs have been used in this model:

- Public transport stops (busses and trams) with GIS representation

- Coordinates of River Mur

- Distance of all cells to city centre (main square)

- All major roads out of the city centre with GIS representation

- Population density data comes from the 259 political "Zählsprengel" of the city of Graz 2006 – 2011 (Magristrat Graz, 2012). Apart from the number of people living in each census district this data set also contains age, citizenship, and whether the residency is used as a main or secondary residency ("Haupt/Nebenwohnsitz"). These population numbers are then divided up between all cells that lie within CLC classes 1 or 2 (urban fabric and discontinuous urban fabric respectively) within that "Zählsprengel" (census district). CLC class 1 (continuous urban fabric) receives four times as many people as CLC class 2 (discontinuous urban fabric).

- Corine Land Cover data from 2006 (version 13: 02/2010) with GIS representation

These data are presented in grid cells of 100m x 100m. We cut out the boundaries of the city of Graz from this data set. 12 of the 42 land cover types used in the Corine Land Cover data set occur within the city limits of Graz. Corine Land Cover class 1 and 2 are "town", which are defined as continuous urban fabric and discontinuous urban fabric respectively. In our Graz data set we have 573 cells with CLC class 1 and 6,241 cells with CLC class 2. The total city area consists of 12,762 cells. Thus, according to the Corine Land Cover data 53 % of the area of the city is covered by populated "built-up" area.

3.3 Scenarios

One of the greatest advantages of modelling urban development with a CA model is the relative ease and economic efficiency with which different scenarios can be "played through". To develop the individual scenarios we have focused on existing trends that are discussed in the local media as well as future infrastructure decisions that are currently discussed by the local municipality. These scenarios are sample inputs – we can easily combine the model with other statistics or incorporate other scenarios that city planners are interested in. We will illustrate three different scenarios here. Each scenario has its own probabilities of change associated with it. These probabilities were obtained by solving a linear optimization problem. Wherever possible we included past population trends in this optimization process.

The following scenarios have been considered so far:

Scenario 1	Fast population growth
Scenario 2	Slow population growth
Scenario 3	Population growth focused on suburban areas

Table 1: Characterisation of the three scenarios.

Scenario 1 assumes an extreme increase in population until 2050. In this scenario we take the predicted population numbers for "Greater Graz" area (Landesstatistik Steiermark, 2010) and allocate them all into the city area. The point of this excersise is to see how the city's infrastructure would cope under this extreme scenario.

Scenario 2 is the most realistic scenario. It is based on a demographic study by ÖROK (2004) for the individual districts of Graz until the year 2031. For the period 2032 – 2050 we use our own extrapolations of these numbers.

Scenario 3 shares the population numbers with scenario 2 – but now we assume that because of socio-economic preference changes additional population is mainly locating in the outer areas of the city.

Figure 2 illustrates the starting situation of land use classes and cell level population density in 2006. Figure 3 shows the outputs of scenarios "fast growth" and "urban sprawl" for 2050 (after 44 model sequences).
Fig. 2: Land use and population density at cell level in 2006.
Fig. 3: Land use and population for the year 2050 for scenario "fast growth" (left) and scenario "urban sprawl" (right).

4 APPLICATIONS

4.1 Ex-post building density evaluation

The zoning plan is the main instrument with which the city's future shape and structure are influenced. The city of Graz has set maximum as well as minimum building densities per square meter building block via their zoning plan (see 3.0 Flächenwidmungsplan Graz, 2002). The official building densities differ quite substantially within the city of Graz. While the inner city area has building densities of up to 2.5 the outer areas generally have maximum building densities around 0.3 or 0.4 and a minimum building density of 0.2 (compare 3.0 Flächenwidmungsplan Graz, 2002). For example, a maximum building density of 0.4 implies that on a 1,000 square meter plot a building can have a maximum living space of 400 square meters. If a minimum building density of 0.2 applies to this plot, then the building needs to have at least 200 square meters of living space. Thus, the legal building densities are given as proportions to the actual land area. These legal requirements expressed in the zoning plan of the city of Graz is available in GIS format and can be incorporated into our model.

Ex-post we can compare how the various scenario predictions of the CA model correspond with these politically set boundaries for building density. The CA model can thus highlight "pressure point" areas where the model predicts a higher building density than the city currently allows. On the other hand it can

also highlight those areas where the model predictions do not reach the minimum density levels. These areas are areas with potential for "densification".

There are no legal restrictions on the population density per square meter. However, we know that the average living space per person in Austria is 42 m² (Lugger, 2002). We use this number to calculate the maximum average population density for each cell (per rata). If a cell consists of two or more zoning classes with different upper and lower building density limits we calculate the proportional average building density rules and use those.

With this information we calculate an average statistical "upper population boundary" per cell which can then be compared with the results of the various simulations of the CA model. This gives us an indication of whether there are population pressures in certain areas. However, the excess population of a cell does not per se mean that the building requirements are violated – as mentioned before a larger than the average number of people can live in one place. But it is an indication that more people want to live in that area than foreseen by the zoning plan.

In this situation city planners have two fundamental choices: They can keep the existing zoning regulations. In this case a cell once "full" will not take on any more buildings or population and the population that feels attracted by this cell will choose a cell with similar attributes. This movement of course illustrates the issue of "urban sprawl". Another possible action plan of city planners in this situation is to loosen the building density restrictions. This will lead to more densely populated cells and a lower degree of urban sprawl as before. This situation illustrates how city planners can influence the future shape of a city through the design of the zoning rules. Both cases can easily be incorporated into our CA model and thus illustrate the long-term consequences of zoning regulations.

The red cells in Figure 4 mark the areas which would require an increase in building densities. On the other hand, the yellow cells in the graph below show those cells that do not reach the minimum building density if each person allocated to those cells uses 42 square meters of living space. Orange cells indicate those areas where the statistically average living space of the allocated people lie within the range set by the present zoning plan.
Fig. 4: Density and zoning rules 2006 (left) and 2050 – scenario "urban sprawl" (right).

We see that in 2006 there still is a lot of potential for densification in the outer areas of the city according to our calculations. If we contrast this picture with the figure of the sprawling scenario for 2050 we see that a large proportion of this potential has been used up by then.

4.2 Dynamic transport stops

An inherent question in urban economics is whether people move into an area because of good public infrastructure, or whether good infrastructure is provided wherever there is population that demands it. While our CA model cannot be used to address the causality issue per se, we can use the model to illustrate influences both ways.

If sufficient population grow exists in a particular area we can for example set new public transport stops. In the example below we stopped the model in certain time intervals and checked for the "need" of new transport stops. We followed the rule that a new public transport stop was created if considerable population growth existed within the area and the distance to the next public transport stop was larger than 375 meters. The arrows in Figure 5 indicate the new public transport stops that would be necessary to provide adequate access for the growing population. In this example the number of new stops was quite low however, because of the already very dense public transport net of the city of Graz. Of course, the additional transport stops will improve the attractiveness of the cells within this area, which will then change the probability of additional population being attracted into this area. Thus the model output for the year 2050 will be different to the original situation.

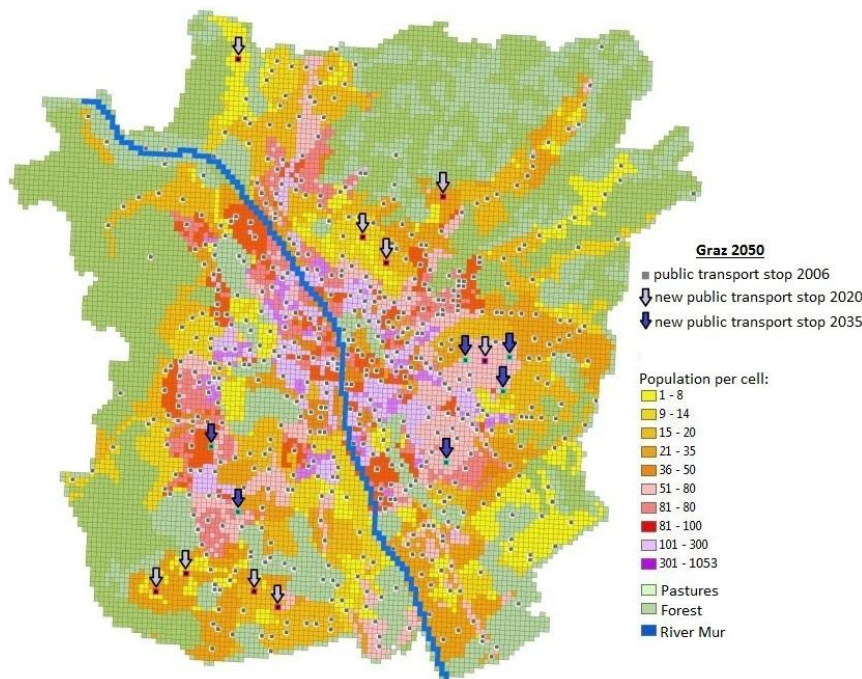
Because of the already very dense public transport system within the city limits, the population results do not differ very substantially from the original model. This example does however provide an illustration of how new public transport opportunities will attract new settlements. In a similar way entire new transit routes could be incorporated into the model to illustrate how these would influence future urban development.


Fig. 5: Dynamically set transport stops 2050 – scenario "fast growth".

4.3 Sewage system checks

Figure 6 is an illustration how the scenario model output can be combined with the existing sewage system of a city. Again we illustrate how our model can be used as a tool to evaluate future needs. The intuitive graphic representation helps in the visualisation of potential problem areas. The GIS based output can also be incorporated into existing infrastructure systems.

For strategic points of interest for each of the three scenario outputs we can calculate whether the capacities of the sewage system are sufficient to meet potential future demands. These calculations can be useful to illustrate bottle-necks in the sewage system, to highlight needs for pipe expansion, or to illustrate the need to restrict future settlement by limiting additional population growth in certain areas via zoning rules.

For two reasons we concentrate on pipe diameters of more than 800mm. First, the bigger pipes illustrate the overall capacities of the sewage system which cannot be altered as easily as the more regional smaller pipes. Another reason is that the CA grid size of 100m x 100m is too coarse to allocate smaller pipes accurately. To illustrate our method we consider the scenario of "fast growth" and check how the existing pipes would handle the scenario needs for the year 2050.
Fig. 6: Sewage system 2050 – scenario "fast growth".
Fig. 7: North-West segment of sewage system 2050 – scenario "fast growth".

We calculate the sewage output of the catchment area by multiplying the simulated population numbers of the cells in the catchment area with the per capita sewage assessment values for the city of Graz (details can be found at the webpage of Holding Graz, 2013). We calculate maximum pipe capacities with the help of the Hazen-Williams formula, which is often used for the design of pipe systems with larger diameters (Bobardelli und Garcia, 2003), the "90 % rule", and the average European conversion factor (which lies at 0.849). For this specific area we find that the pipe diameters are large enough to handle all three of the scenario situations.

5 CONCLUSION

The last decade has seen a surge of GIS data sources becoming available to city planners. Because of its two dimensional model representation via grid cells, Cellular Automata models provide a natural framework within which GIS data can be represented. The CA model we develop in this paper is useful for city planners because it provides an intuitive, fast, and economical representation of alternative scenarios.

By comparing the outcome of the model with the zoning rules of the city of Graz we can highlight areas with potential for densification as well as areas with intense population pressure.

We have shown three different potentially possible scenarios for the future expansion and population structure of the city of Graz. Each of these scenarios is associated with different infrastructure needs. These infrastructure needs can then be assessed by integrating additional layers into the model or by exporting the model scenarios and assessing them with traditional methods.

There is a long list of potential extensions for the model. We have already made some progress in the inclusion of sewage systems and we will tackle the optimal allocation of elementary schools in a next step. The strategic setting of new commercial infrastructure locations (e.g. super market locations) is a further potential extension.

Fig. 1: Entwurf und Simulation in einer Realtime-3D-Anwendung mit „Natural Interface"

1 ABSTRACT

Gestalten Sie ihr Einfamilienhaus in Echtzeit-3D! Diese Forschungsarbeit beschäftigt sich mit der Umsetzung eines computergestützten Mixed Reality Präsentationssystems für die Firma Haslerhaus GmbH. & Co KG. Realisiert wurde dieses System mit Unity in einem Kommerz MRI Framework. Das System besitzt zur Zeit zwei wesentliche Komponenten: (A) einen virtuellen Baukasten zur Bemusterung und (B) eine Echtzeit-Simulationsoberfläche mit virtuellem 3D-Walk-Through und einer integrierten Sonnenstandssimulation. Vergleichbare Entwicklungen von Collaborative Virtual Environments (CVE) nennen Ponto, Doerr, Wypych, Kooker und Kuester (2011), Künz, Dontschewa und Weber (2007), Tizani (2011), Peña-Mora, Golparvar-Fard, Aziz und Roh (2011), Yabuki (2011), Yi-Luen Do (2011) und nicht zuletzt Ren und Tang (2011). Im Mittelpunkt dieser Arbeit steht die Fragestellung, in wie weit der herkömmliche Entwurfsprozess durch interaktive computergestützte Werkzeuge verbessert werden kann. Der hier präsentierte CG Mixed Reality Architectural Workspace vereinfacht den Entwurfsprozess durch eine evolutionäre, iterative Vorgehensweise, kombiniert mit einem benutzerfreundlichen, intuitiven Interface.

Der traditionelle Entwurf entsteht in einer Reihe von Iterationsschritten in verschiedenen Medien (Gespräch, Skizze, CAD-Planung und manuelle Korrekturen). Das hier vorliegende Modell (Realtime 3D-Anwendung mit „Natural Interface") bildet eine gemeinsame digitale Plattform, kann ohne spezielle CAD-Kenntnisse bedient werden, reduziert die Medienvielfalt, vereinfacht die Benutzerinteraktion und macht den Entwurf unmittelbar erlebbar. Mehrere iterative Entwurfsschritte können so in kürzerer Zeit erfolgen. Umgesetzt wurde dieses Projekt mit der 3D-Echtzeit-Engine Unity, integriert in ein Mixed-Reality-Interface. Momentan existiert das System als Mixed-Reality-Installation mit optischem Tracking. Die MRI Plattform erlaubt aber auch, unterschiedlichste Hard- und Software gemeinsam einzubinden. Interessant erscheinen dabei Kombinationen eines 3D-Walkthrough über optische Marker und die simultane Sonnenstandssimulation über einen Tablet-PC. Vorteilhaft gegenüber anderen Entwicklungen ist die einfache Verständlichkeit auch für ungeübte Benutzer und die intuitive Bedienbarkeit über optische Marker. Im Endergebnis generiert das System auch einen personalisierten Prospekt mit selbst entworfenen Hausvarianten. Zukünftig denkbar wäre die Erweiterung des virtuellen Baukastens und des Simulationstools zu einem umfassenden Werkzeug für den interaktiven Echtzeit-Entwurf. Dieses Paket würde in dieser erweiterten Form die Entwicklung des Raumprogramms unterstützen, aber auch die Möblierung, Beleuchtung, die gesamte Innenraumgestaltung und die nachfolgende Simulation.

2 VIRTUAL ENVIRONMENTS – RAUM, ZEIT UND ORGANISATION

2.1 Genereller Aufbau von Collaborative Virtual Environments (CVE)

Ausführlich beschreibt Maher [2011] die Einbettung virtueller Werkzeuge in den Gestaltungsprozess und die daran beteiligten Elemente. Als grundlegendes Charakteristikum virtueller Ambiente sieht sie den Kommunikationsprozess im Mittelpunkt, der nun oft non-lokal, über digitale Medien abgewickelt und gesteuert wird. Maher legt den Schwerpunkt der Bewertung eines CVE auf kommunikative und koordinierende Aufgaben und entwickelt sechs Anforderungen:

- Managing collaborative design processes
- What you see is what I see (WYSIWIS)
- Chance meetings
- Peripheral awareness
- Non-verbal communications
- Designing for two worlds (digital and physical)

Sie nennt vor allem die Gleichwertigkeit der gezeigten Information auf beiden Seiten (WYSIWIS), die Möglichkeit informeller virtueller Treffen (Chance meetings), die Transparenz der Aktivitäten der jeweils anderen Partner (Peripheral awareness), non-verbale Dinge transportieren zu können und die Ausgewogenheit von digitaler und physischer Welt. Sie beschreibt aber auch die wesentlichen Elemente eines CVE. Von diesen Annahmen ausgehend, wird hier folgendes grundlegendes Schema eines CVE entwickelt:
Fig. 2: Genereller Aufbau eines Collaborative Virtual Environments (CVE)

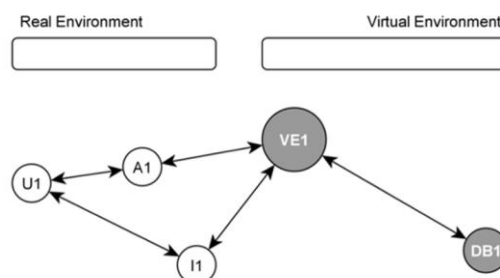
Im Zentrum des CVE steht ein digitales Informationsmodell, oft auch als dreidimensionales Virtual Environment (VE), das den eigentlichen Arbeitsraum bietet und den Gegenstand der Gestaltung abbildet. Das CVE sollte aber auch über Kommunikationswerkzeuge verfügen, oft existieren dort auch Avatare, als eine digitale Repräsentation der Nutzer. Eine digitale Datenbank (DB) lagert alle Assets zur Gestaltung des Informationsmodells. Der oder die Nutzer (U) verfügen über den Zugriff zu einem digitalen Interface (I), das die Steuerung des Informationsmodells ermöglicht, aber auch Kommunikationswerkzeuge anbietet. Parallel dazu hat der Nutzer Zugriff auf analoge Arbeitsmaterialien und Artefakte (A). Vereinfacht erhalten wir daher folgendes Schema:


Fig. 3: Collaborative Virtual Environment (CVE) | Vereinfachte Struktur . Single-User Workspace

2.2 Raum, Zeit und Organisation

Dave [2011] beschreibt den Zusammenhang zwischen Raum, Zeit und Organisation im Gebrauch von Virtual Environments. In gestalterischen Berufen finden sich am Arbeitsplatz neben PC´s auch oft analoge Artefakte, wie Skizzen, Zeichnungen, Fotos, Drucke, Pläne oder 3D-Modelle. Der Zugriff auf diese beiden Mittel und die Kommunikation über diese beiden Möglichkeiten (digitale Schnittstellen und analoge Artefakte) beschreibt er als essentiell bei der Bearbeitung gestalterischer Aufgaben. In der Gestaltung der Arbeitsplätze unterscheidet er zwischen physischem und digitalem Raum, Single-User und Group Workspaces.
Fig. 4: Collaborative Virtual Environment (CVE) | Synchroner und lokaler Group Workspace

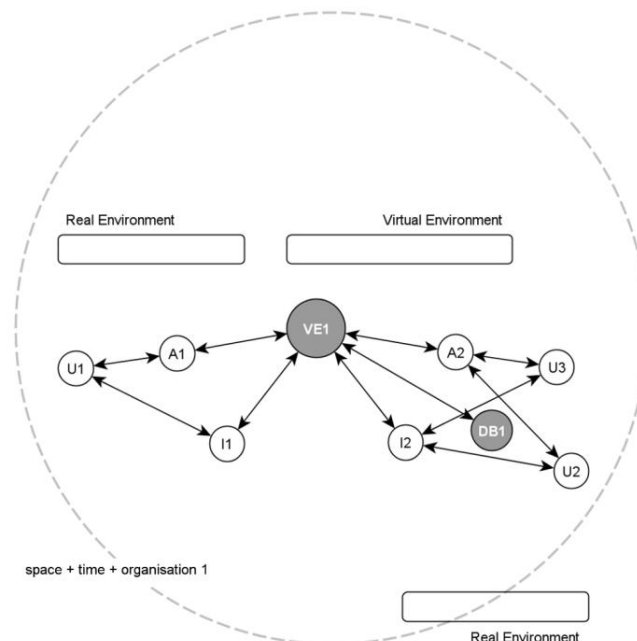
Demnach zeichnet sich der Gruppenarbeitsplatz mit mehreren Nutzern durch gleichzeitigen Zugriff auf dieselben Interfaces und analogen Artefakte am selben Ort aus. Alle Nutzer befinden sich in der selben Organisationsform, das heisst, sie arbeiten nach den selben Standards und nutzen den selben Workflow im Gestaltungsprozess.


Fig. 5: Collaborative Virtual Environment (CVE) | Synchroner und lokaler Group Workspace

Möglich wäre aber auch folgende Konfiguration: hier sind es mehrere Nutzer im selben Raum, zur selben Zeit, in der gleichen Organisationsform, aber an unterschiedlichen Interfaces und analogen Artefakten.

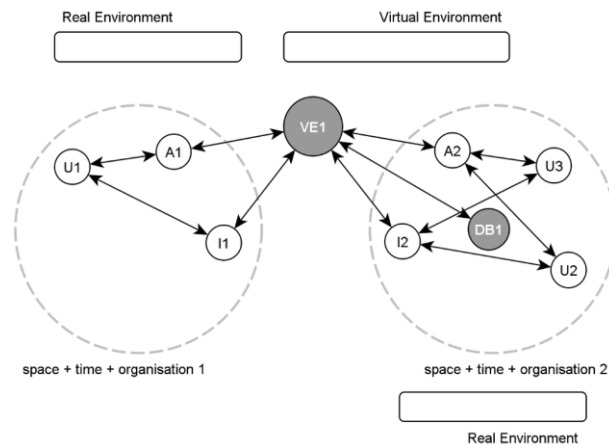
Denkbar wären hier auch Variationen, wie zum Beispiel eine asynchrone Tätigkeit, aber auch eine non-lokale und asynchrone Kooperation in unterschiedlichen Organisationformen wie in der nächsten Grafik dargestellt:


Fig. 6: Collaborative Virtual Environment (CVE) | Asynchroner und non-lokaler Group Workspace

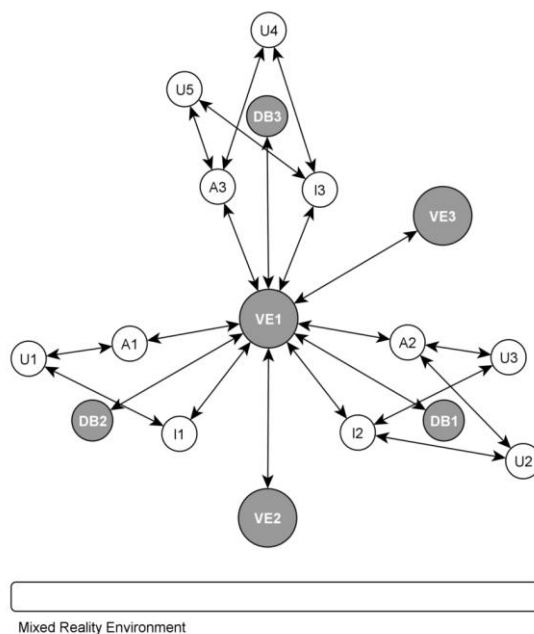
Weitere Variationen sind denkbar, einerseits die Erweiterung um weitere Datenbanken und andererseits die Vernetzung mit anderen CVE zu komplexen Mixed Reality Environments.


Fig. 7: Collaborative Virtual Environment (CVE) | Multi-Database und Vernetzung mit anderen CVE

Diese Analyse eröffnet uns nun Möglichkeiten, das eigene nachfolgende Projekt kritisch zu betrachten und weitere, mögliche Perspektiven zu entwickeln. Dazu mehr im abschließenden Kapitel „6 CONCLUSION".

3 ANWENDUNGSBEREICHE UND BEWERTUNGSKRITERIEN FÜR CVE

3.1 Anwendungsbereiche

Zur Zeit kennen wir folgende Hauptanwendungsbereiche von Mixed-Reality-Echtzeitsystemen:

- Archäologie, Rekonstruktion und Städtebau
- Architektur und Baukonstruktion
- Erziehung und Bildung
- Wartung, Inspektion und Instandhaltung von Anlagen
- Chirurgie und militärische Anwendungen

Beschränken wir uns nun auf das Gebiet der Architektur, gibt es schon einige bemerkenswerte Forschungsarbeiten. Billinghurst und Henrysson nennen folgende generelle Anwendungsbereiche von Echtzeitsystemen: On-Site-Visualisierungen von Gebäuden, speziell auch in der Archäologie und die

Unterstützung des gesamten Gestaltungs- und Konstruktionsprozesses, also auch kollaborative Methoden (Vgl. BILLINGHURST 2009). Speziell in der Architektur scheinen also folgende Anwendungen heute schon umsetzbar und interessant:

- Indoor/Outdoor Visualization
- Architekturentwurf, Gestaltungs- und Konstruktionsprozess
- Energieoptimierter Entwurf
- Design Collaboration, Shared Display und Delokale Visualisierung
- Anwendungen für Weiterbildung und Lehre

Wir kennen fünf wichtige Phasen im Ablauf eines Bauvorhabens: 1. Entwurf und Genehmigungsplanung, 2. Ausführungsplanung und Bauausführung, 3. Bauüberwachung (Qualitätsmanagement), 4. Wartung und Service (Facility Management) und 5. Baudokumentation. Heute sind für alle diese genannten Phasen Echtzeitanwendungen in Entwicklung.

3.2 Bewertungskriterien für Echtzeitsysteme

Allgemein anerkannt sind heute folgende fünf Bewertungskriterien für Echtzeitsysteme in der Architekturvisualisierung und -simulation: Flexibilität, Mobilität, Wirtschaftlichkeit, Leistungsfähigkeit, (Performance) und Integrationsfähigkeit. Die Hardware sollte modular, flexibel und leicht zu transportieren sein. Dadurch werden auch On-Site-Visualisierungen möglich. Flexible und modulare Bestandteile erleichtern die Kombination und Rekombination verschiedener Geräte. Echtzeitanwendungen sollten möglichst wirtschaftlich sein, in Anschaffung und Betrieb, sollten eine gute Performance aufzeigen und sollten sich gut in Standardsoftwarepakete integrieren lassen. Gute Performance, speziell das Laufzeitverhalten und die Integrationsfähigkeit sind wichtige Indikatoren für die Akzeptanz einer Echtzeitanwendung beim Nutzer (Vgl. HÖHL 2009a, S. 24 – 25).

4   RELATED WORK

Es gibt bereits eine Menge an verschiedenen Echtzeitsystemen für alle fünf oben genannte Bereiche, in unterschiedlichen Entwicklungsstufen, vom Prototypen bis hin zu sehr praktikablen Lösungen. Tizani [2011] beschreibt ein virtuelles Environment zur Bauplanung in der Konzeptionsphase. Er orientiert sich dabei am herkömmlichen Workflow des Architekturentwurfs und der Gebäudeplanung und arbeitet mit einer gemeinsamen Datenbank, entwickelt in C++ und OpenGL. Peña-Mora et.al. [2011] beschäftigen sich mit der Design Coordination und dem Monitoring des Gestaltungsprozesses in der Ausführungsplanung. Die soziale Akzeptanz und die Integration von CVE in den Planungsprozess erforscht Yabuki (2011). Yi-Luen Do (2011) beschäftigt sich mit der Integration von 2D-Echtzeitskizzen in die 3D-Grafik von virtuellen Environments. Die Echtzeitmodellierung von Gebäuden mit einfachen Würfeln ist das Forschungsthema von Chen (2011). Er integriert dabei einfache Modellierungsfunktionen in Echtzeitoberflächen. Eine umfassende, integrierte GIS/CAD/VR-Anwendung auf VRML/XML-Basis und angelagerten CAD-Standardprogrammen entwickeln Ren und Tang (2011). Künz, Dontschewa und Weber (2007) zeigen wichtige Möglichkeiten zur Integration von existierenden Game-Engines in Echtzeitoberflächen zur Architektursimulation.

5   CG MIXED REALITY ARCHITECTURAL WORKSPACE

In diesem Projekt wird der Einsatz von Echtzeit-3D-Darstellung und deren Steuerung durch ein innovatives Mixed Reality-Präsentationssystem (MRI der Firma Kommerz) im Rahmen von Kundengesprächen der Firma Haslerhaus untersucht. Das Ziel der Untersuchung ist, durch den Einsatz innovativer und immersiver Technologien das Produkt Fertigteilhaus optimal darstellen und vermitteln zu können. Durch interaktive Echtzeit-Technologie soll im Gespräch unmittelbar auf Kundenwünsche reagiert werden können und das Ergebnis von Änderungen und Planungs-Varianten sofort erlebbar werden. Die dadurch vermittelte, intensivere Einbindung sollte zu einer höheren Kundenzufriedenheit und -bindung führen. In Vorgesprächen zwischen der FH JOANNEUM und der Firma Haslerhaus wurden konkrete Forschungsbereiche eruiert:

- Mögliche Visualisierungs- und Interaktionskonzepte bestimmen und testen.
- Entwicklung eines Präsentationssystems, das es erlaubt, sich in Echtzeit durch einen Entwurf eines Fertigteilhauses zu bewegen

- Veränderung von Faktoren in Echtzeit: Entwicklung eines Systems, das es erlaubt in Echtzeit Faktoren wie Sonnenstand zu verschiedenen Tages- und Jahreszeiten zu verändern

- Entwicklung eines Bemusterungssystems: hier kann der Kunde sein eigenes Haus am Computer mit den zuvor ausgewählten Details (Fenster, Aussenputz, Dachstein, etc.) in Echtzeit bemustern und zur Beurteilung virtuell begehen.

- Unmittelbar abrufbare, weiterführende visuelle Informationen zu Gebäudedetails, die es erlauben dem Kunden die Sinnhaftigkeit gewisser Lösungen eindrücklich zu erklären

Fig. 8: Integrierte Sonnenstandssimulation

Das Projekt wurden in folgenden Schritten umgesetzt:

Präsentation und Auswahl des MRI-Systems der Firma Kommerz – Gemeinsamer Besuch bei der Firma Kommerz, wo zwei Varianten des MRI-Präsentationssystems, eine stationäre Untertisch- und eine mobile Auftisch-Variante, demonstriert wurden.Aufgrund der Anforderung bei Kundenbesuchen mobil sein zu können sein fiel die Entscheidung schließlich auf die mobile Variante. Weiters wurden anhand von bereits umgesetzen Projekten der Firma Kommerz die Möglichkeiten dieses Systems bzw. der Software für Bau- und Architekturanwendungen demonstriert.

Ermittlung einer optimalen Pipeline für 3D-Daten – Es wurden Test durchgeführt wie die bei der Fa. Haslerhaus vorhandenen 3D-Daten am besten von der von ihnen verwendeten BIM-Software Nemetschek Allplan in die für die 3D-Präsentation verwendete Realtime-3D-Middleware Unity 3D überführt werden können. Dabei ging es darum den Aufwand für notwendige Nachbearbeitungsschritte so gering wie möglich zu halten. Neben den 3D-Daten sollten auch UV- und Texturdaten optimal übertragen werden. Eine nahezu optimale Lösung ergab sich mit dem Export der Daten von Nemetschek Allplan in das 3D-Animationsprogramm Maxon Cinema 4D und von dort nach Unity 3D. Dabei spielt sicher eine Rolle, dass diese beiden Programme der gleichen Firma gehören. Der Grund dafür, soviel Energie in das Pipeline-Thema zu investieren ist, dass die Firma Haslerhaus in einer zukünftigen Ausbaustufe des Projekts ihre 3D-Daten möglichst ohne externe Fachleute in das Framework bringen und präsentieren kann.

Aufbereitung von 3D-Daten eines Musterhauses – Die Daten eines konkreten Musterhauses wurden aufbereitet und in die Realtime-3D Software überführt.

Implementierung von Interaktivität in das MRI-System – Dem Musterhaus-Modell wurden in der Realtime-3D-Umgebung einige interaktive Elemente angebunden

- die Möglichkeit Teile des Hauses und den Außenbereich in der 3D-Umgebung und in Echtzeit mit einer „First-Person-Kamera" zu begehen

- die Belichtungssituation durch Sonne kann über den Tagesverlauf dargestellt werden und zwar für Winter und Sommer

- es wurden Beispiele für die Bemusterung implementiert, die Wand- und Bodenoberfläche kann interaktiv ausgetauscht werden

- es wurde ein "Hotspot" eingbaut der eine animierte Darstellung eines Details erlaubt

Eine entscheidende Rolle spielte die Haptik und die Interaktion. Die Steuerung dieser interaktiven Elemente wurden an entsprechend gefertigte reale und haptische Interaktionselemente des MRI gebunden. So wurde z. B. der Sonnenstand zeitlich im Tagesverlauf durch die Drehung eines Sonnenstand-Modells geregelt. Zwei verschiedene Sonnenstand-Modelle repräsentierten jeweils den Sonnenverlauf für Winter und Sommer. Oberflächen wurden bemustert, indem ein (vorbereitetes) reales Muster z. B. eines gewissen Bodenbelags auf den Tisch gelegt wurde.
Fig. 9: Virtueller Baukasten zur Bemusterung

Leihgabe eines MRI-Systems – Das gesamte System aus Soft- und Hardware wurde der Firma Haslerhaus für intensive Tests für einen Zeitraum von 14 Tagen zur Verfügung gestellt.

Abnahme, Feedback, Austausch der Erfahrungen und Überlegungen für eine Fortführung – all die oben genannten Dinge basieren darauf, dass die 3D-Daten und ein abgestimmter Grob-Entwurf eines Hauses bereits vorhanden sind. Für gewisse Aspekte, wie die Bemusterung, können stattdessen natürlich auch generische Musterhäuser herangezogen werden. Der logische nächste Schritt wäre jetzt mit dem System zeitlich noch einen Schritt früher anzusetzen und auf das Erstgespräch mit dem Kunden abzuzielen. Trotz Echtzeit und Interaktivität muss bis jetzt der Erst-Entwurf noch immer konventionell abgewickelt werden. Im Erstgespräche können Ergebnisse des Prozesses nur in der relativ vagen Form von Hand-Skizzen festgehalten und präsentiert werden. Für eine genauere Beurteilung muss ein zweiter Termin angesetzt werden, damit inzwischen ein CAD-Operator die Ergebnisse visualisieren kann. Gerade bei einem Fertigteilhaus-System mit seinen systembedingten Einschränkungen der Elemente würde sich daher ein virtuelle Baukasten anbieten, mit dem man nach dem Lego-Prinzip das Haus zusammen mit dem Kunden erstellen, dann aber gleich auch in Echtzeit aus der Benutzerperspektive betrachten und beurteilen kann. Man kann unmittelbar nach dem Erstellen durchgehen, Beleuchtungssituationen verschiedener Tages- und Jahreszeiten erleben und die Wirkung von Material-Varianten beurteilen.

6 CONCLUSION

Das Gesamtsystem läuft auf einem handelsüblichen Spielecomputer in einer unteren Preisklasse, einem herkömmlichen Bildschirm (HD 1920/1080, Diagonale 46 Zoll) mit einem optischen, markerbasierten Trackingsystem der Firma KOMMERZ. Das KOMMERZ Mixed Realtity Interface (MRI) ist ein Tangible User Interface, das in unterschiedlichen Designs am Markt verfügbar ist. Vom DIY-Kit bis zum hier verwendeten MRI-TableTop. Es basiert auf einer Bilderkennung runder Marker, die unter gestalterischen Gesichtspunkten entwickelt wurden. Das Besondere ist die automatische Plankalibrierung im richtigen Maßstab mit Hilfe einer speziellen Steuerfigur, die auch dem Benutzer die Orientierung erleichtert. Verwendet wird eine USB-Kamera der Firma IDS mit einem 3 mm Weitwinkel-Objektiv. Das 3D-File wird aus Nemetschek Allplan in Cinema 4D importiert, dort vorbereitet und texturiert. Dann kann die Datei in Unity importiert werden. Die Steuerfiguren im MRI liefern Position und Drehung via einer Plug-In-Echtzeit-3D-Software. Das Unity-File kann von einem Mediendesigner erstellt werden, ohne spezielle Programmierkenntnisse. Ermöglicht wird das über das KOMMERZ Unity Framework, eine Scriptsammlung, die unterschiedlichste Funktionen in Unity bereitstellt, um interaktive 3D-Applikationen zu erstellen. Das Betriebssystem ist Windows OS.

Wie in den vorangegangenen Abschnitten beschrieben, entspricht das existierende Setup unseres CG Mixed-Reality Architectural Workspace momentan dem Typ eines „Synchronen und lokalen Group Workspace".
Fig. 10: Synchroner und lokaler Group Workspace

Das VE1 entspricht dem 3D-Walkthrough mit integrierter Sonnenstandsanalyse, die DB1 entspricht dem virtuellen Baukasten zur Bemusterung, A1 und I1 bilden das Mixed-Reality-Interface für mehrere, lokale Nutzer, gleichzeitig und in der selben Organisationsform. Aus dieser Typologie lassen sich weitere Entwicklungsmöglichkeiten ableiten. Problemlos lassen sich bereits heute weitere Interfaces für weitere Nutzer und Funktionen in unser System integrieren, wie Tangible User Interfaces, Multitouch-Tables oder ein IPad für die Sonnenstandssimulation. Zu testen wäre, in wie weit zukünftig auch Umgebungsfaktoren wie Schall, Wind und Verkehr in die Simulation eingebunden werden könnten. Die existierenden Anwendungsbereiche könnten damit geeignet erweitert werden und der computergestützte Gebäudeentwurf könnte dahingehend optimiert werden. Als Anwendungsbereiche bieten sich auch folgende Szenarien an:

- Architektur-Wettbewerbe: Austausch von Beiträgen in Echtzeit, vergleichende Beurteilung, Echtzeit-Begehung, Jury-Arbeit

- Beurteilung der Gestaltung im öffentlich Bereich – Bürgerbeteiligung

- Visuelle Leitsysteme: „schnelles Austesten" verschiedener Varianten in der Gebäude- und Verkehrsplanung

- Präsentation von Planungen mit der Möglichkeit interaktiv zu reagieren – (politische) Gremien

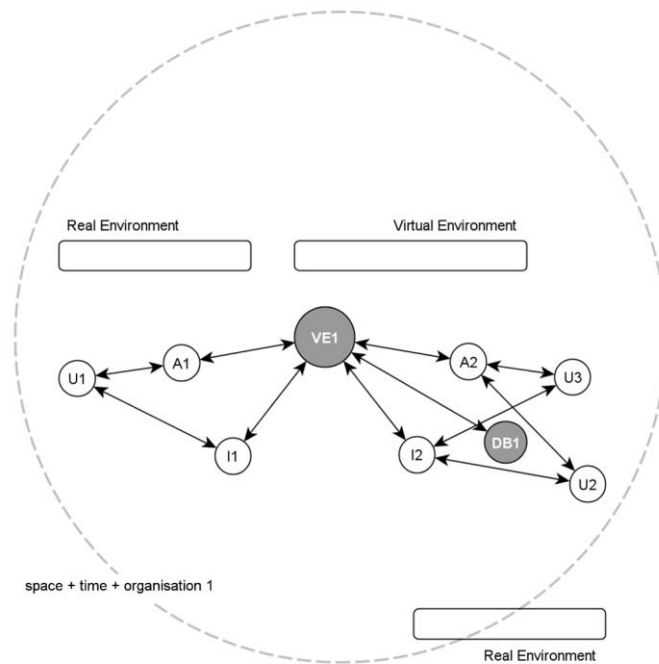
- Urban Code und "Big Data": Vernetzung ortsbezogener Datensätze der Stadt für Planungen – Gemeinbedarfsanlagen (z. B.: Kioske, Apotheken, Bibliotheken, Energieverbrauch, Wetter, Schadstoffemission, Verkehr, Mobilität, etc.), Nutzung von Datenbankinformation auch für Laien


Fig. 11: Integration von weiteren Nutzern und Interfaces (z.B: Tangible User Interfaces, Multitouch-Tables oder IPads)

Eine Chance zum besseren Modellieren im Entwurf und zur Integration in den Echtzeit-Planungsprozess sehen wir in verschiedenen Detail- und Interaktionsebenen. Mittels globaler und lokaler physischer Selektions- und Interaktionselemente können interaktiv einzelne Informationselemente selektiert und manipuliert werden. Zugehörige Detailinfo erscheint in verschiedenen Ansichtsmodi der 3D-Ansicht. Denkbar wäre aber auch eine Erweiterung um weitere Datenbanken für einen „Virtuellen Baukasten" oder eine Anbinduung an ein geeignetes Building Information Modeling (BIM). Mit einem weiteren Ausbau der Kommunikationstools entwickelt sich auch die Möglichkeit zu einer weiteren Vernetzung mit non-lokalen Nutzern, Datenbanken und anderen Virtuellen Environments zu einem neuen, asynchronen und multilokalen kollaborativen Environment.

1 ABSTRACT[1]

Societies in which cities are diminishing are no longer developing and getting wealthier. They decay (Jacobs 2007, 248). Jacobs believes that the cities, not the state, are the engines of economic development. The traditional approach (top-down) is characterized by centralized decision-making and interventionism, management from the center, the sectoral approach to development, the development of large industrial projects as stimulation mechanisms of other economic aspects and financial support, incentives as instruments of economic activity. Due to the fact that this has been proved as negative and unproductive for many reasons, the bottom-up approach is today more favoured. It involves local economic development, which includes the promotion of the development of all community sections, decentralization of vertical cooperation with different establishment levels and horizontal cooperation with economy, territorial approach to development, maximizing the development potential of each region and adjusting the local system to changes in the economic environment, and the creation of conditions for economic activity, ie. improving the local environment. Generally, it should correspond with the environmentally responsible economic, socially-fair and spatially balanced regional development / growth.

Having in mind that Serbia is still a highly centralized state, with only initial forms of decentralization in development management, it is necessary to establish modalities for its inclusion into current trends. Starting from the fact that the general development regulations in the EU reserves the supranational and national levels, and that most of the development documents are adapted at the regional, metropolitan and local level, such an approach should be necessarily applied in Serbia too. Those adjustments would be accompanied by changes in the policy of regional development in the EU, where is, among other things, insisted on an integral approach to policy development, integral territorial management and establishing a sustainable business.

The research focus has been placed on determining the possibilities of applying the concept of "smart cities", "smart regions" or "smart clusters" as a planning tool, which proved to be suitable for the new developmental ideas and initiatives. The starting point is that all areas should better use their own territorial capital/potential, especially activating all stakeholders, as well as available natural, technical and human resources, etc. However, simple downloading of the model is not possible, because of the general and specific conditions that characterize the territory. In order to recognize the code for better functioning and offer guidance for the future, it is necessary to consider the specifics of planning policies and urban development in the period prior to and after 2000.

2 PRECONDITION OF SERBIAN MODERN PLANNING

The Eastern Mediterranean and South-East Europe are burdened by the historical deficit of urban development. Their cities have entered the era of the industrial revolution as conglomerates of immediate rural origin and character, devoid of professional, scientific and technological resources needed for investment in new economic, cultural and social values. In the long era of Muslim domination and Islamization on the sidelines of the great pre-modern civilizations, the periphery of the peripheries, the Balkans have remained isolated from the influence of the Renaissance, the Reformation, the Enlightenment

---

and rationalism. Impacts on the European periphery, nationalism and colonial imperialism of the nineteenth century were also hinder the emancipation of urban culture.

The beginnings of democratization, when there were any, also relied on the prevailing political will of the archaic agrarian society and dominant layers of power. This mentality has contributed to the survival of the patriarchal, paternalistic and authoritarian political model that generated the autarchic economy. Islam and Eastern Orthodoxy rejected individualism, capitalism, and work ethic. The first national writers of Balkan literary realism and naturalism were exposing the local urban civilization in gloomy colors of deplorable and neglected communities, emphasizing the darkest features of the human soul, and the historical spell of ignorance and poverty. At the periphery of the Habsburg Empire Balkan long endured relics of feudalism and clericalism. European peripheral countries in the early twentieth century still had around one half or more of their population dependent on agriculture and with incomes per capita of less than 50 per cent of those of the advanced nations of Western Europe. As being predominantly rural, their demographic potentials have remained weak and badly structured. Post feudal, rural cultures and mentalities have undermined the power of the already thin layers of urban civilization. Cities were identified with the enemies of the nation and the church.

In comparison to already poor Southern Europe, comparing to the West, with 45–50 per cent of rural population, in the Balkans 70–81 per cent were living in the villages at the beginnings of the twentieth century, with very low productivity levels and high illiteracy rate.

A very specific problem related to the urban structure and the place of the cities stemmed from the circumstances in which they were often a national, religious and cultural minorities habitat, or even a refuge. Minority nationality problems were one of the most acute causes of tension in South-east Europe, confronting the cities and their potentially tolerant, pluralistic environment, with the huge rural hinterland and its traditional notions and influences.

The low urbanization level was also connected to a poor industrial development. Mostly basic trade orientated, the Western Balkans remained, through a century, weak and vulnerable economy, closely related to the state and privileged groups, instead to a business-orientated urban society. Low living standards encouraged the survival of traditional strata of economic and social power and the nomenclature. Domestic economic structure dictated the state of economic culture, as the primary commodities, and, in the second half of the twentieth century, low rated industrial products tended to dominate the export trade. Generally, all external parameters of urban development remained extremely unfavorable, as public and commodity transport, communications, housing supply, health care, and educational and cultural service.

Citizenship has never been able to gain a historical reputation and political prestige. Traditional rural society and a violent elite consisted the basic social mass, further filled with the soldiers, clergy and highly obedient bureaucrats, lacking the substantial middling bourgeoisie as the driving force in mercantile and industrial pursuits. The key roles in trade, industry and finance were historically due to the foreigners, to Germans, Jews, etc., and the social mobility was limited as much as its foundations that could be provided in successful urban development. The interwar, "first" Yugoslavia was the state with the smallest percentage of Jews in Europe, and it was one of the symptoms of the modest urban development, rather than some general bad feeling.

3 AFTERWAR SERBIAN MODERN(IST) 'PLANNING TIMES'

From today's perspective, the idea of long-term city planning in Serbia appeared after the WWII, as a part of the general ideological orientation. Namely, the Urban Institute of Serbia was founded in 1945, followed by the first concept of renewal of war-devastated country. Further development path is characterized by a number of modifications as a reflection of general societal changes, impacts from other environments or adjacent disciplines. By the end of the 1960s, the paradigm was established, which remained almost unchanged to this day. With regard to long-term, city planning represented the only institutionalized mode of action. Monitoring of its development is actually monitoring the development of one model. In other words, the process of establishment and implementation of the general planning can be presented as development of single paradigm. Therefore, general planning in Serbia has undergone the whole process of a paradigm change but with very specific dynamic, where some phases last an unusually long, while others very short (Brkovic Bajic, 2002).

Planning in Socialist Yugoslavia was the dominant type of regulation and control of modern society, economy and urban space. It is related to the fundamental processes of domination and social culture, as well as with the growth of modernity. According to Escobar (2001), the concept of planning reflects the belief that social change can be planned, managed and produced at will. Finally, in all its variants, rationalist model of planning is practiced as an 'eminently modernist project' (Vujosevic, 2004).

This model can be recognized in all cities in Serbia. Spatial planning was subordinated to economic, as economic growth is identified with the development. City development was considered through opportunities and the power of a country that has had a leading role in decision-making. Thus, all decisions were taken in the political centre. One of the examples was New Belgrade, built after the WWII on the empty land between two historical cores of Belgrade and Zemun. The initiative for the construction of Belgrade on the left bank of the river Sava came from the leadership of the Communist Party of Yugoslavia and its head Tito. The whole period of conceiving and realization was under the strong influence of political ideology, namely that the city of New Belgrade serves as the capital of a modern and progressive Yugoslavia and its multicultural society. The main actors were professionals working on a plans, politicians and government bodies at various levels. From the very beginning, all the results of the experts have been subject to permanent supervision of the state leadership that gave opinions and suggestions for further work and development. After all, all plans were eventually at the hands of Tito for proofing.

4 'THE CRISIS OF NON-CONCEPT': POST-MODERN TURN AND POST-SOCIALIST TRANSITION

In Yugoslavia, socialism was more open and liberal than in other Central and Eastern European countries. Economic organizations had the opportunity for more liberal market performance, cultural freedoms were recognizable, the citizens were free to leave the country. After Tito's death in 1980, the level of political differentiation increased. Almost a decade later, the fall of the Berlin Wall symbolized the end of the socialist system. At this time, Serbia's position was much better, because in 1990 (as the initial year of transitional processes) most of the republics of the former Yugoslavia was ahead of the socialist countries of Central and Eastern Europe by the level of economic development. However, the price of transition, interrupted by disintegration of the state and war, increased several times, while the time of completion shifted for nearly two decades. As a result, these countries found themselves at the bottom of the list for accession into the European Union.

The way in which Yugoslavia disintegrated determined the transformational path of Serbia during most of the 1990s. As there were certain specifics that were associated with Yugoslavia, the transition process which Serbia entered (as part of the former Yugoslavia) had some different characteristics from Poland, Hungary, the Czech Republic, etc. Taking into account the collapse of Yugoslavia, civil war, UN sanctions, hyperinflation and economic collapse, these processes were difficult for Serbian society. The transition has not appeared in a peaceful way, because the wars strongly influenced newly formed states. These circumstances have created a situation of external as well as internal isolation, under the rule of Milosevic's authoritarian regime. Most distinctive was the case of Serbia under the full UN sanctions since 1992 to 1995. In this situation, the question of 'collective identity' of citizens became confusing, given that Milosevic's structures promoted and had a monopoly on all media, with aim to achieve the new 'national identity'.

In the field of urban planning and design, these processes were most reflected in a changed interpretation of the relationship between interests and values. Interests were based on the needs, which are "individual and collective organic substrate from which they spring" (Vujosevic, 2004). According to Vujosevic, "They may come from kind of value orientation (such as normative criteria, or general ideas about desirable etc.), which is not necessarily about material interests, but also others". In urban planning, the last decade of the century was marked with the trend of 'deplannification', which is legitimized on the basis of decisions made in the political centre, but is achieved primarily through the decentralized decisions of many actors. In terms of the emergence of 'wild capitalism', unregulated privatization and uncontrolled private accumulation, the importance of the public good in planning and social, environmental and spatial implication of these processes has been pushed into the background" (Vujosevic, 2004).

Social enterprises changed their status into the private, and an additional incentive for success is guaranteed by already built political and business connections. In such constellation, the state becomes the user, not the regulator, while more authority is transferred to the municipalities. Urban planning lost its centralized

character causing a hyper production of detailed plans by different offices, without the influence of the Town Planning Institute. New architectural and planning paradigms were embraced by the professionals inclined to post-modern flows, while modernist models lost their importance in a changed socio-economic context (Vujošević, 2004). Consequently, this situation created a fertile ground for different malversations, while urban planning represented an uncoordinated set of fragmented interventions, 'justified' by the lack of funds, regulations, tools for implementation and, above all, well-defined, comprehensive development concepts.

After the 5th October 2000, the great pro-democratic energy went on stronger economic action, partly (and associated with it) in the mass consumerism. In regard of values, this situation "threatens the level of (social) solidarity and blurs the contours of common goals and the constituted community around them in Serbia" (Cvejic, 2010). By strengthening the decentralization, local governments were given greater powers and possibilities for influence in the local economic development. Cvejić also claims that the current developmental crossroad is in the cultural sphere. It can be said as well that the new cultural patterns are most importantly of value. However, the action potential of civil society is reduced by consumerism and its primar orientation on economic goals and activity.

5   REVIEW OF THE CURRENT DEVELOPMENT AND PLANNING SITUATION IN SERBIA

Report on the development of Serbia in 2009 states that the main characteristic of regional development of Serbia is a distinct territorial disparity. This kind of imbalance is manifested through several levels: undeveloped territory, developed centre and insufficiently developed periphery. The same source indicates that uneven development and regional differences are caused by numerous economic, demographic and social factors with the special emphasis on multi-decadal marginalization of the process of regional development strategic management. The consequence is the regional disproportion which is manifested in a high level of unemployment, reducing the scope of a total economic activity and a constant decline in population especially in undeveloped area (Republički zavod za razvoj, 2009). According to the researches of the Republic institute, the regional polarization of Serbia is multi-layered and is evinced in interregional differences manifested in demographic movements in Serbia, regional educational structure of the population, interregional economic differences, infrastructural gap and poverty. Regional disproportions of the level of development in Serbia are the biggest in Europe and in time they grow even bigger.

The most illustrative review of this situation is the trend of evolution of demographic situation, a sort of logic response to the social-economic situation in the country. The migration[2] of population towards economically active centres is noted, all in order to ensure their own existence. This trend would lead to the forming of only one demographically vital territory, the one that would connect present regions of Belgrade and Novi Sad. Centralization is manifested in all levels, the state, the province as well as the level of municipality.[3] Considering negative trend of regional development of Serbia but also strategic orientation to join the European Union, regionalization and more even development are set as a primary goal for solving this situation. Its purpose lies in setting the equalities, not literally but in the form of various opportunities and chances. Edvard Jakopin (2009) determines five reasons for which the regionalization is necessary: (1) Regionalization as the basic instrument of state in terms of economic, social and demographic development, (2) Development of each part of the state with geo-strategic character, (3) Economic and social homogeneity, (4) Dialog and tolerance and (5) Political relaxation. However, the current orientation to regionalization and equal development entails three crucial problems: deficiency of laws regulating restitution, denationalization, laws of public or municipality property, and deficiency of systematic decentralization as an expression of political will and the political appropriation of the system of regionalization (Stojkov, 2009).

In the period of time from 2003, after ratifying the Law of planning and construction, series of activities have been initiated and series of legal acts have been adapted which have as their goal to contribute to more equal regional development of Serbia. Among them stands out the Spatial development strategy, which is based on

---

[2] The facts of the migration without return from urban municipality centers to three large cities in Serbia: Belgrade, Novi Sad and Niš (Kovačević 2009)

[3] If you consider only the examples of the positive example such as the autonomous region of Vojvodina or the city of Belgrade, you will notice the enormous differences in development of the municipalities in Vojvodina between south and north Backa and, for example, municipalities on the east and southeast of Vojvodina, as well as in the city of Belgrade between Belgrade and Barajevo, Sopot etc. Therefore, the relationship between center and periphery appears dramatically on all levels (Stojkov, 2009).

the fact that the cities (urban system and urban net) are in every way a pillar and regional catalyst of the economic development.[4] Zekovic (2009) states that the cause of recession in our cities is rapid decline in industry which led to the most powerful regional deindustrialization in Europe.

After analysing the results of the 2012 Census and forming the Report on establishing the Spatial Plan of the Republic of Serbia and state of spatial development (RAPP, 2012) the following indicators were observed: (1) balanced regional development and social cohesion level, (2) regional competitiveness and accessibility, (3) indicators of sustainable use of natural resources and state of the environment, (4) protection and sustainability of use of natural and cultural heritage and district and (5) indicators of spatial and functional integrity in the surrounding. For the purpose of this paper results which can be observed from the Smart City concept were singled out.

Key performance indicators are represented Serbia in the Report which was published in March 2012and they are presented below. The population density (Fig. 1a) indicator in the capital city area is largely disproportionate to the rest of districts in the country. It is observed that in four border districts the population density is below 50 inhabitants per km2, six districts (all in the zone of influence of Pan-European corridors) have over 100 per km2, while only the Belgrade District has over 200. The average population density is around 85 inhabitants per km2, but if observed from the perspective of districts they range from 40 to 500. As for migration rate level, migratory movement in Serbia is largely directed towards the capital city and to a large extent lower to South Backa, Nisavska and Raska districts, while in the rest of districts the negative migration level is observed, which indicates emigration, or continuation of emigration from those regions. By comparative analysis of the three basic age categories of population it is recorded that the concentration of inhabitants older then 65 is the highest in Eastern Serbia, where at the same time the lowest concentration of young and middle aged population is recorded, which is the bearer of economic development in the observed moment in comparison to the rest of districts in Serbia.

The share of highly educated population (Fig 1b), which is the direct factor of economic and social progress of certain territory is unfavourable, both on the level of certain district and when observed on the national level. The highest share of highly educated population is measured in the Belgrade District (13.76 %), the lowest in Branicevski District (below 5 %). Additionally, except for the Belgrade, South Banat and Nisavska districts, the percentage of highly-educated inhabitants among the population older then 15 is always lower than 5 % which polarizes the development and inequality in terms of living conditions in Serbia. On the national level, the share of the highly educated employed population in the total number of those who are employed accounts to only 14.6 %. In the Belgrade District the share of the highly educated employed population is the highest (26.5 %). This estimate is expected, if considered that the highest number of highly educated inhabitants can be found in the Serbian capital and the labour market and economy are most vibrant. In other three districts, the share of highly educated in the total share of the employed population is similar and it ranges from 10.9 % in the Vojvodina Region, 10.8 % in the Sumadija and Western Serbia regions, while the lowest is recorded in Southern and Eastern Serbia and it accounts for 10.6 %. In all 25 districts for which there are data, the share of dependents and those with personal income, in comparison to active persons with interest is higher, and this difference is the highest in the Toplicka District (28 %) and the lowest in Kolubarska District (7 %). In other words, the highest share of dependents and those with personal income is in Toplicka District (58.97 %) and in Kolubarska District in the total population (48.94 %). On the other side, the share of active persons with interest in the total population in the total population is the highest in Kolubarska (42.16 %) and the lowest in Pcinjska District (31.06 %). Finally, such low number of active persons who are engaged in comparison to dependants and those with personal income generates and it is to generate a series of socio-economic problems, which require the creation of new and/or implementation of existing measure for employment of working-age population, and creation of circumstances for positive development trends and higher level of social inclusion of population in all districts, i.e. regions of the Republic of Serbia.

Average travel time from the centre of district to one of the three centres with over 100.000 inhabitants ranges between 60 to 155 minutes. The inhabitants of the Belgrade, Pomoravska, Sumadijska and South Backa districts take the least time to travel to a regional centre, which can be explained by geographical

---

[4] Over 90 %, and somewhere even over 95 % of the total economic development happens in cities.

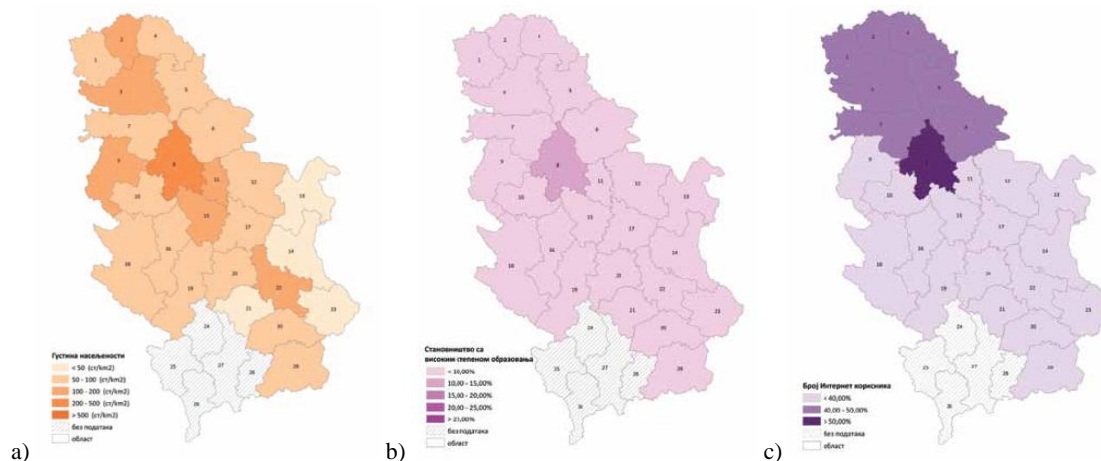
location and position along the Corridor X, while the least accessible are border districts, which can be explained by both distance and level of development of traffic infrastructure.


Fig. 1: a) Population density; b) Highly educated population and c) Internet users in Serbia. (RAPP, 2012)

As for the adapted planning documents in the year or 2011, there were four regional spatial plans and 14 plans on the level of local self-government. In 2009 and 2010 there were 10 plans adapted. The work on other regional spatial plans and spatial plans of local self-governments is in different phase of development (5 regional and 82 local) or harmonization (44 local) with the current legislature. By analysing the date from the municipal yearbook it is evident that tertiary sector of economy prevails, while based on the 2002 Census the results are more heterogeneous and it portraits the predominance of tertiary sector in all areas of big cities such as Belgrade, Novi Sad and Nis, while the primary sector is most present in the Macvanska, Kolubarska and Branicevska districts. The highest number of immovable cultural property is located in the Sremska and Beogradska districts, the high number of protected goods is also in South Banat and South Backa districts and also in Nisavska district. In other districts there is a lower number of protected goods, especially in South Serbia. The participation to international cooperation projects is most evident in the North parts of Serbia, especially in Backa and Banat. Lower number of projects in the central parts of the country is caused by high number of cross-border cooperation projects, which are concentrated in the border areas of the country. Also, in the last report of Republic geodetic authority it can be seen of the total number of cadastral municipalities (4527) 45 % drafted digital cadastral plans and placed in official use, 13 % of the work in progress. Other cadastral plans are in analogue format (RGZ, 2013).

The stated indicators and general long-year experience with implementation of planning documents in Serbia, as well as the actual situation on the global level, demonstrate the need for new approach which is implemented in development strategies of populated areas.

6 SMART CITY PLANNING TOOL

The current period is characterized by a situation in which a large number of cities, regardless of their size, formulate their development strategies on the basis of knowledge city and creative city concepts. These concepts arise as a consequence of rapid economic and social change. In these cities knowledge, creativity and innovation of citizens are considered to be crucial holders of creating prosperity and quality of life. The hybrid concept of smart city is formed by overlapping these concepts: knowledge city and creative city (Vukmirovic/Milakovic, 2012). This conception is also known as intelligent or digital city. Depending on the phrase used the primary focus varies: ICT, highly educated population, creative class etc. Although the smart city concept is already present in development visions of cities, some blueprints begin and end with a vision dominated by the physical design, resulting in a jumbled mess of engineering and architectural ideas supported by various technologies. Such visions are utopian and impossible to implement. However, the key characteristic of this concept is movement from vision to action (OVUM, 2011).

urban production factors in a common framework and, in particular, to highlight the importance of Information and Communication Technologies (ICTs) in the last 20 years for enhancing the competitive profile of a city. We believe a city to be smart when investments in human and social capital and traditional (transport) and modern (ICT) communication infrastructure fuel sustainable economic growth and a high

quality of life, with a wise management of natural resources, through participatory governance (Caragliu et al. 2009). A Smart City is a city well performing in 6 characteristics, built on the 'smart' combination of endowments and activities of self-decisive, independent and aware citizens. These characteristics encompass: smart economy, smart mobility, smart environment, smart people, smart living and smart governance (European smart city project, 2013). All of those can be measured by using the determined indicators: smart economy, smart mobility, smart environment, smart people, smart living and smart governance (Fig. 2). These indicators also serve as separate fields in which a city is to make an improvement.
Fig. 2: Smart city indicators. Source: http://www.smart-cities.eu

The concept of the 'smart city' has recently been introduced as a strategic device to encompass modern Advantage of this conception is reflected in the possibility of implementation on cities of various sizes (from a metropolis to a small size city). Also, this principle favourise bottom-up planning approach. In this way, the size of intervention which is to initiate urban development varies from those of smaller scale to those on the regional level. Having this in mind, implemented strategies can be ranked as smart point, smart network, smart cluster, smart city and smart region. Specifics of the smart city approach are seen in several important elements (OVUM, 2011):

- The paradigm for a top-down approach is a tightly managed enterprise resource planning system for the entire city, including its distributed physical assets. The paradigm for a bottom-up model is an open source platform that supports instead of prescribes the creation of modular and diverse applications and extensions by third parties.

- Projects in Europe and North America tend to be focused on "retro-fitting", which is the use of ICT as an overlay for existing infrastructure. In these regions, it is more challenging to deploy an integrated approach as existing cities already have systems in place to discharge their functions. In addition, most cities have grown on a piecemeal basis as a result of individual initiatives and projects.

- Opportunities for complete retro-fits are also limited. While in the 1850s and 1860s, Haussmann could drive great boulevards through Paris's inner-city districts to fix the city's perceived circulation and political security problems, there are unlikely to be many "digital Haussmanns" as it is simply not possible to replace existing urban systems because too much relies on them. Therefore, urban projects increasingly make use of a "living laboratory" methodology. This methodology explicitly recognizes that new systems must be deployed in a real life context, with the experimental subjects drawn from the population of future service users.

In this way an advantage is given to ICT sector, which is seen as quick to develop and complementary to the existing infrastructure, which is underdeveloped in Serbia. The stated approach is implemented in the proposal for development of Trstenik. The development concept of this small size city is observed from three levels: (1) at the State level and its connections with other centres in the region, (2) at the regional level and (3) at the level of municipality.

- At the State level, Trstenik is recognized as the local centre in which agriculture has the potential to become the dominant sector of the economy. This would be achieved by specializing in specific production sectors of agriculture such as production of coils, fruits and vegetables. Furthermore, specialization would be reflected in the application of modern technologies and knowledge. This would aim to improve the yield, but also the retention of natural (organic) quality that is highly

desired and valued in developed countries. The creative agriculture is seen as a concept, which seeks the city development on the basis of the activity recognized to have great potential.

- At the regional level and the level of local centres network, position of Trstenik could be seen as a specialized centre – a smart town, which would aim to complete the offer.

- As the centre of the municipality and the network of rural settlements, Trstenik should direct its actions towards the development of these settlements, primarily for the purpose of promoting various forms of rural tourism, which is becoming increasingly attractive to both domestic and foreign population (Vukmirovic/Milakovic, 2012).

The stated idea is presented at the competition Small Towns of Serbia organized by the Agency for Spatial Planning of the Republic of Serbia in 2011. The jury composed of six spatial planning experts evaluated the proposal as good in a visionary sense, but requiring several massive factors which are to initiate it during the development process of a city. However, the jury considered that the way this idea communicates can be improved in the qualified professional circles, but it is at the same time harder to achieve in the general public.

7 CONCLUSION

Hitherto urban planning experience in Serbia and current development indicators demonstrate a rather complex situation. Still, planning tools have managed, to a certain extent at some periods, to produce good results, which indicates their necessity. The inconsistency of expert opinions with those of the public is seen as a main problem for implementing planning documents, which leads towards something which can be named "spontaneous occurrence".

The contemporary approach to planning is primarily based on sustainable development and it implies education and inclusion of citizens in the process of decision-making and creation of planning documents. Although this trend is in the development phase, certain positive results can be observed. However, the specific mentality/identity of this region and its inhabitants is observed as a second important factor, which is clearly seen from the historical analysis. For this reason, it is necessary adapt best practices which are "imported" to areas where they are implemented, so as to avoid misbalance and unexpected results – spontaneous occurrences. Accordingly, the contemporary concepts such as smart city should be implemented in the "local way", which implies their adaption to the local area and mentality.

City Works: A New Model for Management of Public Landuu

Lapo Cozzutto

(Dott. Lapo Cozzutto, Consorzio Ferrara Ricerche – webgislab, lapo.cozzutto@webgislab.org)

1 OBJECTIVES

The main goals of City Works are the following:

(1) Improve the quality and duration of roads;

(2) Reduce the impact of the work on the mobility of citizens, eliminating traffic jams;

(3) Retrieve economic resources by controlling of the territory;

(4) Provide a service to the economic operators, reducing the time of investigation.

1.1 How to activate

Agencies that have joined this new management model have enabled a virtual one-stop-shop online that is accessible from any computer connected to the internet.

You can submit requests for digging permits, encroaching, scaffolding, exhibitions and more, in general any type of use of public soil.

In addition to textual information, it is mandatory to trace on map the geometry connected to the request, showing what will be the impact on the territory.

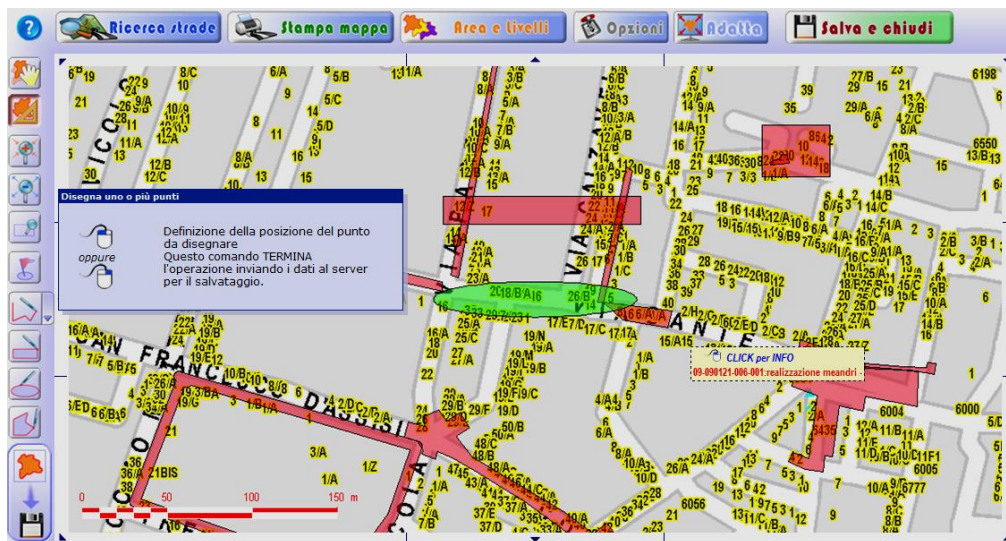
The system shows what are the possible overlaps and interference with other encroaches, allowing to have a true co-ordination in real time.


Figure 1: Sample of new geometry tracing: when the user terminates the geometry (green oval) the system displays the possible overlaps (red polygons).

1.1.1 The situation before City Works

The amount of daily activities on the territory are increasing year by year and it is becoming more and more difficult to control all the encroachments insisting on the territory. Sometime it is possible to authorize public events and at the same time excavations on the same or on adjacent areas. This can cause damage to City Council's image and sometime to people, if an emergency service could not reach the target. With City Works we wanted to include all the possible encroachments, including also all the public works opened for broken pipes.

1.1.2 What is the technical coordination of the territory

In some Municipalities it has been decided to activate a dedicated department for the coordination of these requests, and the department is transversely, checks all the events both activated by the infrastructure companies and by the other departments of the town (public works, mobility, traffic, land planning, building

permits, sports, culture, etc.). The task of the coordination is preventing overlaps and avoiding discomfort to citizenship (i.e. traffic jams).

1.1.3 City Council Departments

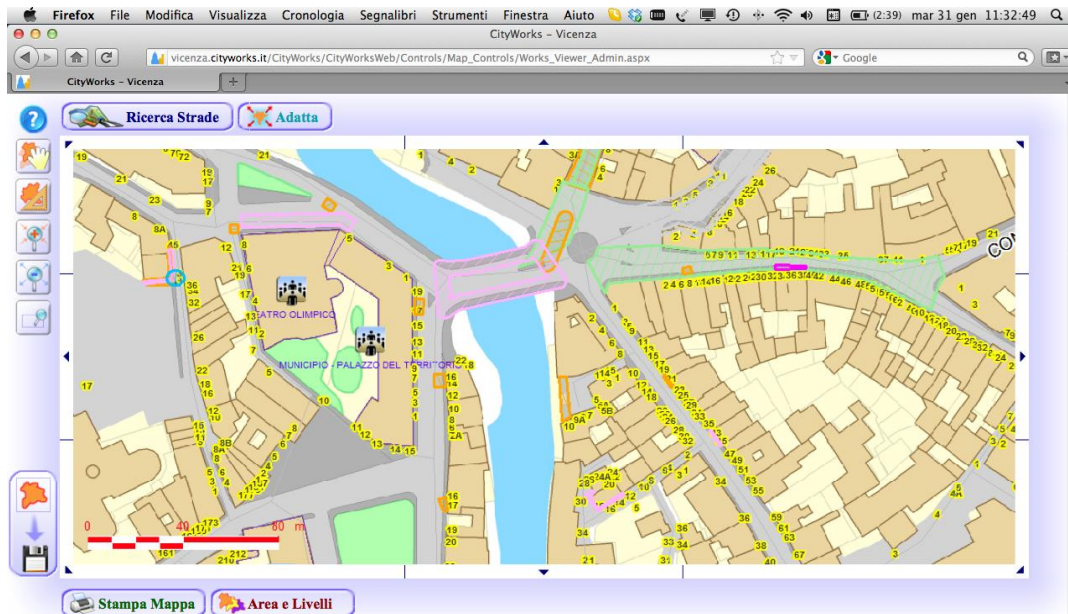
Each department has the ability to enter all their own planning, and check in real time what is already set by the other departments. In addition, the City Council can see the encroachments inserted by the infrastructure companies (i.e. water, gas, telephone companies). The main objective is to aggregate all the street works, therefore optimizing the economic resources of the City Council and of the infrastructure companies (digging and resurfacing one time for several public works).


Figure 2: Sample of Vicenza City Works: Pink polygons are planned street works, Purple in progress, Orange temporary completed.

1.1.4 Quality of the roads

The streets of the towns contain potholes, cracks, and damage of various kinds. These problems are normally determined by works on infrastructures. Very often the streets are not well restored and the City Council is forced to resurface the road in shorter times than those already scheduled.

1.1.5 Requests for compensation and insurance

In recent years, we have a considerable increase of citizens claims caused by bad streets maintenance. Some Italian City Councils will not even be insured anymore, thus creating a considerable damage to the budgets of the Municipalities. Therefore, it is necessary to have a better control of street works, reducing potholes and cracks, having a better restoration process of roads.

1.1.6 Improvement of technical analysis

We wanted also to improve the quality of the documentation, having all the necessary information (Project Tracks, Sections, Pictures etc.) to properly analyse each request.

1.1.7 Integration with the taxation department

In order to send a new request, the user will also be prompted to enter all the information which is normally managed by the Tax Department. The system automatically calculates taxes required. The incomes are automatically verified by the system, and this allows to not having to proceed with the recovery of fees not paid by the applicant.

1.1.8 Integration digging permits and traffic ordinances

City Works has, moreover, allowed to unify encroachments and traffic ordinances. The two permits are completely hooked and one should not exist without the other. We wanted to create a system that integrates activities usually handled by separate departments, but that, when they are not synchronised, procuring several issues to the territory.

1.1.9 One-stop-shop: paperless workflow with the use of digital signature

In the municipalities that have adopted the City Works system, it is possible to submit requests for digging and encroachment directly from the office without having to bring the „piece of paper" to the City Council. It is possible to query in any moment the status of the request.

The entire process of analysis of requests is shared among all the City Council's departments, to avoid overlaps and interferences.

1.1.10 Result of the complete process

The City Council has a true dashboard of what is happening in the city, what has already done and what is already scheduled. This makes possible to control the contractors, see immediately what operations have been completed and which are to verify. This new process must also prevent a road just resurfaced to be broken after a few months for scheduled replacement of an infrastructure.

1.1.11 Certified Cartography

All the information produced are recorded in a WebGIS application. The end users are generating the information and this is certified by the City Council.

1.1.12 A true emerging system already used most common in cities with following sizes: from 30,000 inhabitants on

City Works is a true emerging system: each user, even with non-computer skills, inserts information in the system. This data is immediately available to all the other. It is like a "public land social network", to improve the economic management of government companies and reduce the discomfort to the citizens. A new way of managing the public body since is possible to understand the transformations of the territory and what activities are handled by the City Council day to day.

2 THE CONTROL OF THE INTERVENTIONS: AS LENGTHEN LIFE IN THE STREETS, ELIMINATE THE ABUSIVE ACTIONS AND REDUCE THE REQUIREMENTS FOR COMPENSATION

The City of Florence has activated with the City Works a new model for control and verification of the territory: having knowledge of the planned street works, twelve inspectors come out every day to check each yard or construction site, they verify the used filling, the quality of the concrete and asphalt.

2.1 New developments to improve the model

We have already planned to develop new Apps which will allow the contractors to insert the emergencies (broken pipes) directly from the territory: the app will collect GPS coordinates, Photos, technical data, and all of these information will be immediately sent to City Works.

Another App will be developed to collect possible issues of the territory (potholes, cracks, dangerous cross roads etc.).

To improve the control management system, we will create another application for the City's inspectors to collect all the street works information using a tablet device. This application will be connected also with the City's Police to have an integrated process for the control of the territory (street works safety, mobility and traffic etc.).

All of these software modules will be developed to have a better organisation of human resources, since it will be possible to plan from the office the routes of verification for planned and emergency street works.

2.2 Effects in using the system

Twelve Italian City Councils already acquired City Works, having very positive results with the use of this new management model. In particular, Florence, Brescia, Prato and Livorno, City Councils allow sending of requests for digging and ordinances directly online. Also Municipalities like Vicenza, Pordenone and Castelfranco Veneto have a one-stop-shop to manage digging permits directly by the Internet.

2.3 Average results achieved with the use of this new operational model

After 8 years of operation, we can collect an average of results obtained in City Works City Councils:

Description	Income/Savings
Increased number of authorizations	From +15 % to +26 %
Occupation taxes	From +18 % to +42 %
Paper warehouse	From -93 % to -100 %
Potholes	From -30 % to 57 %
"Useless" street resurfacings	From -22 % to -35 %
Fines for irregular application of authorization	+ 200 %
Time dedicated to front office activities	-93 %
Time dedicated to assistance	-88 %
Data entry activity	-96 %
Quality of territorial control	+ 400 %

Table 1: tangible and intangible results using City Works (average results of 8 City Councils).

3 CONCLUSION

City Works has proven itself as a model of efficient management and particularly efficient because it allows to recover economic resources, and have a better spending avoiding useless street works. This new management model improves the quality of the roads and reduces the number of claims asked by citizens for bad road maintenance. In this case, the technologies are helping the control of the territory, and the City Councils are providing a better service to businesses, professionals and citizens, having the transformations of the territory under control.

Climate Data Analysis on IGIS

1 ABSTRACT

The paper deals with a system of algorithms used in the intelligent GIS for solving problem of environment monitoring based on integrated data from various data sources, statistical and operative data on meteorology and oceanography in the first place. The described set of algorithms is developed for solving tasks that arise at three main stages of data analyses: data verification, regularization and recognition. Derivative parameters calculation algorithms that allow to compute relevant parameters of the environment in case of limited computational power without computationally complex models solving recognition and forecasting problems play discrete role. Example of the software implementation of the system is considered for the problems of climate monitoring in the Arctic.

2 INTRODUCTION

Exponential increase of the information content in all spheres of human activity at the end of the twentieth and in the beginning of the twenty first centuries called for principally new approaches in information treating and apprehending. Critical breakthrough in informational technology (IT) related to geo-referenced information was achieved due to the development of high-tech intelligent geographical information systems (IGIS) [19]. Although the existing systems provide wide opportunities to be adapted to specific objectives and/or geographical areas they are not sufficiently effective to meet the scope of challenges constantly arising as a result of changing climate conditions. The research overall goal is to develop an algorithm set to empower IGIS-based decision making support system that will synthesize ocean/ice/atmosphere observation-based and model-based products for the purpose of fast access to the available information about the given region.

3 GENERAL STRUCTURE OF DATA PROCESSING

The developed system is expected to handle large volumes of heterogeneous information, at that, taking into account the constraints imposed on available computing resources. To overcome the difficulties encountered in these problems solving three areas of scientific and technological research are formed: data harmonization, integration and fusion [10].

(1) Harmonization in the broadest sense can be interpreted as the standardization of data. Its distinguishing feature is an orientation to a great number of consumers.

(2) Integration, whose hallmark is the orientation to solving some particular class of problems, is supposed to have a specific data model.

(3) Fusion is aimed at obtaining information of higher quality, the exact definition of "quality" depends on the application. Data fusion is accompanied by a decrease in data content.

In view of the described paradigm the data processing within the developed system can be divided into the following stages:

(1) Pre-processing stage (verification).

(2) Regularization stage.

(3) Analysis stage including recognition and forecasting.

3.1 Verification stage

Main purpose of data verification stage is to structure storage, analysis and processing of received data meant for preparing them to meet the challenge of building a regular data grid.

The main requirements to verified data are:

(1) data should not contain duplicating values;

(2) data must be converted to a common format for data submitting and integrated into a single data storage;

(3) metadata should be described in terms of subject domain;

(4) data, if possible, should not contain noise or outliers;

(5) data, if possible, should not contain gaps;

(6) should be formed statistical evaluation of data quality, including:

(6a) techniques of processing and analysis for each type of data received from each source;

(6b) results of statistical processing and analysis of data;

(6c) comparison of results of statistical processing with statistical background.

The considered requirements are provided by:

(1) developing a single model of subject domain and single model of measurements and results of their processing representation;

(2) using expanded set of methods and models of measurements processing and analysis;

(3) using unified analysis methods of measurements;

(4) using a set of self-trained algorithms that provide a choice of adaptive processing parameters;

(5) fuzzy measures application intended for compliance of processing results with the admission values limits and with statistical background.

The stage of data verification received from various sources assumes the consecutive solution of the following key tasks:

(1) development of algorithms for the harmonization of data generated at different times by different data sources;

(2) development of algorithms for data integration, including search for and elimination of duplicating values, usage of specialized techniques for processing data from each data source, statistical data processing;

(3) development of algorithms for data fusion, including algorithms for data interpolation, creation of data formalized description, creation of statistical data models for different regions.

3.2 Regularization stage

The main objective of the regularization is development of a regular grid using gathered measurements and estimation of data accuracy in knots of the regular grid.

The main requirements to the formed regular grid are as follows:

(1) high efficiency of new data assimilation;

(2) application to development of regular grids' methods and models should be universal, and specifics of the area on which data are processed should be considered;

(3) the highest possible resolution of regular grids should be used;

(4) flexibility of a regular grid provided by changing resolution in time, height/depth and coordinates depending on data volume;

(5) ensuring absence of data accuracy loss in presence of large data volume at the expense of low grid resolution;

(6) providing accompanying data on reliability of provided data;

(7) possibility of rebuilding grids locally for an area the new data are received for.

Providing the considered requirements is possible with an allowance for:

(1) applications of multiresolution approach to grids' creating;

(2) use of statistical data models as bases for grids' development;

(3) use of the data processing complex method based on currently existing methods.

The stage of data regularization assumes the consecutive solution of the following key tasks:

(1) development of a general statistical model based on all collected measurements;

(2) development of a regular grid based on collected data and using statistical model;

(3) recalculation of a regular grid through the reanalyze procedures, grid specification when acquiring new data.

3.3 Analysis. Forecast and recognition tasks

Two important problems solved at the stage of analysis is the task of forecasting the given variable (or set of variables) values and the problem of recognizing objects of a given class. Here and below, by pattern is meant an n-dimensional column vector $X = [x_1, ..., x_n]^T$, where $x_1, ..., x_n$ are non-negative numbers, and "T" is the symbol of matrix transposition. Under the data recognition is meant a mapping of arbitrary pattern X, where integers 1, ..., c represent the class. The feature i is an element of the vector X with the index i. The set of classified patterns is denoted as U.

The problem of pattern recognition is formulated as follows. Given:

(1) The number of classes c ;

(2) A set of m training patterns: $X_1, ..., X_m$;

(3) Class of any training pattern: $f(X_1) = c_1, ..., f(X_m) = c_m$;

(4) Arbitrary n – dimensional vector u from U.

(5) A set of weights for classes $\beta_i \in [0; 1]$, i=1,…,c.

(6) A set of weights for features $\gamma_j \in [0; 1]$, j=1,…,n.

(7) On the set of vectors U is set a metric $\rho(u_1, u_2)$, where $u_1, u_2 \in U$.

(8) The distance d is set – the value of the metric, that determines the size of the neighborhood to be considered for classification.

Search for:

The class of vector u: f(u)=?

The prediction problem can be formulated as follows. In a given area in some way are chosen points p(φ, λ, h) with the coordinates φ, λ and h, where φ and λ are geographic coordinates of a point (latitude and longitude), and h is the depth / height. For these points are known the measured values of various parameters (temperature, pressure, humidity, etc.) for a sufficiently long period of time T, obtained with a discrete time ΔT. The values of these parameters x_i at each point p(φ,λ,h) at time t, t = 0, ...,ΔT forms a row-vector X(φ,λ,h,t)=[x1,...,xn], where n is the total number of investigated parameters, xi=xi(φ,λ,h,t). It is necessary to determine the value of vector X at all points p(φ, λ, h) in a given time T + mΔ, where m – is a constant. The parameters of the forecast are:

The forecast depth. History of the variables' values at a given point taken into account when calculating the future value.

The forecast horizon. Time when the forecast is carried out; it is set by the value of the constant m.

3.3.1 SVD Classification Method

As a unified approach to recognition and forecasting algorithms we use SVD-classification algorithm [21] as fast, reliable and simple method of data orthogonalization and dimension reduction. The method is also can be used as pattern recognition technique for forecasting purposes.

3.3.2 SVD Classification Algorithm

The idea of SVD classification has been previously discussed in several papers like [3, 20] published by the authors. Let us outline only basic concepts of the proposed idea. Two main stages of SVD classifichion are being studied: training phase; and – recognition one. The training phase is reduced to forming a new space of smaller dimension properties and displaying the training sample elements in it. Recognition consists of

classified vector display in the received space and search for the next nearest element out of the training sample.

3.3.3   Training Phase

Brief description of the algorithm training phase is given below:

For each property $j=1,...,n$ find and store maximal value from all elements of training set - E_j .

Normalize each property (element X_i) to $[0;1]$ via dividing it by E_j .

Multiply every element of every training vector X by its weight γ_j .

Create training matrix $A=[X_1 ... X_m]^T$ with dimension $m \times n$.

Calculate maximal singular value s , as well as left and right singular vectors L and R jf training matrix (can be done using different algorithms).

Set s = s(k) , L = L(k) , R = R(k) . Store singular value s and right singular vector R.

For each $i=1,...,m$ store component l_i of the left singular vector L and class c_i that corresponds to training element X_i .

3.3.4   Recognition Phase

(1) Normalize each element u to $[0;1]$ via dividing it by E_j .

(2) Multiply each element u by its weight γ_j .

(3) Calculate direct image of u in new feature space:

$$w=\frac{u^T R}{s} \qquad (1)$$

(4) Find max value from $l_i, i=1...m$:
$$M=max\{l_{1,}...l_m\} \qquad (2)$$

(5) Calculate P_i :

$$P_i=\frac{|w-l_i|}{M} \qquad (3)$$

(6) Calculate values t_i for each $i=1...m$ and find minimal value; where t_i are calculated as:

$$t_i = P_i \blacktriangleleft -\beta_i \qquad (4)$$

(7) Set the class c_i as a calculated class for u .

The properties weights and classes are entered for the contribution accounting, at that, for separate properties into recognition results and change of errors' ratio of the first and second kind. For classification an accuracy increase, the proximity of classified objects in space and/or in time is also considered [20].

3.4 The derivative parameters calculation task

Derivative parameters (DPs) are oceanic/atmospheric/ice parameters; they are not directly measured in the field or can be received remotely. Calculation of the most of these parameters generally requires an application of high-resolution 3D modeling systems. Technically these modeling systems are too complicated and computationally too costly. Another approach is to estimate DPs with reasonable accuracy by theoretical/empirical algorithms (models). Models take measured parameters as the input data and produce DP at the output. For the developed prototype (see below) list of the used DPs is given below.

3.4.1 Calculation of water density

Water density (WD) is an important parameter of the sea water primarily determined by thermohaline properties (water temperature and salinity) and hydrostatic pressure. Two types of WD are used for oceanographic applications: (i) potential WD that only depends on thermohaline properties and (ii) in situ WD that additionally depends on hydrostatic pressure and geographical latitude. Importance of WD for oceanographic conditions is dictated by the fact that WD determines distribution of mass around the ocean and therefore controls density (geostrophic) currents [4].

3.4.2 Calculation of sound speed in the water

The sound speed (SS) is the distance traveled in unit of time by a sound wave propagating through an elastic medium. SS in the seawater depends on hydrostatic pressure, temperature, and salinity, and empirical equations have been derived to accurately calculate the sound speed variables. For calculation of the sound speed Wilson's empirical formula proposed in 1960 is commonly used. Wilson's formula is accepted by the National Oceanographic Data Centre (NODC), USA for computer processing of hydrological information.

3.4.3 Geostrophic current

Dynamics of horizontal flows (synoptic and large scale ocean currents) on the rotating Earth is substantially determined by the balance between the horizontal pressure gradient and Coriolis force [4]. This balance in oceanography is known as the geostrophic balance, which determines geostrophic currents (GC). Far from the boundaries (ocean surface, bottom and coasts) the GC provide rather precise approximation of real currents, if the latter are averaged over time scale of the order of few days or more.

3.4.4 Wind current

Dynamics of the upper layer in the sea (down to about 20-30 m) is mainly controlled by the wind. In accordance with Kamenkovich's theory [6] the wind forcing is transfered to the water column through the wind stress at the ocean-air interface. Wind stress initiates motion of water, affected by the Coriolis force. These two forcing equilibrate in about pendulum day. As a result the WC distribution arrives to a steady state.

3.4.5 Wave height

Wave height (WH) is one of the most important parameters which determines the navigational conditions in the sea. Therefore reliable information about WH is highly practical for planning the optimal navigation routes, selection of the locations for running scientific and industrial operations in the sea and providing for safety and economic efficiency of such operations. Currently sophisticated models are used in prognostic centers around the world for WH operational forecasting. However, these models often may not be used because of time-consuming computations. This is why the empirical models based on statistically obtained relationship and providing reasonable accuracy are applied.

3.4.6 Ice drift

Ice drift (ID) is important navigational parameter in the ice-covered seas and in seas with seasonal ice cover, like the Barents Sea. The major forcing, affecting ID is the surface wind. The direction of ID in the low concentrated ice massive coincides with the direction of geostrophic wind (along sea level pressure contours). Simple empirical relationship between the surface wind speed and ID speed was suggested by Shuleikin [13]. In consolidated ice zones this relationship is more complicated and depends on other factors, including total ice concentration, ice thickness, rafting etc. [2]. At present for practical purposes ID could be estimated from sequential satellite images with high resolution.

3.4.7 Ice thickness

Ice thickness (IT) is an important climatological parameter and together with ice extent it allows for estimating the total ice volume and its variability. This parameter is also crucial for navigation and planning of various operations in the ice covered seas. So far IT could be accurately measured only by ice drilling, or by remote sensing measurements from ships (submarines) or aircrafts. It is expected that new satellite-based sensors, like CryoSat [17], will be able to provide the detailed information on IT over entire Arctic in the nearest future. Indirect method of estimating the ice thickness is based on the concept that ice of different

type (nilas, grey ice etc.) and different age (fast ice, one year old or over one year old) has different thickness [2]. Empirical relationship between ice type, age and thickness are generally known.

3.4.8 Heat flux at the water-air interface

Turbulent heat flux (HF) at the water-air interface is the major factor that governs energy exchange between the ocean and the atmosphere in high latitudes. HF determines the heat content of the upper ocean layer and through it controls ice freeze/thaw processes. Due to large horizontal inhomogeneity, precise calculation of HF can only be done via direct measurements in the field [11]. The latter can only be executed under the aegis of special targeted experiments from board of research vessels, or at ice camps. Well established empirical method of approximate HF calculation is widely used in oceanography and meteorology. This method is based on Monin-Obukhov theory of atmospheric boundary layer, which allows for linking HF with temperature difference between water and air and surface wind speed through the so-called bulk-formula (see [1]).

4 ROLE OF THE ARTIFICIAL INTELLIGENCE BASED SCENARIO APPROACH

The peculiarity of IGIS project is the need to integrate the existing heterogeneous software into a single system of scientific computations, as well as rapid development and embedding into the system of a set of new software for the emerging research in the additional computational tasks.

An adequate development environment software for the design of complex research system would be environment, allowing for visual, in the form of block diagrams, representation of complex data processing algorithms, that include existing as well as newly developed computation blocs, automatic execution of these algorithms, their easy modification and correction in the process of execution. Such an environment exists. This is a visual environment for scenario simulation DroolsTab [18].
Fig. 1. Scenario development Window

The expert system is used to design, visualize and execute scenarios (algorithms) of data processing. Herewith during the execution of scenarios are automatically invoked existing data processing algorithms and also executed newly developed computational blocks, embedded in the scenarios. The scenarios also contain blocks of decision-making in which data processing branches depending on various conditions.

5 CASE STUDY

Computer prototype of the system was developed by OOGIS research lab.[1] Technically the system will consist of two major components: IGIS-engine, i.e. the program package capable of storage, manipulation and visualization of various types of geo-referenced data, and the data[2] itself. The novel feature of the proposed system, compared with the existing analogues (e.g., Ocean Data Viewer (ODV), http://odv.awi.de/) is its multidisciplinary character.

Here are some screenshots of working system.
Fig. 2. Windows show the results of calculations at scenario execution

In Fig. 3 the examples of regularization of basic data for temperature are presented.
Fig.3. Examples of regularization of temperature values. Color represents temperature value.

5.1 Ice recognition example

The example of ice situation assessment according to MODIS satellite for the Barents Sea region is given in Fig. 4.
Fig. 4. Example of ice situation assessment according to remote sensing. Input data – at the left, result of ice distribution – to the right. Areas of recognized ice are marked by white color.

5.2 Forecast example

In the system SVD method is applied to the atmosphere parameters forecasting. In the presented example forecasting of temperature, pressure and humidity is executed based on the data received within the previous stages of the project. For comparison the method of the next nearest neighbor is chosen.
Fig. 5. Comparison of SVD classification and a method of the next nearest neighbor for the pressure values forecast.

At a forecast by the next nearest neighbor method for this station the row site (stories of values), being characterized, the maximum proximity to the current values is chosen. Results of comparison of SVD classification with a method of the next nearest neighbor in forecast accuracy on the basis of over 50000 values of atmospheric parameters (humidity, pressure, temperature) for forecasting for the period from 3 to 24 hours in atmospheric surface layer are presented in Fig.5.

The dependency diagram presents an average dependence between accuracy (Y – axis) and the forecast horizon (X – axis) for all WMO stations. As follows from the diagram SVD-classifier (the red line) shows a steady increase in the forecast accuracy over the next nearest neighbor method (the green line) in the whole range of values. The highest increase of SVD accuracy (approximately 3 %) is observed for short term forecast (under 10 hours).

6 CONCLUSION

Presented basic technology allows to cover the entire range of tasks confronting the system for data processing and storing, as well as visualization of the results and system adaptation for particular current task. Using a scenario approach and unified ontology allows to configure the system according to the peculiarities of the problem. Unified approach to the problems of classification and prediction, based on SVD-classification allows to optimize the detection accuracy or running time. Together with the use of algorithms for calculating the derivative properties that allows to solve the full range of data analysis problems with limited computational resources. Further development of the proposed system can be used (1) to increase the set of avianle algorithms and (2) to develop a system of evaluation criteria for data input to automate the selection of algorithms optimal for the problem solving.

Collaboration in the Brownfield Regeneration Process – Legally Binding or Informal Approach?

Ana Perić, Danilo Furundžić

(Ana Perić, Faculty of Architecture University of Belgrade, Department of Urban Planning, Bulevar kralja Aleksandra 73, Belgrade, anaperric@yahoo.com)
(Danilo Furundžić, Faculty of Architecture University of Belgrade, Department of Urban Planning, Bulevar kralja Aleksandra 73, Belgrade, danilo.furundzic@gmail.com)

1 ABSTRACT

The research subject is the analysis of the possible ways to achieve stakeholder compliance in the brownfield regeneration process. The aim of the paper is to show urban planning mechanisms that are used for the establishment of cooperation between different stakeholders involved in brownfield regeneration. It is important to explain the possible ways of collaboration between different institutions, but also between different sectors (public, private and civil society). In the very beginning of the paper, the current trends in the brownfield regeneration are shown, both in developed and post-socialist countries. However, the rest of the text relates to the topic of brownfield regeneration in Central European states. Precisely, the overview of the institutional aspect of brownfield regeneration within the planning system in the Czech Republic and Hungary is indicated. The determination of the responsible institutions for the brownfield regeneration process is of particular importance. Also, it is significant to examine if the collaboration is prescribed by the main laws in the field of spatial planning or not. However, the focus of research concerns the collaborative procedures to achieve the successful regeneration of brownfields. Those results stem from the analysis of the brownfield sites examples. Namely, the first example relates to the regeneration of military complex in the Czech town of Uherske Hradiste, while the second case indicates the regeneration of unhygienic settlement in Budapest. The final section of the paper systemizes the experiences from the developing countries in terms of collaborative procedures in brownfield regeneration process. This provides insight into the possible general model of brownfield regeneration.

2 INTRODUCTION

Brownfield redevelopment is defined as a redevelopment of „any land or premises which has previously been used or developed and is not currently fully in use, although it may be partially occupied or utilized, (…) and which may also be vacant, derelict or contaminated" (Alker et al., 2000: 49). Also, brownfield regeneration can be described as one of the mechanisms for sustainable development (Dorsey, 2003; Grimski & Ferber, 2001), which is specific due to its complexity. Namely, brownfield regeneration involves different instruments – planning, social, economic, political, environmental, etc. Thus the main challenge in such a process is to achieve successful collaboration between different sectors (private, public and civil society), on the one side, as well as between various institutions (within public sector), on the other.

Since the 1980s brownfield regeneration has become a central topic in the most important international documents (RESCUE, 2004; CABERNET, 2009; Stanilov, 2007). This especially relates to urban practice in North America (U.S. and Canada) as well as Western Europe. However, the new millennium trend of sustainable regeneration has also spread to the so-called transition countries. Nevertheless, the mentioned countries tend to integrate European models of urban transformation. Since they established market economies, these countries have become open to global influences and foreign direct investment. According to the views of certain authors, cities have fallen under the simultaneous influence of the local system of social transformation as well as global processes, which created a specific ‚post-socialist' context of urban restructuring (Stanilov, 2007). This is particularly done by the creation and adoption of many local planning documents, which were prepared on the base of western experience.

The issue of the collaboration among various actors in the brownfield regeneration process is considered to be complex, because it is often very difficult to examine and define the interests of different stakeholders. This problem is present even in the developed countries as evidenced by the studies where brownfield regeneration is seen as a specific urban process due to a large number of participants (Dixon & Doak, 2005; Dixon et al., 2008). Communication, understanding and trust among stakeholders are the key goals in brownfield regeneration process. According to the research studies in developing countries, there are two main obstacles to brownfield regeneration. The first one concerns the land ownership, while the second one

relates to the interest compliance and coordination of participants in such a process (Garb & Jackson, 2006: 276; Stanilov, 2007; Zeković, 2007).

The main research hypothesis is that brownfield regeneration process should be placed within the collaborative planning paradigm, i.e. within the context of multiple stakeholders and their often contradictory interests, where the final aim of such collaboration is a consensus building and solution achievement. The aim of the research is to assess the nature and the extent of collaboration in the brownfield regeneration process within the selected cases.

3 REGULATIVE FRAMEWORK OF BROWNFIELD REGENERATION

In the following part of the paper the main institutions – their roles and responsibilities, on different government levels (national, regional and local) will be shown. Also, it is interesting to notice the level of mutual collaboration in order to formulate brownfield regeneration policies. Beside this, the main legislative documents in regard with the brownfield regeneration will be mentioned. In fact, it is important to notice if the collaboration in such complex planning processes is prescribed by the law or not.

3.1 The Czech Republic

As the most important actors in the process of brownfield regeneration in the Czech Republic, the following institutions under the jurisdiction of public administration can be distinguished: the Ministry of Regional Development, National Property Fund – a state agency responsible for the privatization process which after the year 2005 was transformed into the Ministry of Finance, the Ministry of Environment, CzechInvest – a government agency to promote investment in brownfield regeneration projects and the Ministry of Finance (Garb & Jackson, 2010). The review is given in the Table 1 below.

Institution	Functions and Responsibilities
Ministry of Regional Development	• Its role is to provide support to cities and regions in better understanding of the problem as well as the greater cooperation with the stakeholders involved in the process of brownfield regeneration. • Although this ministry does not have all the necessary information regarding the mentioned problem, it can choose outside consultants, with the possible including of foreign experts as well. • It is closely linked with the local government in terms of technical training and preparation for participation in the brownfield regeneration process. • It has the important role in formulating and adopting the Planning and Construction Law.
National Property Fund	• It was founded for the necessity of introducing the guarantees to potential private investors during the regeneration of brownfields that carry not only financial but also environmental risk. • Its role is to provide financial cover for brownfield clean-up costs that were found to be contaminated during the regeneration process. • The key to the success of this organization lies in the accurate re-allocation of money, as well as the exploitation of financial resources only for the brownfield regeneration and not for other state projects.
Ministry of Finance	• It is a key stakeholder in the brownfield regeneration. Firstly, the budget for the process initiation must be approved by this Ministry. Secondly, many aspects of brownfield programs, as well as the legislative reforms directly fall under its jurisdiction. • It has the ability to strategically act on the long-term costs of deferred problems.
Ministry of Environment	• It acts as a technical consultant and supervisor for the National Property Fund. • As the orientation of the Ministry of Environment is primarily focused on meeting environmental demands, the lack of economic pragmatism can make the rigorous standards for environmental protection counter-productive.
CzechInvest	• The success of this agency is primarily based on technical assistance from the European Union in terms of cooperation with European development agencies, and financial support as well.1 • During the years CzechInvest was on the way to become national brownfield support agency, due to its skills and awareness regarding brownfields. • Its main task is not only to make an inventory of the brownfields of industrial origin, but to rethink their use in broader urban context, i.e. offer back brownfields to the market.
Regional Development Agency	• Its function is the regional information system coordination. • Urban planners here have a role in preparing the register of brownfield sites and its update. • The experts represent the key stakeholders who participate in a timely providing of information about all data related to brownfields and to all stakeholders in the brownfield regeneration process. • Also, regional authorities are in charge of preparing development strategies, compiling planning documents and policies, and, finally, using the brownfield priorities in structural funding.
Local government	• The power of this government is guaranteed by the law. • The national Czech government has an active role in providing mechanisms for direct communication between local governments and citizens.

Table 1 – Institutional framework for brownfields in the Czech Republic. (Source: Prepared by author according to Garb & Jackson 2010, 2006, 2001)

---

1 CzechInvest has been awarded with 3 million euro for the three brownfield regeneration projects in the Czech Republic (Garb & Jackson, 2001).

Collaboration and joint decision-making on spatial development guidelines is stipulated by the Planning and Construction Law (183/2006Sb). Specifically, planning on the basis of an agreement between the parties (primarily public and private sector) implies in particular at the local planning level. According to the same law, institutional collaboration is needed between the local and regional level planning (PLUREL, 2010). Therefore, it is considered that an appropriate institutional framework exists, but the cooperation of different sectors is required. This would contribute to the effective brownfield regeneration.

3.2 Hungary

When it comes to the topic of brownfield regeneration, several important institutions on the different levels can be outlined (Table 2). Although some experts agree that there is no guiding strategy for the mentioned urban problem at the national level (Foldi, 2006; Kauko, 2010), the activities of some institutions will be mentioned here.

Institution	Functions and Responsibilities
Hungarian National Development Agency	• It is the state agency responsible for the supervision of the „New Hungarian Development Plan" (NHDP) implementation. • Its main role is to collaborate with the representatives of national government, regional development agencies and expert institutions (Hungarian Academy of Sciences and numerous scientific institutes).
National Development Council	• Its main role is to coordinate all the sectors in the field of spatial planning at the national level • It has the important role in monitoring and evaluation of development policies implementation.
Ministry of Interior – Department for Regional Development and Construction	• It has the important role in formulating and adopting the Act on the Formation and Protection of the Built Environment. • It is responsible for the preparation of the Law on Spatial Planning.
Regional Development Council	• Its role is to monitor calls for application for the action period of NHDP and then to evaluate the follow-up applications. • The crucial significance of this authority lies in its function of a mediator. On the one hand, RDA forward information to the Hungarian National Development Agency and, on the other, it is the institution with decision-making competences toward local government.
Metropolitan Government of Budapest	• All the urban regeneration programmes are under the jurisdiction of the chief architect's department within the mayor's office of the municipality of Budapest.

Table 2 – Institutional framework for brownfields in Hungary. (Source: Prepared by author according to Grisel & van de Waart, 2011; Ricz & Salamin; 2010)

Collaboration of institutions that are responsible for the physical development of Hungary is regulated by the Act on the Formation and Protection of the Built Environment only for different sectors at the local level. According to the same document, the local government is responsible for the involvement of local stakeholders in the formulation of urban development policies (Pallai, 2008). Also, one of the priorities in the document „Medium-Term Urban Development Programme of Budapest – The Podmaniczky Programme 2005-2013" is the cooperation of private and public sector at the local level (The Municipality of Budapest, 2005).

4 COLLABORATIVE PROCEDURES FOR SUCCESSFUL BROWNFIELD REGENERATION

The collaborative procedures for successful brownfield regeneration are going to be presented and examined on the two selected case studies. The methodology used for the determination of the nature of collaboration and its extent within the cases is based on the semi-structured interviews (Bičan, 2012; Molnár, 2012; Alföldi, 2012) conducted among the selected actors who were directly in charge of the preparation (planning) phase of brownfield regeneration process. The structure of the interview as well as the section of the article that follows consists of several parts:

- Major stakeholders who have contributed to the project initiation;
- Planning experts in this project – their actions, organization and project management;
- Negotiation process and decision-making procedures in the specific project;
- Identifying the ways to conflict resolution.

4.1 The Czech case – Ex-military complex, Uherske Hradiste

Czech case study for the analysis of the nature of collaboration during brownfield regeneration process is ex-military complex located 500 m east of the historic centre of the city Uherske Hradiste.[2] Location of the former military complex occupies an area of about 17 hectares, which is, on the one side, bounded with the river Morava, and, on the other, with industrial zone. So, this site is a buffer zone between the old town and the industrial area (Bergatt Jackson, 2012).

Initiation of brownfield regeneration process. Although the idea of the regeneration of a given military complex appeared earlier, formal conditions for it have been created during the year 2000 due to the army transformation. In 2001 the official decision of the Ministry of Defense was made according to which the military complex location was no longer needed by the army, and, therefore, could be transformed with a different purpose. The location is then assigned to the city government. At the beginning this was seen as gift of the Czech army, but over a longer period of time the responsibility of local government for the military complex increased. The interviewee emphasized the advantage of the period in which the planning process started, since the beginning of the millennium was marked by „economic growth, the possibility of co-financing by EU funds, cooperation with the scientific community – the newly established state and private universities, as well as the interest of the private sector to new, mostly commercial, zones" (Bičan, 2012). Therefore, the role of planning experts within the local government from the very beginning was not only related to urban development, but also to the strategic planning of the site.

The organization and management of the planning process. In 2003 city administration department for spatial development prepared the first urban location study for the military complex („Land-use study of former military district in Uherske Hradiste"). It served as a basis for future discussions and amendments in accordance with the demands and needs of different stakeholders. In fact, this study was a joint effort by local experts and external consultants – represented by the experts from the planning sector of regional government. This was the typical „form of vertical collaboration, necessary for the regeneration of large brownfield sites in the city central core" (Bičan, 2012). After the public debate within the local government, the study was approved by the City Council. As the local government had to conform to the demands of future financiers (private investors, EU funds, state budget, Zlin region), it was necessary to monitor the planning process and the compliance of future proposals with the existing urban concept. Specifically, in order to control the progressive transformation of former military complex, the city government has established the so-called Management Commission. At the head of the four-member group was mayor, while the rest were directors of different departments of local administration. The mentioned urban concept was first updated in 2004 after the adoption of a tender for a strategic partner in a commercial zone. The decision on financial support for the construction of educational zones from EU funds and budget of the Czech Republic was made next year. Therefore in 2005 original concept underwent additional changes (especially to the educational zones for compliance with the requirements of the EU as a funder). This document was then presented to the public in the form of exhibitions organized by local government, where they could hear the comments of the local community. The final version of the document entitled „Study of the conversion of a military complex in Uherske Hradiste – 3 Update" was adopted in 2007.

Negotiation process and decision-making procedures. Although the Management Commission was responsible for planning process organization, it should be noted that a strategic approach was applied in order to effectively promote brownfield regeneration in the local market. Specifically, all the decisions were made by the Mayor, but on the basis of expert knowledge (local and external experts) in the field of spatial development as well as economy, given that the concept should attract public donations and European regional development fund. In addition to this, from the very beginning direct negotiations were conducted with interested investors. The interviewee particularly stressed the importance of their early involvement in the planning process. In fact „the harmonization of the interests of the public and private sector was the basis not only for the subsequent planning phases, but the financial support of investors in the very beginning accelerated the regeneration process, i.e. the implementation of the concept" (Bičan, 2012). It is also important to note that, due to the successiveness of planning and construction phases for specific zones

---

[2] The city of Uherske Hradiste is located in the Zlin region, i.e. in the vicinity of the eastern state border. It has quite good position to two European capitals – Vienna and Bratislava, but the major infrastructure corridors are underused.

across the entire site, the Management Commission throughout the period „was open to new suggestions and solutions" (Bičan, 2012).

Conflict resolution. Among the mentioned stakeholders in the planning process, most conflicts have emerged between local government, which, on the one hand, was weighing the preservation of public interest „without radical modification of the given complex" and, on the other side, private investors whose goal was to "build as much as possible" (Bičan, 2012). However, due to the „pragmatic approach" of the mayor during the negotiation with investors, the so-called 'win-win' solution was achieved. Also, it should be stressed that local governments and private investors were not the only participants in a given process. In fact, applying for European funds implied certain ways of organizing processes (in terms of time limits), but also in terms of conditioning and limiting the domination of only one stakeholder. Therefore it can be concluded that „well-planned and prepared approach to regeneration has created clear and less risky conditions for the arrival of new investors and their activities and investments" (Bičan, 2012).

4.2 The Hungarian case – Ex-unhygienic settlement, Budapest

The selected case study from Hungary is the area of the former unhygienic (Roma) settlement called Corvin (Corvin-Szigony). The site is located within the wider centre of Budapest city, and belongs to VIII district named Jozefvaros (Józsefváros). Corwin covers a territory of 22 hectares and has an excellent strategic position. In fact, the location is well connected to the central city core, it is close to two subway-stations, and also belongs to the corridor route that leads to the airport. On the site there were a total of 1100 social housing units in extremely poor building condition, 800 of which were unacceptable for living.

Initiation of brownfield regeneration process. The regeneration of Corvin site was initiated by the district authority. The reasons for this were numerous, such as ghettoization, dilapidated infrastructure networks, poor building stock, etc. However, having in mind the advantage of this location (its central position in Budapest), district administration decided to initiate the brownfield regeneration process whose "goal was not just to improve the building stock, but also economic, social, and cultural benefit" (Alföldi, 2012). Therefore investors should be included in the process, but also it was important to keep most of the original population (if not at the site, then in the VIII or surrounding districts). However, the initial status of the site was unenviable. A third of the Corvin population was members of the Roma community. In addition to this, at the beginning of regeneration process, private sector representatives were not reliable partners for collaboration. In fact, none of the investors has been able to financially support regeneration in accordance with the original decision of the district to keep the majority of the local population on the site. Only in 2004 the company called Futureal, the largest residential construction contractor in Hungary, managed to buy the site. This emphasizes that from the very beginning, "the most important roles in the planning stages of brownfield regeneration were awarded to public sector" (Molnár, 2012).

The organization and management of the planning process. In 1997 district authority founded Rév8, the Agency for Rehabilitation and Urban Development, which had the role of "expert branch" of local government in the process of Corvin location regeneration (Molnár, 2012). It should be emphasized that the importance of this agency was not only reflected in the technical expertise (the formulation of strategies and policies in urban development, management planning process, development of a plan), but also in an intense mediating the communication between other stakeholders, particularly investors, as well as the local community. The agency was comprised of an interdisciplinary team of highly educated experts (sociologists, geographers, spatial planners, architects). Their task took place on two levels. In addition to the detailed analysis of the social structure of population and the identification of their needs, the detailed analysis of the current building stock state was conducted. The main disadvantage of such an approach related to the long time required for the analysis of about 2500 households, but the advantage of this approach was invaluable. In fact, in this way the interests of those social groups with very low power compared to other stakeholders were protected. Practically, with some benefits from district authority, local people were able to obtain housing unit at the same location (Corvin) or to choose another apartment in the same or neighbouring districts without any financial compensation. Bearing in mind that the original construction stock was of very poor quality, this move of district authority was considered "socially acceptable compromise" (Alföldi, 2012). In the later stages of the planning process, the significant role of the agency Rév8 was reflected in the inclusion of external expertise – representatives of Hungarian and foreign universities. Also, at the request of

investors, the planning process involved both domestic as well as international experts from different fields (architects, experts in real estate, tourism and communications).

Negotiation process and decision-making procedures. Rév8 agency had a key expert position and, what is more important for the complex developmental processes, its representatives were the epitome of mediation and facilitation skills among different stakeholders. However, the decision-making was not within the jurisdiction of the agency, but within the district office called Corvin office. The main role of this office was the control of the agency Rév8, and the control of limits for each phase of the site regeneration. Specifically, at each stage of a complex process, proposals and measures formulated by Rév8 were forwarded to district administration through this office. Although originally Rév8 agency was formed jointly by the district administration, and the administration of the city of Budapest, in the later stages of regeneration process, communication with the metropolitan administration was not intensive. The reason for the lack of vertical collaboration is reflected in the fact that "the mayor did not understand the need for the regeneration of a given location" (Molnár, 2012). However, in addition to negotiating with the local community, the most important role of the agency Rév8 was the mediation between district administration and the private sector – company Futureal. According to the original regulatory district plan from 2002 only residential purposes were prescribed. But in 2005, due to the demands of investors, the plan changed with the aim of increasing mixed-use areas. Local authority of VIII district also showed good negotiation skills with private investor. Although part of the original plan had to be revised due to the requirements of investors, this was actually a reward for a very risky investment, not only financially, but also in political terms. In addition, the investor agreed to the achievement of social benefits (construction of schools and health centres in relation to the planned population, employment of local people in the process of demolition and construction of the building stock, planning of public open space). In addition to expert input, significant negotiations were held with local residents who had been constantly kept informed about new proposals for developing the plan. This form of negotiation was conducted within the agency Rév8 office, within the territory Corvin location, which "is very informal form of communication during the planning process for Hungarian standards" (Alföldi, 2012).

Conflict resolution. The major conflicts during the planning process appeared between district government and the metropolitan administration of Budapest, which resulted in changes to previously established developmental priorities. Namely, the original concept of brownfield regeneration was conceived as a public-private partnership which, with the same investment fund, should involve private sector, local government, as well as the administration of Budapest. Disregarding this rule led to the need for increasing the housing stock on the site. The administration of Budapest donated only 15 percent of the total investment, as opposed to the originally intended one third. District government was not able to fund the remaining 15 percent, so this shortcoming was compensated by increasing the number of housing units compared to originally planned number. However, as the agency Rév8 sought sustainable solution in economic and in social terms, the quality of public space was certainly a priority. Therefore, the realization of the necessary capacity was provided by adding another floor, and not, for example by construction of new facilities (Molnár, 2012). One of the conflicts that arose during the planning phase of brownfield regeneration was the resistance of a number of local people to being moved the site. However, the interviewees submitted that this resignation was the result of political manipulation, because it was inspired by print media, but did not reflect the true attitude of the local population (Molnár, 2012).

5 CONCLUSION

The previous analysis both on macro-level, i.e. regulative framework (institutions and documents regarding brownfield regeneration) and on micro-level, i.e. case study (collaboration in the concrete process of brownfield regeneration) is the sound base for formulating the general conclusions about the nature of stakeholder collaboration in the mentioned process. To be more precise, it is interesting to observe if the collaboration was legally binding or it was a kind of a more informal approach.

When it comes to the Czech Republic, active participation of the city government in the process of brownfield regeneration caused the necessity of finding new approaches to the management process, as well as new methods of obtaining investment (from various sectors). This had the overall impact on the unconventional way of planning and outcome of the planning process. However, as the collaboration in the planning process was required by the law (Planning and Construction Law), we have to stress that the final

document was not the result of only informal forms of cooperation (Bičan, 2012). Namely, the urban study was made in accordance with the mandatory documents at higher levels of planning – "Spatial development policies" (national level) and "Spatial Development Principles of Zlin region". Besides, the formulation urban study was in accordance with the requirements of several different sectors at the national level (which operated in the form of external consultants). In addition to this vertical collaboration, there was also intensive collaboration on a horizontal level between experts in various fields. Interviewee estimated this as a "necessary and very inspiring" (Bičan, 2012).

However, something that makes the regeneration process of a given military complex different to other examples of brownfield regeneration was a way of formulating planning instruments and their character. In fact, it was a "constant process of brainstorming between local government and stakeholders" (Bičan, 2012). So, the process was not accompanied by workshops, roundtables and other forms of collaboration at a steady pace, but the ability to opt for new ideas lasted throughout the whole process of regeneration, thanks to its parallel organization of the different phases (planning and implementation). The result of this planning process was the formulation of urban studies as a final document, i.e. the base for later construction. Although according to the law these studies are not binding, in a given planning process they turned out to be the best solution, for several reasons:

- The study, as opposed to planning documents, is not approved by the administrative body;
- The study does not require a long period of time or a large cash outlay required for its development;
- The study is not "rigid" document and, if necessary, it can be simply changed, which is especially suited private sector.

From the Hungarian case study, we can draw several conclusions. Even though public-private partnerships are prescribed on the local planning level (especially within the "Integrated Urban Development Strategy") as the preferred mechanism for collaboration within the complex developmental process, in planning practice there are very few examples where the mentioned guidelines take effect. However, a public-private partnership in the process of Corvin location regeneration is one of the "most successful examples of long-term cooperation between the public and private sectors, and as such it is recognized at European level" (Molnár, 2012).

Firstly, something that makes the public-private partnership in the Corvin case different to other similar examples is the fact that the key role of the planning process was entrusted to an independent expert agency Rév8 who mediated between both sectors (public and private). This kind of planning process organization was for the first time in Hungarian urban planning practice implemented at the site Corvin, and since then it has been used in other similar cases (Alföldi, 2012). The special value of this approach is seen in the fact that "urban planning is understood as a management process, and not a rigid adherence to the planning basis" (Alföldi, 2012). The specificity of stakeholder collaboration is their common pursuit of sustainable vision of site development (in economic, social, and cultural terms), as well as of including a number of other stakeholders, which are important for different aspects of the planning process. Thus, graduate students from Harvard University participated in the formulation of the planning concept in accordance with determined vision and development objectives formulated at the beginning of the planning phase on the basis of consensus among relevant stakeholders. Local community was not active in the creative sense, but they had economic benefits. Namely, one of the conditions of district authority was the creation of new jobs while promoting employment of the original inhabitants of the Corvin location.

Also, what makes this case specific in terms of collaboration is the cooperation with civil society. The role of this sector in formulating brownfield regeneration policies is often limited, and decisions are made without public debate (Keresztély & Scott, 2012). However, the case of Corvin regeneration was different. Namely, the investor interests were not achieved at the expense of the interests of the local community. The local population succeeded to preserve local values through an organization called Grund. Namely, a former gathering place of local people was recognized as a local cultural value and, with the involvement of local community and agency Rév8, it was accepted by investors as a carrier of identity of Corvin site.

Conceptual Assessments on Epistemological Differences in Tactical and Strategic Spatial Planning

Aynaz Lotfata

(Ph.D. Researcher Aynaz Lotfata, Middle East Technical Universiy, Ankara, Turkey, a.lotfata@gmail.com)

1 ABSTRACT

Purpose: In spatial processes, the terms strategy and tactic have frequently appeared without any clear distinguishing. Strategic knowledge have tries to defining visions of urban space through answering "What" and "Why" questions and its knowledge is the abstract knowledge, while tactical knowledge is the experiential knowledge via answering "How" question. Strategy and tactics are both terms from a military context where strategy has referred to long-term war planning and worked from the power position to force its components to accept the prevailed condition in contra to tactic as short-term flexible battle planning. The strategic conventional ideologies empty of tactical policies have therefore destroyed built spaces memories to organize urban society according to elite's tendencies. The Equivalent of strategy in urban planning is Master plan.

Tactics have not operated such dictated forces since They are bottom-up spatial practices. Bottom-up dynamics causing to flexibilities of the prevailed ideologies of the upper policies, Hayden calls those short-small actions (Tactics) "power of places" to challenge homogenous urban planning to keep planning far from a frozen platform of time.

Findings: Thereby, strategic spatial planning without tactics has justly characterized as an abstract phenomenon. The tactics developed by ordinary people are at root attempts to negotiate power relationships, discourses and representations of identity. To develop the empowered spatial planning, the synergic relations amid localities tactics and strategies have implemented for tackling with the stochastic world.

Results: The paper has aimed to solve the problem of misunderstandings in tactics and strategies definitions and applications in urban planning. Additionally through explanations of strategies and tactics differences in spatial planning, the project has tries to argue that strategy of locality cannot be duplicated like spatial tactics imitating all over the world. Localities got used to dismantling other localities strategies and tactics to enhance their situation in the competition platform of neo-liberalism. However, a strategy is hard to duplicating such tactics. Strategies and practices (Tactics) have shaped the everyday life of inhabitants. And urban planning should make balance in utilizing both. Additionally locality should not imitate spatial tactics and strategies of other localities. Otherwise, it has reified spatial tactics and strategies. Every locality has own priorities to consider in urban planning.

Originality: In planning literature, implementing spatial strategies have not been the recent phenomena. The differences have reverted to the deficiency of synergic relations amid tactics and strategy. The conventional regulated spatial planning has generally formulated without spatial tactics to reach spatial goals while to tackle the real world future, the reciprocal connections of tactics and strategy have gotten priorities. In other words, planning has to move on toward an experimental science of planning.

With considering the novel re-configuring urban planning, the paper has tries to shed light based on simulating urban planning via "Artificial Intelligence" achievements. This will support arguments on systematic planning definitions to control the uncertain world. In moving form toy-world domains that characterized early conventional planning, we are looking at a wide range of issues, including reasoning in uncertain worlds, interacting with processes and events beyond the agent's direct control and controlling systems in real non-linear time. The disciplinary background of the paper is philosophical-epistemological. The enquiry is conceptual.

2 INTRODUCTION-DYNAMIC AND UNCERTAIN DOMAINS; PLANNING WITH STOCHASTIC ACTIONS

One of the main concerns of socio-spatial policy makers all over the world is to improve their ability to anticipate and control the future. Designing human futurity, whether long or short-term is not a simple matter. The sophistication involved in dealing with ongoing fundamental changes in modern societies challenges the ability to control human futurity and to sustain continuity. Here our concerns in the following exploration are time perception and time management in public policy. Public policy literature is generally farmed in terms of long term and short term policies where this study suggests juxtaposing "tactical policy

time" and "strategic policy time". Tactical policy time- short time- is defined as "taking a specific time-related plan or action aimed at achieving a defined policy result". Strategic policy time has defined as "taking a specific time-related plan or action with the aim of coping better with uncertainty in the future". These arguments have invited attentions on time-related planning or action aiming to achieve a defined policy result or cope better with uncertainty in the future". The mapping of time management in public policy generally indicates two main trends: 1- a pragmatic trend-short-term policy has based on the response-oriented policy (Tactic) and 2- a normative trend-long-term policy inspired by "the voice of the future" to avoid uncertainty" (Strategy).

In other words, "Why do we plan?" Planning is to respond necessities of real world. To control real world, there are two focus points: coping with uncertainties and real time planning. The planning knowledge is incomplete process. The process definition of planning has gotten back to non-predicted events in the world by which control and pre-determination of domains have not been done completely. The planning has to discovery new approaches of intervention in the world such reactive planning, tactical planning and conditional planning.

The arguments have supported that the planning process has not only defined due to theoretical discussions but also that has included the practical exercises. The planning process requires mutual connections of theory and practice. Tactical, reactive and conditional planning has justly supported the incremental practical planning. Controlling the world with stochastic actions where linear and universal plans have not functioned any more, incremental and conventional spatial practices combinations have insistently emphasized.

Therefore, planning in realistic domains has forced us to confront two main issues: uncertainty and urgency. Uncertainty arises since the planner is neither omnipotent, omniscient one nor alone in the world to control stochastic actions. The paper aims to consider spatial planning as the automatic planning by which planning has prepared to any stochastic actions of the world in which has witnessed the social, economic, environmental and politic upheavals. That does not mean, refuting result rationality of conventional planning in which its rationality measures how efficiently the plan achieves its specified objectives. Planner should re-construct planning with making balance between result rationality of conventional planning and process rationality of tactical planning.

The lost and disregarded part of planning in dynamic and uncertain world has characterized via tactical planning. Planning has been a process changing its long term focus point toward short term planning. Nilsson has proposed the concepts of actions networks for reactive planning/tactical planning. Actions networks differ from universal plans in that they allow the formation of action hierarchies (Hanks, 1990). This supports argument that we view planning as the process and planning has been converted from long term prospects into short term tasks and That does not equal to throw out the strategic planning and justly focused on tactical planning since the planning process must consider both the strategic and tactical aspects of planning to achieve empowered spatial plans.
Fig.1: from an initial configuration (solid square) to a goal (open circle) – Source: (Alterovitz, 2007)

Tactical or incremental planning has emphasized on tasks/ actions which achieve short term goals. Purely strategic planning cannot immediately react to a changing world while tactical planning can answer changes quickly. The traditional planning logic is Boolean logic where the values of variable are the truth values, truth and false, usually denoted 1 and 0. However planning is the process and it has formulated in between 1 and 0. The deductive knowledge of Boolean planning has distrusted on urban society with stochastic actions. The figure 1 has simulated spatial planning with intervention of Artificial Intelligence (AI) in the sphere of urban planning to emphasize on importance of tactics in controlling the stochastic world. There is a

Robotic motion planning that explicitly considers actions (Tactics) to control probable uncertainties, avoid collisions and successfully reaching a goal. To reduce system failures, Markov decision process formulates dynamic planning to optimize Robotic motion in the selected path to achieve its goals.

The remainder of paper is organized as follows; section 2 explanation on non-linear world and the world of cause and effect to declare necessity of dynamic planning, section 3 discussion on planning re-cognition names "empowered planning", "synergic phenomena" and "strategic and tactic imitation", section 4 discusses result and future work.

3 PLANNING AS TEMPORAL REASONING; NECESSITY OF DYNAMIC PLANNING

We have invited attentions on modeling dynamic planning rather static traditional planning due to realities of the non-linear real world. Traditional conventional planning has been a model of planning with certain goals whereas in a-changing world, witnessing planning with certain goals has not been the possible phenomenon. The linear world and the perception of cause and effect is simply a trick of the mind to create the illusion of predictability and control. Thereby, tactical spatial planning which has characterized as a short range planning emphasizing on the current operations of various parts of the spatial complex and non-linear system has not been ignorable anymore. Short range has defined as a period of time extending about one year or less in the future. Figure 2 has discussed on the time non-linearity amid events in spatial system. Inhabitants often claim that it is easy to see how the events unfolded with hindsight in linear time. However, it is often possible to understand events reasons with foresight. Additionally events can happen simultaneously instead of the linear pre-determined perspectives and the spatial layouts have been witnessed hidden and complex non-linear causes and effects.
Fig.2: dashed line: linear time, filled points: events in spatial layout – Source: by Author

In the real-world framework, there is not any linear reality. The complex spatial system has embedded with pluralities of actions by which the urban system has directed to complexities of causes and effects. The spatial temporal actions have taken place on self-emergencies and planned bottom-up activities. Figure 3 has explained realities of real world where actions have made influences upon each-others and created complex non-linear systems.
Fig. 3: Cause and effects dynamics of bottom-up spatial activities – Source: by Author

The bottom-up planned actions are spatial tactics/reactions by which time and space proximity is achieveable to control urban society's upheavals, in figure 4, the incremental tempo-spatial changes have been manifested. The emphasizing on relationship between space and time has been formulated in the most diverse planning theories.

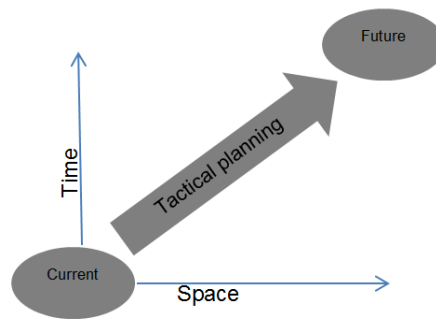
The next section of the paper has discussed on re-formulating planning named "empowered planning" through integrate tactical spatial practices in conventional classical planning to configure planning system.


Fig.4: co-existence of time and space in tactical planning; 1- the efficiency: is the operational level of planning via asking" how can we best deploy and control resources?" 2- the effectiveness: is the tactical level of planning via asking" how can we best organize ourselves to reach success?" 3- the competitiveness: is the strategic level of planning via asking" what are our aims and what are marketable to do global competitiveness?" – Source: by Author

4   PLAN RECOGNITION; EMPOWERED PLANNING

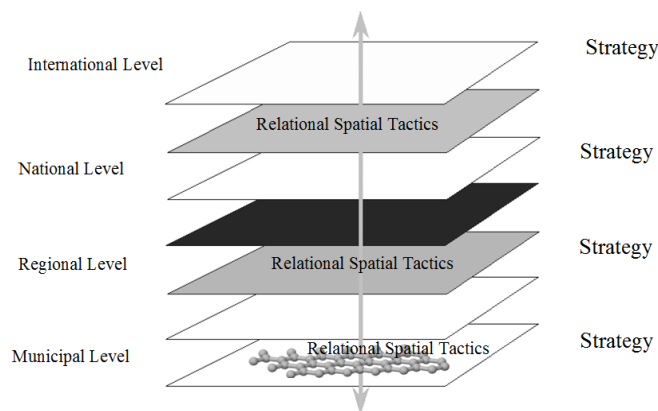
Strategic planning has emphasized on the analyzing future and tactical planning has functioned on controlling everyday life, despite their differences, tactical and strategic planning is internally related. System without strategy only based on tactics leads to shooting in dark. Sun Tzu innovation on "The Art of War" has taught the strategy such the timeless lesson as humans' nature. Strategy and tactics have depended on each other. Goldratt has defined "Strategy" as, simply, the answer to the question: "What for?" (The answer is the objective of a proposed change). "Tactic" has been defined as, simply, the answer to the question "How to?" (The answer is the details of the proposed change). From these definitions, it is clear that every Strategy (What for?) should have an associated Tactic (How to?) and therefore Strategy and Tactic must always exist in "pairs" and must exist at every level of the organization (Figure 5).


Fig. 5: every level of organization such Municipal level has composed of strategic vision and relational spatial tactics which has connections with the upper plans such regional levels orderly – Source: by Author

Tactical planning should focus on what to do in short term to contribute the spatial organization achieving the long term objectives determined by strategic planning. The short term tactical policies are more common in the political competitive sphere where citizens involvement in public sphere management. In the area of planning, there has been considerable debate about whether top-down or bottom-up planning is best spatial practice. However the empowered planning model has combined and made balance between long term and short term planning. Foucault's (1991) notion of 'governmentality' has also composed of active tactics and strategies by governments and agents. Strategy without tactics is the slowest route to victory. Tactics without strategy is the noise before defeat.

The conventional instrumental planning has modeled relied on the rational calculation is also the strategic challenge apart from tactical policies. However, great upheavals in uncertain world have led to the lack of trust on rational calculation empty of spatial tactics to control the stochastic actions. To support the argument, Friedman (1987) said that municipal level of the spatial development cannot justly answer local

spatial dynamics via upper policies strategies, but it has to consider the local bottom-up knowledge and plan spatial tactics to reach strategic goals of the locality. In planning literature, it is time to integrate tactical spatial practices in conventional strategic planning. In this sense, the planning organization has simulated the novel "process policy" on spatial planning which Habermas (1995) has put forward that on "communicative action theory". Generally, "strategy" is really at the highest level of spatial systems by which the directions of all activities are dictated and "tactics" are lower down in spatial systems and define the activities that are needed to implement the Strategy, then where does "Strategy" end in which do "Tactics" begin.

The figure 6 has represented differences on strategic and tactic perspectives in detail by which the paper next argument has clarified via declaring difficulties on imitating spatial strategies rather socio-spatial tactics.

Strategy	Tactic
Future (Longer Term)	Now (in the moment)
Preparing and Planning	Doing activities
A journey	A trip
Broad perspective	Narrow perspective
A purpose	A task
Anticipation	Reaction
Risk	Caution
Important	urgent
Difficult to copy	Easy to copy
Large scale	Small scale

Fig.6: strategic and tactics differences-source: by Author

4.1 Strategic and tactical imitations

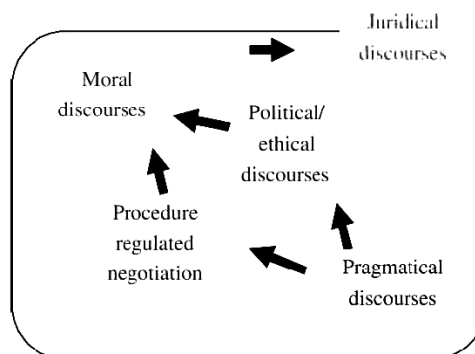
Imitation strategy is the strategy that mimics the strategy of other territories where have performed this kind of the imitation strategy to attract global capitals. This strategy is an illegal and unethical activity on condition that territories inner dynamics have refuted (Figure 7).


Fig.7: the bottom-up ethical process- Source: (Nielsen, 1994)

Duplicating spatial tactics without paying attention on territories authenticities and dynamic bottom-up knowledge should keep away. In reality, tactics vary with circumstances and, especially, technology. Alan Emrich says, "If I were to teach you how to be a soldier during the American Revolution, you would learn how to form and maneuver in lines, perform the 27 steps in loading and firing a musket, and how to ride and tend to a horse. Naturally, yesterday's tactics won't win today's wars – but yesterday's strategies still win today's wars… and will win them tomorrow and into the future. Therefore, strategy and tactics require a different focus." After debating on necessity of strategic and tactical planning authenticity to dismantle empowered spatial planning, it will be more interesting to concentrate on in what manner spatial tactics have integrated in urban planning through "synergic planning".

4.2 Synergic Planning

Synergy comes from the Greek word synergia, meaning joint work and cooperative action. Synergy is when the result is greater than the sum of the parts. Synergy has been created when things work in concert together to create an outcome that is in some way of more value than the total of what the individual inputs is. The synergic phenomena have supported "What to change, but more importantly, what not to change and especially How to implement the changes and Why." Empower planning has ethically planned socio-physical-spatial changes owing to making synergy amid different spatial localities of urban systems such

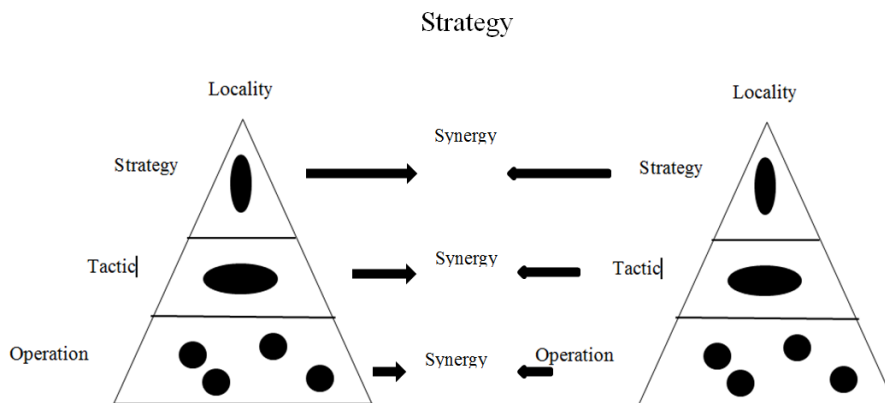
synergy in between two localities strategies and tactics towards planning overlapping to reach mega goals of a territory (Figure 8).


Fig.8) synergy in between two localities strategies, tactics and operations – Source: by Author

5   CONCLUSION

The conceptual discussed arguments have attracted attentions on empowered planning not to avoid uncertainties, but to control uncertainties. This supports arguments that inclusion two planning epistemologies ; tactical and strategic policies have led to easily deal with stochastic world. And planner and geographers have attracted on "real time planning" where the long term planning and short term planning have combined and utilized in balance. This research has tries to introduce a new mode of intervention in planning since the empowered planning is the sub-ordinate to system theories. System theories focus on complexity and system inter-dependencies. The system theory followers in the field of sociology also give light to what is happening in the socio-spatial context. Among them, Nikolas Luhmann argues the significance of the continuity of social processes and inter-activities among parts in such processes.

Creating Collective Memories in Urban Spaces of Iran

Nasim Iranmanesh, Elham Amini

(Architect &Urban designer ,Nasim iranmanesh, Islamic Azad University , west Teharn branch,deparment of architecture, niranmanesh@yahoo.com)

(Assistant Professor, Elham Amini, Islamic Azad University , Pardis branch, department of Urban planning, Dr.Elham_Amini@yahoo.com)

1 ABSTRACT

The aim of all kind of arts such as painting, theater, music, and cinema is impressing on their users and we can find it in architecture and urban designing as well.

In the other words urban designers like other artists want to make a permanent impression on their users who generally are citizens and tourists.

In this matter a designer faces with two major categories to make a memorable urban space:

(1) Spaces where a historical – social event have happened on them. So this space has become special and memorable and designer should try to amplify and emphasize on this space and its memory both.

(2) Designing some spaces that could create a pleasure and eternal memory in mind and make a suitable container for social interaction and civic vitality. Hence citizens and tourists encourage using this spaces continually.

In Iran the factor of being memorable has been ignored in most of our urban spaces so we have some ugly, messy, and unvalued urban spaces in our cities.

However the greatest responsibility of an urban designer is making some spaces that make all the visitors to appreciate and remember it and even advise other people to see and use that space ,but unfortunately today there is a very few attempt to make such memorable spaces which make the identity of our cities.

In Iran we also use some kind of art working in our urban spaces such as fresco, sculpture, tile working and so on, but here again we see that most of these objects couldn't impress the people perfectly and nobody pay attention or remember them. So these designs and spaces become unsuccessful in spite of the fact that Iran has a very rich and considerable history in art and architecture and urban designing.

The propose of this article is discussing about making memorable "urban spaces" and "collective spaces" in Iran and how we can amplify and reinforce the factor of memory in them and what strategies could be suggested about it .

2 COLLECTIVE SPACES

Collective space is the place of social living of people and creates the spirit of the city. In recent cities most of these spaces have been disappeared or are being destroyed.

These spaces are often completely open but in some cases they can be covered partly or completely.

Collective memories are not only some negative spaces which merely relate buildings to each other and unify them but they identify the special function by locating entrances and buildings in a collective space.

Two kind of collective spaces : (right) Iran – (left) Vienna

2.1 Collective memory

Collective memory is a common image from the space which is created in visitor's minds because of an important historical event or a beautiful and exclusive view and forms a common sense in them.

2.2 Locations and places to form a collective space

We can categorize the collective spaces as follows:

- Squares ,main streets and major urban complexes

- Parks and urban green spaces

- Passages , open spaces, and green spaces in regional and district scale

- Elements of the services of city such as : the courtyard of large mosques, "Hosyniye"[1] , common passages of Bazar

Mir Chaghmagh Urban complex-Iran, courtyard of mosque- Iran

Traditional Bazar –Iran, pedestrian passage – Iran

2.3 The effective elements and spaces to create collective memory in users

Furniture is necessary to complete the decoration of cities. There are like some decorative elements such as flowers on walls or on the dining table in a house. All of them intend to give pleasure to users. Function is the main role of various urban facilities. Columns, clock tower and fountains all have function even they are some simple natural elements such as plants.

2.3.1   Urban furniture

Furniture has an important role in making a space memorable. If furniture create the possibility of attendance and stop of visitors and make a memorable image in minds, we can say that this collective space is successful in making memorable. Here we just discuss about two major elements of urban furniture, benches and kiosks:

Benches:

Benches in urban spaces could be a simple cubic form which is suitable for a short rest.

The other kind of bench is a more comfortable bench supports the body properly, distributing weight evenly over the surface of the seat.

---

[1] some spaces in Iran which religious activities hold in them

The location of bench is important. It should be placed at a natural resting point on a path or in a square, but located with its back protected, in a shelter position from which it is possible to see interesting views and observe the activities of others while still feeling secure.

A cubic bech – netherland

Kiosks:

This word drives from a Turkish word "Koshk". The Parisian kiosk used for advertisements and newsstand is a best method to present the news and if plaster over walls takes on the appearance of graffiti. There are many types and uses of kiosks such as the telephone box. Probably the most interesting and potentially the most decorative kiosk is the bandstand. They can be found in many European cities, often taking from of a light circular or octagonal structure with raised platform and pyramid roof. They are usually placed in a space surrounded by benches. If kiosks correctly judged, the form, location and surrounding space can create a vital, lively and decorative place in a city scene.

A bandstand- England

3 URBAN SPACE AND INFORMATION FIELD

Urban spaces should have a rich information field and it is proved that increasing of the information in an urban space create a beautiful, exiting and memorable scene and it is the reason of why there are a lot of visitors for historical cities such as Venice , London , Paris and Esfahan and not for modern urban spaces.

Here two elements are essential:

- Context
- accessibility

Context is the information that exist on a screen (like a message on a paper)

Accessibility is affording to receive the information (like the simplicity in reading a message).

3.1 Being fractal

Being fractal in spaces allows getting new details by zooming in several stages. These fractal elements present the whole of themselves but modern urban spaces don't have this property so they are not attractive. Details of traditional urban space and buildings which are clear and coherent have fractal property and it cause that the visitor be impressed. Permeability is another property of fractal. In historical cities colonnades, arcades and facades of buildings have a great permeability which makes the exchanging of information

easier, like a roundabout river that has a complicated route which prevents from simplicity and monotonous of the scene of river.

The main problem is imposing the fractal property in human scale. For example a colonade could be fractal when the distances between its columns are 1 to 3 meters because these measures are compatible with human percept.
A colonnade with 1-3 meters between their columns is fractal in human scale
Not respecting of human scale prevent the perception of fractal structure

Old cities are interesting, visitable and memorable because of being fractal in human scale but contemporary urban spaces because of following the modern style which suggest purity and avoiding ornaments and complicating are spaces that don't have influence of their visitors.

Actually a tree has a lot of points to touch and see than a modern glass cube which modern architecture recommend it. Today our cities have become some places that are inhuman and decayed for people especially for children. So we can conclude that a collective urban space couldn't be a successful and memorable space without having fractal property in human scale.

Being fractal makes the collective space more visitable and attractive – Iran

3.2 Three principles of a successful urban space

Regarding to above information to create a successful urban space we should respect three major principles:

- Urban space should be surrounded by some surfaces which present clear information
- The network of pedestrian and vehicle should be neat and identified
- The core of urban space should be allocated to pedestrian to be preserved from non-pedestrian traffic

3.3 The influence of the style of civic art on common perception

Surveying shows that using realistic style in urban spaces causes more perception and user can remember these spaces more clearly and in contrast using abstract styles will cause less memory from these spaces.

Civic arts with realistic style are always more attractive and memorable than artworks in abstract style – Iran

3.4 Categorizing collective spaces in various scales

After considering the criteria of urban spaces we can categorize these spaces in various scales such as "urban", "regional" and "sectional" scale.

Squares are major type of these kinds and in urban scale it has a large role in civic life. These squares could be used by citizens as a pleasant and functional place and in this way some special places with individual feature will be appeared.

The centers of historic district of Iran in old fabric all reflected the social – cultural features because of some nodes and some distinct elements such as mosque, "Hosyniye", stores or even an old tree. In these places meeting and social interaction occurred and in the other word civic vitality was enforced in these spaces.

A collective space in sectional scale –Iran

3.5 Definition of users of urban spaces

The activity of people can be divided in two groups: essential activities and optional activities. All of these activities have different features so they need different physical environment.

Essential activities are mandatory such as going to school or work, shopping, and standing in the line of bus, these activities is affected from the physical environment very few because they should be done every day and anywhere.

The optional activities will be occurred when people intend to do it and time and place help them to do that such as walking in fresh air, standing and watching the people and so on.

These activities are occurred when the circumstances of outdoor places are pleasant and the weather is fine. The relation of this kind of activities with designing of common spaces is more than other activities, because most of recreational activities are being done outdoor.

If outdoor places have low quality people will just do necessary activities but if outdoor environment creates a beautiful and favorite atmosphere people prefer to attend in streets and squares much more and even they would rather walk than pass through with vehicles. Architects and urban designer can improve social interaction in a city.

Like an architect who can provide an invitatory space by using suitable material, forms and colors, urban designers can produce pleasant and unpleasant spaces as well. They can provide a vivid city or apathetic one.

Improving urban spaces can effect on social interaction and daily activities. This effect can be seen in passages and common spaces. Scattered houses will diminish social event and also remove the relation between people. In many old cities people gathered in the squares and encouraged to walk and attend in open spaces.

3.6 Imposing some codes for designing urban spaces to enforce collective memory

The quality of vitality in a city is measured by its social relations and attendance of people in its space. If the citizens of a city don't want to use the urban spaces, it doesn't have a good quality. An urban designer with respecting all aspects could create a city with better civic vitality and here we mention some factors and guidelines in doing that:

(a) Enforcing social relations

People needs social interaction, increasing social relations causes the vitality of cities. We can use these guidelines to enforce social interaction:

- Holding ceremonies and rituals which create social interaction and made people to be familiar with each other
- Respecting hierarchy in the sections of city and locating distinct elements (kindergarten, educational centers, mosques, clinics) in the middle of districts
- Supporting NGOs , organizations and association in the way that this associations could attract all ages and groups of people
- participating of citizens in governing the city

These are some guidelines that we can use them to enforce social interaction and relationship of residences to enforce "the neighborhood" concept as much as possible which have very good side effects.

Holding "Ashoora" ritual ceremony as an important social event – Iran

Holding some festivals – Iran

(b) pedestrian accessibility

Strolling in city and its urban spaces means that this city should have pedestrian accessibility.

Experience in a city without walking in city is impossible and events couldn't be found without strolling in city. A pedestrian network makes different images and pictures from the city in minds.

By this pedestrian network scattered parcels in contemporary cities could be jointed to each other and create a coherent image in minds. This network can create a collective memory as well.
Pedestrian streets :(left) Netherlands-(right) Iran

(c) Thresholds

A threshold is a joint between different spatial, social, cultural or political territories. Passing through threshold means arriving to another territory and exiting from pervious territories.

Threshold is a place that strollers, passengers and residences stop there and perceive the urban space with their five senses.

Creating threshold or joint spaces can be used for reorganizing the spaces. In these spaces, conscious and unconscious memories, individual and collective memories will form.

The threshold of a "mosque" between street and the mosque- Iran

A threshold of a commercial complex

(d) Mixed land use

Zoning in cities leads to forming lost and indefensible spaces. Single land use works in limited hours in a say and in the rest of day these spaces will be completely indefensible. Making mixed land use spaces in a city will create new common areas. The multipurpose spaces which usually located near pedestrian routs will lead to a busy and memorable space.

A street with mixed land use-Turkey

(e) Recreating the concept of neighborhood

Recreating the concept of the center of neighborhood, lane, and alley and so on can produce a new concept in neighborhood. A neighborhood which doesn't has passing through and fast traffic in the fabric. This kind of neighborhood has a defined population and services and it can response to emotional, social and recreational requirements of the community.

4 CONCLUSION

It is more than two centuries that a traditional artist couldn't respond to the problems of cities. Cities become more crowded and technological and the attendance of human in urban spaces was reduced. The result was some polluted, strange, unnatural and ugly environment.

Human being is social and he needs some spaces for having sound interaction and relation with other people and he searches something around himself to remember them as a pleasure and identified memory as well.

In spite of that a traditional artist couldn't be able to respond to all aspects of urban planning, the requirement for beauty and proportion and coherent is always necessary in cities.

Of course it should be mentioned that imitation from some historical spaces in recent designing will not be enough! A contemporary artist should design spaces with considering the values and criteria that enrich an urban space, some factors which were exists in historical architecture and now they are often ignored.

Without this factor the high quality in the environment of people won't be created, and it is the main aim of urban planners: "improving the quality of life".

Two traditional collective spaces – Iran

A contemporary collective space in a commercial complex- Iran

Creativity and Innovation in a Mid-Urban Size Learning Infrastructure – Designing Spaces for Thriving Innovation Communities

Markus F. Peschl, Thomas Fundneider

(Univ. Prof. Dr.DI. Markus F. Peschl, University of Vienna, Franz-Markus.Peschl@univie.ac.at)
(DI Thomas Fundneider MBA, theLivingCore GmbH, Vienna, fundneider@thelivingcore.com)

1 ABSTRACT

This paper presents the design of an urban structure for about 1000-2000 persons originating primarily from the so-called creative class, a creative settlement. This settlement provides a smart working environment for innovation (driven companies) and start-ups, an area for high quality living as well as for leading edge education. Both, the theoretical concepts, their background, and the research-driven design process having lead to this creative settlement are presented. The methods applied in this approach include ethnographic methods, qualitative interviews, quantitative surveys as well as approaches from design thinking.

This paper represents a case study applying and explaining theoretical concepts form the Enabling Spaces approach. A balanced and sustainable research-based ecosystem integrating the poles of innovation/creativity, qualitative living, and high quality educational concepts and facilities is presented. This paper presents the basic concepts of a master plan for the creative settlement that is planned to be realized in Russia.

2 INTRODUCTION: AN ECOLOGY OF INNOVATION ARTIFACTS

The case study presented in this paper is based on an architectural and innovation project for a small urban settlement of about 20-40 hectares (1.000–2.000 inhabitants), which will be realized approximately 20 kilometers outside of major Russian cities. The goal is to develop a "creative settlement" as a resilient and self-sustaining innovation eco-system which is based on sound scientific research results. It represents an eco-system that is sustainable as it regenerates itself through its social design (people working and living there), as well as its knowledge and innovation processes (education, working/business). It provides an ecology of innovation artifacts (cf. Krippendorff 2006, 2011) with self-regulating the in-, through-, and out-flows of knowledge, people, innovations, discourses, etc.

At first, the client's brief was to create a role model for a well-balanced integration of living, education, and work. However, during the research and design process, the "creative settlement" emerged as a place fostering responsibility through people with an entrepreneurial and innovation-driven spirit—a place for people who inherently want to move things forward—with focus on the Russian context.

This project is the result of a cooperation in an transdisciplinary team of (both academic and business) innovation experts, architects, urban planners, cognitive scientists, a sociologist and psychologist, as well as an entrepreneur. As it was the goal to develop a radically new design, the project team itself approached the whole development as an innovation process, which is based on the concept of so called "Enabling-Spaces" (Peschl and Fundneider 2012, 2013)—this approach will be discussed in detail in the following sections.

The first part of this paper discusses the theoretical foundations of the Enabling Space approach and gives an introduction to the design process leading to such multidimensional spaces.

3 DESIGNING ENABLING SPACES

3.1 Enabling Spaces

Enabling spaces are spaces that are designed in such a way that they enable and support processes of collaborative knowledge creation and innovation. Enabling spaces try to give an answer to the question: How do we have to design environments that enable processes of bringing forth fundamental innovations and thriving social systems?

It will be shown that we have to apply a rather broad notion of space going far beyond architectural/physical space: several dimensions have to be considered including the social, cognitive, emotional, technological, epistemological, and organizational dimensions and aspects. Hence, in Enabling Spaces these dimensions have to be orchestrated and integrated in a highly interdisciplinary manner in order to support knowledge (creation) processes (see Peschl and Fundneider 2012, 2013 for details).

Space is understood as a container providing a set of (active and passive) constraints that are offering an enabling structure that is integrated with enabling process dynamics; they are allowing knowledge processes to flow and to develop their own dynamics in such a way that (radically) new knowledge may break forth. The challenge is to develop a stable design process integrating these dimensions into a holistic framework or ensemble, which functions as a coherent Enabling Space.

Fig. 1:. The Enabling Space design process

3.2 The Enabling Space design process

The project design of the "creative settlement" follows the Enabling Space design process/approach (see Figure 1): its goal is to devise and develop architectural design concepts for spaces cultivating and supporting processes of knowledge creation and innovation. The integration and orchestration of various space-dimensions having been mentioned above is one of the most challenging problems, yet powerful features of the Enabling Space approach. One has to follow a design process for achieving this integration. The design process being proposed in this section is the result of five years of the authors' interdisciplinary research (in the fields of cognitive science, theory of innovation, epistemology, and innovation spaces) and of a large number of applied projects that have been realized in different industrial and cultural contexts (for examples see Peschl and Fundneider (2012, 2013) and http://www.theLivingCore.com).

This whole design process is based on a profound understanding of the social system under investigation and its systemic environment. Starting with an extensive research phase ("Observation"), the core knowledge and innovation processes of the social system as well as its cultural, organizational, and structural parameters are identified. This is achieved by applying a wide variety of participatory and ethnographic (qualitative and quantitative) observation methods. The experiences and perspectives of a wide variety of stakeholders are studied through qualitative, generative in-depth interviews. Furthermore, the behaviors and desires of potential users are identified by using a comprehensive quantitative online questionnaire. The observation/research phase is completed by ethnographic studies, as well as by observing and studying artifacts, processes, relationships, etc. that can be found in the organization or system.

In the next step, the "sense-making phase", this systemic multi-perspective and multi-stakeholder view is transformed into a so-called "core-process model" illustrating the research findings in a highly condensed manner. In this phase, the observation results are analyzed, described and reflected by identifying patterns, (hidden) assumptions, polarities, discrepancies, and potentials in a complex qualitative inductive process so

that a coherent overall profile being based on a profound understanding of the social system can be developed. In this highly challenging inductive process it is necessary to work on big tables and literally/physically move items around, (re-)group and relate them (many methods that are relevant here are part of the design thinking approach [e.g., Brown 2008, 2009;]). These core processes represent the essence of the social system and act as a solid theoretical and conceptual foundation for all subsequent design as well as for decision-making processes.

This abstract model is then transformed into design patterns (Alexander et al. 1977) describing and explicating design qualities: Their aim is to provide the foundation for translating and transforming these abstract core knowledge processes into concepts for concrete (materialized) structures, activities and processes. They are a necessary prerequisite for understanding and realizing the various (architectural, technological, organizational, etc.) dimensions of the Enabling Space. On the basis of these design patterns, a holistic urban design concept is developed in transdisciplinary workshops bringing together experts from different fields, such as architecture, urban design, information and communication technology, landscape planning, etc. The resulting design concept goes far beyond architectural aspects and—in many cases—brings about changes in the social structures, processes, and culture. Architecture transforms social systems and vice versa.

Whenever crucial decisions are to be taken in this process, the client and a steering team are involved in the transparent planning of further steps, thus assuring continuous feedback between decision-makers, the teams of architects, researchers and experts, and possible users.

4 CREATIVE SETTLEMENT — RESEARCH PHASE AND OVERVIEW OVER INSIGHTS AND RESULTS

In the first phase ("Observe"), more than 30 extensive qualitative interviews (generative/appreciative interviews; e.g. Cooperrider, Sorensen, Whitney et al., 2000; Scharmer 2007) with a wide spectrum of relevant stakeholders (entrepreneurs, digital natives, investors, business angels, property developers, etc.) were conducted. An interview lasted for about two hours and aimed at establishing deeper insights into topics of the original client's briefing (education, creativity/innovation, working, living) in order to develop a profound understanding of possible core processes for the "creative settlement". Since this project aims at generating a radically new—at that point in time unknown—innovation eco-system, we could not speak with potential "users" as—at that stage—the project was not yet defined. Hence, most of the interviewees could not yet imagine what this settlement would be about; nevertheless, the interviews were conducted in such a way that we tried to listen to the hidden desires and needs of the stakeholders so that we could derive new perspectives from questioning and reflecting their assumptions (partly in a process of co-creation).

On top of these interviews, the authors visited the site several times and conducted ethnographical studies observing and investigating the context, urban setting, cultural issues, etc. (e.g. Kawulich 2005; Laurel 2003; Spradley 1979). Finally, extensive desktop research was carried out: on the Russian context, relevant Russian value systems/terms (e.g., personal power, family, stability, security, etc.), Russian culture and mentality, Russian economy, the political and demographic situation, on specific functions of the settlement (e.g., interactive science museums, alternative education/pedagogical approaches, learning spaces), etc. The interviews plus all of the remaining research has brought about a huge collection of data, information, first insights and ideas, as well as contradictory issues and polarity fields.

Phase 2 of the research process, the phase of "Sense-making", tried to make sense out of these vast amounts of information from the field. This step aims at identifying patterns, finding implicit orders, achieving an understanding of background/hidden assumptions, etc. within this information in order to come up with the most important and essential processes or activities ("core processes") defining the "creative settlement". The result is a highly condensed model of the core processes depicted in Figure 2; it has turned out that children surrounded by family, living and education, as well as an enabling, inspiring, and vibrant working environment were the key processes for this settlement.

Up to this point, one could follow several well known scenarios that address these core processes quite well, for instance, in the form of a special business park, satellite town, or a science city (having some tradition in Russia); however, these solutions are not really innovative and—furthermore—were not in line with the expectations of the client.

5 GUIDING PRINCIPLES AND DESIGN PATTERNS FOR A SUSTAINABLE INNOVATIVE CREATIVE SETTLEMENT

Instead of falling back into or just adapting already existing solutions of urban settlements or business parks the design team developed distinct guiding principles/design patterns that are applied throughout this project. These guiding principles have been developed from so-called "polarities" (apparently contradicting issues that are excellent starting points for new ideas), from the design patterns, from insights from the research phase; they emerged out of the above-mentioned inductive processes and out of rigorously questioning and reflecting on the assumptions that stand behind the interviewees' statements:
Fig. 2: The Harbour-Analogy illustrating the steady in-, through-, and outflow of new knowledge and people. Start-up businesses (S and SK) dynamically move through the creative settlement in order to bring in fresh and new perspectives. The established business people (S+ and E) are cultivating the stable pole.

(a) Role of creativity, innovation, and entrepreneurship: creativity and innovation are at the core of the creative settlement; they are embedded into entrepreneurial dynamics creating buzz and aiming for a thriving social, knowledge-, and innovation-dynamics.

(b) Openness: is present on various levels and in several domains: knowledge, open-minded people, socially open, open to the public vs. security issues

(c) Balancing the in-, through, and out-flow of new knowledge and people: start-up companies and a so-called established user group (people in strategic positions of bigger companies) are settling and working together in a mutually synergetic cooperation. Figure 2 illustrates the process of renewal (e.g., start-up companies have to leave the creative settlement, once a certain size and economical stability is reached and new start-ups move in).

(d) We are following here a well-known principle from biology, cybernetics, cognitive science, and systems science, namely the principle of autopoiesis: This concept was originally developed by the biologists H.Maturana and F.Varela (1975) for describing the dynamics of living systems: according to the concept of autopoiesis living systems have to be understood as self-sustaining and self-regulating systems, (re-)creating themselves and their borders in a continuous process of transient stabilities (a homeostatic equilibrium) by interacting with, reacting to, and actively acting on their environment. We are applying this principle here to

describe the knowledge dynamics and the social dynamics of the "creative settlement". The goal is to maintain this tension, this "stable instability", this state of homeostasis of inflow of new knowledge and people, assimilating this knowledge, developing it further, getting inspired, creating new knowledge, using and exploiting this new knowledge and, by that, creating new realities, innovations, as well as social structures. The whole system aims at producing a thriving ecosystem of new knowledge, creativity, prospering individuals and a stable social dynamics in accordance with the surrounding environment.

(e) Primacy of incubation: the creative settlement offers protection and at the same time it stays open for new ideas, knowledge, innovations, technologies, etc. (compare also the issue of exploration vs. exploitation (on the scale of a small-sized urban knowledge ecology (e.g., Corso et al. 2009)).

(f) Providing leading-edge education: from créche to academia, education is organically embedded within living and working; furthermore, these educational places are open for people living outside the "creative settlement", such as from surrounding cities and existing villages.
Fig. 3: The core-processes of the creative settlement.

Above these guiding principles various issues had to be solved and integrated in an interdisciplinary manner in the form of an overall process design. Figure 3 shows these core processes that are interacting and mutually causing each other:

(i) "Enabling the New": innovation, spirit of entrepreneurship, start-up dynamics

(ii) "Learning as a foundation for the Future": highest quality and leading edge education on all levels ((pre-)kindergarten, school, entrepreneurial academy, science museum)

(iii) "Living a good (family-)life": good balance between life, family, and work; high quality living environment; providing a safe harbor for living.

All these considerations led to the identification of the user-groups by relating the desired knowledge and innovation processes to potential users, their skills, their business contexts, as well as their needs for living (e.g., family live, good quality houses, education). Examples for such user groups are the start-up founders, people working at the start-ups, established business men (investing in the start-ups), young families living in this creative buzz, etc.

Furthermore, scenarios have been developed that offer quantitative measures concerning balancing of number of users per user groups and balancing the different functions (school, smart working, different residential areas, sport facilities, entertainment, science museum etc.).

6 REALIZATION OF THE CREATIVE SETTLEMENT

Departing from the above-developed guiding principles and design patterns the architects as well as the social designers started to transform these rather abstract concepts into concrete architectural and social forms (see also Figures 4 and 5); here are the most important realizations:

(a) Communication plaza: this element is a meeting & communication space around a central plaza for residents, business people, as well as the general public. A gradient from public (entrance, restaurants, science museum, etc.) to private areas (living, school, etc.) allows for different levels of privacy and openness. Inside, the plaza reveals the functions of the adjacent elements by opening up the architectural skin, thus becoming public experiences. The communication plaza is defined by the surrounding elements/functions, such as smart working spaces, a science park, an entertainment center, sport facilities, and a school. Thus, the communication plaza acts as a connecting interface, creating a buzz and a vibrant atmosphere just by being there at the intersection of these units and functions.

(b) Open and public educational spaces: open to the public and offering courses, activities, events, etc. on a regular basis. The concept is to provide a high quality educational offer, which goes far beyond classical school offerings or curricula. The authors suggest to view these educational infrastructures in a plug-and-play manner: i.e., to combine a set of the following modules according to the affordances, needs, preferences, etc. of the specific context and the environment of the "creative settlement": (i) science and technology: newest insights and results from various fields of the natural sciences and technology are presented and collectively experienced, explored, and further developed. The goal is to involve the visitors in the process of doing science and research. One can think also of a science park of jointly creating new knowledge and insights in various settings (workshops, labs, fab-labs, simulations, etc.); (ii) arts and humanities: these modules comprise a wide variety of offerings as well as zones for different fields of arts: painting, sculpture, performing arts, dance, etc. There will be need of specific spaces for these fields of art (ateliers, stages, etc.); (iii) entrepreneurial thinking and innovation: provides state-of-the art approaches in different fields of entrepreneurship and innovation. Both theoretical and practical aspects will be taught. The work being done in these courses and workshops might result in innovations, prototypes, and or co-operations with start-ups in the creative settlement (e.g., internships, etc.); (iv) thinking styles, interdisciplinary thinking, reflection, and personality development: Teaching in this module provides generic skills that are necessary for any kind of knowledge and innovation work and education. This is a unique offer, as these things are normally not taken care of in classical educational systems and curricula.

(c) Focus on balancing user groups and functionalities: in order to establish a fruitful symbiosis (entrepreneurial activities) between the various target groups it is important to keep the ratio of start-up people and established people (individuals in strategic positions of larger companies) well-balanced. Either group dominating would result in a shift of the character of the proposed "creative settlement"—especially a shift towards loosing the creative buzz. Consequently, the design of the "creative settlement" is focusing on the links and relationships between functions, rather than on single functions. Hence, it is not possible to just remove or add certain elements or functionalities of the "creative settlement", as this could imply a destructive pertubation of the autopoietic dynamics of the creative settlement.

7 CONCLUDING REMARKS

It is important to understand that this settlement does not primarily address a romantic view of living and working in the countryside or a kind of "wellness" program for a good work-live balance. Rather, by focussing on the core processes—in this case, knowledge and innovation processes—it is a well-balanced eco-system continuously bringing forth new knowledge, innovations, as well as educated and cultivated individuals and social structures. One has to know that there exists a long tradition of research settlements or science cities in Russia, e.g. Naukograd or Zelenograd—they have a rather positive reputation.

From this perspective, the "creative settlement" is located in a positive distance (accessible but remote) from a major city, this supports the above discussed creative processes and innovation dynamics in a highly efficient manner. Historically, cities emerged around (road) junctions, water routes, etc., since most products and processes were—and still are—based on material structures. In our age, this material foundation of products gets relativized: knowledge processes and knowledge creation are inherently immaterial, they are not bound to roads, but require new epistemological, social, as well as technological eco-systems in which they can thrive: Enabling Spaces.

This leads to a second important issue: the "creative settlement" is both open and closed: closed, because (radically) new knowledge is highly fragile and needs some kind of a "safe" container, where this knowledge can be incubated, explored, tested, etc. On the other hand, there has to be a steady stream of new people, knowledge, technology, etc. moving in and out in order to enable the creative settlement to regenerate itself,

re-create itself, re-define its borders, etc. (compare the analogy with an autopoietic system). In an analogy the settlement can be thought of as a harbor (see also Figure 2). Ships of young (start-up) entrepreneurs are entering the harbor (inflow of new knowledge, ideas, etc.) and after a period of protection (regarding their fragile ideas), incubation, and exchange (with other entrepreneurs and experienced business people) and when their business models have proven successful or at least promising, they are ready to leave the protected place and sail out across the ocean (entering the business environment). In this sense, the harbor (respectively, the "creative settlement") is a place to anchor, a place for incubation (protection). However, it is of utmost importance that the ships are not becoming permanent residents of the harbor, since then the flows from the external world will be inhibited.

The project team has translated the concept into concrete architecture and process structures; that process has been finished by the end of June 2012. First visualizations are shown in Figure 4 and can be found under http://www.thelivingcore.com/realized-projects/ and http://sferiqtown.com/. Negotiations with potential investors and political stakeholders in Russia are underway.

1 ABSTRACT

Every new period of planning evolves its own gadgets and tools. Whereas the relation between crime and urban space has been part of research for almost 200 years, new techniques like geographic information systems and mobile communication devices could have huge effects for this topic. Data analysis and visualisation could be brought to a new level and furthermore, the data could be distributed immidiatly to citizens. In this context interactive Crime Mapping Systems emerged during the past decades. These online platforms visualize criminal events freely available on maps and become more and more popular for normal citizens looking to evaluate their area of town. Based on the historical development of this topic, data gathering and distribution are showing the impact of crime on urban areas and their population. Hence, such platforms will gain importance in planner's life and a critical evaluation about chances and risks from the point of spatial and urban planning is needed, which will be done in this paper. For this purpose different examples from the U.S. and Europe will be examined and compared. These systems will be analyzed in detail on the basis of the following three characteristics: data set, functionality and type of visualization. It is the aim of this paper to consider the feared and hoped effects of these platforms on urban areas, their population, local players and in particular urban planners. This includes the correlation between systems with public access and unpredictable effects for urban areas. Nevertheless, the paper will give some insights about the possible positive effects of crime mapping systems. The intention is to provide an approach, for the possible use of such platforms for urban planning while avoiding the described risks like as data data protection or the evocation of a generation of fear.

2 INTRODUCTION

The combination of crime data and urban areas is as old as traditional urban planning. This paper will give some insights about the relationship of crime in urban areas and how the circumstances have changed in the last decade and which are reasons for this new field of research. One of the key factors for the quality of life in urban areas is the subjective well-being of its inhabitants. Many circumstances influence this subjective impression (social and ecological issues for instance), but feelings about their sense of security are often considered as very dominant (Floeting & Seidel Schulze 2012, p.1). Due to the fact, that crime is mostly taking place in public areas, and the fear of crime is an important factor for the quality of life, there has to be a scientific debate for urban planners about crime mapping platforms in order to improve the urban environment, because an increased use of such platforms by public authorities could be observed. In the light of these developments, this examination aims to provide a critical analysis for its effects for cities and planners. From an urban planning perspective, some questions about the use of such system are obvious and should be handled in this paper:

(1) What is crime, which are the effects for citizens?

(2) What are interactive crime mapping systems and how will data be gathered?

(3) What are the chances for the use of such platforms from an urban planning perspective?

(4) What are the risks for the use of such platforms from an urban planning perspective?

(5) Considering chances and risks, under what conditions could such an approach be promising for urban planning?

2.1 Crime in urban areas

Already in 1829, Balbi and Guerry mapped different kinds of property crimes in France in correspondence to their educational level (Boba Santos 2009, pp.7-12) and drew their conclusion of possible connections. Nearly 100 years later, Park from the Chicago School did some research about "Social Ecology" and crime locations (Vogt 2001, pp. 11-12). Hence, monitoring crime in urban areas was and still is an essential issue for urban planning, because it's an important influencing factor for citizens well-being. Nevertheless, research was done particularly from urban sociology. Accordingly, the topic was only accessible for experts

for 180 years, (planners, city councils, scientists or the police). However, during the last 180 years, this was a topic which only experts (planners, city councils, scientists or the police) were able to access to relevant database.

As before, crime or especially the impression of urban crime is strongly connected with subjective impressions, which is part of urban research (Vogt 2001, pp. 11-12). From a terminological point of view, the explanation of crime is considered to be very complicated. Simplified, it is described as "something, which deviates from legal regulations" (Belina 2011, p.12). This deviance depends on the current political and social circumstances. This means, that an action (e.g. drinking alcohol in public) could be considered as crime in one specific place at a specific time, whereas the same act isn't necessarily seen as a crime in other countries with other circumstances. Besides the fact, that due to the mentioned problems, the statistical crime data gathering by the police is not able to entirely illustrate crime in urban areas realistically, many other problems have to be revealed: Unreported issues, reporting behavior, suspects- and offender statistics, and contradictory interpretations. These issues make a complex analysis of crime mapping systems for urban planning necessary.

2.2 State of research and planning methods

As previously mentioned, Balbi and Guerry have done some research almost 200 years ago (Boba Santos 2009, pp.7-12). The topic came back in the scientific focus about 100 years later, as the Chicago School did the research about "Social Ecology" and crime locations (Vogt 2001, pp. 11-12). Some investigations about this were also done for example in the context of the combination with mental maps (Matei et al., 2001). The research focus to crime mapping platforms is intensifying, because there has been an immense growth in numbers of such platforms, especially in Anglo-American countries. First of all, this was possible because of the new capabilities of GI-systems, which were able to analyze crime data very detailed and get useful data out of it. Even more important is the fact, that this data could be published through the web, which makes all of it accessible. This was despite of the uncertain complex interactions with the urban environment. Alone in the USA, there are more than 125 crime mapping systems. Great Britain for example empowers the public platform "police.uk", where various kinds of crime mapping data for the United Kingdom can be accessed. Furthermore, these services are getting more and more available through mobile devices. From a planning perspective, there are plenty of potentials for implementation. These embrace different spatial and urban planning issues as well as the urban sociology perception. As well important is the fact, that this data could be published through the web, which makes all of this data accessible for every citizen and other laypeople. Furthermore, mobile phones are making this data accessible everywhere, allowing users to contribute own crime data by User-Generated-Content (UGC). These mentioned topics are barely integrated in planning processes or researches yet. Hence, aim of this paper is a comparative analysis of the existing crime mapping systems and approaches and to assess the potential positive and negative effects of these platforms for urban areas as well as for planners.

2.3 Methodology

The paper examines the theme on the basis of the earlier mentioned research questions. In this regard, it first analyzes theoretical questions, such as the definition of criminality and its distinction to other forms of deviancy, its connection to the planning field, the challenges of the data collection and finally, the history of crime mapping. Secondly, the technical basis of the interactive crime mapping platforms is studied. Because of the diversity of different systems, three main categories were developed, in order to comprehensively illustrate all functions, types of visualizations and base data. In the next step the paper discusses the possible positive (hoped) and negative (feared) effects of such systems, based on these theoretical and technical facts. In both cases, effects for urban areas, their inhabitants, stakeholders and city planners will be illustrated. Although the paper was composed from a planner's point of view, especially the hoped positive effects will include and discuss numerous aspects, which derive from the perspective of the police. Finally the paper summarizes the assets and drawbacks in order to picture the proportion of chances and risks which come with the use of such plattforms in urban areas. Considering these results, a few recommendations will be outlined and possible future developments will be discussed.

3 EMPIRICAL STUDY CASES

The various forms of crime mapping platforms are almost as complex as the phenomenon of crime itself. Therefore the technical basis was analyzed detailed in three separated categories in order to ensure an essential comprehensibility:

- Data set
- Functionality
- Type of visualization

These three categories will be illustrated in the following on the basis of exemplary study cases.

3.1 Example A

The first category, respectively the first group of study cases is defined by the type of the underlying data set. It can be illustrated, that most of the platforms are based on police data, whereas only a few platforms use user generated content (UGC) for their visualizations. This general segmentation of base data in two groups is quite oversimplified. In fact, the data set relies profoundly on platform operators and their aims. In this context four types of data sets can be revealed, that are substantially affecting the platforms. As pointed out in the illustration below these four groups are: Systems operated by the police, systems operated on behalf of the police, independent systems using police data and independent systems generating own datasets.
Figure 1: Types of base data

3.2 Example B

The second category examines the functionalities of crime mapping systems. Superficially, all platforms can be described as interactive, allowing users to investigate all designated areas in a freely scalable map-interface like Google Maps or Microsoft Bing. Furthermore all platforms offer a few tools to analyze the visualized crimes. In nearly all cases this includes the sampling of different kinds of crime, times of offences or areas of crime scenes.

However, some platforms provide much deeper analysis tools. The following example of the platform raidsonline.com, allows users to put further data layers such as population density or underemployment rate underneath the crime incidents. This gives the user to chance, to make multi-level analysis with results, which can be very valuable from an urban planning point of perspective. On the other hand it has to be mentioned, that correlations between additional information and crime incidents have to be checked carefully, in order to prevent misinterpretations.
Figure 2: Combination of registered Crimes and further data layers

Other platforms also offer solutions for mobile phones. It has to be mentioned, that these solutions are not as detailed as the platforms for real computers, but usually they provide maps and functions that include the actual position of the user, allowing him to search for possible threats in the surrounding area. Very often the solutions for mobile devices are quite specific, which is on the one hand a limitation, but on the other hand a chance. The example aside shows an application (FindAPad for Windows Mobile) that displays free houses near by the location of the user and offers him information about crime incidents in

Figure 3: Example of the mobile phone app FindAPad

These two examples clarify the range of functions interactive crime mapping platforms are offering. However, there is an advancing number of mobile applications available for mobile devices. For the United States, there are already lots of iPhone applications like "Crimemapping.com Mobile for iPhone", "Crime Reports for iPhone", or "RAIDS Online for iPhone". These applications are also available in Asia ("CrimeMap for iPhone"). Some of them use data by public authorities like the police, but there are more and more applications, which enable the user to contribute data with their mobile devices.

3.3 Example C

The last case group examines the different types of visualizations of crime mapping systems. There are various kinds of visualizations, but here the focus is put on the three most common groups. Generally the visualization of the platforms can be divided into 3 classes, which implicate different pros and cons:

- Symbol Maps illustrate all crimes with an own symbol. Accordingly, these maps are easy to understand, but in the case of big map extracts it can get overloaded. This can be seen especially, when various kinds of different crimes have to be visualized.

- Graduated- Symbol- Maps add up all crimes of a certain area, generating a symbol for that area according to the amount of events. These types of maps are much easier to read, but in case of missing knowledge harder to understand.

- In contrast to the maps described above, the heat map does not visualize crime scenes punctual, but it illustrates the density of committed crimes. This approach leads to maps, which are easily to read, but also harder to understand. In programs to generate heat maps there are possibilities to modify the visualizations, which is good for customized solutions, but vulnerable for manipulation. This manipulation does not necessarily mean falsification, it can simply mean the specific configuration in terms of colours or radiuses.

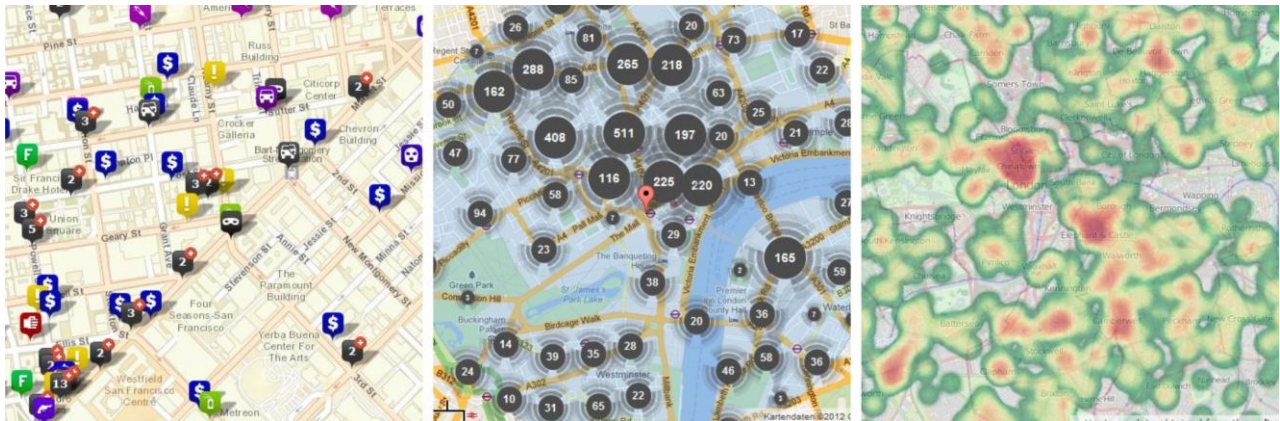
The following illustration displays all three kinds of visualization types.


Figure 4: Visualization Types of interactive Crime Mapping Systems (Symbol Map, Graduated Symbol Map and Heat Map)

Furthermore, there is also the possibility to combine geospatial analysis and 3D-mapping (Wolf & Asche, 2009). However, it has to be stated, that visualizing 3D-content is very "eye-catching", but it can be very complicated for laypeople to understand and not to misinterpret the given data. Though there is no intense use of 3D-Heat Maps through crime mapping systems worldwide, which is the reason why there is no deeper analysis in this paper.

4 POTENTIALS FOR URBAN PLANNING

As previously mentioned, crime mapping tools offers a wide range for analysis approaches. Though, the use of such systems and the provision of this informations can be a two-edged sword. Hence, the described platforms will generate positive as well as negative effects for urban areas, their inhabitants, local stakeholders and also planners. In this context, the paper examines in two steps first the hoped positive effects and secondly the feared negative effects for cities and the named groups.

4.1 Chances

The positive effects can be seen from two different angles, first of all from the view of the police, secondly from the view of a planner. On the one hand, the aims of police departments should be considered, because they were the primary reason for the implementation of the platforms. Nevertheless, these hoped effects concern particularly urban areas and their inhabitants:

(1) Better information for citizens, reducing the fear of crime and the workload of the police

(2) Increased transparency of police work and more confidence of citizens

(3) The bond between citizens and local police departments will be strengthened, enhancing their cooperation

(4) Inhabitants will be empowered to independently avoid dangerous situations and to adopt prevention measures

On the other hand, further effects can be identified from a planner's point of view. Besides the urban areas and inhabitants, these effects additionally concern local actors and planners. However, they have to be reconsidered in their relation to the earlier mentioned aims of the police:

(5) Assistance in processes of urban and regional planning, e.g. in the preparation of development plans

(6) Benefits for other urban actors like the detection of trends and the identification of emerging problems

(7) The public could use the platforms as pressurizing medium

(8) Image promotion for slightly affected areas

(9) Crime Monitoring serves all stakeholders for early trend detection and it can be used, to test the effects of measures for crime reduction

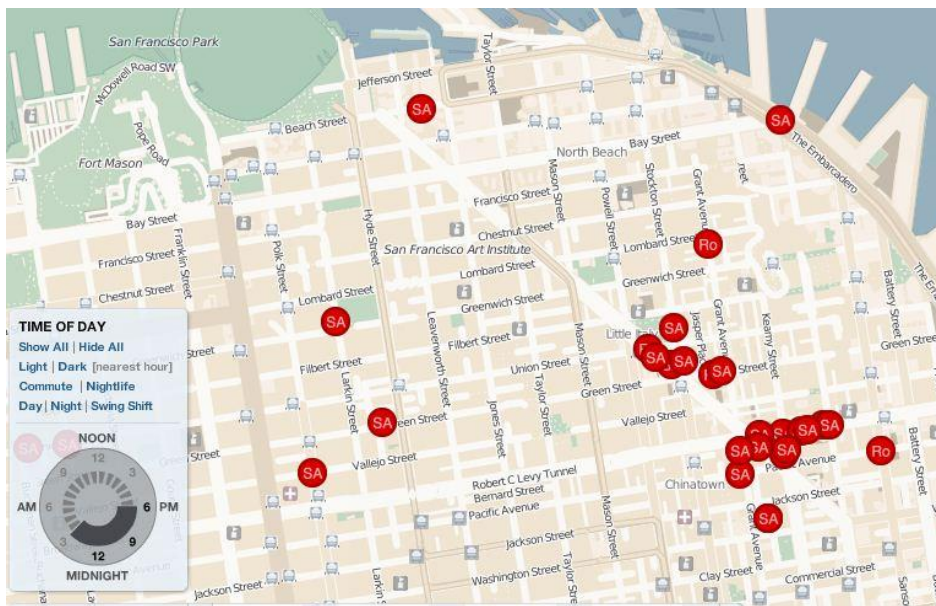
A possible realization of such a tool for visualizing crime can be seen in the subsequent figure. The following map of the Stamen Design Group illustrates the desired results exemplarily for the city of San Francisco (Stamen Design, 2012). The example map visualizes crimes, which took place during the nightlife in a specific part of the city. This map can be used by several of the defined groups, fulfilling different of the hoped effects. In particular, citizens could avoid the highlighted crime hot spots during the nighttime which could lead into an improved cooperation between citizens and police, as it is described in point (3). Furthermore planners should include this information in their work and use them for more precise geo-localisation of urban problems as it is described in point (6). This could leads for example to reconsidering the concepts of illumination and visibility during nighttime in order to improve the subjective well-being of the citizens.


Figure 5: Registered crimes during nightlife

4.2 Risks

In addition to the discussed hoped effects, the paper considers possible negative effects. The feared consequences are also strongly correlated, alongside with the different positive effects. In this context misinterpretations are particularly relevant for the other outcomes, causing or intensifying many of them. This embraces the problem of stoking of fear (d) in the affected areas or the possibility to manipulate the user perception (b). Following problems could occur:

(a) Misinterpretations by users, due to a lack of expertise, a lack of information about the published data and visualizations that provoke misinterpretations

(b) Manipulations of the platforms by outsiders and operators, especially in the case of user-generated content. This will be even more relevant through the massive use of mobile communication devices, which enables their users to tag crimes in urban areas at every time at every place. Furthermore, through the easy use of geo-mash-ups, it is very easy to develop own crime mapping applications, which aren't under any kind of public or scientific surveillance

(c) Commercial use of the platforms, including severe consequences for the population (Example: Redlining of insurance companies or credit institutes)

(d) Crime- Mapping- Systems are stoking the fear of crime, like all other mass media

(e) Crime- Mapping- Systems are supporting the stigmatization of areas and their inhabitants.

(f) Criminals can use the platforms like all other people. They could use the published information to find possible victims and identify less controlled areas

(g) The platforms are not able to reduce crime, its just a displacement of the crime locations

(h) The platforms violate the individual right to decide which personal information should be published and which not, because of the effort to ensure absolute public safety

Especially the last point will be reflected in detail. It is impossible to publish geographically referenced crime data and to protect the victims of crimes at the same time. If a crime is referred to a specific location and is published in a crime mapping system, this means that it can be seen from the general public. Although there are some regulations about data privacy, if there is a specific place marked with a crime (or even more as area with a general high rate of criminality), it could be directly referred to this specific location and the people who are living there. This could lead to a negative image in terms of criminality and all its corresponding consequences. This stigmatization would have consequences for the whole neighborhood and could lead into affecting real estate prices for example. Whereas there is some legal regulation from services offered by public authorities, this won't be the case for data distributed by private companies and especially for UGC-crime data. How strongly privacy rights of single persons could be affected can be seen on the subsequent figure. "Homicide watch D.C." publishes personal data of murder victims like home addresses, personal photographies and the exact crime spot in order to "remember" them (Homicide Watch, 2012). According to this, the platform doesn't even have the aim to prevent any possible future crimes, but it violates the privacy of family members.
Figure 6: Visualization of homicide victims

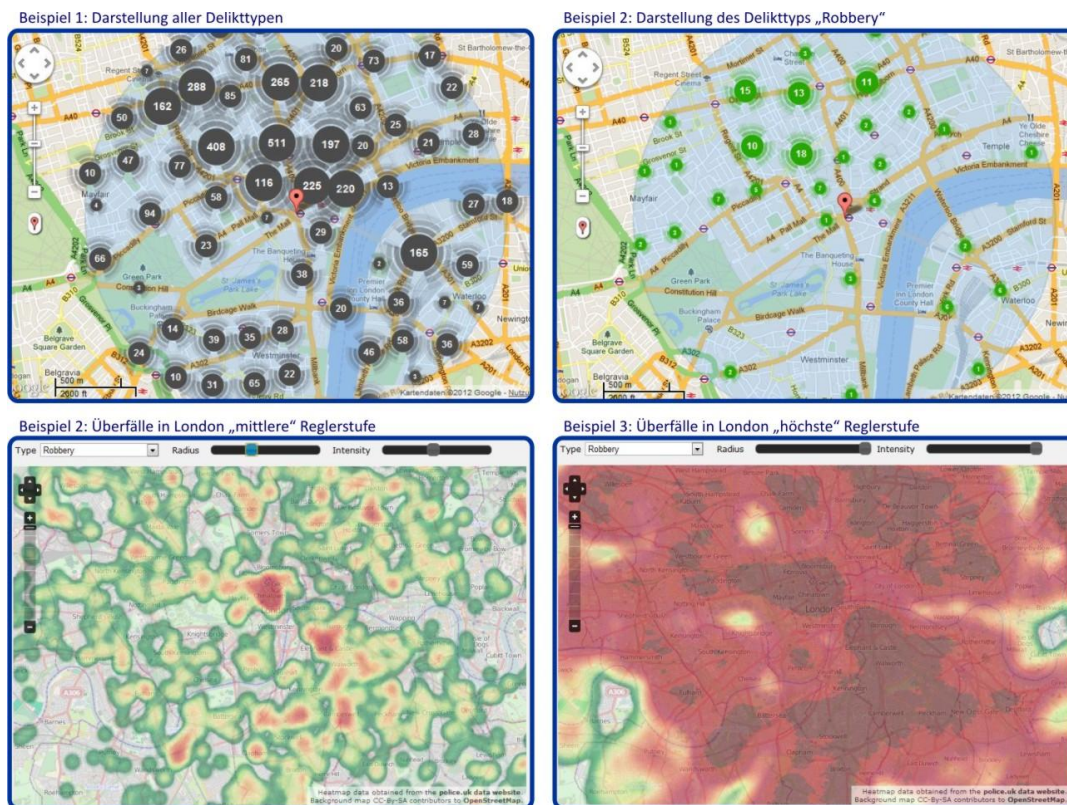
Another example is given in the second illustration, which is visible below. All four maps visualize crimes for the same area in the city of London (Police UK, 2013). Actually, the last three maps show the same type of crime for the same time period. This example demonstrates how easy the offered maps can be misinterpreted or manipulated. This problem is very relevant, because there will be a communication between technical specialists (planners, employees of the city council) and laypeople. Hence, this could lead to massive misinterpretation on the citizens' side. Finally, the number of possible negative effects raises the question, what kind of institutions should decide about the handling of such sensitive data. The paper discusses this question, offering possible solutions to protect the privacy of victims, while taking advantage of the information the platforms provide.


Figure 7: Examples for data misinterpretation and manipulation

5 CONCLUSION, RECOMMENDATIONS & FUTURE RESEARCH

In view of the dynamic developments in the crime mapping sector in the last years, the increasing prevalence of these tools and methods will continue. This is mostly due to the fact of the technological development for data processing and the possibility for accessing and contributing data via mobile phones. And of course, there will be a high demand for such service on side of the citizens. Due to that, there will be a relevant momentum in the development of such approaches in developing countries as well. This is where crime mapping systems meet urban areas with relatively high crime rates and a society that could rely on big promises of such systems. Hence, the mentioned feared negative effects of such platforms can be expected as much worse than in these countries.

From a planning perspective, these crime mapping tools provide a wide range of analysis possibilities though it has to be stated, that after evaluating the potentials and risks of crime mapping systems, it is very problematic to find a compromise in use of such systems by free availability for the public society. Furthermore, it is quite impossible to estimate all direct and indirect consequences, if crime related geodata will be made public for all citizens. As mentioned, monitoring urban crime is very complex and there has to be some contextual knowledge to deal with it. Usually this is not the case for all citizens. This problem is even more relevant due to the fact, that through data publishing via Internet, all of this data is theoretically accessible for all citizens – at every time and in every place. Furthermore, it is also possible for them to create their own "crime geodata" with their mobile phones, which could be seen by other citizens. If there is an open and unrestricted access to crime mapping data and systems, negative impacts like misunderstanding of visualizations, exaggerated fear of crime as well as data manipulation could occur. This is mainly because of the lack of knowledge in terms of crime research or geodata visualization. Though, there is a potential of crime mapping methods for urban planning, in the case of a restricted access for urban actors or tailored for citizens with the contextual knowledge. If there is a political will to embed these systems in public services of a city, the dependence on legal (data privacy regulations), social-cultural, political regulations has to be discussed. The use of such systems has to be considered wisely, particularly from an ethical point, in order to achieve a benefit for the society. Besides these official approaches, crime relevant data created by User-Generated-Content with mobile phones will also be more important in the future and there has to be a broad scientific debate how to deal with it in an urban context. Furthermore, crime mapping platforms driven by private companies should be seen very critically. Unrestricted publications of crime data through crime

mapping platforms could raise negative effects for the urban environment. Through stigmatization or other effects, self-amplifying effects could occur and lead for example to misled development in these quarters. There is also the possibility for planned manipulation of real estate prices for example. Such negative effects should be avoided by urban planning approaches if possible. Urban planners have to be aware of these topics and have to consider potentials and risks of crime mapping systems for public authorities, police and especially the citizens before an implementation of crime-mapping tools in the daily working routine. Although there is a potential for future planning approaches in order to detect new urban patterns and to prevent crime in urban areas, there will be also an ethical question to discuss, what kind of data is suitable for the public society and which should be better handled by experts. Hence, there has to be more research on these crime mapping systems as well as on its effects on urban areas.

1 ABSTRACT

For transport planning, as well as for other planning jobs, it is necessary to have information about the general conditions. To estimate traffic volumes and to identify the need for measures, knowledge about the future transport demand is necessary. The development of transport demand depends on many factors as well as on the general situation, so an estimation is quite complex. Therefore transport models are often used as a basis for the decision-making- and planning-process. At the moment different stakeholders usually use different models with different data and their own focus – even in the same city. In many transport planning processes different stakeholders (e.g. from the city council, transport association) are involved, so collected data and results have to be discussed many times and difficulties in the coordination and decision-making-process can occur. Aachen is located on the border to the Netherlands and Belgium, so there is a tight interaction between the municipalities (e.g. cross border business park, cross border public transport), which are located close to the border. Data and information which is needed for the planning process are kept and used in wide differentiation and with a variety of definitions and considered areas by the different institutions and stakeholders (e.g. city council, road administration, transport association) in Germany, Belgium and the Netherlands. Therefore, the plausibility and consistency is not always given in the regional context. Essential for future projects as well as for coordinated planning across the borders is a reliable and coordinated basis between the different institutions.

The StädteRegion Aachen (association of municipalities), Straßen.NRW (road administration) and the AVV (Aachen Transport Authority) are responsible for different spatial and traffic planning tasks. Therefore they have awarded the development of a cross-border and georeferenced data platform combined with a macroscopic cross-border transport model to create and keep a high quality and consistent basis for regional planning in the region of Aachen. The aim is to build up a standardized and continuing database, which provides necessary basis data for different types of planning for every stakeholder in the region. This is a challenging process in which most regional stakeholders of the three countries should participate to guarantee reconciled data. During the development of the data platform and the transport model due to the data a lot of inconsistencies can occure which are required to be solved. Just two of them are the use of coordinate systems and commuter statistics. In the process of building up the model available data and information about the over 60 municipalities in three countries are used. Therefore it was necessary to combine map bases (e.g. private traffic network, zonal structure) of different suppliers. It has to be taken in consideration that all countries of the planning area, are using different coordinate systems. In Germany mainly Gauss-Krüger is used, whereas in the Netherlands Rijksdriehoekstelsel and in Belgium Belge Lambert 2008 System is common. A transformation of coordinates can lead to distortions. So it is necessary to check different key factors of the model (e.g. distances) and correct them. There is always a problem with merging maps form different suppliers. Inaccuracies on border crossings can occur even in areas of the same country. The trip generation is based on commuter and structural data. When comparing the correspondent balances (e.g. gainfully employed persons – jobs compared to commuter balance) there are great differences especially in the cross-border balance. Therefore it is necessary to rework and to adjust the data, but the reliability of the chosen approach has to be taken into account. The national statistic of people who commute to work depicts the interconnections very detailed. NRW and the province of Limburg for example are collecting commuter data on municipality level. Looking at the cross-border commuter data it is obvious that this data was collected on a more aggregated level. And due to different methodologies the data cannot be combined easily so it is necessary to develop an approach and reconcile it with all stakeholders. This preparation work has to be communicated well to all regional stakeholders, so that they understand and support the data adjustments. The participation of all regional stakeholders in the process of setting up the data platform and the transport model is crucial so that in the end all stakeholders trust the data and use this model as base for planning actions. Therefore the process of participation consists of a broad involvement of the stakeholders in data collection, data adjustments and information about the model calibration.

2 INTRODUCTION AND BACKGROUND

For transport planning, as well as for other planning jobs, it is necessary to have information about the general conditions. To estimate traffic volumes and to identify the need for measures, knowledge about the future transport demand is necessary. The development of transport demand depends on many factors as well as on the general situation, so an estimation is quite complex. Therefore transport models are often used as a basis for the decision-making- and planning-process. At the moment different stakeholders usually use different models with different data and their own focus – even in the same city. In many transport planning processes different stakeholders (e.g. from the city council, transport association) are involved, so collected data and results have to be discussed many times and difficulties in the coordination and decision-making-process can occur.

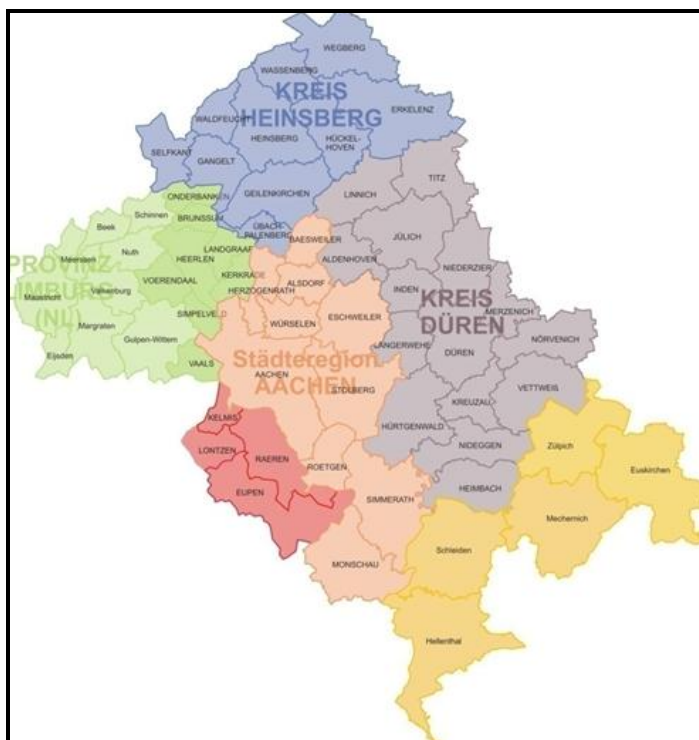
Aachen is located on the border to the Netherlands and Belgium and is a part of the Meuse–Rhine Euregion. In this region there are a lot of cross-border trips concerning different areas of life such as studies, work, shopping or leisure . Therefore a tight interaction between the municipalities located close to the border exists. Examples for this cooperation are the cross-border German-Dutch business park (AVANTIS), the successful concept of the regional train called "eureogiobahn", which operates in Germany and the Netherlands or the platform especially for the problems concerning the cross-border public transport (such as tariff regulations or improvement of international connection). Data and information, which is needed for the planning process are kept and used in wide differentiation and with a variety of definitions and considered areas by the different institutions and stakeholders (e.g. city council, road administration, transport association) in Germany, Belgium and the Netherlands. Therefore, the plausibility and consistency is not always given in the regional context. For future projects as well as for coordinated planning across the borders a reliable and coordinated basis between the different institutions is essential. Therefore the StädteRegion Aachen (association of municipalities), Straßen.NRW (road administration) and the AVV (Aachen Transport Authority) have awarded the development of standardized and continuing database combined with a macroscopic cross-border transport model, which provides necessary basis data for different types of planning for every stakeholder in the region. This is a challenging process in which most regional stakeholders of the three countries should participate to guarantee reconciled data. Therefore the process of participation consists of a broad involvement of the stakeholders in data collection, data adjustments and information about the model calibration. Representatives of the regions and cities are informed and participate in regular meetings about the structure and calibration of the model. Furthermore they provide data and are involved in the development of data adjustment methods.


Fig. 1: study area

3 STUDY AREA AND MODEL STRUCTURE OF THE TRANSPORT MODEL

The aim is to build up a standardized and continuing database, which provides necessary basis data for different types of planning for every stakeholder in the region. The cross-border traffic model is based on the four-step approach. In this trip-based model trip generation, distribution, mode choice and route choice are calculated sequentially although there is a feedback between the different stages. To forecast the travel demand for the study area (area where expected policy impact should be analysed) it is necessary to take into account the interaction areas outside the study area, where trips into the study area are generated or out of the study area are destinated (external stations ES). Therefore all municipalities with relevant commuting traffic are included in the model but on a more aggregate level.

The study area consists of the four German regions StädteRegion Aachen, district Heinsberg, district Düren and a part of the district Euskirchen with 40 municipalities, the region of Südlimburg in the Netherlands with 17 municipalities and the four German speaking municipalities of Belgium (see fig. 1).

These municipalities are divided into 1226 traffic analysis zones (TAZs) taking into account data availibility, main traffic borders and an possible aggregation on district and minicipality level.

4 CHALLENGES BUILDING UP A CROSS-BORDER TRANSPORT MODEL

Data availability and the comparability and/ or compatibility of this data is always a challenge developing transport models. Due to the different methodologies and data aggregations the data cannot be combined easily. These difficulties increase in cross border planning processes even more.. Therefore building cross border transport models it is necessary to develop an approach and reconcile it with all stakeholders (see also other cross border transport models e.g. VKM AT-CZ-SK-HU 2009). This preparation work has to be communicated well to all regional stakeholders, so that they understand and support the data adjustments. The following examples should explain the related problems and resulting consequences in the process of developing a cross-border transport model.

4.1 Compatibility of map bases

In the process of building up the model available data and information about the over 60 municipalities in three countries are used. Therefore it was necessary to combine map bases (e.g. private traffic network, zonal structure) of different suppliers. It has to be taken in consideration that all countries of the planning area, are using different coordinate systems. In Germany mainly Gauss-Krüger is used, whereas in the Netherlands Rijksdriehoekstelsel and in Belgium Belge Lambert 2008 System is common. A transformation of coordinates can lead to distortions (see fig. 2). So it is necessary to check different key factors of the model (e.g. distances) and correct them. There is always a problem with merging maps form different suppliers. Inaccuracies on border crossings can occur even in areas of the same country. Therefore the adjustment of maps, before generating data through intersection between different maps, is unaviodable although it is an time-consuming work.
Fig. 2: Inaccuracies due to merging different maps

4.2 Commuter and structural data of land-use and travel behaviour

The calculation of the trip generation is based on commuter and structural data of land-use and travel behaviour.When comparing the correspondent balances (e.g. gainfully employed persons – jobs compared to commuter balance) there are great differences especially in the cross-border balance. Therefore it is necessary to rework and to adjust the data, but the reliability of the chosen approach has to be taken into account.
Fig. 3: imbalance of commuter and structural data (hypothetical example)

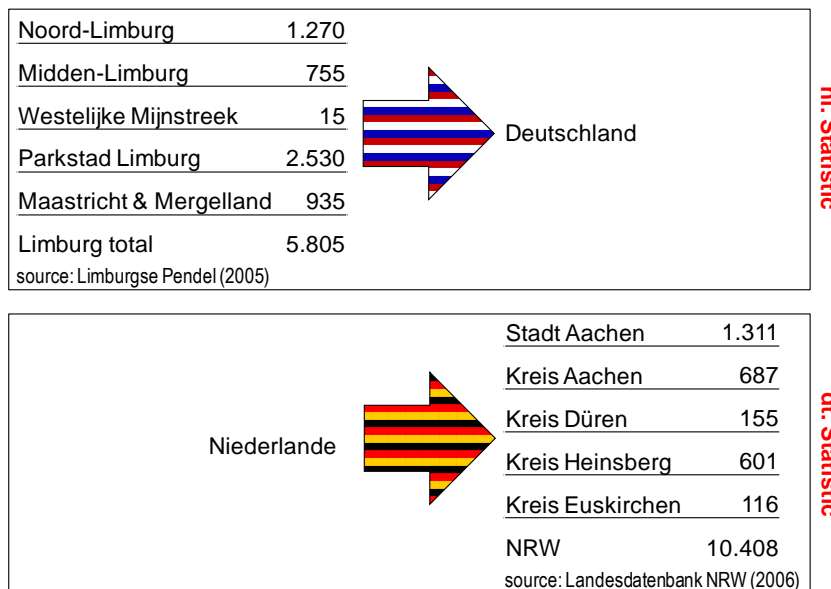
The national statistic of people, who commute to work, depicts the interconnections very detailed. In the German region of North Rhine-Westphalia and the province of Limburg in the Netherlands for example commuter data is collected on municipality level in national statistics. Looking at the cross-border commuter data it is obvious that this data was collected on a more aggregated level. Cross border commuter data does not show the originating or destinating municipality for foreign countries but only the country (e.g. the Netherlands or Belgium) the people commute to or from. The commuter data from the Netherlands for example just shows the number of people, who commute to Germany. There is no differentiation in German regions or even municipalities. Same for German statistics, they supply the number of commuters from the Netherlands to Germany but not the district or municipality of origin in the Netherlands (see fig. 4). Due to this fact it is necessary to disaggregate this data to obtain an origin-destination matrix on municipality or


Fig. 4: Commuters from Limburg to the region of Aachen in German and Dutch commuter statistic

There is not only the problem with the spatial aggregation but also with the availability of cross-border data in general. The Dutch commuter statistic for example shows the commuters to and from Germany, whereas the German statistic only supplies the number of commuters from the Netherlands to Germany but not the other way around (see fig. 5). The reason for that is a differentiation in the methodology. In Germany the

number of jobs liable for social insurance contribution is recorded, whereas foreign employers do not send any information about German employees to German agencies . Due to that fact the employment statistic does not show how many German employees work in foreign countries. In The Netherlands everyone who works abroad is recorded by his health insurance. Every employee living in the Netherlands and with a certain maximum income has to have a Dutch health insurance. Therefore in comparison to Germany the Dutch department for statistics (CBS) is able to record every Dutchman and Dutchwomen living in the Netherlands and working abroad.

Fig. 6: Commuters from Netherland to the Germany in German and Dutch commuter statistic

Due to the differentiation in the methodologies recording the commuters and the definition about what commuters are, the data about the commuting transport differs between Germany and the Netherlands. A closer look to the statistics verifies this fact clearly. Due to the German statistic North Rhine-Westphalia has 11.000 commuters from the Netherlands whereas the Dutch statistic has recorded only 9.000 commuters from the Netherlands to whole Germany (see fig. 6). One reason is that the responsibility for Dutchman/ Dutchwomen, who are living in the Netherlands and working abroad, to have a Dutch health insurance is related to their income. If they have a certain income, they do not need a Dutch health insurance anymore. That means that a certain amount of cross-border commuters is not recorded in the Netherlands. The Dutch research office E,til estimates that the actual amount of commuters is 10 % higher than the CBS records (E,til 2011, page 22). Additionally the CBS does not record any cross-border commuters, who work less than

twelve month in a foreign country. But these two reasons just explain some part of the difference in the commuter statistic, so there have to be more explanations. To analyse this discrepancy enquiries to identify the differentiation of the recording methodologies. The research work is complicated by the accessibility of data and communication problems. Another challenge lies in the development of a useful approach how to handle the noticed differentiation and reconcile it with all stakeholders.

To develop an approach this data was first verified by the methodologys of the used statistics and compared with the number of jobs and employed persons in the region. In the next step this data was verified by known cross border traffic (counting stations) and the percentage of work trips.

4.3 Travel behaviour

To forecast travel demand information about travel behaviour is necessary. The calculation of trip generation requires knowledge about how many trips are made and for which purpose are they made by different groups of people (e.g. elderly, students, employees). To model the distribution of trips and the mode choice data about trip length and mode choice of people differntiated by trip purpose are used. The travel behaviour varies due to the group of people and region because of different activities and land-use. Since the land-use is heterogeneous in the study area (urban and rural districts) and the variety of travel behaviour between regions is even stronger between different countries a region-specific survey would be the optimal database for data about travel behaviour. But such a survey is very expensive and takes a lot of time, so existing surveys have to be used. For Germany there is the MiD (Mobilität in Deutschland) and for the Netherlands the MON (Mobiliteitsonderzoek Nederland). Both surveys are carried out in the whole country to analyse the mobility behavior of the inhabitants. Belgium has a comparable survey for Flanders but not for the Walloon region, where the Belgium study area is located. Moreover there is a local mobility survey carried out in the StädteRegion Aachen. A comparison of mode choice in the Netherlands and Germany shows the necessity of a cross-border traffic model that depicts the travel behaviour differentiated by the countries. In the Netherlands for example the bicycle (as a mode) is more important than in Germany, whereas in Germany the public transport plays a bigger role in commuting traffic (see fig. 7).
Source: MiT 2008
Quelle: MON 2007

Fig. 7: Mode choice in German and Dutch surveys

Besides the country-specific travel behaviour, the location of regions close to the border influences the destination choice. There are existing impediments and incentives (e.g. language skills, difference in price, fare or a differentiation in the job markets), which have an influence on the modal and destination choice of a person. Due to that fact it can be assumed that the travel behaviour in the inland is different to the travel

behaviour in the border areas. To verify this, according to AHRENS/SCHÖNE (2008, page 87), the following information is needed:

- Frequency of border crossing/journey to the neighbouring country
- Motive/purpose for border crossing
- Modal choice for border crossing
- Activities in the neighbouring country

Since there is no such empirical survey for the region of Aachen, which takes the characteristics of the border area adequately in consideration, available surveys and data have to be used. The frequency of border crossings by car are counted at some streets and the activities in the neighbouring country can be taken from regional and municipal statistics. To estimate mobility indicators for the different regions different surveys have to be used. The differentiation of the German MiD would take the entire region North Rhine-Westphalia into consideration, with this the characteristics of the examined planning area cannot be emphasized totally. But for some parts of the German study area there has been carried out a local survey, which can be used additionally. The use of the Dutch MON for the Netherlands seems to be suitable because the data refers to the province level and the Dutch planning area is the province of South Limburg. When using both mobility surveys (MON and MiD) there is a problem with the compatibility. Due to the different survey methods and definitions a classification is not simple. Whereas the MiD has seven trip purposes the MON has nine (see fig. 8). The Dutch trip purposes "Visit", "relaxation" and "tour/walk" could be combined by the German trip purpose "leisure". A classification of the private and on business purchase is much more complicated. To find an exact equivalence it is necessary to have a closer look on the survey methods of MiD and MON, which is again complicated by the language barrier and the availability of the relevant data.

Mobiliteitsonderzoek Nederland 2007 (MON)		Mobilität in Deutschland 2008 (MiD)	
Work (Van en naar het werk)	16,4	Work (Arbeit)	15,7
Business trip (Zakelijk bezoek in werksfeer)	2,6	Official purchase (Dienstliche Erledigungen)	1,3
Official/ private supply (Diensten/persoonlijke verzorging)	3,6	Private purchase (Private Erledigungen)	13,1
Shopping (Winkelen, boodschappen doen)	20,7	Shopping (Einkaufen)	20,8
School/ apprenticeship (Onderwijs/cursus volgen)	8,9	Education (Ausbildung)	6,7
Visit (Visite/logeren)	16,7	Leisure (Freizeit)	33,4
Relaxation (Sociaal recreatief overig)	13,8	Company (Begleitung)	9,1
Tour/ Walk (Toeren/wandelen)	9,5		
Others (Overige)	8,2		

Fig. 8: trip purposes in German and Dutch surveys (source: MON 2007, MiT 2008)

The data and information of MON, MiD and the local survey have been compared and comparable trip purposes have been built by aggregating or disaggregating the data of the surveys.

4.4 Traffic counts and traffic volumes

To check the plausibility of traffic assignment results counter values from the traffic census are used. In the study area continuous counts and manual counting data are available. The results of counting stations which are located close to the border of the neighbouring country should be used if available. For many border crossings between Germany and the Netherlands there are counter values available on both sides. Comparing the border crossing-point A4 (GER) or rather A76 (NL) near Vetschau shows a difference of 2 % in the average weekday daily traffic in 2008. There are no slip roads or exits between these two continuous census points. Still there is a difference in the counter values. On a border crossing-point further north, A57 (GER) or rather A77 (NL) is even a difference of 8 % (see fig. 9). Without an adjustment and a plausibility of the counter values difficulties in the calibration of the traffic assignment can occur because two alongside census points indicate different counter values. For a practical adjustment or rather a selection of counter values it is helpful to analyse possible reasons for the differences noticed. Reasons could be for example the counter- and processing methodology, the number of valid days and possible term definitions. To clarify this, a close

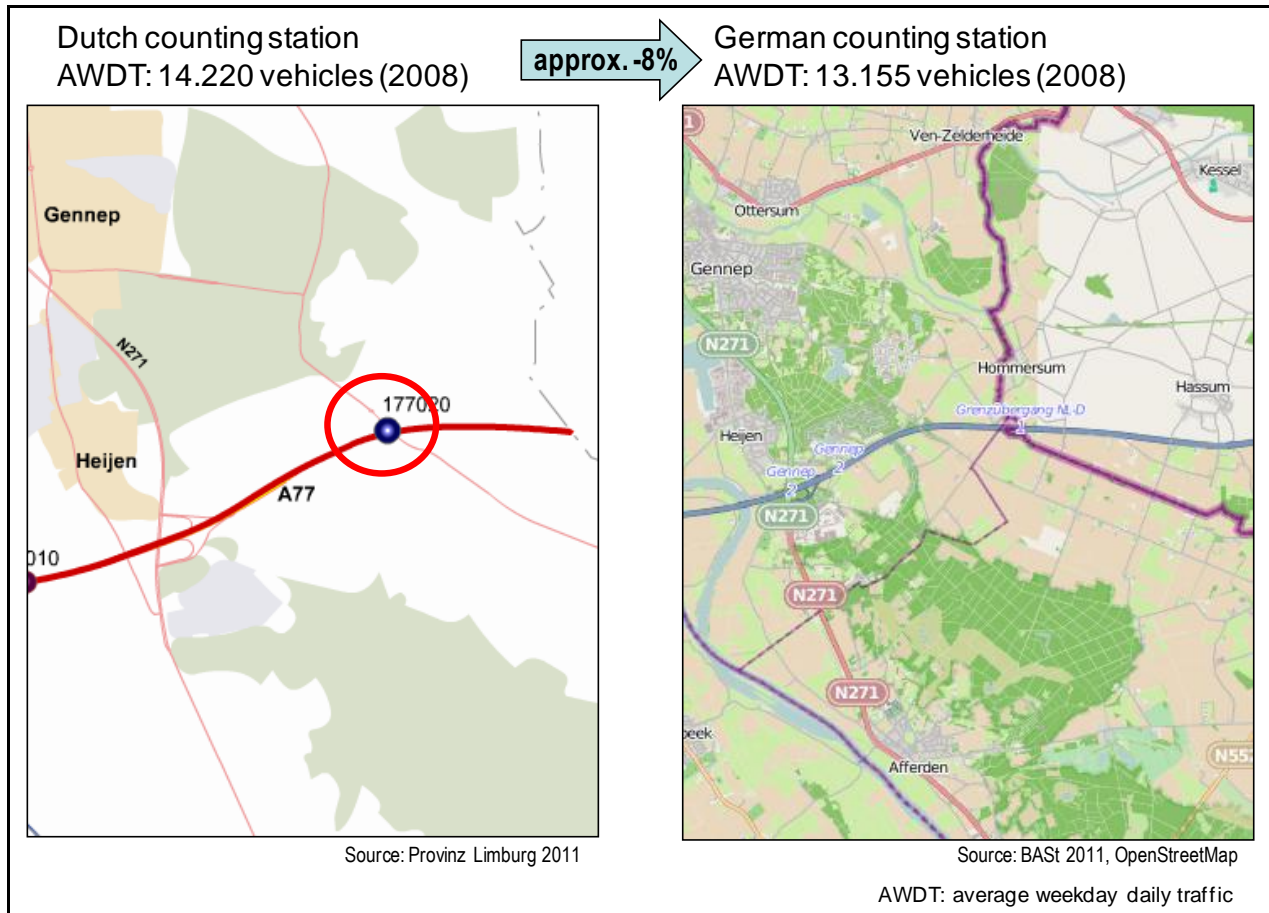
and intensive exchange with the Dutch colleagues is very important. Based on this information adjustments and the selection of counter values can be made.


Fig. 9: Comparison of Dutch and German counting stations

5 CONCLUSION AND PERSPECTIVE

For transport planning, as well as for other planning jobs, it is necessary to have information about the general conditions. Therefore transport models are often used as a basis for the decision-making- and transport planning-process. In these processes many different stakeholders are involved and data and information which are needed for the planning process are kept and used in wide differentiation and with a variety of definitions and considered areas by the different institutions and stakeholders (e.g. city council, road administration, transport association).So collected data and results have to be discussed many times and difficulties in the coordination and decision-making-process can occur. These difficulties increase in cross border planning processes even more.

Therefore the development of a cross-border data platform combined with a macroscopic cross-border transport model in the region of Aachen is an important step to create and keep a high quality and coordinated and consistent basis for regional planning data. The process of the development is challenging since many stakeholders have to be involved and the difficulties due to data inconsistencies based on different methodologies and definitions have to be solved. The developed approaches for data adjustments have to be discussed and reconciled with all stakeholders and these discussions have to be prepared well like most stakeholders aren´t used to think about data variation and the effects different methodologies might have on results. So these topics need to be communicated well to all regional stakeholders, so that they understand the reasons and support the choosen aproaches for data adjustments. Therefore the process of participation accompanying the development of the data platform and transport model consists of a broad involvement of the stakeholders of the three countries in data collection, data adjustments and information about the model calibration. This has been done by an accompanying advisory broad and a broad interaction with each municipality and region of the planning area. All basis data (e.g. inhabitants, employees) and the apraoches of data adjustments due to regional consitency have been discussed with each municipality.

Commuter data, mobility behavioral, data from counting stations and for the calibration of the model were discussed in regular meetings of the advisory board. The next step is the discussion of the model (calibration, results) with all participants (advisory board and each municipality/ region).

Data Analysis Methods for Urban Planning – Problem-Oriented Stakeholders Maps Building

Victor L. Kuriashkin, Natalia A. Zhukova

(Victor L. Kuriashkin, Scientific and Engineering Center of the Electrotechnical University , St. Petersburg, Russia, nazhukova@mail.ru)

(Natalia A. Zhukova, Scientific and Engineering Center of the Electro-technical University, St. Petersburg, Russia,, vk4arm@gmail.com)

1 ABSTRACT

A stakeholder is that which can affect or be affected by the actions of the business or interests area as a whole. The stakeholder concept was first used in a 1963 internal memorandum at the Stanford Research Institute. It defined stakeholders as "those groups without whose support the organization would cease to exist." [1]. The theory was later developed and championed by Edward Freeman in the 1980s. Stakeholders mapping is a creation a map of stakeholders in simple for usage format. This paper treats automatically creation problem-oriented stakeholders maps for urban planning purposes. Proposed method includes decision data mining, clustering, creation a stakeholders map in the mind map format.

2 INTRODUCTION

Today the urban economy is a complicated heterogeneous system, which includes a big number of different elements. Each concrete problem can affect or affected by the various organizations, social groups, officials and simple citizens. In a modern world resolving most complicated urban problems is impossible without data analysis, finding, who may be interested in the current state, who need or can to help to change it and which groups should be affected.

Stakeholders theory was created for business problems resolution, initially for competitor analysis, but nowadays it is a part of the decisions making in a different areas.

We propose to analyze on-line media, including social media (websites and social networks), official electronic directories and official web sites for automatically analysis and stakeholders maps creation. In additional we offer processing an official statistics and documents, where it is accessible.

As a result of analysis we builds a kind of knowledge base, and another task is a presenting this map in usable format for decision makers.

Classical systems for operations with knowledge base are not simple for use by businessman or officials. For example, well known Protege system [2], created by Stanford University, could be used only by knowledge engineers or advanced users. Modern management should have an instrument, which can be simple to integrate into the business processes, inserting into reports and presentations, and which could be extremely simple to use in any technical environment – desktops, web and mobile.

We propose to use a Mind Maps format. There are some commercial applications, like a MindJet by the JetBrains (http://www.jetbrains.com/), but we propose to use open format mind maps by the open source project FreeMind [3]. User can export FreeMind xml files into the html and flash for integration to the websites or presentations.

In this article we propose to use a 4-levels maps.

- Problem name (Topic). Examples: medicine, education, road planning, migration politics. In some cases it should be more precision problems like: "traffic jam in the center of the city", "criminal situation in the specific area"

- Objects, affected by actions in this problem or to be affected.

- It could be names of officials, organizations/businesses, businessman/competitors names, some social media authors, bloggers, etc. For further implementations we can include into this level affected small social groups.

This level includes 2 types of items:

- Affiliate objects.

Example: organization, where author works, relatives, and so on.

- Affected problems. In general, it is a set of links to another problems in the 1st level.

3 INFORMATION RETRIEVAL

System should be designed for working in semi-automatic or full automatic mode. It should gather information from the on-line media for real-time mind maps rebuilding. This option should make a possibility always to work with actual information.

It means that critically important part of the system should be a web crawler and pages parser. We designed a crawler, which can solve a different types of technical problems.

For example:

- article text extraction from the different web pages formats with knowledge extraction using Kuriashkin and Kazekin pages processor [4]
- render a page and execute a javascript on the server side for retrieving information from the ajax requests

Another problem is that we can not trust to anything from the Internet, and it means, that we should build a fraud-safe system.

In some cases, on-line authors could add some personalities into the discussions about criminal situation (black PR).

Fraud safety in our case is a dividing information sources into the trust-level groups and extraction author names for evaluation an authors confidence level.

Data sources are divided into the following groups:

- Official organizations (government, business) and directories
- Serious media
- "Yellow" press
- Blogs and social networks

Current system should skip article comments in the on-line media.

As a social networking data source we use a livejournal.com, which is very popular in Russian Internet segment. We could not propose to use another sources as a social right now, except it, because of a big number of spam messages and copy-pastes between all social on-line media sites.

4 BUILDING A VECTOR SPACE

For data analysis texts should be converted into the vector space. Classical approach in building vector space from the text includes: stemming, n-grams extraction, n-grams tf-idf calculation, selection for the vector space building only significant n-grams. By making decision about what n-grams are significant it is possible to increase a quality of the space for the concrete problem. Usually vector space builders skips n-grams with too high tf-idf value, because it could be syntax errors or very specific terms, and a "long tail" with low tf-idf values – non-significant terms.

For our task, building a vector space, besides the classical approach should include directory records analyzing.

In addition, for Russian language extremely important to process: prefixes and word endings, which could be extracted in a separate dictionary and could be used as a separate vectors elements.

Thus, we have 3 groups of the vector elements: directory components, syntactic components and n-grams analysis components. For each space types components we calculated a separate kind of tf-idf measure, which it is possible to use in the distances measure. Weights could be selected for tuning our algorithm, but we suggested to use:

w=2 for directory

w=1 for syntactic

w=0.5 for texts from the official sources and 0.3 for blogs and social networks.

All weights should be corrected for the concrete problem investigation.

5   TEXTS DISTANCE MEASURE

We have a 3 type of vectors components, so, we should use a weighted distance measure. In our case it is possible to use a weighted Euclidean distance or weighted Manhattan distance. In case of Manhattan measure [5], we have reduce an importance of the outlets, so, this approach is more usable for our case.c

We propose to use following distance measure:

$$D = \sum w_i * (A_i - B_i) ,$$

where w is a weight, selected for the components category.

6   PROBLEMS EXTRACTING AND MIND MAP TREE BUILDING

We propose two problems extraction methods:

- "Learning without teacher" approach
- Using a classification and learning dataset for the problem specification.

First method should be useful for the timely response to the emergence of the problem. We propose to use a Fuzzy C-means (Soft K-means) clustering algorithm [6].

The FCM algorithm attempts to partition a finite collection of n elements

$$X = [x_1, x_2, \ldots x_n]$$

into a collection of c fuzzy clusters with respect to some given criterion. Given a finite set of data, the algorithm returns a list of c cluster centers

$$C = [c_1, c_{2\ldots} c_c]$$

and a partition matrix

$$W = w_{ij} \in [0,1]$$

where each element w_{ij} tells the degree to which element x_i belongs to the cluster c_j

We propose to use a standart objective function for minimization:

$$w_k(x) = \frac{1}{\sum \left(\frac{d(center_k, x)}{d(center_j, x)} \right)^{\frac{2}{m-1}}}$$

The fuzzyfier m is a level of clustering fuzziness. In the common cases m=2, and we use this value of the fuzziness for our case.

For the real analyzing process we suggest to use a different number of initial clusters for receiving adequate results.

In our project we used an Apache Mahout library [7] for clustering process, which can use a calculations in the distributed or Cloud computation environment in case if we need to analyze a big amount of data or need to receive result in a critically short time or even in real time.

We can suggest to use such computation in the Amazon Cloud, because significant computing power we need only in process of data analyzing, which could not be a permanent process.

The result of the clustering is a set of clusters, which can be processed by operator for selection a names for each cluster, which can be used as a name of the problem.

System could select a set of directory objects, which could be used as an objects, could be affected or affect by the selected problem. It could be a person, government or business organization.

Next step is an association of this object with another objects through common problems/clusters.

Example of the part of the map could be the follows:
Where is possible to add a data sources.

Second approach, which is called "Supervised learning" implies a classification and test dataset using. We suggest to use a Wikipedia articles categories for the root of classification.

Work flow algorithm should contains following steps:

- Getting an articles tree from the Wiki. It could be not a full tree, but just a part, which is interesting for the customer.

- Crawling each category and subcategory for the wiki pages, extracting texts from the each page.

- Crawling on-line data sources and extracting texts, same as in the first approach.

- Use a Naive Bayes algorithm for finding the best category (problem, in our terms) for each predefined category.

$$p\left(C \mid F_{1,} F_{2,} \ldots F_n\right) = \frac{p\left(C\right) * p\left(F_{1,} F_{2,} \ldots F_n \mid C\right)}{p\left(F_{1,} F_{2,} \ldots F_n\right)}$$

In our case we should calculates a comparison of probabilities, denominator is a constant for the selected data set, so, we can decrease a computations to the numerator calculation and comparison.

We proposed to use a NaiveBayes [8] (MAHOUT-9) algorithm, implemented in the Apache Mahout library.

- Extracting directory objects from the selected texts and place it into the second level of the mind map tree.

- Selection an objects from the another problems, where each of the selected object has found and creation next level of the tree.

We proposed to use a Naive Bayes classifier, because it gives satisfactory results, but it is not correct in the strict sense, because it works in case if components in the vector space is independent from each other. In our case, n-gram analysis could contains terms, includes in the directory term set. This algorithm is not use a weights, selected in the vector space, and could takes not precision enough results, but it could works correctly for the case of small number of categories or in case of searching for the events in the news flow for the selected categories and problems.

Certainly, for the problems classification could be used not only Wikipedia, but any another data source. Better approach is an official data sets usage. In this case it is possible to use only objects finding in the texts from the Internet.

7 HELPFULNESS OF THE SYSTEM

System, which is based on the proposed approach, could be used for on-line monitoring a social media and building an easy to use mind maps. It could be used by government organizations for finding an affected stakeholders of the selected problems (in case of predefined problems classification) and making investigations of the media environment for some important problems for the urban planning. Business organizations can use approach for finding a competitors in the specific area of activity, customers and suppliers.

Proposed approach can be used for both long-term analysis and short-term problems monitoring.

8 PROBLEMS AND SOLUTIONS

Systems is depends on the sufficiently large directory of the personalities, organizations and government structures. Partially it could be found in the Internet using external services. We can suggest to use Open Calais API (Reuters inc) [9], which was used for some project for the Forbes Media. Problem is that it have

not Russian texts, accessible for the on-line API. For some cases it is possible to translate texts to English language, extraction personalities and organization names (Reuters has this base for Russia) and translate it back. It could be a source of some mistakes, but useful for some non-critical investigations.

Proposed algorithms could be tuneup with the following coefficients:

- m – fuzziness – for the clustering. Default value is 2

- n – n-gram length.

- Google [42] uses n<=5, but in our case we proposed to use a 3,4,5-grams, filtered by tf-idf measure

- tf-idf borders for the vector space building.

We can not build a space for all texts elements, and propose to make a filtering and reducing a vector space in process of crawling and texts processing to reduce a number or calculations and memory efficiency. This approach could save memory, but it could be follows to the loose of the some data, which is means, that it is unusable for algorithm tuning for the selected use-case.

1 ABSTRACT

Landscape development is increasingly characterized by collaborative processes involving multiple stakeholders of heterogeneous groups. An essential prerequisite for effective collaboration and sound decision-making in landscape development is the understanding of participating stakeholders of required landscape information and the interrelationships between factors influencing landscape development. The tools for representing, processing, analyzing and combining spatial data have evolved and diversified enormously in the last 30 years. This has influenced also the set of media that is applied in participatory planning workshops. Current technology offers great opportunities to allow broad access and to support deeper understanding of landscape processes by implementing web-based platforms. These comprise 3D landscape visualizations and spatial analysis functions. However, an analysis on how to prepare these platforms, their technical structure, their user interface, and the spatial data is missing.

In this paper we present a technical framework of a collaborative web-based platform that takes into account basic user demands for understanding and evaluating landscape processes. Further, we show an initial prototype of a user interface and its information content that was tested with stakeholders. The evaluation results show that the complexity and amount of information offered by the user interface should be customizable for different user groups. New approaches have to be developed to integrate realistic real-time visualizations into the system. Overall, for securing the final tool's effectiveness, it is essential that the technical development of the system is tight to its implementation in collaborative planning situations. These results provide helpful advice for targeted development of the collaborative web-platform system's components.

2 INTRODUCTION

The style of collaborative workshops in land use planning has undergone big changes during the last three decades. These are also related to the development of new communication techniques (Arciniegas & Janssen 2012). Workshop techniques 30 years ago based on large hard copies of maps combined with sheets of tracing paper maps for presenting characteristics of proposed plans or planning areas. With the implementation of Geographic Information Systems (GIS), a new communication tool was offered that allowed to present various map layers on a computer screen and could partially replace hard copies of (tracing) maps for examination (Longley et al. 1999). A next step, which is still under development, takes into account functions and services or the related policy configurations and connects them with related land use patterns. To reveal these relationships can facilitate a better integration of participating stakeholders e.g. in a planning process (Grêt-Regamey et al. 2013).

The workshop style also changed over the years from an emphasis on one-way communication to participation with active stakeholder involvement (Sieber 2006). Today, the major focus is on collaboration: stakeholders shall actively work together to identify a landscape development strategy that is sustainable and acceptable for the majority of the stakeholders (Arciniegas & Janssen 2012). But how can we use the existing technologies to support these collaborative processes? How can we prepare and provide spatial data that is accessible, understandable and useful for all participating stakeholders?

GIS-based 3D landscape visualizations have shown great potential as valuable communication tool in planning processes (Wissen Hayek 2011). Linking quantitative, spatially explicit indicators and realistic 3D visualizations of landscape change scenarios can facilitate the communication of relationships of factors that lead to certain landscape change. This allows to bring in different opinions on a topic and to create public

interests (Wissen Hayek et al. 2012b). Furthermore, experiences show that interactive and participative tools help to understand coherence between prioritization of different indicators and possible land use change. For example, in Figure 1 participants of a workshop on wind farm planning choose the priority of economic viability, landscape aesthetics, nature protection, and noise emission. Depending on the indicators' priority, the amount of wind turbines differs. The interactive tool allows users to understand trade-offs between indicator values as well as between different demands of the landscape and landscape aesthetics (Grêt-Regamey et al. 2013).

Figure 1 – Real-time modeling and visualizing approach with slider control of selected indicators' priority

The variety of planning processes and the diversity of workshop settings and goals complicate the development of an all-purpose decision support platform. The effectiveness of such a platform depends on two major factors. First, it has to provide useful participatory GIS functions, comprising interactive elements of GIS-analyses producing indicators as well as of GIS-modeling producing scenarios of landscape change. Second, it needs to be suitable for participatory settings. With regard to the application, e.g. workshop or self-exploration, the content load and detail of information have to meet the users' demand. Particularly, if the user should understand the relationships between different indicators, overloading the interface is a problem, which can lead to lack of time for appropriate implementation of the tool and even deterrence (Salter et al. 2009). The problem of overloading the interface might be overcome by providing layman and expert modes with a customized offer of spatial information with a useful level of detail. However, there is a general conflict of required detail of information and suitable time investment in collaboration sessions. On the one hand, the need of detailed information on indicators is required to communicate what they state and how they are related to each other. On the other hand, these details need time to be understood. A multi-user-group interface might provide a solution for reducing the complexity of available information. However, with this interface type addressing more specific demands of different user groups might become more difficult.

In this paper we present a technical framework of a collaborative web-platform system that takes into account basic user demands for understanding and evaluating landscape processes. Further, we demonstrate a first prototype of implementing parts of this system, which was tested in a workshop and at an exhibition with different stakeholders. The prototype was designed to addresses basic user demands by implementing participative GIS functionality. This included a user interface design with certain interactive functions as well as preparing visual information content according to a defined level of detail and complexity. The evaluation results were analyzed in order to further specify user demands and to discover expected functions of the platform. They provide advice for enhancing the prototype of the collaborative web-platform.

3 THEORETICAL FRAMEWORK

In the early stages, GIS was used mainly for providing spatial information, but with increasingly active stakeholder involvement and the failure of tracing map paper sheets, a demand of interactive GIS was given. Participatory GIS is designed for improving stakeholder participation within group spatial decision-making (Carver 2003, Janowski 2009). Two function types of Participatory GIS must be distinguish: (1) Public

Participation GIS (PPGIS) focuses on an enhancement of public access to geospatial data and maps, providing possibilities for participatory learning and analysis by the general public, community groups and marginalized groups in planning and decision-making for their communities (Craig et al. 2002). In contrast, (2) Group Spatial Decision Support Systems (GSDSS) focus on supporting the identification of trade-offs, conflicts and compromises between stakeholder groups (Boroushaki & Malczewski 2010).

Our hypothesis is that to create an applicable and full-efficient decision support platform, both participatory GIS types (PPGIS & GSDSS) must be combined. Furthermore, the following functions should be available: general information on the planning topic and use of the platform, spatial analysis and evaluation functions, and interactive indicator-based decision support. In the following chapters these three functions are further explained.

3.1 General Information Content

For understanding complex topics and being capable of evaluation and decision-making tasks, first of all background information must be available and provided in a useful manner. In addition to texts, tables and graphs, maps are the basis for providing relevant information for spatial decision-making. Often stakeholders preferred maps as source of information for spatial decision-making, although they are not easy to understand and use (Janssen & Uran 2003).

Maps can show various and complex information in a spatially explicit way. They can present alternative solutions, scope for decision-making options or spatial patterns (Kraak & Ormeling 2003). Further, they can be used for developing scenarios and alternatives, e.g. by drawing in or modifying it (Carton & Thissen 2009), as well as to handle conflicts among stakeholders. In this way, they can support feedback loops in the planning process (Arciniegas & Janssen 2012; Andrienko et al. 2007). Another function of maps is that they provide base-layers (e.g. thematic and topographic maps) for the before mentioned functions (Arciniegas & Janssen 2012). In addition, map information can provide the input for GIS-based 3D visualization of alternative scenarios, which provide a common communication basis and support mutual concept development (Hehl-Lange & Lange 2005; Wissen Hayek 2011; Grêt-Regamey & Wissen Hayek 2013).

3.2 Spatial Analysis and Evaluation

GIS-based analysis is key for gaining information on the current landscape state or alternative development scenarios. Multi-Criteria Decision Analysis (MCDA) is an effective method to perceive the necessary trade-offs of different demands of the landscape. By weighting different criteria addressing economic viability, ecological or social quality of the landscape, and possible scenarios of landscape change are calculated. Integrating a MCDA in the workflow provides a method to evaluate, compare, rank, map and present the performance of decision alternatives on the basis of several criteria and/or objectives (Malczewski 2006, Grêt-Regamey & Wissen Hayek 2013).

Ideally, stakeholders with different backgrounds should choose criteria and indicators as well as their weighting themselves. In order to avoid mismatches and misunderstandings between the stakeholders' decision-making problem and the answers produced by the system, it is necessary that constraints are set with regard to the interactive modification of criteria and indicators in the user-interface (Uran & Janssen 2003). This might influence the required user-interface complexity.

3.3 Interactive Decision Support

Depending on the functions of an interactive decision support tool aimed at, a selection and combination of various interactive methods is possible. User-friendly interfaces are necessary to allow multiple users to provide input and generate real-time output for supporting to form an opinion and decision-making (Arciniegas & Janssen 2012). Interactive exploration and interactive allocation of map content is required to secure credibility and provide information for specific areas of interests. Furthermore, real-time output of analyses and landscape change models is important for dynamically exploring the spatial outcomes. Iteratively testing different input parameter settings and exploring results can facilitate the comprehension of spatial environmental effects. In this context, linking the quantitative, abstract modeling results to more qualitative 3D visualizations interactively is seen as a promising way (Grêt-Regamey et al. 2013, Wissen Hayek et al. 2012a).

4   METHODS

The goal is to develop a collaborative web-platform that integrates both types of participatory GIS (GSDSS and PPGIS). We elaborated a general technical framework for such a platform and tested parts of it in order to start its implementation. First, the technical framework is described. Then, the prototype of an interactive tool called "Landscape Impact Assessment Controller" is presented. Finally, the evaluation method of the effectiveness of the prototype is explained.

4.1 General technical framework

The various demands of different user groups call for a dynamic user-interface in order to provide a useful decision-support tool. We developed a technical framework that combines modeling and visualization functions essential for interactive landscape impact assessment by different user groups.

Resulting from the literature review (see chapter 3) essential functions are:

(1) The selection of indicators/parameters and their characteristics can be controlled interactively and the related landscape changes can be presented as spatial information. For example, the amount of economic incentives for farmers can be modified and as result the agricultural area that might be managed or abandoned are shown as abstract and realistic 3D visualizations at the area of interest. Thus, the user can identify trade-offs, limitations and restrictions with regard to the choice of the parameters' characteristics. Implementing this functionality requires a real-time user control of the GIS-model.

(2) The GIS-model scripts have to be standardized to make them accessible to different software and thus allows for linking different GIS-models. This standardization of indicator values and labeling, attribute labels, input/output data types, coordinate system, projection, etc. is also necessary for further processing of modeling results, e.g. in visualization workflows.

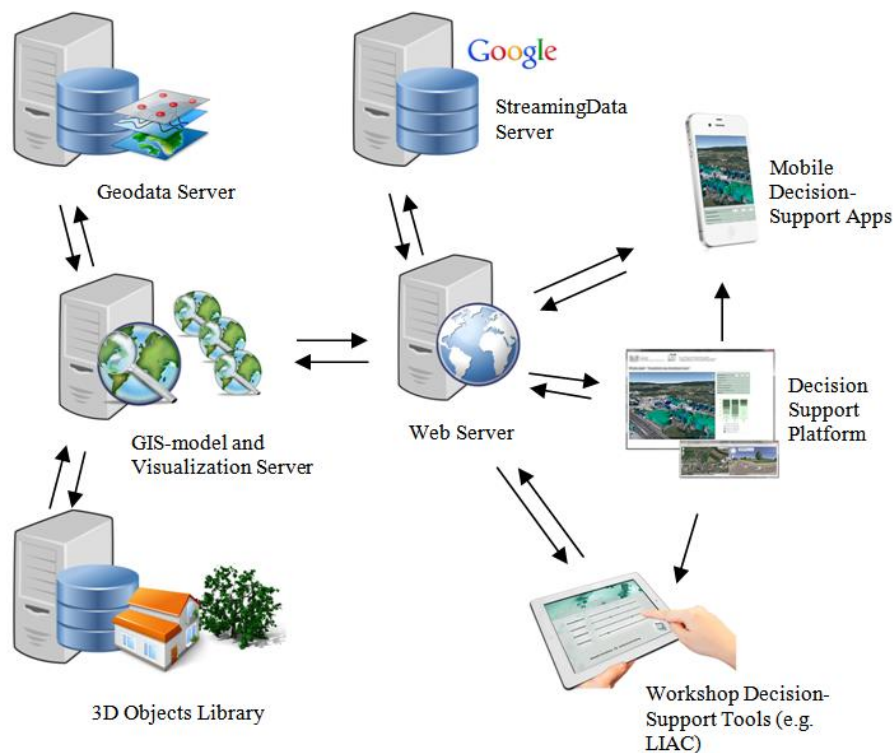
Figure 2 shows the schematic framework of a decision-support system. The system consists of five different servers and three workshop decision-support tools that are the front-end decision support platform interface and peripheral devices and software, such as mobile decision support apps.


Figure 2 – Schematic framework of a Collaborative Web-Platform Decision-Support System for landscape planning

The web server is the core of the platform and serves as hub for all applications. All requests and replies pass the technical interface of the web server and are linked to spatial data and mapping information streams like GoogleEarth from the streaming data server. The users interact only through the web platform. Platform inputs, e.g. information requests are forwarded to the GIS-model server. This server runs the requested

models and analysis modules (e.g. ArcGIS Server, R-Scripts), queries necessary data from the geodata server and sends the results back to the web server. Produced model outputs are also interpreted and linked to 3D objects and textures for 3D visualization. The resulting 3D visualizations are sent to the web server and displayed on the platform. This workflow is similar to existing ones (e.g. Pettit et al. 2013) with the difference, that we try to integrate a full controllability of models by adapted user-interface design.

3D landscape visualization of high detail requires the use of 3D objects for built and natural landscape structures and elements. The standardization of the input and output data of the spatial modeling processes allow for accessing the 3D objects automatically. However, in a library the 3D objects have to be structured in a meaningful way so that their access is secured. For example, a land use pattern of forest is defined by the forest type (e.g. deciduous, coniferous, or oak-hornbeam forest (Carpinion betuli)). This information should ideally already be available in the output of the GIS-model. The forest type defines the plant types of the trees, e.g. for an oak-hornbeam forest there are oak (Quercus robur) and hornbeam (Carpinus betulus), and further plants of the shrub and ground vegetation layer such as anemone (Anemone nemorosa), that are selected by data base queries. Finally, a realistic distribution of the individual plants of the forest type is necessary (Röhricht & Clasen 2006; Paar et al. 2008).

One major bottleneck is the time required for the real-time modeling processes. Saving produced model outputs to an archive on the GIS-model server allows for showing the results immediately on request. This archive option would allow users to share their evaluated scenarios among each other and discuss them for example in group rooms using the platform. The users feed the archive by using the platform and optimize the processing time by enlarging the amount of already processed model outputs. Of course, this procedure makes only sense for time-consuming models and analyses. A further option for achieving a real-time modeling approach is to implement interactive selection methods. Models and associated visualization workflows might then only be run for preferred perimeters. Perimeter selection could be carried out by a list of regional boundaries (e.g. administrative districts) or by designating a user specified perimeter by drawing a polygon on a map.

4.2 Prototype of the Landscape Impact Assessment Tool (LIAC)

In order to overcome the problem of different user capabilities and interface design complexity, we developed a first prototype of a decision support tool. A user-evaluation of the prototype should provide us with information on the users' demands and on useful designs of the user interface. Figure 3 shows the multilayer structure of the prototype of the "Landscape Impact Assessment Tool (LIAC)", which was designed to show the relation between indicators and the impacts of defining certain indicator values on land use. The tool is applied in a workshop setting. The target group for our web-platform are experts in land use and landscape development. The survey in the workshop revealed that participants were more heterogeneous than expected. To facilitate a "hands-on" experience for the participants, the thematic direction was leaned at a workshop series conducted in another study area in central Switzerland.

As indicated in Fig. 3, the main screen shows sliders with different optional value settings (low to high) for five indicators, which indicate different states of GIS-model parameters. The change of the indicator values is a direct input to a land use change model. A further option on the main screen is changing the view style to an "abstract view" in the second and third screen. In these screens the land use is shown either as a draped raster map on a digital elevation model or as realistic 3D visualization. Screen 2 presents a large view frame of the 3D visualization (realistic and abstract view mode), while screen 3 shows two close-up views of specified areas and an additional graph for information on land use values.

Considering the large amount of possible combinations of the indicators' values and resulting scenarios, visualization approaches that require many manual steps are not advisable. Furthermore, with a rising number of indicators the number of scenarios is increasing exponentially. A direct GIS-model link to the user-interface is one solution to produce scenarios in real-time with full controllability of the output. This was not implemented in the prototype yet. Instead, scenario outputs of a GIS-based land use model were prepared as visualizations and graphs, which were linked to the respective indicator value settings that were input to the respective scenario output. Criteria for the land use modeling of the rural, alpine case study area Andermatt in Switzerland were the degree of liberalization of the agricultural market, agricultural incentives for the farmers, farming income, provision of residential area and the degree of implementing a regulation

for second homes in Switzerland. All these criteria have an effect on landscape development and interact with each other.

Figure 3 – Schematic screenplay of LIAC (Landscape Impact Assessment Controller), which presents land use scenarios that are defined through the interactive setting of indicator values in the controller interface

Figure 4 – Questionnaire of the survey carried out at an exhibition stand providing an overview on indicator characteristics and animating visitors to apply LIAC

4.3 Evaluation of the prototype

We applied the prototype in the case study area Andermatt in two different settings, at an exhibition stand and in a workshop situation, and evaluated it applying empirical methods. Visitors of the exhibition were animated to use LIAC by a small survey that also gave an introduction to indicators and their characteristics

(Fig. 4). About 30 participants explored the tool at the exhibition. The participants were a heterogeneous group including local inhabitants and representatives of Swiss and international governmental and non-governmental organizations from different departments. In open interviews we asked these users about their impression of the tool.

The about 20 participants of the workshop were international experts of land use management, spatial planning and nature protection from governmental and non-governmental organizations, private enterprises, and academic institutions. They were briefed on the prepared planning topic and the GIS models. In addition, the workshop moderator used LIAC to introduce the participants to the information content as well as the functionality and handling of the tool. The decision tool was controlled by a tablet PC that was synchronized to a projector screen presenting the chosen value settings of the indicators. The idea of this setup was to hand over the tablet to workshop participants for supporting their argumentation or explanations implementing the tool interactively. In a group discussion we received the users' feedback on the potential application of the tool and the quality of the user interface. Furthermore, we observed the users in both settings to record their reactions and if the controlling of the user-interface was easy to handle.

5 RESULTS

During a short personal and individual introduction of the available information, the participants at the exhibition "played" with the indicator settings of the LIAC tool to find out how the virtual landscape changes (Figure 5-A, -C, -D). Teenager used the tool more explorative than adults. However, all participants understood that the future land use patterns depend on the five indicators' value settings. The users recognized by themselves, how the indicators influence each other. Furthermore, they recognized on which scale the indicators can influence future landscape aesthetics. For example, less agricultural incentives for farmers effect an abandonment of fields and leads to an increase in forest in certain areas.

In the workshop the participants were rather interested in detailed explanations of the correlation between indicators than in a self-exploration of the tool (Figure 5-B). In conclusion of the group discussion the participants appraised the tool as innovative and useful as discussion basis in a workshop. However, participants stated that the interface offered too much information on the three screens. Furthermore, they asked for more user control on the models to verify effects and impacts of priority settings. Additionally, the participants mentioned that an interactive navigation through the 3D visualizations would have been desirable to see changes in detail, to have a better overview of the site, and better impressions of the view of the landscape.

6 DISCUSSION & CONCLUSION

The fast developing technical possibilities of providing spatial data in various types of forms and in different types of accessibility offer sophisticated means for supporting public participation in spatial planning.

However, combining the available tools to a coherent and powerful system that can facilitate collaboration of heterogeneous stakeholder groups effectively is a major challenge. We focused in this paper on how to prepare a collaborative web-platform and presented a possible technical structure. Stakeholder feedback on a prototype of a user interface and spatial data presentation provided helpful insight for further development of the system.

Generally the stakeholders were interested in the new means. The users stated that a tool with interactive control of input parameters for generating scenarios of landscape change could help to understand complex landscape issues and offer a new basis for discussion in workshop situations. Even with rather general scenario information the prototype enabled participants to identify relationships of the five indicators controlling the land use change model. But we received also information on missing functions of the tool, which should be available to meet the users' demands.

Obviously younger participants (aged < 20 years) had less fear of contact with the interactive application than older ones. A reason might be that these young people are so called "digital natives" that grew up with the digital technologies (Lange 2011). Through interacting with digital technology from an early age (e.g. mobile devices, smart phones), they should have a good concept of these tools. The higher reservation of older participants might, however, be ascribed to a more critical examination of the technical means due to larger expert and case knowledge. Their requests for more information on the GIS models indicate that their focus was clearly on the meaning of the tool to provide reliable and thus useful information.

The first feedback of the users of LIAC shows that there is a need for a customized user-interface design depending on the user group. In particular the knowledge and capability of the users is crucial for defining a useful complexity of the user-interface design. Overstraining users might be avoided by a customized restriction of interactive parameter control and offer of information for the specific groups. Increasing the accessibility of GIS models seems necessary for a satisfying use of decision support tools by experts. This option might also support an even improved understanding of correlations between indicators and between prioritization of certain demands and resulting landscape changes.

The necessary investment of time for the users to understand and to control the tool as well as for processing the provided information turned out to be problematic. The required time might even increase with rising complexity of the interface and of the offered information content. The available time in the workshop was not sufficient to give the individual user the time he required. This experience reveals that the design of applications has to be developed in parallel with the tool to secure its meaningful implementation. Probably trade-offs must be taken into account due to a reduced complexity of the user-interface depending on the respective application situation (workshop vs. self-exploration).

Beyond user-related requirements we also discovered technical problems that have to be solved. Manual workflows for visualization are not feasible anymore if the amount of landscape change scenarios increases exponentially and if these scenarios can be defined interactively by the users. Furthermore, the degree of realism of the visualizations has to match the landscape development topic, e.g. vegetation types might have to be recognizable if the focus is on the ecological effects of agricultural management or landscape aesthetics. Hence, visualization workflows have to be redesigned to create sophisticated – and from the users expected – visualizations with a sufficient visual quality and appropriate level of detail in an automated way. In order to allow for analyses and visualization of output for any location on demand a generic, automated approach is necessary. This would ensure that the decision support platform is highly flexible and spatially independent.

Overall, it is hard to cover all aspects and demands and develop a useful user interface according to the ideas of different user groups. Particularly, it is challenging to satisfy all users. Generating a user interface that allows for adapting the amount of information, and thus its complexity, might be a constructive approach to meet the users' needs. Of great importance is an iterative approach for the development and testing of web-based platform system. Hence we aim at progressing by stages and with a particular focus on the interfaces to meaningful information provision in planning situations.

Density Exercises in Projects of Oriol Bohigas. Density as a Tool for Suburbs Regeneration

Cecilia De Marinis

(PhD Student Cecilia De Marinis, Roma tre university, DIPSA – Dipartimento di progettazione e studio dell'architettura, Piazza della Repubblica, 10 00135 Rome, arch.ceciliademarinis@gmail.com)

1 ABSTRACT

The starting point of this research is the assumption that nowadays to regenerate – rather than to build from scratch – is a necessity. Regeneration is fundamental to avoid further land consumption, curb urban sprawl and reduce resources consumption.

In the context of urban regeneration, residential periphery deserves special attention.

Residential peripheries are nowadays marginal, because they are awfully connected, undifferentiated, mono-functional and lacking in basic services. They are unable to respond to changed housing requirements, and inadequate from morphological, typological and energetic perspectives.

At the same time, these neighborhoods are a significant resource, because of their size and transformation potentialities.

The chosen approach considers density as the main criterion to guide and check the projects of reconstruction of residential periphery.

Density, as an urban variable, is a quantitative parameter that affects both architecture and life quality, i.e., the quality of life of the inhabitants of the architecture. In this research the concept of density is extended to a three-fold meaning: density of buildings (with particular attention to density interpretation in terms of surface: FAR – floor area ratio), density of encounter (whose values are randomness and closeness), and density of uses (differentiation of activities and functions).

The choice to focus on Oriol Bohigas, architect that works in Barcelona since 1951, is justified by his vision of planning and also by his determination to promote city reconstruction rather than city expansion. Indeed, he is in favor of a compact city, with a high density of people and activities. The work of Bohigas takes place in the space between plan and project: the plan tends to the project and the vision of the process is always recognizable.

From this perspective, the local dimension gains a relevant value and the transformation strategy for the city is improved through punctual actions for services development and reconstruction of public spaces. The elements involved in regeneration are housing, city block and urban space, whose hierarchies and forms are pivotal points for planning. Following this recipe, the urban project becomes a strategy for high impact changes.

To compare with criteria and solutions in plans and projects of Oriol Bohigas, a selection of representative projects will be analyzed, through the reading key of density, with focus on residential themes and actions in the consolidated city.

The outcomes of this research will include an evaluation of the relevance of cognitive contents that relate the work of Bohigas with the concept of density. Also included will be the extrapolation by deduction of a possible "Bohigas Method", an intervention method, defined by project and process strategies, for the regeneration of urban periphery. These strategies are based on concepts like: functional differentiation, strong relation between plan and project, local dimension, city block as regulation element and urban space differentiation, through hierarchies and forms.

2 URBAN REGENERATION AND SUSTAINABILITY

Urban regeneration, a central issue in current urban planning, is a strategy for the sustainable development of cities.

The term urban regeneration has taken partially the place of more traditional terms like renewal, redevelopment, renovation, and restoration. The term refers to something "organic", embodying the changing and unpredictable transformation of the contemporary city.

Cities are among the main culprits and victims of ecosystem destruction. The first step towards limiting the damage caused by cities to the ecosystem is overcoming the linear metabolism model, which consumes

energy and produces huge amounts of waste. The alternative approach is the circular metabolism model (Rogers and Gumuchdjian, 1997), that reduces resources consumption and increases recycling, thereby reducing the production of waste, in a circular system of use and reuse.

The aim of urban regeneration is therefore the construction of a sustainable built environment, in which the word sustainability applies to welfare, safety and environmental care. Urban regeneration aims at improving the quality of life in the city, in a constant comparison between the potential of existing buildings and user's changing needs.

3   BUILDING ON BUILT

The starting point of this research is the assumption that, today, regenerating rather than building from scratch, is a necessity. Regeneration is fundamental to prevent further land consumption, limit urban sprawl and reduce resource consumption.

The compact city is the best model to reduce consumption. It focuses on the density of compact urban fabric as opposed to uncontrolled urban growth. This defines a new paradigm: building on built.

Nowadays choosing regeneration over substitution is an ethical imperative that becomes an aesthetic choice, which has been named duration aesthetic (Magnago Lampugnani, 1999).

The regeneration process has an added value: temporal continuity. The radical break accomplished through demolition and reconstruction is replaced by a continuity in urban development: it's the renewal, achieved through building the city layer by layer. It's a mechanism that allows a gradual and seamless urban development, like the process of a river's bed sedimentation (Van Schagen Architekten et al. 2009).

The history of the place is a value, the traces of the past can be found in the ground, in buildings, in the countryside, in the views, but also in space, obstacles, borders, links, intentions, successes and the failures.

There is a need to understand and exploit the opportunities offered by the existing buildings, trying to awaken their potential, rather than destroy them.

The renewal of existing assets is today both a requirement of sustainability and an opportunity. The existing assets is not only a problem to be solved, but also a great resource.

4   RESIDENTIAL SUBURBS: PROBLEM AND RESOURCE

Suburban districts merit a special attention in the context of urban regeneration. Suburban districts are today marginalized places, because they are badly connected, undifferentiated, monofunctional, lacking the most basic services, and gravitating around overcrowded urban centers. Furthermore, this housing stock is incapable of responding to changing housing needs and inadequate with regard to morpho-typological and energy requirements.

At the same time, these neighborhoods are a substantial resource, because of their size and potential for transformation.

Periphery is often defined by negation: as the place of lack or the place of loss [1]. The suburbs lack quality, meaning, and identity. Space organization, consistency, shape, boundaries are all lost.

The term periphery derives from the greek "peri" ("around") and "pherein" ("carry") and indicates areas of a city outside the historic center, in a vision antithetical between center and periphery.

Today it is more evident than ever that the geographical dichotomy center-periphery is passed. It is common to come across suburban areas that are part of the urban development. The definition of these areas is no longer based on geographical location but depends on the their characteristics. One can speak of a new peripheral condition [2] which includes space, society and culture.

---

[1] Concept defined by Paola Di Biagi in her article "La periferia pubblica: da problema a risorsa per la città contemporanea" (2006).

[2] Giovanni Caudo in his article "Periferia di cosa?" (2009) says that there is a way to be peripheral even before being grounded in a peripheral location in a interstitial city, where the casualization of the statutes draws unexpected geographies that out alongside forms of so-called exclusion with normal integration. Original text: "Emerge un modo di essere periferici prima ancora di radicarsi in localizzazioni periferiche descrizione di una città interstiziale nella quale la

Today two main features identify the peripheral areas: provisionality and incompleteness, especially in the use of the open space and community facilities. Often these areas are incomplete with respect to the original project. Planned services are missing or there is no design of public space.

These characteristics of impermanence and non-finiteness reveal the potential for transforming the suburbs. The suburbs are indeed able to regenerate themselves and become an active resource.

The provisional character is accompanied by a number of problematic aspects that define the peripheral areas. The existing buildings are increasingly lacking and defective, they do not meet changed and changing needs of users, and do not meet minimum requirements for energy efficiency. Buildings built before the 70s did not include any device for energy saving and need today a strong action in this regard. Moreover, we are witnessing an increasing diversification of housing demand: increasing number of families, progressive reduction of the nuclear family, aging population, growing presence of foreign families, young people living in the household. This diversification compels to act on the existing offer of undifferentiated accommodation in residential complexes.

Other problematic aspects of the suburbs are size and proportion. Size is often too large, distances are too wide, open spaces are empty and huge. The large scale discourages people to stay and do activities.

This leads to a lack of recognition and identification and to an almost total disuse of those spaces that should contain the core of urban life in these neighborhoods, at the expense of those relationships that could and should occur in those open areas. "Great distances between people, events, and functions characterize the new city areas. Transportation systems, based on the automobile, further contributed to reducing outdoor activities. In addition, the mechanical and insensitive spatial design of individual building projects has had a dramatic effect on outdoor activities" (Gehl, 1987).

Furthermore, the post-war planning has changed the way of life between the buildings. Urban life was taken outside of the housing complexes, forcing them to depend from the nearest urban centers. This has discouraged pedestrian circulation in favor of motor traffic.

Fig. 1: Examples of peripheral areas where regeneration is completed or in progress. 1) Park Hill, Sheffield. The housing complex was built in '60s and partially renovated. 2) Bijlmermeer, Amsterdam. Housing complex built in '70s and completely renovated. 3) San Cristobal de los Angeles, Madrid. Neighborhood built in '60s and partially renovated.

precarizzazione degli statuti disegna geografie impreviste che rendono contigue forme di cosiddetta esclusione con situazioni di normale integrazione basterebbe a testimoniare di una simile evoluzione".

An interesting term to define this type of urban planning is desert-planning [3]; peripheral areas take the form of no man's land, lifeless places, deserts.

The negative characteristics mentioned above are at the same time considerable potentials for transformation. One example are the great outdoors, today among the largest green and open spaces, that creep in urban areas and are very useful elements for action.

The redevelopment of peripheral housing is a key element to restore urban quality of life in large degraded urban areas.

5 DENSITY AS REGENERATION TOOL

In the proposed approach density is the main criterion for guiding and controlling the redevelopment of residential suburbs. As an urban variable, density is a quantitative parameter, that has implications for the quality of both the architecture and the life of those who live there.

In this research the concept of density has a triple meaning: density of built, density of encounter and density of uses.

The first aspect, built density, reads the density in terms of quantity measured in numbers. Density is a ratio, a tool of analysis, interpretation, planning and control of urban development.

In this analytical approach, density is defined as the "relationship between architectural consistence and anthropized surface"[4] (Reale, 2011). It has a great value in measurement and control of urban space, indeed "to study urban density means going back to measure the space"[5] (Reale, 2011).

There are three main types of density measurement from the point of view of urban planning: lodging per hectare; inhabitants per hectare; surface per hectare.

The last type of measurement highlights a value equivalent to the ratio between all floor area and the settlement area, and it's called FAR: floor area ratio. This type of measurement does not give functional information but volumetric consistency information. It's useful to represent the relation between the density and shape of built. Thus it refers to morphological and volumetric features of urban system, rather than to population's demographics.

Different densities define different qualities of space. It may be interesting to do an analysis of this type applied to Rome, comparing center and periphery. Comparing the density values of some peripheral areas of Rome with the values of some areas of the center is possible to have an immediate feedback on the relationship between density number and the quality of life in the considered areas. The density in the central districts of the city settles something over 2 [6]: 2.71 in Prati district, 2.91 around Bologna Square, Balduina district is 2.56, and nearby Re di Roma square the ratio is 2.38. In remote areas density drops significantly: 1.01 in San Basilio district, 1.34 in Laurentino, 0.69 in Val Melaina, 0.64 in Spinaceto.

These data by themselves speak of how density can be a powerful key for reading urban quality.

In this research we want to emphasize density understood in qualitative terms, i.e. urban intensity. The idea is to go beyond quantitative measurement of urban environment's density to measure qualitative density, i.e. the features of built environment. These features affect relationships between people by realizing, hindering or facilitating them.

The degree, extent and nature of outdoor activities are influenced by the physical design of space "through planning decisions to influence patterns of activities, to create better or worse conditions for outdoor events, and to create lively or lifeless cities" (Gehl, 1987).

Accordingly, it is possible to speak of encounter density. Proxemics is the discipline dealing with personal and social space and the way in which man perceives it. In addition, proxemics considers distances between

---

[3] The term desert-planning was introduced by Gordon Cullen in his text "Townscape" published for the first time in 1961.

[4] Translation by the author. Original text: "il rapporto tra consistenza architettonica e superfice antropizzata"

[5] Translation by the author. Original text: "Studiare la densità urbana significa tornare a misurare lo spazio"

[6] All values are calculated as F.A.R. floor area ratio. Values are defined by Luca Reale in his text "Densità, Città, Residenza" (2011).

people, which vary according to culture and history. In our culture, proximity is a value and a necessary element of the definition of the city. Together with random personal interaction and neighborly relations.

The density of meeting refers to frequency, character, and controllability of random encounters. It defines the quality of urban life, in contrast with loneliness and dispersion of the suburbs: " This density of encounter is the substrate of sociability and the material basis of democracy"(Sorkin, 2003)

A neighborhood where you can live well is also represented by another type of density: density of uses. The quality of urban density refers to the quantity and diversity of functions, necessary elements for promoting the variety of everyday experience: " Cities are public reservoirs for the production of private experience" (Sorkin, 2003)

Hence to act on urban density "is not simply to densify or infill but establishing new relationships, building close relationships"[7] (Caudo, 2009). The goal is to grow what has been called the third city [8], which is not city's expansion nor conservation, but is the city of regeneration, of redevelopment, transformation of what was built, in relation to ability to create a human scale city. In such a city the boundary is not a site of separation but a meeting place between differences.

6 ORIOL BOHIGAS: A REFLECTION ABOUT THE CITY

The choice to focus on Oriol Bohigas, architect active in the city of Barcelona from 1951, is based on his work's appraisal. Since the '80s, Oriol Bohigas was an advocate of city reconstruction versus city expansion. He promoted returning to a compact city, with a high density of people and activities. He has actively contributed in the '80s and '90s, to transform the city of Barcelona, participating both as a designer and as technician of the municipality city-plan office, moved by the idea to give urban value to architecture. Bohigas planned expansion and opening of the city towards the sea, through the transformation of the Barceloneta neighborhood.

He has a vision with a planning flavor. His work is at the junction between plan and project: the plan tends to the project and the relationship between them is always recognizable.

Oriol Bohigas sees the city not as an unicum but as a juxtaposition of parts. He defines the neighborhood as the main urban planning unit. In this view, the local dimension acquires great value. The strategy of city transformation is implemented through precise actions for services development and reconsideration of public spaces.

He has contributed greatly through ad hoc actions to urban transformation through interventions in the consolidated city, that is inside the Eixample district, created by the Cerdà plan [9], focusing on the theme of the city block.

Oriol Bohigas, as designer, has in fact worked a lot on housing, mainly focusing on urban space design and community services. Indeed, he considers urban design a strategy for high impact changes. City regeneration begins from building community space. Hierarchies and forms of urban space are key points for planning. Streets and squares are pivotal points for designing public space. The street is important on a small scale, corresponding to the dimension of urban life. The square is also important on a small scale, because it expresses place's spatial culture. It is necessary to understand and interact with the site to build quality public spaces.

The elements involved in regeneration are: housing, city block, and urban space. The latter with its hierarchies and forms. Actions should be taken to regenerate attraction capabilities and recovering formal dignity, that helps improving the sense of community (Bohigas, 1986).

Bohigas, in his reflections on the transformation of the city, attaches great matter to density. He believes in the necessity to rebalance city's density and uses. A qualitative and quantitative homogenization of the city is, for Bohigas, necessary. You have to rebalance meanings and uses, and restore or provide urban quality of

---

[7] Translated by the Author. Original text: "Non è semplicemente densificare o riempire (infill) ma stabilire nuovi rapporti, costruire relazioni di prossimità"

[8] The term Third city is defined by Giovanni Caudo in his article "L'abitare e la città al tempo della crisi" (2009). Third city is densification, is building the city into the city (...) therefore is not a merely quantitative operation". Original text: "La terza città è densificazione, è costruire la città nella città (…) quindi non è operazione meramente quantitativa"

[9] Urban plan for the expansion of the city of Barcelona, created by Ildefons Cerdà and approved in 1860.

life in the spaces of suburbs. Indeed, he focuses on the density of use. An effective method for regeneration is to reconsider the intended use of a neighborhood in a sort of Plan of Uses. The combination of work, housing and leisure activities allows to define the city.

It is important to include the work of Bohigas in the regulatory environment in which he operates, and then study what he achieved in relation to city laws. The reference urban plan in Barcelona is the PGM-76, which is the achronym for Plan General Metropolitano de Ordenación Urbana, drawn up in 1976. This plan defines rules for soil use, density limits and standards.

The regulation of soil regime is very interesting for this research. Urban development areas are defined according to the intensity of use. Areas with specific physical features and urban classification are assigned a definite intensity of use [10].

The plan does not give a detailed order, but clearly defines the proportions between volume and empy space. The plan defines first the minimum standards to be met, and then gives an index of buildability based on the different density of use attributed to the various areas.

Reflections on urban density and intensity are strongly considered in the urban plan that includes Bohigas's projects.

Fig. 2: Some case studies: projects of Oriol Bohigas. 1) La Maquinista Block, Barcelona, 1983. 2) La Salut Block, in Sant Feliu de Llobregat (Barcelona), 1973. 3) Housing block in Mollet (Barcelona), 1983.

7 RESEARCH METHOD: AN EMPIRICAL COGNITIVE PROCESS

To evaluate the criteria and solutions in the plans and projects of Oriol Bohigas, a sample of representative projects will be analyzed. The key to select the projects is density, with a focus on residential themes and actions in the consolidated city.

Case studies will be selected that meet the following criteria: must be a predominantly residential complex, must be actions on a whole city block. The latter criterion permits to understand clearly the practices applied.

The research is based on an empirical cognitive process. The analysis is based on detailed and thorough study of physical features and use of space, as defined in the projects.

A table of assessment indicators will be defined for case studies analysis. Indicators aim to provide an assessment as objective as possible of building complexes rated by qualitative density. That goal is to gather information about those design procedures that modify space and the way in which it is lived, and that determine ultimately whether or not there is a good quality of life in urban areas.

---

[10] Normes urbanístiques del Pla General Metropolità. Títol II, Règim urbanístic del sòl.

Indicators for analyzing projects will be divided into two main types: indicators describing physical space and indicators showing interaction between space and users. Indicators of the first type refer to build space in function of its physical, dimensional, aesthetic properties.

Indicators that describe physical space will respond to the following questions: How are inner and outer space connected? Are boundaries defined or fluid? Is there a gradual transition between the public and private space? What is the relationship between built and empty space? How much outdoor space is green? How much open space is walkable and how much is private? How is the ground floor organized? What is the relationship between building height and open space width? Are there any services for residents? Is there a differentiation in colors? How is the system of routes configured? Distances are long or short? Walkways are covered or not? Are there are spaces to rest, to walk, to sit? What kind of paving is used?

Indicators which describe the interaction between space and users respond to questions such as: In outdoor space are there optional activities besides the basic ones [18] ? What is the frequency of interactions between people? Are there passive, chance encounters? What is the traveling speed outdoors? What activities will be carried outdoors and for how long? Is a sense of safety perceived? Is there a protection against noise, weather, traffic, hazards?

The method of analysis is to be based on perceptions of space. Carrying out such an analysis requires a prolonged stay in the building complex being analyzed, in order to understand how the space is used at different times of day. Indicators are therefore analytical tools necessary to give objectivity to observations.

The next step, after case studies description, is comparison between cases. By comparing data obtained through the indicators it is possible to deduce the constant features which determine the good quality of urban spaces.

8 CONCLUSIONS

These constant features can become design guidelines for the reconstruction of city character in peripheral urban areas. Those areas where this character has been lost or city qualities have never existed. The goal is to extrapolate by deduction design strategies to be applied extensively. The outcome of this research prefigures the definition of a possible method based on intervention design strategies, extrapolated from the comparative analysis. Such strategies are based on architectural devices, able to provide urban quality of life in spaces of suburbs.

This method can be an answer to the regeneration requirement of peripheral areas. This method can provide information about the elements on which to act and the methods of intervention, modifying urban density and intensity. The final goal is to provide or restore urban quality of life in degraded urban areas and thus allowing a wide-ranging regeneration.

The research will add an innovative contribution to the issue of regeneration of suburbs, using urban density as means of regeneration, using the example of Bohigas's work.

A possible development of this research is a feasibility test of this method applied through a simulation. The simulation could be applied for a suburban area in Rome metropolis, with the involvement of city government and inhabitants.

Deprived Neighbourhoods in Neo-Liberal Times – the Role of Public Funding in Education

Cecilia Scoppetta, Caterina Scoppetta

(Cecilia Scoppetta, PhD. Sapienza University of Rome)
(Caterina Scoppetta, IC "Federico Fellini", Rome)

1 ABSTRACT

In the light of what has been called "actually existing neo-liberalism" the issue of spatial segregation and exclusion of deprived peripheral neighbourhoods is analysed by challenging the pseudo-concept of the so-called "mixed communities", whose ultimate goal seems rather to be encouraging home ownership through a mix of tenures. Preliminary findings on a still ongoing on-field research are presented.

2 NEO-LIBERAL GUIDELINES FOR URBAN POLICIES, PLANNING AND DESIGN

Within what Brenner and Theodore (2002) have called «actually existing neo-liberalism», being different from pure neo-liberal ideology, Peck and Tickell (2002) further distinguish a «roll-back» and a «roll-out» model, or «laissez-faire» («let-do») and «aides-faire» («help-do») neo-liberalism (Purcell, 2009; see also: Raco, 2005). While the former is associated to Margareth Thatcher's and Ronald Reagan's policies in the context of the 80s, when market logics and the reduction of the State to a minimum were proposed as an effective approach for facing the economic recession, the latter, based on a more active role of the State in facilitating the accumulation of capital, is explicitly associated (see e.g.: Allmendinger, 2011; Peck & Tickell, 2002) to the New Labour's centre-left government in the UK (see also: Levitas, 1998; Newman, 2001; Cochrane, 2003; Raco & Imrie, 2003; Hills & Stewart, 2005; Holden & Iveson, 2003).

Brenner and Theodore (2002) also suggest «recognising the extraordinary variations that arises as neoliberal reform initiatives are imposed within contextually specific institutional landscapes», and the need to more overall analyses on such «variegated neo-liberalism» (Huw, 2009; see also: Peck & Theodore, 2007; Birch & Mykhnenko, 2009; Brenner et al., 2010a) is highlighted (e.g.: Brenner & Theodore, 2002; Peck & Tickell, 2002; Peck, 2004; Peck et al., 2009b).

But, despite «the path-dependent character of neo-liberal reform projects» (Brenner and Theodore, 2002) and the different ways in which «established institutional arrangements significantly constrain the scope and the trajectory of reform», as Scoppetta (2012) has noted in the case of regeneration of industrial port-cities (see also: Scoppetta, 2011a; 2011b), a general well-established neo-liberal planning recipe exists and can be easily individuated: «finding a derelict industrial or port area (in the latter case, delocalising port activities in a deepwater zone); adding a lot of public/private partnership, a pinch of trendy "creative class" according to Landry's (2000) and Florida's (2003) theories, a quantity of entertainment and leisure, a spoonful of (luxury) housing, offices, malls and public spaces, and a handful of tourism. Seasoning with IT facilities; then mixing with an international Olympic or cultural event and with a slowly and carefully cooked strategic planning tool. Finally flavouring with a tasty slogan – such as "young city" or similar – and with an "inclusive" and "shared" participatory process».

Such neo-liberal planning recipes can be seen as «knowledge apparatus» (Sum, 2009), based on competitiveness as a «hegemonic "knowledge brand"» (ibid.), «persuasive, widely accepted and powerful simplifications of the world» (McCann, 2004), such as the so-called "best practices", that effectively functions in spreading neo-liberal discourses and approaches, by forming a sort of disciplinary power over different countries and rooted planning traditions, so that they are often used by various actors to support arguments and to express the need for certain projects (see: Peck, 2010), which, in turn, refer to a specific (and often imagined) «urban neoliberal subjectivity» (Beaten, 2011) mirroring particular ideas about work, free time, and (above all) pattern of consumption (see: Atkinson, 2003b; Zukin, 1995; 1998).

In fact, as MacLeod and Ward (2002) and Lees (2003) underline, this happens especially as concerns public open spaces (on which urban regeneration schemes are particularly focused) by promoting an idea of "quality" that precisely mirrors a specific, «selective and systematically discriminating» (in: MacLeod, 2002) aesthetic model, which, in turn, both emerges from and promotes specific social groups, i.e.: young single or childless urban professionals with high income, and high social, educational and cultural capital. And, as Jensen and Richardson (2007) argue, «when particular subjects are imagined in particular ways, this will play a more or less visible part in the formation of policies and plans».

Such «technology of representation», which is incorporated within a «technology of renewal» based on detailed design guidelines, tends to reproduce «guidelines for a favoured kind of urban citizenry, figuratively embracing them in a landscape informed by a bohemian aesthetic while other residents are rhetorically and materially recast as outsiders» (in: Hoskins & Tallon, 2004) through the use «interdictory architecture of the new built environment» (MacLeod, 2002) implying expectations of specific behaviours, often supported by surveillance systems (Atkinson, 2003b).

3 DEPRIVED NEIGHBOURHOOD IN THE CONTEXT OF NEO-LIBERALISM

3.1 Neo-liberal spatial exclusion

The French sociologist Jacques Donzelot (2008) claims that, while the twentieth century was the age of confrontation, ours is one of polarization and spatial segregation. In fact, being the epicentre of the neo-liberal «geographically uneven, socially regressive, and politically volatile trajectories of institutional/spatial change» (Brenner & Theodore, 2002), cities are at the heart of processes of exclusion/inclusion, as the transformations linked to the process of both economic restructuring and globalisation have led to a polarisation of the labour market due to the growth of the demand for high-skilled labour on one side, and low-skilled labour on the other (see: Sassen, 1991; Mollenkopf & Castells, 1991; Hamnet, 1996; 2004; and many others).

While the polarisation thesis by Sassen and by Mollenkopf and Castells tends to highlight how specific processes of economic restructuring and labour market changes affect the social and spatial structures of cities, Hamnett's contribution (1996; 2004) has been pivotal in addressing the importance of welfare regimes in shaping the social outcomes of economic restructuring. In the European context, the debate was taken forward, with many authors insisting on the significance of welfare regimes without disputing the spatial inequalities affected by economic restructuring (see: Maloutas 2004, Musterd & Ostendorf 1998). Therefore, the phenomenon of spatial polarisation can be seen as an additional outcome of that characterising both the labour market and population (Maloutas, 2004).

As a consequence, the issue (or the rhetoric) of the included and the excluded who are (also) spatially segregated permeates the recent European literature and policies. The broader "spatial turn" in policy discourses has led to widely acknowledge space as a crucial dimension in the structuring process of exclusion. In fact, many scholars (Murie and Musterd, 2004; Musterd et al., 2006; Andersen, 2003; Forrest & Kearns, 1999; Atkinson & Kintrea, 2001) particularly emphasise the spatial dimension and the role of place in social exclusion, especially in the case of run-down inner city areas or peripheral public housing estates, so that the emphasis on social issues has shifted from notions of social class to notions of place: Therefore, both mainstream literature and political discourse in many European countries focus on the dimension of the neighbourhood, especially if dangerous, deprived and involved in a downward spiral that contributes to the further concentration of low-income households.

"Downward spiral" involving people, buildings, the environment and the image of the place, stigmatisation, "post-code discrimination", predominance of negative role-models, spreading of anti-social behaviours, concentration of disadvantaged low-income inhabitants, and the escape of householders as a result (see e.g.: Taylor, 1995; Power, 1996): these are the interpretative categories– coming from the US context, with a higher and more rooted level of segregation due to racial issues – generally used for explaining the «neighbourhood effect» (Bolt et al. 2010; see also: Musterd & Ostendorf, 2005; Ostendorf et al., 2001). The latter is not without implications in policy terms, as it linked with the idea of introducing a"de-concentrative" social mix (see: Musterd, 2002; Musterd & Andersson, 2005; Ostendorf et al., 2001; Musterd, 2003).

Lindsey (2007), however, underlines how the exclusion is «manifested both physically (within the actual space of the city) as well as discursively (within the space the city occupies in the imaginary)». In other words, this means that the exclusion is not only spatial, but it also is an exclusion from city's narratives. This allows assuming the existence of dialectical relationships between the (essential) economic motives and the (not irrelevant) ideological connotations of neo-liberal globalised and market-led urban renewal initiatives. As Scoppetta (2012) notes, «this relationship clearly reveals how not only the end result of rent-seeking urban policies, but also the socio-spatial transformation process are determined by (and are able to reproduce) hegemonic relationships».

3.2 A "pseudo-concept" is roving Europe!

On the background of the abovementioned spreading of neo-liberal pre-established recipes, guidelines and (presumed) "best practices", a «pseudo-concept» – as Bourdieu (2004) would say – is roving Europe (sic!): the assumption that more balanced communities can be achieved by encouraging the social mix through the differentiation of housing tenures. Well-designed open public spaces for imagined citizens (consumers) to be attracted in regenerated neighbourhood constitute the obvious corollary of the basic assumption.

Jacques Donzelot (2006) – an urban sociologist from a country where concerns about self-segregation are strong in the political debate, as the main objective is to assimilate minorities into mainstream society – has critically analysed such trend towards social mix by deconstructing, in order to reveal its ambiguities, the use of the concept of "mixitè social" as a key-tool to achieve social cohesion in French urban policies over the past twenty years. He nderlines how this concept has been translated in two type of policies: imposing minimum quotas of social housing to local authorities, and encouraging "middle class residents" back into deprived neighbourhoods (mostly post-war housing estates) through selective demolition and housing differentiation measures. According to Donzelot, this means that the ultimate goal is to increase the variety of housing typologies in order to encourage home ownership, rather than assuming as primary objective the mix of population groups with different incomes. In fact, such projects are often aimed at enticing middle-class residents into deprived neighbourhoods, rather than deprived households into richer areas.

Donzelot's analysis offers useful insights into a better understanding of both rhetoric and hidden reasons staying behind public discourses on social mix, which seem to be mainly led by the need of attracting middle classes residents and private investments in the (no longer public) restructuring of the existing public city. We can also interpret in this sense the shift towards ownership of housing policies in Berlin (Bernt & Holm, 2004), which used to be a tenant city: while subsidisation of condo conversion is expanded, funding for social housing has been drastically curtailed, and rent control has been reduced. In addition, each year 30,000 housing units are "freed" from being reserved for low-income groups, and the public housing associations are being sold. The goals of social programs for "problematic neighbourhoods"– such as "Social Stadt" – are not desegregation or redistribution (since such goals are no longer seen as feasible), but rather an attempt to mitigate the worst effects of the restructuring.

It is not a coincidence, however, that the concept of social mix – exclusively applied in social housing estates (Darcy, 2010) and not, as in case of the Home Ownership and Opportunities for People Everywhere VI or Moving to Opportunity programmes in the USA, where vouchers to rent private dwelling in richer neighbourhoods are given to low-income households – as an engine of cohesion and sustainable communities constituted one of the main principles underpinning the vision of New Labour's so-called "urban renaissance" (that involves, in the reality, just a part of the "urban"), and it was strictly linked to that of "sustainable community". In this sense, many scholars have highlighted the coexistence of two contradictory New Labour's agendas (Cochrane, 2003, 2007; Holden & Iveson, 2003; Levitas, 1998; MacLeod & Ward, 2002; Ward, 2003; Jones & Ward, 2004; Amin et al., 2000). In fact, while the term "social mix" was already present in the first period, "sustainable community" appeared for the first time in 2003 and progressively substituted the term "urban renaissance" – the major slogan of the New Labour's agenda immediately after the coming into power in 1997 (Rogers & Coaffee, 2005; see also Gordon, 2004) – in public discourses.

In key policy documents, the «new sustainable urban realm» to be achieved through the "urban renaissance" was explicitly intended as an instrument aimed at «attracting the suburban knowledge and service industrial demographic back to the city» (Cochrane, 2003, 2007), i.e.: to stop the "escaping" of the middle-class towards the suburbs (the process of sub-urbanization started in the '80s) and to enhance the (global) competitiveness of the city in the new knowledge economy. In other words, the vision of the New Labour's "urban renaissance" was based on the assumption that the return of the middle classes to the inner city could be the key-way of reducing concentrated poverty and its long-terms effects (DETR, 2000). Therefore, being the concept of "social mix" framed within these basic ambiguities and contradictions, it clearly shows its rhetoric nature.

In this sense, it is not a coincidence that what is to be "mixed" remains highly unclear in key policy documents such as the Urban White Paper (DETR, 2000; see also: Lees, 2003), where the term "mix" refers to uses and functions («mixed development») as well as to social issues («mixed communities») or, as

Rowlands et al. (2006) note, it is presented as a (prodigious!) tool for delivering both income and social mix as well as social interaction, broader social cohesion, "sustainable communities", cultural and ethnic diversity (OPDM, 2006) (surprisingly, happiness, richness and eternal youth are not mentioned!). Further (supposed) positive effects of mixed tenure are individuated by the Williams's and Daly's de-constructive analysis (2006): dilution of disadvantage, improved sustainability (of services), change in resident behaviour and change in non-residents perceptions. But, anyway, they conclude that empirical evidence shows that while tenure mix surely is a necessary precondition for social mix, it is not sufficient to achieve it.

In the reality, indeed, «tenures are spatially separated as a result of the land assembly methods» and «this not necessarily being conducive to social integration» (Williams & Daly, 2006). Many other scholars (Kleinhans, 2004; Galster, 2007; Cheshire, 2007, 2009; Chesire et al., 2008; Lupton & Tunstall, 2008) agree on the fact that there is little or no evidence neither of the increasing of social interactions between social housing rental residents and the owners of newly built housing units, nor of the leading to better life chances and opportunities. On the contrary, beyond the obvious loss of social housing and public assets, regeneration policies based on a mixed-tenure approach rather tend to lead to a transformation of local services and retail (Rowlands et al., 2006) for the benefit of higher income groups. Furthermore, while seeing in mixed-tenure strategies a form of gentrification (Cameron & Coaffee, 2006; Johnstone & MacLeod, 2006; Lees, 2008; Aktinson, 2003; Davidson & Lees, 2005; Watt, 2009; see also: Urban Studies, 2008), British scholars underline that the tenure mix rather tends to produce «utopian and dystopian spaces», «physically proximate but institutionally estranged» (MacLeod & Ward, 2002) leading to daily micro-conflicts over the use of green or social spaces (Richards, 2005; Taylor, 2005). Richard Rogers himself – one could say: the "father" of the Urban White Paper – highlights the risk of segregation «with ''haves'' occupying their trendy new apartments and the ''have nots'' living not far away in substandard housing» (Hetherington, 2002).

By underlining that the New Labour's idea of "urban renaissance" is focused on a «civilized middle class» (Atkinson, 2003a), other scholars (Jupp, 1999; Atkinson & Kintrea, 2000) highlight a further paternalistic assumption of a (supposed) "civilizing" influence of tenure mix, based on the idea that contacts and interactions with "role model" from a different socio-economic background could "motivate" the deprived groups or individuals, even though there is «no specific evidence of role-model effects or increased social capital» (JRF, 2006).

Anyway, it is worth noting that in the UK the increasing of negative perceptions of Muslim residents, due to the bombing of 11th September 2001 in the US and 7th July in London as well as the riots in Northern English cities in 2001 led to growing debate in the British media and political sphere on the spatial segregation/clustering of immigrants and on its potentially dangerous consequences as well as to the re-emerging of assimilationists discourses (Philipps & Harrison, 2010) within which residential segregation of ethnic groups was seen as undesirable (Bolt, 2009; Musterd, 2003). A clear ideological affinity with such kind of discourses can be found in the highly controversial declaration by Prime Minister David Cameron (Helm et al., 2011), elected in the spring of 2010, and by the new Conservative-Liberal Democrat coalition government's reaction to the urban riots of the summer of 2011.

4 CONSTRUCTING CITIZENSHIP AND URBANITY.

4.1 Lessons from a (too easily) forgotten work.

Although it has become a sort of «professional orthodoxy» (Bailey, 2005), given the scarce evidence about its positive effects for low-income or marginalised residents, together with so many abovementioned British scholars that livened up a passionate debate on the issue at least since the 1996 (a review in: Inch & Marshall, 2009; Marshall, 2009; see also: Inch & Marshall, 2007) we can affirm that the mixed-tenure approach is an uneffective or at least insufficient tool «for delivering social mix and long term sustainability» (Rowlands et al., 2006) for low income or marginalised urban residents.

Such approach, in fact, tends to treat the symptoms of urban deprivation and inequality rather than tackling its causes (Cheshire, 2007; 2009; Cheshire et al., 2008), by shifting the focus of public intervention away from the fundamental question of structural inequalities, with a useless and uneffective use of public resources (Musterd et al., 2006; Beaumont, 2006; Arbaci, 2008; Cheshire, 2009), as it seeks to solve larger-scale problems – such as labour market and structural economic transformations, the changing role of the welfare state, the dynamics of the national housing market, or ethnic discrimination in various spheres –

which are rooted outside the borders of the neighbourhood. An example of the uneffectiveness of the mixed-tenure approach is given by the fact that, despite the emphasis (and the rhetoric) on the so-called "sustainable mixed communities", social interaction in mixed neighbourhoods is not self-evident, as social worlds, places of consumption or education of children from low and middle/high-income families remain highly separated. In fact, even though tenure mix may imply a (relative) physical proximity between social groups having different incomes, it does not automatically mean a real mix in public spaces, schools, public services and shops.

Therefore, a broader consideration of non-residential forms of marginalisation is to be suggested, and this raises questions on what other spaces focusing on to construct a shared concept of contemporary urbanity. Amin (2002), for example, suggests the spaces of daily negotiation of differences, such as workplaces or schools. In particular, as regards schools, it has been noted (Burgess et al., 2005) that, even in the less criticised cases of UK neighbourhood regeneration, new middle class residents tend to perform exit strategies by sending their children to private schools or to public schools outside the (clearly still stigmatised) neighbourhood, so that the degree of class or ethnic segregation in schools within the regenerated areas remains higher with respect to that of the surrounding neighbourhoods.

Therefore, schools and, more generally, the access to welfare services (such as education, training and employment opportunities) (see: Musterd & Andersson, 2005) – i.e. the integration of area-based and people-based policies – seem to be a more crucial factor for the construction of "sustainable communities", even for avoiding the «potentially detrimental gentrifying effects» that only mixed-tenure regeneration processes «may inflict on the communities they intend to help» (Lees, 2008).

In 1961, at the beginning of both the so-called Italian "economic boom" and the uncontrollable sprawling growth of the city of Rome, Vittoria Calzolari and Mario Ghio wrote together an unfortunately too easily forgotten book – "Verde per la città" ("Green for the city") – based on a detailed comparison (showing a gap which appeared as really hard to bridge) of educational provisions (in terms of school buildings and related green and sport areas as well as of educational systems) between Italian (and, particularly, Rome) and highly welfarist Northern European cities (Copenhagen, Amsterdam, Zurich, Ulm).

This is a work that should be considered a possible new starting point for the integration of place-based and people-based approaches as well as for the spatial rethinking of the welfare system. Italian planning scholars use to connect this work to the concept of "standard" (in quantitative terms) of public services, but this is a reductive misunderstanding. In fact, even if such word was not fashionable at that time, this is a book that clearly talks about what we today use to call "urbanity", since it stresses the role of public schools (to be connected to both playing fields and public libraries) within urban neighbourhoods, by addressing their design in terms of both spaces to be devoted to young citizens and inter-relationships between these spaces and the neighbourhood as a whole. During the tumultuosus highly rent-guided growth of the city of Rome in the 60s, highlighting the existence of children and the need to consider public spaces, structures and contexts within young people operated meant linking together the issues of education and citizenship.

4.2 Preliminary findings from a still ongoing interdisciplinary on-field research.

The current sprawled and fragmented urban morphology of the periphery of the city of Rome is the result of a rent-seeking (Natoli, 1953; Cederna, 1956; 1965; 1991; Insolera, 1962; Della Seta & Della Seta, 1988; Tocci, 2009) urban regime occurred since the post-World War II, that led to the emerging of three different cities: the "private city", i.e.: the result of what Parlato (1970) has identified as «the ideology of privately owned house»; the «spontaneous metropolis» (Clementi & Perego, 1983; see also: Berdini, 2010), i.e. illegal unplanned settlements (28 % of the urbanised areas within the municipality of Rome in 1981) in what between the eighteenth and nineteenth century had been called "Roman Campagna"; and, finally, the "public city", i.e. the answer to the emerging, during the 70s, of the periphery as a new active social subject due to both innovative approaches in sociological research (e.g.: Ferrarotti, 1970; 1974) and Pasolini's literary works (1955; 1959), and to the consequent urban struggles for social housing.

The result is the current «fragmented morphology formed by "islands" which are defined by visible (e.g.: architectural shapes) and invisible borders (sometimes implying a still rooted sense of belonging of settled communities)», and which «tell us about different ideas of both city and society», so that «architectural objects, separate powers, public, private and illegal projects, images and cultural constructions, differences and conflicts are currently casually spread» (Scoppetta, 2009). What joins the different islands is a metropolitan condition in which distance (from city centre, from working places) due to a severe lack of public transport (and a consequent strong car-dependent mobility) «constistutes the unit for measuring exclusion» (ibid.). Neo-liberal policies developed since the 90s, by shifting from the periphery (i.e.: from the city as a whole) have privileged a «rhetorical narrative of urban renaissance» (in: Scandurra et al., 2007), focusing on the role of culture in re-positioning the city within the global arena of the new "cultural economy" (a review on the issue in: Scoppetta, 2013) through both the valorisation of the historical centre, mainly focusing on tourism and consumption, and culture-led policies, based on the (outsorced) promotion of spectacular events as well as of contemporary architecture (e.g.: the Renzo Piano's Auditorium Music Park) (see: Scandurra et al., 2007; Berdini, 2008).

The neighbourhood of San Basilio, in the north-eastern periphery of Rome, originally was one of the "borgate" (Insolera, 1962; Berlinguer & Della Seta, 1976; Martinelli, 1990), which were established in 1929 by the fascist regime in the "Roman Campagna" far from the already urbanised areas, as a displacement tool for freeing the central areas of the city in order to give room for the magniloquent representation of the fascist "empire" on the background of archaeological remains. After the World War II, the borgata was partally demolished and reconstructed with a low-density typology. Furthermore, thanks to the funds coming from the Marshall plan, a further nucleus of public social housing was added, and illegal settlements arose. A further settlement of social and affordable housing was then added, but it still remains separated from the others. In 1974, the neighbourhood of San Basilio emerged (with many political consequences at the national level) as a sort of symbol of urban struggles for housing: in fact, due to the problems of overcrowding and lack of transparency in establishing allotment lists, the existing nucleus of social housing was occupied, and this resulted in an armed conflict that ended tragically in the death of a young demostrator and dozen injured among both police and occupants. The initial ruralisation of the displaced originally urban craftmen and, then, the riots that involved the neighbourhood as a whole (not only the occupants) produced a shared and persistent strong sense of belonging that, in a certain sense, seems to be favoured by the architectural shapes, provided by common spaces and connected courtyards.

Due both to the presence of the still occupied blocks and to the spreading of illegal activities, such as the direct selling of hard drugs especially within the original nucleus – an enclave which is easy to control by pushers thanks to its architectural shape – San Basilio is currently considered as a neighbourhood at risk. At the same time, an "official" controlled gypsy settlement has been established (after its dispacement from an inner urban area) close to the neighbourhood immediately after the coming into power of the new right-wing government of the municipality in 2008. Thus, even if drug-market activities are confined only in certain areas, and although, given the distance from the city centre, flats' prices are more affordable than in other neighbourhoods so that new inhabitants are immigrant workers but also young families from the middle class under the pressure of the economic crisis, San Basilio is currently involved in a "neighbourhhod effect".

Within such a context, exclusion and segregation clearly appear in the neighbourhood's secondary school, with the increasing emerging of racist behaviour: middle against lower classes (mirroring the different parts of the neighbourhood), Italian against immigrants, Italian and immigrants against Roma pupils. In fact, even

if they share the same living environment, these are separate worlds with profound differences in knowledge, language, behaviours, lifestyles, interests, and expectations. School compositions, for example, clearly highlight a different use of free-time as well as the fact that the most advantaged tend to use the neighbourhood as a dormitory, as they do not use (and, therefore, do not know) the neighbourhood's public spaces. The latter are also differently perceived: on the one hand, they are intended as dangerous places to be avoided, since the living environment is inside home and movements are always by the parents' car. On the other hand, public places in the neighbourhood are perceived as a familiar networked space which tells about a shared "antagonist" collective memory, and in which it is difficult to clearly distinguish from legal and illegal behaviours because of daily interaction of street-life.

Anyway, the school is the unique welfare space for gathering, socialising and for culture, and it could really be a relevant resource, as it could act as a mean of contact and dialogue between parallel networks that otherwise risk to never cross. Exploiting the existing school's creativity and opening it to the territory could mean considering it as a social centre not only for pupils and parents, but for the whole neighbourhood, hosting in its spaces cross-section initiatives (e.g.: courses of Italian language for immigrants, cinema, library, and so on) that address different categories of inhabitants. But, surprisingly, even if many projects have been developed in the neighbourhood in order to face the "neighbourhood effect", no one of them involves the school: both the forecast path network aimed at reconnecting the different parts and the improvement of public spaces paradoxically does not consider the school, and only two of the 120 students analysed know the existence of the new built social space (resulting from a "participative" process!).

More generally, despite the rhetoric of the so-called "knowledge society", in the current phase of restructuring of the welfare system, education in Italy seems to be the privileged sector of public dis-investment. In fact, between 2008 and 2011 "cuts" in funding have amounted to 8,5 billions €, and between 2012 and 2014 further 13,683 billions are foreseen. As underlined by the OCSE report 2012 "Education at glance", Italian investment in public education (9 %) is lower than the European average (13 %), so that Italy is at 31th place among 32 EU members. Spending for public schools has been dramatically decreasing in the last 10 years: in 1990 Italy spent for school 10,3 %, while in 2008 the percentage was reduced, by subtracting about 80 billions €. In addition, in 2008 Law no.133 by the Berlusconi's government led to further cuts of around 7,8 billions for the period 2009-2012 concerning teachers employed: from 824,178 in 2001 to 795,342 in 2010 and 744,260 in 2012. When considering all different (and necessary!) figures employed in public schools: 1,137,619 in 2007, 1,043,284 in 2010, 950,000 in 2012. All this means the disappearing from classrooms of over 1,000,000 teachers in the last five years. This also means that public education is considered as one of the main resources to be used for improving the national budget. At the same time, public funding (223 millions € in 2013) to private (mainly Catholic and often elite) schools remain uncut, even though in such schools a (often very expensive) fee is required. In fact, although according to the art. 33, par. 2, of the Italian Constitution «private entities have the right to establish schools and educational institution at no cost to the State», the Law no. 62/2000 (by the D'Alema's progressist government) equaled private to public schools, so that they are considered as part of the national educational system, and since 2000 public funding to private schools is tripled (from 179 to 545 millions in 2007) – not to mention further funds from local authorities.

In the secondary school of the neighbourhood of San Basilio – where the most disadvantaged students can, however, easily earn 50 euros per day as useful non-punishable under-age pushers – such neo-liberal devolution results in less laboratories and equipments, less time devoted to lessons, impossibility in opening the school during the afternoon, increase of student per classes, less adjunctive teachers for non-Italian speaking or problematic children (currently from 5 to 9 in each class), elimination of social and psycological support. All this finally unavoidably leads to an "exit strategy" of the most advantaged students towards the schools in the surrounding neighbourhoods, while the most deprived remain excluded since the beginning.

On the contrary, beyond constituting a possible physical focus for the requalification of the surrounding network urban open and/or green spaces, the school could really play a role within a broader rethinking of the concepts of urbanity and citizenship in order to make them suitable for children, and not only for the thirty-years-old high-income single gentrifier, typical of the London's "urban renaissance". This obviously means usefully concentrating public investments (reduced because of the economic crisis) on both material and immaterial components of educational system rather than looking for "zero-cost" and "zero-tolerance" solutions to face social problems due to the still ongoing economic restructuring.

1 ABSTRACT

Soil is one of the worldwide most important resources. Some scientists are afraid that due to the expected massive urbanization in next two decades, a "soil peak" can be reached because of e.g. urban sprawl and the massive construction of traffic areas. It means that the amount of soil which is in use for agriculture or for natural purposes decreases more and more. One problem is that traditional regulative approaches of spatial planning are failing to deliver a sustainable land use. Urban sprawl supports unsustainable land use with negative economical and ecological effects, like loss of the resource soil, increase of traffic, etc. New integrated land management approaches and policy mixes are needed, to address the stakeholders varied interests in land more comprehensively. The project Circular Flow Land Use Management (CircUse) fosters sustainable land use in Central Europe by promoting the principle "avoid – recycle – compensate".

12 partners from 6 countries are for 3.5 years implementing the project CircUse Circular Land Use Management principles and concepts. In 6 participating countries these partners promote an integrative policy and governance approaches in respect of the urbanised land utilization.

For the first the CircUse strategy has been developed to illustrate what is necessary to implement the approach of a circular land use management. According to these requirements further steps have been taken by the project partners. The project CircUse has firstly unified the urban land use typologies and then prepared a pragmatic inventory tool, focused on the local/regional land use management. This tool can assist municipalities to become aware, what is the size of their development potential within their urbanised area. On working with such a data management tool further, analyses of the actual accessibility of this urban development potential can be made and mainly measures can be proposed to improve the inner urban development potential accessibility.

Data gathering can usually help to size up an issue and monitor the situation. But the solution of a more effective land use can be only achieved through a coordinated action, which aims to deliver the good intentions, identified in various policies. As a tool which could achieve this, was by the project CircUse chosen the action plan, focused on improving land use effectiveness. Six action plans based on a common template were produced, one per each project CircUse partners´ country. A scale of these action plans varied from a site specific (Piekary) to a city based (Asti, Freiberg) to a peripheral regions based ones (Trnava, Voitsberg) to a NUTS 3 based plan (Ústí Region). In the last three plans the multilevel governance approaches and the stakeholders´ participation were tested. To help municipalities to implement a sustainable land management a guideline for the preparation of a CircUse training course was produced. The guideline consists of 6 learning modules which are: 1. Land consumption – the problem analysis, 2. Principle of CircUse, 3. Land potentials and scenarios, 4. Stakeholders, 5. Instruments and 6. Action plans. Also education materials for secondary school children have been produced and translated into 6 languages as well as the pilot training has been conducted.

A concept of institutional solutions serving the management of circular land use is another important output of the CircUse project. Here two different approaches were employed: one was based on an existing institution, to which additional or specific tasks and competencies have been transferred. This was the case of the Industrial Park – EkoPark in Piekary. Another approach was presented by establishing a new land management agency which was founded in Austria, specifically focused onto the management of circular land use. Both solutions of institutional set ups acting as local operators for management of circular land use can serve as a good practice example for other European towns and regions.

This paper would share various experiences, which partners gained, while implementing the CircUse project common approach of the Circular Flow Land Use Management in their countries.

2 INTRODUCTION

The key urban issues such as land consumption, urban sprawl and brownfields are experienced not only in Central European regions. Majority of the urbanised areas increases are not based on population growth, but they are based on increases of urbanised land per head of population. This puts higher demands on energy consumption and increases the cost of development externalities, which then reduce competitiveness of the cities. An excessive consumption of land for urbanisation also diminishes the soil environmental services capacity and contributes to global climate problems.

The existing tools, policies and forms of governance so far failed to prevent ever increasing consumption of land for urbanization. Also the traditional regulative approaches of spatial planning are failing to deliver the land use sustainability.

Therefore new integrated land management approaches and policy mixes are needed to address the stakeholders varied interests in land more comprehensively. Also new governance approaches are needed, which can reach above the local authorities´ jurisdiction and can protect specific public interest in land from a broader regional level. In the past 5-7 years, a search for an optimum solutions resulted in preparation of new national/regional policies, targets and programs, which were supported by collective efforts of many consultants and research teams.[1] But the actual outcome of these new policies and programs in the Central Europe so far, has not yet delivered the desired goals and targets.

Project CircUse – the full title „Circular Flow Land Use Management" is aiming at working out a transnational model of circular land use management. The approach is consistent with sustainable development requirements therefore stakeholders´ involvement is an important element in the model implementation. Within the project 6 pilot sites in 6 countries are developed. The main objective is to provide a transnational applicable solution which would enhance counteracting urban sprawl and creation of dispersed land use patterns. Partners of CircUse are developing and implementing a climate friendly land use concepts in coherence with new instruments and pilot actions. The project targets will be reached by a strategic approach to urban and peri-urban development based on the principle of Circular Land Use Management.

The main results of the project are:

- overall strategy towards circular land use management including policy and action plans,
- tools and instruments of circular land use management: transnational land use data base produced for each pilot case
- manual on tools and instruments,
- education materials,
- CircUse compendium,
- pilot projects.

The project consortium consists of 12 partners from 6 countries: Austria, Czech Republic, Germany, Italy, Poland, Slovakia (see. www.circuse.eu)

3 CIRCUSE STRATEGY

One of the most significant project outputs was the circular land use management strategy. The strategy is presenting characteristics of the approach of circular land use management by 9 theses which constitute features and conditions of successful implementation of this methodology.

Thesis 1: Common problems and diversity of national and regional frameworks could be faced by a common strategy of circular flow land use management

Thesis 2: The setting of quantified and qualified targets is a necessary requirement for successful implementation of a management strategy according to circular flow land use management.

---

[1] See for an example the German programme "Research for the Reduction of Land Consumption and for Sustainable Land Management (REFINA)" funded by the Federal Ministry of Education and Research (BMBF) (www.refina-info.de)

Thesis 3: Circular flow land use management needs a comprehensive definition of land types (incl. greenfield and brownfield areas)

Thesis 4: The development and application of information instruments and data management for registration and monitoring of space oriented potentials is one of the key activities towards a circular flow land use management.

Thesis 5: Circular land use management in urban regions cannot be driven by the actions of a single primary stakeholder but can only be achieved through the coordinated efforts of the various public and private stakeholders who, as planners, property owners and land developers, influence or govern how land is used.

Thesis 6: The implementation of circular flow land use management needs an integrated course of action which encompasses the wider spectrum of policies and activities providing a package of instruments (policy mix). In this instance current and potential new instruments should be pooled according to regional differences in framework conditions.

Thesis 7: The implementation of action plans need the selection of an applicable policy mix, stakeholder institutions, financing sources that meet the regional demands.

Thesis 8: In general new forms of organization need to be implemented by the stakeholders of a circular flow land use management. There are wide opportunities for institutional solutions in the EU.

Thesis 9: Permanent knowledge acquisition and awareness of circular land use management are crucial preconditions for a successful implementation of a strategy for reducing land take and strengthening inner development.

4 ACTION PLANS

Action plans present examples of implementation of the project approach to circular land use management with all required features. They also integrate instruments, activities and materials developed as other project outputs. The universal unified contents concerning action plans for each of six cases has been proposed by partners and according to it, the documents of action plans have been worked out. These documents include the elements constituting the realization of the concept.

These are:

- description of the area with areas of impact, constraints definition of areas of impact
- vision mission and process of creating the AP,
- management structure with stakeholders, education activities, division of responsibilities,
- action plan itself with budget, time schedule, monitoring and outcomes for local and regional beneficiaries.

For each case the proposed structure was followed and it was a basis for general conclusion on practical steps which have to be made to develop an instrument supporting sustainable land management in the region or municipality.

4.1 Action Plan for Asti

The Municipality of Asti has to face the management of many abandoned areas, with very different locations and characteristics. The restoration of former Way-Assauto area, one of the biggest and most problematic ones, has been included in the Development Plan of the Municipality of Asti: this is a strategic plan that involves all brownfields areas and abandoned buildings. The aim is the integration of multi-task actions to reuse derelict areas in the city with the participation of various stakeholders.

With reference to the current need to provide decision-making support for those problems concerning the development, transformation and management of the urban and territorial system by means of a sustainable approach, a key role is played by the Spatial Decision Support Systems (SDSS) developed by the second Italian partners withing the project CircUse. The SDSS are tools for the analysis of complex systems in the field of spatial semi-structured decision problems. The public decision support system on land use planning would benefit from the application of a SDSS, as it could reduce the decision time and increase the accuracy and consciousness of individual decision-makers (analysis of variance, the study of solidity and sensitivity variables, application of multi-criteria analysis).

The former Way-Assauto area is an interesting pilot case, as in the past years it has been contaminated by a chemical shedding that reached the underground water level. A chemical reclamation plan for the site is in existence and reclamation is on going as a remediation of a brownfield site implies the removal of all known contaminants to levels considered safe for human health. Redevelopment can only take place after all environmental health risks have been assessed and removed. Remediation can be expensive and complex, and this needs to be seriously considered before purchasing brownfield land. Not all sites are deemed suitable for remediation, particularly if the costs exceed the value of the land after development. In the last few years several new remediation technologies started to emerge. These are proving to be relatively low-cost compared to traditional processes, with the benefit of protecting and preserving the environment. With the CircUse project, the Municipality of Asti is interested in an update of this plan by the participation of the University of Turin.

4.2 Action Plan for Saxony

The development plan 2012 of Saxony indicates "Efficient land use and reducing of land consumption". The significance of land consumption and the need of land management are increasing. Since 2008 the Free State of Saxony is working on the goal on the reduction of land consumption. In 2009 the government noticed this action programme and defined the target for Saxony to reduce the daily land consumption under 2 ha until 2020. To reach this goal an "inter ministerial working group (IMAG)" has been established. The region of Saxony and the city of Freiberg, as one of the leading cities of innovative environmental actions and research, supports the principle of Circular Land Use Management and will be a model city for the regional development targets of Saxony. Support to the inter-ministerial working group is provided by the introduction of circular flow land use management as a tool for sustainable city development, climate and soil protection in the context of the management of demographic change. The implementation of the CircUse land management system is planned in the City of Freiberg. Based on a pooled inventory usage scenarios will be developed of the pilot site – former porcelain factory in Freiberg – and a development plan will be submitted as part of CircUse.

4.3 Action Plan for Trnava

The Municipality of Trnava has had to face the problems of a very dynamic development of its economic basis bringing thousands of new working places into the city and at the same time a critical situation with exhausted capacities of social infrastructure, housing and leisure-time activities as well as internal sources of available land for their further development. This led to strong flow of population towards the sub-urban areas looking for price-friendly housing possibilities and using the infrastructure of the city, causing extraordinary load on transport and other urban services. On the other side, the city and surrounding municipalities have to deal with many abandoned areas of very diverse characteristics, looking for their new functional use and structural refurbishment. This determined the idea to cope with this very complex problem by development and implementation of a joint strategy of Trnava and surrounding suburban micro-region municipalities. By using the possibilities of joint know-how and experience exchange various actions were implemented in the frame of EU funded project CircUse.

The common agreed vision is the development of functioning, efficient and flexible cooperation structure and interlinks between different aspects of micro-regional development, different actors and interests in one interlinked strategy as a reaction to existing problems with brownfields, abandoned buildings and growing requirements concerning new capacities of public services and land for private investments. The aim is to integrate multi-task actions to re-use derelict areas in the city and municipalities and involving various stakeholders into the planning, decision making. Implementation of the joint strategy as gives a new chance to improve the quality of life in Trnava and other municipalities in the micro-region. This new approach of the joint strategy and actions is the core philosophy of the Trnava action plan and at the same time of the development towards participative governance as the new quality in municipal politics.

By optimizing the development localization from the micro-regional perspective it will both maximize use of existing potential of individual communities. It would as well minimize the take of un-built territory reflecting thus the limiting factor for extensive development throughout the region of high quality agricultural land and environmental protection. Optimising the location of functions on micro-regional level would also make the movement of population within the Trnava micro-region more efficient. It would also

help with effectivnes of operational services, with particular emphasis on services provided by public sector. Therefore it would contribute to saving municipal finances. Given the considerable similarity of the range of problems perceived by the local population (lack of green spaces, low services by public transport, incomplete services, long-term unemployment) it opens a possibility for using the cooperation within the Trnava micro-region also for the associated projects financed from structural funds, respectively from social EU funds.

4.4 Action plan for Usti Region

The Ústi Region (UR) Action Plan (AP) preparation preceded a concentrated action of both Czech partners of CircUse project to increase regional stakeholders´ know-how on matters of circular land use management principles. For the ÚR stakeholders´ use the CircUse strategy, the CircUse education materials and the land use typologies were translated into Czech.The course materials were also adapted for ÚR use by inclusion of regional particulars. Parallel to this action, extensive analyses were performed on the regional and national policies and legal frameworks, which addressed the regional land use. These material were introduced to the ÚR stakeholders and were followed by a seminar, encouraging stakeholders to share experiences, opinions and barriers, they have encountered in their attempts to steer land use effectiveness. The goals and priorities of the AP were discussed, main activities outlined, commitments to AP were pledged and means how the AP could be financed and implemented were addressed and considered.

The action plan activities can be divided into 3 main groups. The first group supported local communities with gathering urban land qualitative data and evaluation of the accessibility level of the local urbanised land inner development potential. The second group supported mitigation measures (regional demolition program, proposals for amendments to national legal framework, etc.). The third group have focused on increasing public awareness of the issue. As the key source for financing the AP initial activities the INTERREG A Cross Boarder Program Saxony – Czech Republic was identified. Preparation of this new project is now taking place.

4.5 Action Plan for Voitsberg

The region of Voitsberg is a traditional former coal mining area and is facing the structural transition since the 1990ies. Therefore numerous unused brownfields are available for revitalization in the region. The principle of Circular Land Use Management shall be implemented in the region via a land management Agency. In spite of a wide range areal spatial reserves because of former mining or industrial activities there is a wide land take of agricultural greenland for areas zoned for economic activities and housing. To reduce the land consumption in the future the principle of Circular Land Use Management shall be implemented in the region via a land management agency.

The overall task of the agency is to support a sustainable and ecological compatible development of brownfields (former industrial, commercial and coal mining areas) in the pilot region „Kernraum Voitsberg" (consisting of five municipalities: Koeflach, Voitsberg, Baernbach, Rosental und Maria Lankowitz) according to the concept of Circular Land Use Management (this is an integrative strategic approach which primarily and systematically seeks to exploit the development of existing building sites and reuse derelicted land).

To achieve the goals of the agency the development of an action plan (masterplan) for the next years for the pilot region Voitsberg (Kernraum) by the Telepark Bärnbach is necessary. To get a significant feedback by the target groups of the region, several meetings were organized and a questionnaire (online) was developed and distributed to the specific target groups.The outcome of the definition of the areas of impact differs when considering recycling of brownfields and new sustainable land use. The definition of the points of contacts, the formulation of the principles (political, economic) and the identification of dependencies is described in the new agency framework requirements.The management structure includes also the description of roles and responsibilities.The developed Action Plan considers activities in two phases a) until the end of the project CircUse and b) in the first phase after CircUse is finished.

The Action Plan List covers the following:

Action 0: Joint actions – deliverables of CircUse as basic tools for the local implementation.

Action A: Establishment of the agency: the establishment of the agency is part of the CircUse project.

Action B: Day by day activities of the agency: Building up of database and website as well as the production of PR-material is still part of the project. All other activities are started during the project and continued by the agency.

Action C: Analysis and actualization of existing concepts: The analysis and actualization of the projects has been started in summer 2012, after the end of the project these activities will part of the agency tasks.

Action D: Project development: Project development as a long term measure has been started in autumn 2012 and after the end of the CircUse project the activities will be continued according to the business plan of the agency.

4.6 Action plan for Piekary

The Action Plan prepared for the selected location is an example of implementing the circular land use management in areas of a typical district of Silesian municipality, a district, where the environmental, social and economic problems have succeeded previous intensive industrial activities (with all their negative consequences). The aim of the Brzeziny Śląskie district Action Plan was to restore the natural value of degraded areas, followed by regional economic development, ensured by provision of favourable conditions enhancing the commencement of the new projects as well as assistance in their implementation. Therefore within the Action Plan of Brzeziny Śląskie district the following categories of activities were included:

- feasibility studies (analyses, examination of the ground contamination, detailed stock-takings of the ground),
- analyses and concept (analyses and concepts of the possible land use management),
- project activity (technical projects relating to communication and territorial development),
- marketing operations (the preparation of offers for potential investors),
- support of investors' activities (advisory),
- investment activities (implementation of the „incubator for the enterprise" project, realization of the pilot project regarding greenfield development),
- activities focusing on social issues and communication.

The action plan was followed up by the pilot investment project. The CircUse Polish pilot project is placed on a highly exposed brownfield site in the Brzeziny district of the Piekary Śląskie Municipality. The size of the pilot area is approximately 14 ha and this Polish investment was planned in the framework of the CircUse project.

Picture 1: Ilustration of preparation work for planting at the Brzeziny district pilot project, photo by authors

The Brzeziny district pilot project has focused on a systematic "re-greening" of a part of the post- industrial site and on upgrading of an overall image of the local landscape. The pilot project was set up to demonstrate the innovative example of a possible remediation action, which as an added value has a sustainable financial support for its future maintenance.This is an example that can be easily transferred to other regions, in other countries. The strategy of the land use management within which the investment was implemented also demonstrates an innovative long term thinking of the circular land use, which is the key idea promoted by the CircUse project. This pilot investment is consisting of planting trees and shrubs on the site located in-between an industrial area and a residential area. But two separate functions are being realized by this one action on the pilot area. On one side an insulation zone is being created, shading the neighbouring housing from the industrial site and on the other side a tree belt of public space is being created – a kind of park – which could serve for leisure and recreation activities of the neighbourhood. On the picture 1 above the results of work already done are presented.

5 CONCLUSION

The work on action plans following the framework discussed and adapted by all the project partners has shown the reality of a concept implementation with participation of various groups of stakeholders. It has been the most difficult step but at the same time the most satisfying when the agrrement was achieved. This experience is very special, since the CircUse project has given the opportunity and the platform for meeting and discussion betweend various parties on the necessity for firther common stpes and common actions serving for common needs. It has evidenced and convinced that it is worth (simply economically) to act together in land use management which could be more efficient and sustainable. And it is may be the most important unmeasurable value of the CircUse project.

Einkaufsstättenwahl, Einzelhandelscluster und räumliche Versorgungsdisparitäten – Modellierung von Marktgebieten im Einzelhandel unter Berücksichtigung von Agglomerationseffekten

Thomas Wieland

(Dipl.-Geogr. Thomas Wieland, Georg-August-Universität Göttingen, Geographisches Institut, Abteilung Humangeographie, Goldschmidtstraße 5, D-37077 Göttingen, twielan@gwdg.de)

1 KURZFASSUNG

Die Bildung von Agglomerationen branchengleicher und -ungleicher Einzelhandelsanbieter zum Zweck der Ermöglichung von Kopplungs- und Vergleichskäufen für die Kunden ist ein allseits zu beobachtendes Phänomen, das auch in den einschlägigen Standorttheorien behandelt wird. Gleichzeitig wird Einzelhandelsangebot in nicht oder weniger agglomerierten Lagen abgebaut, was zu steigenden räumlichen Disparitäten der Versorgungssituation führt. Dem tatsächlichen Einfluss der Clusterbildung auf das Konsumentenverhalten wurde bisher jedoch nur wenig Beachtung geschenkt. In dieser Untersuchung wurde geprüft, ob die räumliche Konzentration von Anbietern (Lebensmittel-, Bau- und Elektrofachmärkte) einen positiven Effekt auf ihre Marktgebiete hat. Auf der Basis einer Haushaltsbefragung in sieben Gemeinden wurde mittels eines MCI (Multiplicative Competitive Interaction)-Modells der Einfluss räumlicher Nähe von branchengleichen (d.h. konkurrierenden) und -ungleichen Einzelhandelsanbietern auf die Einkaufsstättenwahl empirisch-ökonometrisch getestet; als Messgröße für die räumliche Ballung fungierten hierbei verschiedene Konzentrationsindices. Es konnte nachgewiesen werden, dass sowohl die Nähe zu Konkurrenten als auch zu anderen Anbietern in den meisten Fällen die Einkaufsstättenwahl und somit den Kundenzufluss aus dem Marktgebiet positiv beeinflussen. Neben dem empirischen Beleg für diesen Effekt ist es ferner möglich gewesen, durch die Nutzung der geographisch gewichteten Regression als Schätzmethode räumlich differenzierte Modellparameter zu ermitteln. Da das empirisch parametrisierte MCI-Modell in das häufig genutzte Marktgebietsmodell von Huff überführbar ist, konnte so ein Ansatz zur Simulation von Kunden- bzw. Kaufkraftströmen unter Berücksichtigung von Agglomerationseffekten entwickelt werden, der z.B. als Planungstool in Einzelhandelsgutachten zum Einsatz kommen kann.

2 HINTERGRUND

2.1 Theoretischer Zusammenhang

Das Prinzip der (positiven und negativen) *Agglomerationseffekte* ist auf einige Theorien der neoklassischen Ökonomie zurück zu führen, in deren Fokus die Standortwahl von Industriebetrieben stand. Insbesondere werden hier zu den positiven Agglomerationseffekten *steigende Skalenerträge* (Reduktion der Stückkosten durch Ausweitung der Produktion) als *interne Effekte* und *Lokalisationseffekte* (Räumliche Konzentration gleichartiger Betriebe z.B. aufgrund von *Labor pooling*) bzw. *Urbanisationseffekte* (Räumliche Konzentration verschiedenartiger Betriebe z.B. aufgrund einer diversifizierten Infrastrukturausstattung) als *externe Effekte* gezählt. Der betriebswirtschaftliche Nutzen einer räumlichen Ballung (*Clusterbildung*) von Einzelhandelsbetrieben ist hingegen maßgeblich dadurch bedingt, dass solche Standortkonfigurationen den Konsumenten *Kopplungs- und Vergleichskäufe* ermöglichen und somit deren *Einkaufsstättenwahl* vorteilhaft beeinflussen. Diese *Agglomerationsvorteile* im Einzelhandel sind in verschiedenen Raumwirtschafts- und Standorttheorien behandelt worden (Parr, 2002; Mulligan et al., 2012).

Demnach bevorzugen Konsumenten Standorte mit mehreren gleichartigen und verschiedenartigen Anbietern gegenüber Einzelstandorten, um einerseits mehrere Besorgungen miteinander zu koppeln (zwecks Zeit- und Transportkostenersparnis) und andererseits Preis- und Qualitätsvergleiche zwischen den Anbietern durchführen zu können. Hierfür sind sie durchaus bereit, weitere Wege als bis zum nächstgelegenen Angebotsstandort auf sich zu nehmen, da die Möglichkeit der Kopplungs- und Vergleichskäufe diesen Mehraufwand ausgleicht (Popkowski Leszczyc et al., 2004; Kulke, 2005). Sowohl für verschiedenartige als auch für konkurrierende Betriebe besteht deshalb ein Anreiz zur Bildung von Agglomerationen, da sich die Nähe zu anderen Anbietern gegenüber nicht-agglomerierten Betrieben positiv auf den Kundenzufluss und die Umsätze auswirkt. Einzelhandelsanbieter ballen sich daher in *gewachsenen* (Innerstädtische Geschäftsbereiche, dezentrale Agglomerationen mit guter PKW-Erreichbarkeit) oder *künstlich geschaffenen* Einzelhandelsagglomerationen (Shopping-Center), deren Branchenmix und Außenauftritt zentral gesteuert werden (Teller, 2008; Mulligan et al., 2012).

Die ersten Überlegungen zu Einzelhandelsagglomerationen stammen aus der Mikroökonomie. Hotelling (1929) leitete aus dem von ihm formulierten *Prinzip der minimalen Unterscheidung* ab, dass für zwei branchengleiche Anbieter ein Standort unmittelbar neben dem Konkurrenten die optimale Lage im Hinblick auf die Kundenabschöpfung darstellt und nicht, wie es das traditionelle Marktmodell nahelegt, die maximale Konkurrenzmeidung. Auch Chamberlin (1933) erklärt in seiner *Theorie des monopolistischen Wettbewerbs* die räumliche Ballung von Einzelhändlern aus der Überlegung von Kopplungs- und Vergleichskäufen.

Das Grundmodell der *Theorie der zentralen Orte* von Christaller (1933) geht vereinfachend davon aus, dass Konsumenten immer nur *ein* Gut auf einer Einkaufsfahrt erwerben und den nächstgelegenen Standort aufsuchen (*Nearest-Center-Bindung*). Die dynamische Weiterführung der Theorie berücksichtigt hingegen Kopplungskäufe, deren Effekt die räumliche Ballung unterschiedlicher Anbieter ist, während kleinere Angebotsstandorte an Zentralität verlieren. Diese Überlegung wird von Lange (1973) in seiner *Wachstumstheorie zentralörtlicher Systeme* weiter verfolgt, mit der er die parallel stattfindenden Wachstums-, Stagnations- und Schrumpfungsprozesse in einem System unterschiedlich ausgebauter Angebotsstandorte erklärt. Ausgehend von wachsenden Einkommen, höherer Mobilität und steigenden Konsumentenansprüchen bei gleichzeitig geringer werdendem Zeitbudget folgert er eine zunehmende Notwendigkeit der Kopplung von Besorgungen. Konsumenten würden demnach Angebotsstandorte mit vielen Kopplungsmöglichkeiten bevorzugen, was sich in Kombination mit darauf abgestimmtem Anbieterverhalten, ähnlich wie bei Christaller, in einer Angebotskonzentration und räumlichen Versorgungsdisparitäten niederschlägt. Auch einige andere Weiterentwicklungen der Zentrale-Orte-Theorie stellen Kopplungskäufe in den Mittelpunkt der Ausführungen (z.B. Ghosh, 1986).

Nelson (1958) formulierte basierend auf empirischen Studien mehrere Gesetzmäßigkeiten zur positiven Agglomerationswirkung im Einzelhandel; demnach setzt sich der betriebswirtschaftliche Erfolg eines Einzelhandelsanbieters aus seiner eigenen Anziehungskraft (*Generative business*), der Anziehungskraft benachbarter Anbieter am Standort (*Shared business*) und der Nähe zu externen Frequenzbringern (*Suscipient business*) zusammen. In Bezug auf den „Shared business" betont Nelson die *Komplementarität* zwischen bestimmten Sortimentsbereichen, die bevorzugt miteinander gekoppelt werden (*Kompatibilitätsvorteile*), und die *Konkurrenzanziehung* mehrerer branchengleicher Anbieter in einer Agglomeration (*Kumulationsvorteile*), die aufgrund der Möglichkeit von Vergleichskäufen insbesondere bei Gütern des langfristigen Bedarfs mit einem hohen Kundenanspruch hinsichtlich der Auswahl auftritt. Nelson erarbeitete hierzu eine Formel zur Schätzung der Umsatzsteigerung zweier benachbarter Anbieter aufgrund des Kundenaustauschs (*Rule of retail compatibility*) sowie umfangreiche Kompatibilitätsmatrizen.

Durch das Aufkommen der *New Economic Geography (NEG)* sind Fragen der Agglomeration von Unternehmen und der damit zusammenhängenden (möglichen) Zunahme räumlicher Disparitäten wieder in den Fokus gerückt; in der Folge werden auch „alte" Raumwirtschaftstheorien (z.B. Christaller) wieder mehr diskutiert (Fujita, 2010; Mulligan et al., 2012). Einige NEG-Modelle beziehen sich explizit auf den tertiären Sektor (Fujita/Thisse, 2002) oder lassen sich darauf übertragen, wenngleich hierbei keine Zusammenhänge aufgearbeitet werden, die nicht bereits in den Zentralitätstheorien integriert waren (Güßefeldt, 2003).

2.2 Modellierung von Marktgebieten im Einzelhandel

Im Rahmen der betrieblichen Standortplanung sowie der Analyse möglicher Auswirkungen von Einzelhandelsansiedlungen existiert eine große Fülle von Methoden zur Modellierung und Prognose von Marktgebieten und Umsatzflüssen (Müller-Hagedorn/Natter, 2011). Eine besonders prominente Methode zur Simulation von Kunden- bzw. Kaufkraftströmen ist das Marktgebietsmodell von Huff (1962; 1963; 1964), das zur Familie der gravitationstheoretischen Interaktionsmodelle zählt.

Das Grundmodell basiert auf einer multiplikativen Nutzenfunktion (U_{ij}) mit zwei Einflussgrößen (Formel 1), wobei die erste die Eigenattraktivität eines Angebotsstandortes (A_j) darstellt und die zweite, als interaktionshemmende Kraft, die räumliche Distanz zwischen Nachfragern und Anbietern (d_{ij}). Als Attraktivitätsindikator fungiert die Verkaufsfläche des Angebotsstandortes, was damit begründet wird, dass die Verbraucher ihre Einkaufsstättenwahl unter Unsicherheit treffen, da sie nie genau wissen, ob sie die gewünschten Güter am Standort auch wirklich bekommen; je größer das Angebot (also die Verkaufsfläche), desto höher die Wahrscheinlichkeit, dass die Bedürfnisse am Angebotsstandort befriedigt werden. Die Verkaufsfläche repräsentiert demnach die Auswahl bzw. die internen Kopplungsmöglichkeiten. Die Distanz wirkt überlinear negativ (λ ist betragsmäßig größer eins), da angenommen wurde, dass die Konsumenten

Entfernungen überproportional wahrnehmen. Das im Huff-Modell unterstellte Konsumentenverhalten ist also *nutzenmaximierend* unter der Bedingung *unvollständiger Information* (Huff, 1962; 1963).

Für die Analyse mittels Huff-Modell wird das gesamte Marktgebiet in einzelne Nachfragestandorte aufgeteilt. Die Attraktivitäts- und Distanzwerte für alle Kombinationen von Angebots- und Nachfragestandorten werden in einer *Interaktionsmatrix* abgetragen. Zielgröße des Modells ist die *Wahrscheinlichkeit*, dass die Kunden aus den einzelnen Gebieten den jeweiligen Angebotsstandort anlaufen (p_{ij}). Sie errechnet sich aus dem Nutzen der Alternative *j* für die Kunden am Nachfragestandort *i*, dividiert durch den Nutzen aller Standorte (Formel 2); diese Wahrscheinlichkeiten können als *Marktanteile* interpretiert und mit dem lokalen Kunden-/Kaufkraftpotenzial (C_{ij}) verrechnet werden (Formel 3). Im Ergebnis werden die Kunden- bzw. Kaufkraftzuflüsse aus den Teilgebieten ($E(C_{ij})$) zu einem gesamten Kunden- bzw. Umsatzpotenzial summiert.

(1) $\quad U_{ij} = A_j \, d_{ij}^{-\lambda}$

(2) $\quad p_{ij} = U_{ij} / \sum U_{ij}$

(3) $\quad E(C_{ij}) = p_{ij} C_i$

Das Huff-Modell wird im Rahmen der Expansion von Einzelhandelsunternehmen für die Standortplanung eingesetzt (Clarke, 1999); eine weitaus größere Relevanz hat es aber in raumordnerischen Wirkungsprognosen, die in Einzelhandelsgutachten zum Zweck der Abschätzung von Umsatzumlenkungen bei Einzelhandelsneuansiedlungen bzw. der Erweiterung bestehender Anbieter durchgeführt werden. Diese Untersuchungen, deren Notwendigkeit aus der vermuteten negativen raumordnerischen und städtebaulichen Auswirkung von (großflächigen) Ansiedlungen (BauNVO § 11) abgeleitet wird, stehen aufgrund ihrer Intransparenz und inhaltlicher Ungenauigkeiten immer wieder in der Kritik (Wolf, 2012).

Huffs Ansatz ist Gegenstand unzähliger Weiterentwicklungen gewesen (Müller-Hagedorn/Natter, 2011). Als maßgebliche Erweiterung im Hinblick auf die Analyse des Konsumentenverhaltens ist das *Multiplicative Competitive Interaction (MCI)-Modell* von Nakanishi/Cooper (1974) zu nennen, dessen Prinzip es ist, das Huff-Modell durch eine Linearisierung in ein ökonometrisches Modell zu transferieren und hierbei noch weitere Erklärungsvariablen zu berücksichtigen. Auf dem selben Prinzip basiert die Modellierung von Einkaufsentscheidungen mittels *Multinomialer Logitmodelle (MNL)*; hierbei wird durch logistische Regression die Wahl einer Alternative in Form einer qualitativen Variable auf individueller Ebene modelliert (Sullivan/Adcock, 2002; Lademann, 2007). Recht neu ist die Modellierung des räumlichen Einkaufsverhaltens unter Nutzung von *Multiagentensystemen*, denen umfangreiche empirische Daten zum individuellen Einkaufsverhalten zugrunde gelegt werden (Rauh et al., 2012).

2.3 Berücksichtigung und empirischer Nachweis von Agglomerationseffekten

Dass Einkaufsfahrten häufig Mehrzweckfahrten sind und am Point of sale mehrere Geschäfte besucht bzw. Besorgungen miteinander verbunden werden, ist umfangreich empirisch nachgewiesen. Tendenziell wird auch eine Steigerung der Relevanz dieses Einkaufsverhaltens diagnostiziert, hervorgehend aus höheren Kundenansprüchen einerseits und einem geringer werdenden Zeitbudget andererseits (Heinritz/Theis, 1997; Popkowski Leszczyc et al., 2004; Arentze et al., 2005; Kulke, 2005; Brooks et al., 2008).

Die Ballung gleich- und ungleichartiger Einzelhändler lässt sich am deutlichsten in Shopping-Centern aufzeigen, deren Prinzip ein strategisch optimierter Angebotsmix zum Zweck einer kumulierten Anziehungskraft ist. Agglomerationsvorteile werden hier sowohl von Geschäftstreibenden als auch von Kunden deutlich erkannt und durch ein zentrales Management bewusst gesteuert (Hesse/Schmid, 2007; Teller, 2008; Schnedlitz/Teller, 2008). Mitunter lassen sich auch für Standorte in der Umgebung von Shopping-Centern positive Wirkungen dieser räumlichen Nähe feststellen (Hardin et al., 2002; Lademann, 2011). Die Bildung von Angebotsclustern ist aber auch abseits geplanter Agglomerationen zu beobachten; einige Einzelhandelsunternehmen suchen im Rahmen ihrer Expansion sogar explizit nach Standorten in unmittelbarer Nähe zu Konkurrenten (Wieland, 2011; Jürgens, 2012; Krider/Putler, 2013).

Der Ballung von Angebot steht ein deutlich erkennbarer Abbau von Betrieben in nicht oder weniger agglomerierten Lagen gegenüber, wie sich zum Beispiel anhand der räumlichen Verteilung von leerstehenden Geschäftsflächen zeigt (Popien, 1989). Abseits der vorwiegend in Bezug auf Innenstädte

diskutierten Leerstandsproblematik sind Disparitäten der Angebotsausstattung vor allem für die flächendeckende Nahversorgung ein großes Problem (Baumgarten/Zehner, 2007; Wieland, 2011).

Bisher wenig berücksichtigt wurde allerdings der tatsächliche Einfluss räumlicher Ballung auf die Einkaufsstättenwahl von Konsumenten und die Integration dieses Effektes in gängige Marktgebietsmodelle; auch das ursprüngliche Huff-Modell geht implizit von einer Einzweckeinkaufsfahrt aus (Huff/Batsell, 1975). Einzig das *Competing Destinations Model* von Fotheringham (1985) berücksichtigt die räumliche Konzentration eines Anbieters als Größe in einem erweiterten Huff-Modell; ein diesbezüglicher Effekt auf das Konsumentenverhalten wird allerdings nicht empirisch erwiesen, sondern als Teil des mathematischen Modells formuliert. Hingegen sind in verschiedenen empirischen Studien mit MNL-Modellen bereits Kopplungseffekte bzw. Agglomerationsvorteile untersucht worden (Popkowski Leczcycz et al., 2004; Arentze et al., 2005; Gijsbrechts et al., 2008), ebenso in Multiagentensimulationen zur Einkaufsstättenwahl (Rauh et al., 2012) oder zum Kopplungsverhalten in Shopping-Centern (Hesse/Schmid, 2007).

3 UNTERSUCHUNGSGEGENSTAND UND METHODIK

3.1 Fragestellungen und Hypothesen

Theorie und Empirie legen nahe, dass Agglomerationsvorteile im Einzelhandel eine sehr große Rolle bei der Standortwahl von Betrieben und der Einkaufsstättenwahl von Konsumenten spielen. Es galt nun, einerseits den tatsächlichen Effekt dieser räumlichen Konzentration auf die Einkaufsorientierung empirisch nachzuweisen und andererseits diese Einflussgrößen in ein Huff-basiertes Modell zu integrieren, das beispielsweise als Planungstool in Einzelhandelsgutachten zur Geltung kommen kann.

Da sowohl für die räumliche Nähe zu andersartigen als auch zu gleichartigen, also konkurrierenden, Anbietern ein positiver Effekt unterstellt wird, musste beides separat geprüft werden. Die erste Hypothese lautet demnach, dass Einzelhandelsanbieter generell von der räumlichen Nähe zu anderen Anbietern im Hinblick auf ihren Kundenzufluss profitieren, da hierdurch Kopplungskäufe ermöglicht werden. Die zweite Hypothese bezieht sich auf die Konkurrenzanziehung: Demnach profitieren Einzelhändler auch von der räumlichen Nähe zu ihren Konkurrenten, da auf diese Weise den Konsumenten die Möglichkeit einer größeren Auswahl bzw. zu Preis- und Qualitätsvergleichen gegeben wird. Es ist also in beiden Fällen von einem positiven Einfluss auf die Einkaufsstättenwahl auszugehen.

Im ursprünglichen Huff-Modell sind die Eigenanziehungskraft der Anbieter sowie die Distanz zwischen Kundenwohnort und Angebotsstandort als Erklärungsgrößen herangezogen worden; bei einer empirischen Analyse der Marktgebiete müssen sie dementsprechend berücksichtigt werden bzw. als Kontrollvariablen fungieren. Ausgehend von früheren theoretischen und empirischen Arbeiten (Huff, 1962; Lademann, 2007; Kubis/Hartmann, 2007) ist bei der Verkaufsfläche von einer unterlinear positiven, bei der Distanz von einer überlinear negativen Wirkung auszugehen.

3.2 Untersuchungsgebiet und Analysemethodik

Das Untersuchungsgebiet liegt im Grenzbereich von Nordrhein-Westfalen und Niedersachsen (Deutschland) und besteht aus den drei mittelzentralen Gemeinden Höxter (29.941 Einwohner, 13 Ortsteile), Beverungen (13.811 EW, 12 Ortsteile) und Holzminden (19.835 EW, 4 Ortsteile) sowie der Samtgemeinde Boffzen (6.947 EW) mit vier Gemeinden, davon zwei mit dem Rang eines Grundzentrums. Zum Zweck der Erfassung der Ausgangssituation im Untersuchungsgebiet sind zunächst Expertengespräche (Verwaltung, Einzelhandel, Stadtmarketing) geführt worden. Im Anschluss erfolgte eine GPS-gestützte Erhebung (Kartierung) des gesamten Einzelhandelsbestandes im Untersuchungsgebiet (Finaler Stand: März 2012).

Kern der Untersuchung ist eine telefonische Haushaltsbefragung im Januar/Februar 2012 zur räumlichen Einkaufsorientierung der Befragten bei Lebensmittelmärkten, Elektrofachmärkten, Baumärkten und Möbelmärkten. Das Ziel der Haushaltsbefragung ist vor allem die Erfassung von lokalen Marktanteilen der relevanten Anbieter auf der Ebene der Ortsteile bzw. der daraus aggregierten 19 Teilgebiete gewesen. Die empirisch ermittelten Marktgebiete waren die Grundlage für eine ökonometrische Analyse mit Hilfe des Multiplicative Competitive Interaction-Modells (MCI) nach Nakanishi/Cooper (1974).

Diese lineare Transformation des Huff-Modells ermöglicht die regressionsanalytische Prüfung des Einflusses verschiedener Größen auf empirische Marktanteile bzw. die Schätzung von Gewichtungsparametern und

deren Überführung ins Huff-Modell; es handelt sich beim MCI-Modell also nicht nur um eine Generalisierung des Huff-Modells im Sinne einer Erweiterung der multiplikativen Nutzenfunktion (Formel 1) auf eine Vielzahl von Variablen, sondern vor allem um die Umwandlung einer theoretischen mathematischen Gleichung in ein ökonometrisches Modell, das sich mittels üblicher multipler linearer Regressionsanalyse parametrisieren lässt. Die Schätzung setzt eine Standardisierung mittels geometrischer Mittelwerte und eine Logarithmierung aller Variablen voraus (Formel 4). Eine Rückübertragung der geschätzten Parameter ins Huff-Modell ist entweder über die konventionelle Huff-Formel (Formel 2) oder über eine Exponentialfunktion möglich (Kubis/Hartmann, 2007; Huff/McCallum, 2008).

$$(4) \quad \log(p_{ij}/\tilde{p}_i) = \sum_{h=1}^{H} \gamma_h \log(A_{h_j}/\tilde{A}_{h_j}) + \lambda \log(d_{ij}/\tilde{d}_i)$$

Da es zu überprüfen galt, ob die räumliche Ballung von Anbietern einen positiven Einfluss auf ihre Marktgebiete hat, war es notwendig, diese zu operationalisieren. Hierzu gibt es verschiedene Möglichkeiten der Bildung von Konzentrations- bzw. Zentralitätsindices (Orpana/Lampinen, 2003). In diesem Fall wurden Konzentrationsindices für die Ballung mit konkurrierenden Anbietern (Formel 5) und für die räumliche Nähe zu allen Anbietern (Formel 6) gebildet, um in beiden Fällen den positiven Effekt separat prüfen zu können. Sie errechnen sich, in Anlehnung an Fotheringham (1985), aus der Summe der Attraktivitätswerte (Verkaufsflächen) der anderen Anbieter (A_k bzw. A_a) und der (gewichteten) Distanz zu diesen (d_{jk} bzw. d_{ja}).

$$(5) \quad K_{K_j} = \sum A_k / d_{jk}^{\lambda}$$

$$(6) \quad K_{A_j} = \sum A_a / d_{ja}^{\lambda}$$

Die erhobenen lokalen Marktanteile (p_{ij}) dienen im MCI-Modell als abhängige (d.h. zu erklärende) Variable. Als Prädiktoren (erklärende Variablen) fungieren im vorliegenden Modell die beiden genannten Konzentrationsindices (K_{A_j}, K_{K_j}) sowie die Verkaufsfläche des Anbieters als Attraktivitätsmaß (A_j) und die PKW-Fahrtzeit zwischen Konsumentenwohnort und Angebotsstandort (d_{ij}). Die für die Berechnung benötigten Distanzwerte sind mit Hilfe eines geometrischen Netzwerks im GIS auf der Basis eines realen Straßennetzes und Durchschnittsgeschwindigkeiten berechnet worden. Die Standorte, Verkaufsflächen und Branchen sämtlicher Einzelhandelsbetriebe wurden im Zuge der Kartierung erhoben.

Das MCI-Modell wurde zunächst mittels konventioneller linearer Regression parametrisiert; in Anlehnung an Huff/McCallum (2008) wurde hierbei das Verfahren der *schrittweisen Regression* benutzt. Danach erfolgte eine Analyse mit Hilfe der *geographisch gewichteten Regression* (*Geographically weighted regression, GWR*). Diese Methode beruht auf der Annahme, dass empirisch messbare Zusammenhänge nicht räumlich konstant wirken, sondern Unterschiede im Hinblick auf die Stärke ihrer Beziehung aufweisen; demnach werden räumliche Objekte, die nah beieinander liegen, stärker gewichtet als weiter entfernte. Im Ergebnis werden für jedes Geoobjekt (hier: Nachfragestandorte) separat Parameter geschätzt und Modellgütestatistiken ausgewiesen (Fotheringham et al., 2002). Dieses Vorgehen ermöglicht eine belastbare Prüfung des Einflusses der Prädiktoren sowie die Ermittlung räumlich differenzierter Modellparameter.

4 ERGEBNISSE

4.1 Untersuchungsrelevanter Einzelhandel und räumliche Einkaufsorientierung

Für die Analyse der räumlichen Einkaufsorientierung sind 27 Lebensmittelmärkte (insg. 31.086 qm Verkaufsfläche), fünf Elektrofachmärkte (6.900 qm), vier Baumärkte (20.735 qm) sowie zehn Möbelmärkte (16.575 qm) relevant. Alle drei Angebotsformen sind vorwiegend in großen Fachmarktagglomerationen in den Mittelzentren lokalisiert, die Lebensmittelmärkte finden sich aber teilweise auch in kleineren Standortgemeinschaften (z.B. Verbrauchermarkt und Discounter) und vereinzelt in Solitärlagen.

Abgesehen davon zeigt die Auswertung der Einzelhandelskartierung bereits eine, je nach Branche unterschiedlich starke, räumliche Angebotskonzentration auf; auch der Vergleich mit früheren Angeboterhebungen belegt, dass im Zeitverlauf bereits viele Einzelhandelsbetriebe an nicht oder weniger

agglomerierten Standorten weggebrochen sind (z.B. nahversorgungsrelevante Anbieter in Dorfzentren), während einzelne Agglomerationen (insb. in dezentralen Gewerbegebieten) deutlich angewachsen sind.

Im Rahmen der Haushaltsbefragung wurden 412 Personen interviewt und insgesamt 4.026 Einkaufsfahrten erfasst (Lebensmittelmärkte: 1.235, Baumärkte: 1.011, Elektrofachmärkte: 1.059, Möbelmärkte: 721). Abgesehen von den Möbeleinkäufen beschränken sich die erfassten Einkaufsfahrten fast ausschließlich auf die relevanten Anbieter im Untersuchungsgebiet, weswegen die Möbeleinkäufe auch von der weiteren Analyse ausgenommen wurden.

Abb. 1 zeigt beispielhaft die lokalen Marktanteile der Elektrofachmärkte auf der Ebene der Ortsteile bzw. der daraus aggregierten Gebiete (z.B. „Beverungen-Südost"). Deutlich zu erkennen ist vor allem eine starke Orientierung der Nachfrager im gesamten Gebiet auf zwei in einem Gewerbegebiet benachbarte Anbieter im nördlich gelegenen Mittelzentrum Holzminden („Expert", „Media Markt").

4.2 MCI-Modellergebnisse

Das linearisierte MCI-Modell (Formel 4) ist ein konventionelles multiples lineares Regressionsmodell und lässt sich dementsprechend mit Hilfe der Methode der kleinsten Quadrate schätzen und auf dieser Grundlage interpretieren; aus inhaltlichen Gründen enthält das MCI-Modell jedoch keine Konstante. Die Prädiktoren sind in vorliegendem Fall die Fahrtzeit zwischen Konsumentenwohnort und Anbieterstandort in Minuten (d_{ij}), die Verkaufsfläche der Anbieter (A_j), der allgemeine Konzentrationsindex für die räumliche Ballung mit allen anderen Einzelhandelsanbietern (K_{Aj}) sowie der Konzentrationsindex für die räumliche Nähe zu konkurrierenden Anbietern (K_{Kj}). Die abhängige Variable ist der lokale Marktanteil des jeweiligen Anbieters (p_{ij}). Alle Variablen sind gemäß der Vorgaben des MCI-Modells durch den geometrischen Mittelwert normiert und logarithmiert (Formel 7).

$$(7) \quad \log(p_{ij} / \tilde{p}_i) = b_1 \log(d_{ij} / \tilde{d}_i) + b_2 \log(A_j / \tilde{A}_j) + b_3(K_{A_j} / \tilde{K}_{A_j}) + b_4 \log(K_{K_j} / \tilde{K}_{K_j})$$

In Tabelle 1 sind für die drei Marktgebietsmodelle (Lebensmittelmärkte, Baumärkte, Elektrofachmärkte) jeweils die unstandardisierten Koeffizienten (*b*), die standardisierten Koeffizienten (*β*), das Signifikanzniveau und die Bestimmtheitsmaße (R^2, Korrigiertes R^2) als Modellgütekriterien angegeben. Bei den Modellen handelt es sich immer um den letzten (d.h. vierten) Schritt der schrittweisen Regression.

Modell	(1) Lebensmittelmärkte			(2) Baumärkte			(3) Elektrofachmärkte		
Prädiktoren	b	β	Sig.	b	β	Sig.	b	β	Sig.
Log $(d_{ij}/GM\ d_i)$	-1,747	-0,781	***	-2,100	-0,620	***	-1,632	-0,603	***
Log $(A_j/GM\ A_j)$	0,658	0,330	***	1,368	0,659	***	0,951	0,720	***
Log $(K_{Aj}/GM\ K_{Aj})$	-0,090	-0,104	**	0,259	0,188	***	0,336	0,275	***
Log $(K_{Kj}/GM\ K_{Kj})$	0,083	0,176	***	-0,173	-0,156	**	0,101	0,211	***
R^2	0,596			0,800			0,770		
Korr. R^2	0,590			0,789			0,760		

Abhängige Variable: Log $(p_{ij}/GM\ p_i)$ 　　　　　　　　　　GM = Geometrischer Mittelwert

*** = 99 %-Signifikanzniveau, ** = 95 %-Signifikanzniveau

Tabelle 1: Modellschätzer und Modellgüte der MCI-Modelle (Quelle: Eigene Erhebungen und Berechnungen)

In allen drei Modellen beeinflussen die vier Prädiktoren die zu erklärende Variable in statistisch signifikanter Weise; in den meisten Fällen wird ein Signifikanzniveau von 99 % erreicht, ansonsten das 95 %-Niveau. Die Bestimmtheitsmaße zur Messung der Modellgüte (R^2, Korrigiertes R^2) sind zumindest im zweiten (Baumärkte) und dritten Modell (Elektrofachmärkte) außerordentlich hoch, wohingegen die Varianzaufklärung im ersten Modell (Lebensmittelmärkte) noch ausbaufähig ist.

Die Distanz wirkt in allen Fällen weit überlinear negativ, wie die unstandardisierten Regressionskoeffizienten (*b*) zeigen; am stärksten ausgeprägt ist die interaktionshemmende Distanzwirkung bei den Baumärkten, am schwächsten wirkt sie bei den Elektrofachmärkten. Die standardisierten Koeffizienten (*β*) belegen, dass die Distanz im Fall der Lebensmittelmärkte die mit Abstand einflussreichste Größe darstellt, im Fall der Bau- und Elektrofachmärkte die zweitgrößte. Die Eigenattraktivität (Verkaufsfläche) hat bei den Lebensmittelmärkten einen vergleichsweise schwachen, weit unterlinearen Effekt, wohingegen sie bei den Fachmärkten eine größere Rolle einnimmt; im Fall der Baumärkte wirkt sie überlinear, bei den Elektrofachmärkten leicht unterlinear positiv.

Die Konzentrationsindices wirken sich in den meisten Fällen positiv aus: Im Modell für die Marktgebiete der Elektrofachmärkte haben sowohl die räumliche Ballung mit konkurrierenden als auch mit anderen Betrieben einen positiven Einfluss auf den Marktanteil. Im Fall der Baumärkte ist der Parameter für die Konkurrenznähe negativ, der für die Nähe zu branchenungleichen Anbietern aber positiv. Bei den Lebensmittelmärkten ist das Gegenteil der Fall: hier wirkt die Konkurrenznähe positiv, die Nähe zu anderen Anbietern hingegen noch knapp auf dem 95 %-Signifikanzniveau negativ.

In allen drei Modellen hat die schrittweise durchgeführte Regression aufgezeigt, dass signifikante Modellverbesserungen durch die Hinzunahme der Konzentrationsvariablen erreicht wurden. Die statistisch gemessenen Effekte dieser Erklärungsgrößen sind jedoch deutlich geringer als die der Distanz und der Eigenanziehungskraft.

4.3 GWR-Modellergebnisse für die Marktgebiete der Elektrofachmärkte

Exemplarisch für die Modellierung mit Hilfe der geographisch gewichteten Regression werden die Modellergebnisse für die Elektrofachmärkte dargestellt. Es zeigt sich hierbei, dass alle vier Parameter zwischen den einzelnen Teilgebieten deutlich variieren (siehe Abb. 2). Beispielsweise schwankt der positive Gewichtungsparameter der Verkaufsfläche zwischen 0,89 im südlichen Marktgebiet und 0,99 im nördlichen Teil; die negative Wirkung der Distanz variiert zwischen -1,65 und -1,52. Vergleichbar verhält es sich mit den Konzentrationsindices, die zwischen 0,30 und 0,36 bzw. 0,07 und 0,11 schwanken. Vor dem Hintergrund der Tatsache, dass diese ermittelten Parameter in den Modellen vom Huff-Typ als Exponenten eingehen, ist dieser Unterschied sehr gravierend.

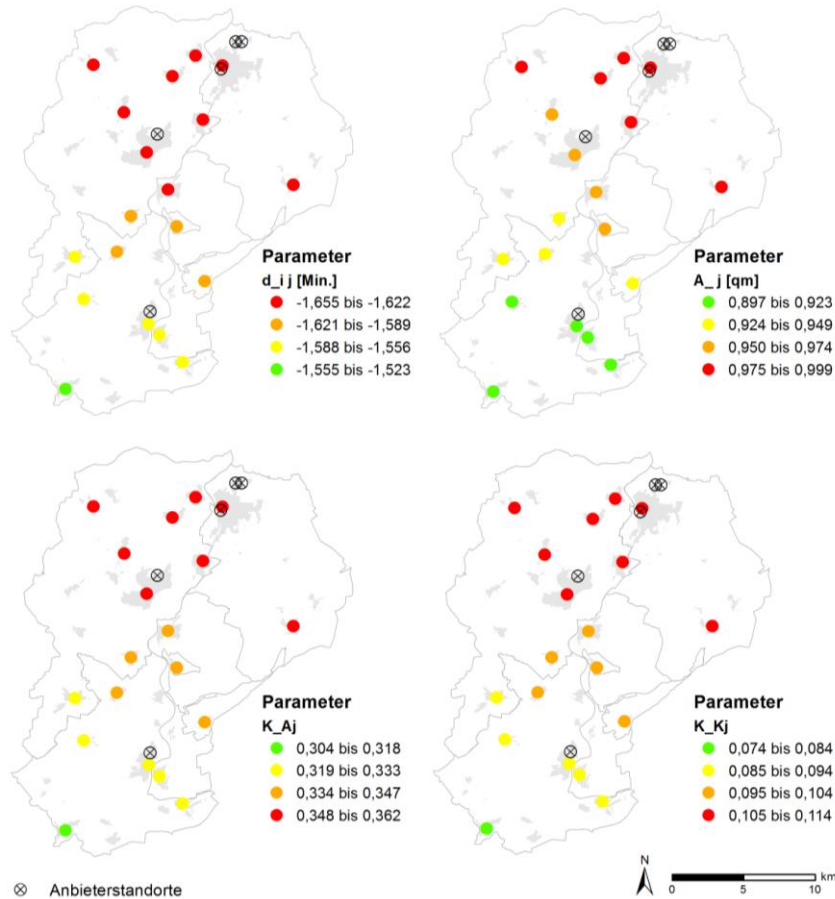
Es fällt hierbei ein Zusammenhang zwischen der Größe der Modellparameter und der Lage der Anbieterstandorte auf: Alle Parameter haben ihre stärksten Ausprägungen im nördlichen Teil des Untersuchungsgebietes. Sowohl die Attraktivität und die Distanz als auch die Konzentrationseffekte wirken hier, im Umfeld der Kernstädte von Höxter und Holzminden, in denen vier der fünf relevanten Anbieter angesiedelt sind, am stärksten. Die jeweils geringsten Werte sind in den eher abgelegenen Ortsteilen im südlichen Teil Höxters und Beverungens zu finden.


Abb. 2: Räumliche Variation der Modellparameter im GWR-Modell für die Elektrofachmärkte, klassifiziert in gleichen Abständen (Quelle: Eigene Darstellung, Datengrundlagen: OpenStreetMap, Eigene Erhebungen und Berechnungen)

5 DISKUSSION

Die MCI-Modellergebnisse zeigen auf, dass in allen Fällen (Lebensmittel-, Bau-, Elektrofachmärkte) die Berücksichtigung räumlicher Angebotskonzentration zu einem höheren Erklärungsgehalt der Modelle führt. Daraus folgt, dass diese Größen mit an Sicherheit grenzender Wahrscheinlichkeit einen Einfluss auf die konsumentenseitige Einkaufsstättenwahl ausüben; da dieser Einfluss meistens, wenn auch nicht immer, positiv ist, sind die theoretisch hergeleiteten Hypothesen weitgehend zu bestätigen.

Im Fall der Elektrofachmärkte wirken sich sowohl die räumliche Nähe von konkurrierenden als auch von andersartigen bzw. komplementären Anbietern positiv auf den Kundenzufluss aus. Das Prinzip der Konkurrenzanziehung aufgrund der Ermöglichung von Preis- und Qualitätsvergleichen für die Kunden ist hier also nachweisbar. Da es sich bei den dort vorgehaltenen Produkten überwiegend um Güter des längerfristigen Bedarfs handelt, deren Anschaffung mitunter kostspielig ist, ist es nachvollziehbar, dass hier die Möglichkeit von Vergleichen und eine breite Auswahl für die Konsumenten eine große Rolle spielen.

Der positive Effekt von Konkurrenznähe lässt sich ebenso für die Lebensmittelmärkte belegen; diese sind häufig (bewusst) in Standortgemeinschaften lokalisiert und ermöglichen auf diese Weise den Kunden, ihren persönlichen Warenkorb des täglichen Bedarfs je nach individuellen Präferenzen bei beiden Anbietern nacheinander zusammen zu stellen. Die vielfach anzutreffende Kombination aus zwei Betriebsformen (i.d.R. Verbrauchermarkt und Discounter) eröffnet nicht nur den preis- *oder* qualitätsbewussten Kunden ein großes Angebot, sondern auch der wachsenden Zahl von Konsumenten, die preis- *und* qualitätsorientiert einkaufen. Dass kein positiver Effekt für sonstige Kopplungsmöglichkeiten nachgewiesen werden konnte, lässt sich möglicherweise damit interpretieren, dass kleinere Standortgemeinschaften eine schnellere Besorgung ermöglichen und weiteres Angebot (z.B. Bekleidung, Möbel) ohnehin nicht für eine Kopplung beim Lebensmitteleinkauf in Frage kommt. Ergänzendes Angebot durch z.B. Anbieter des Lebensmittelhandwerks (Bäcker, Metzger) ist hingegen im Umfeld von jedem der untersuchten Lebensmittelmärkte verfügbar.

Die Modellergebnisse für die Prädiktoren Verkaufsfläche und Distanz sind höchst plausibel und entsprechen den in der Literatur diskutierten Richtgrößen, wonach die Distanz überlinear negativ, die Verkaufsfläche unterlinear positiv wirkt. Einzig im Fall der Baumärkte wirkt die Verkaufsfläche überlinear positiv, was sich damit erklären lassen könnte, dass in dieser Branche der Wettbewerb um die Kunden tatsächlich maßgeblich über die Angebotstiefe bestimmt wird. Möglicherweise wird dies noch dadurch forciert, dass im Untersuchungsgebiet ein hoch frequentierter „OBI"-Markt präsent ist, der nahezu dreimal so groß ist wie der nächstgrößere Baumarkt. Auch finden sich im Gegensatz zu den anderen Angebotsformen keine branchengleichen Anbieter in unmittelbarer Nachbarschaft, was den negativen Konkurrenzeffekt bei den Baumärkten erklären könnte: Es befinden sich zwar Märkte in der selben Standortgemeinde, jedoch sind sie für eine kumulierte Anziehungskraft zu weit voneinander entfernt.

Allgemein ist die Wirkung der räumlichen Nähe im Vergleich mit der Verkaufsfläche und der Distanz deutlich geringer; dies ist damit zu erklären, dass es sich bei den untersuchten Anbietern fast ausnahmslos selbst um großflächige, filialisierte Betriebe handelt, die ihrerseits als „Magnetbetriebe" anzusehen sind, also eine hohe Eigenanziehungskraft bzw. einen hohen Anteil an „Generative business" besitzen. Eine Ausweitung der Untersuchung auf kleinere Anbieter, die stärker von externer Anziehungskraft abhängig sind („Shared business"), müsste demnach weit höhere positive Effekte der räumlichen Ballung (insb. im Hinblick auf komplementäre Anbieter) erzielen.

Aufschlussreich ist ferner die Schätzung räumlich variierender Modellparameter gewesen. Die Kritik, dass in Marktgebietsmodellen vom Huff-Typ die Nutzenfunktion entgegen plausibler Annahmen überall identisch ist, kann somit konstruktiv beantwortet werden. Interessant ist hierbei, wie die räumlichen Unterschiede diesbezüglich verlaufen, was hier am Beispiel der Elektrofachmärkte illustriert wurde. Dass die Regressionskoeffizienten im Umfeld der größten Angebotsstandorte am höchsten sind, lässt sich damit interpretieren, dass in diesen Teilräumen das konsumentenseitige Anspruchsniveau und somit der Wettbewerbsdruck aufgrund der geringen Entfernung zu mehreren Anbietern besonders hoch ist.

6 FAZIT

Die Untersuchung zeigt einen deutlichen Einfluss der Clusterbildung auf das räumliche Einkaufsverhalten auf. In den meisten Fällen wurde nachgewiesen, dass stark agglomerierte Einzelhandelsanbieter – alle anderen Bedingungen konstant gehalten – tendenziell höhere Kundenzuflüsse generieren können als isolierte oder weniger agglomerierte; dies gilt zumeist sowohl für die räumliche Ballung mit andersartigen als auch mit konkurrierenden Anbietern. Während die Filialisten des Einzelhandels diesen Umstand offensichtlich größtenteils erkannt und für sich nutzbar gemacht haben (was sich teilweise explizit an ihren Standortanforderungen ablesen lässt), berücksichtigen z.B. Verträglichkeitsanalysen in Einzelhandelsgutachten diesen Effekt zumeist nicht. Die vorliegenden Ergebnisse zeigen aber auf, dass Agglomerationseffekte in jedem Fall einkalkuliert werden sollten, wenn es darum geht, negative raumordnerische und städtebauliche Auswirkungen von Einzelhandelsansiedlungen und -erweiterungen (im Sinne einer disparitären Angebotsentwicklung) zu prüfen. Das vorgestellte Marktgebietsmodell, das Agglomerationseffekte und räumlich differenzierte Nutzenfunktionen berücksichtigt, bietet hierfür eine mögliche methodische Grundlage, da es direkt in das häufig genutzte Huff-Modell überführbar ist.

Endangerments on Schools

Sascha Henninger

(Prof. Dr. Sascha Henninger, University of Kaiserslautern, Dept. of Physical Geography, Pfaffenbergstr. 95, 67663 Kaiserslautern, Germany, sascha.henninger@ru.uni-kl.del)

1 ABSTRACT

The project "Endangerments on schools" maintained by the Department of Physical Geography within the Faculty of Regional and Environmental Planning at the University of Kaiserslautern, Germany, analyzed the air quality of elementary school sites primarily not to be viewed as air hygiene loaded places. However, surveys of the traffic situation of the nearby vicinity of diverse schools in the city of Kaiserslautern indicated that these must be regarded as potentially polluted. In many cases, the combination of local emission sources and the locally limited exchange rate of the urban canopy layer proves to be a little-noticed negative factor. Pursuing this fact at the beginning of the project several elementary schools were selected within the city of Kaiserslautern, which could be classified as an urban, suburban or rural location due to its location and to the adjacent building structure. At all school sites meteorological as well as air quality parameters were measured simultaneously to allow a direct comparison of the assessed data. Initial results have shown that some analyzed school sites not only have short-term air pollution exposure, following the concentration peaks of the morning and mid-day traffic of the children. In dependence of the reduced near surface atmospheric exchange, due to the current weather situation and diverse environmental aspects the air quality limits, e.g. for particulate matters (PM10), were exceeded over longer periods. These could verifiably accumulate within the nearby vicinity of the school and even worse, within the schoolyard, respectively.

2 SCIENTIFIC BACKGROUND

2.1 Urban Geometry

What we need is to understand microclimatological modifications within urban areas so that we may affect the spaces to create a better environment from the biometeorological sight. At the same time, understanding and especially being able to predict these microclimates may also help to improve aspects of the performance of the adjacent buildings. If the environmental quality of the outside spaces is enhanced, there will be more opportunity for the people to stay outdoors, with beneficial effects on health (Erell et al. 2011).

Due to the heterogeneity of every urban structure it is useful to describe the fabric of buildings, open and green spaces respectively. Though, it is possible to give a statement that expresses e.g. the density or other physical properties influencing the micro-scale climate. One of the most used models for making such a description is the urban street canyon. This refers to a linear space bounded on both sides by vertical elements (walls of adjacent buildings). All in all the geometry of an urban street canyon could be described by three principal descriptors:

- the aspect ratio (height-width-ration),
- the canyon axis orientation and
- the Sky View Factor (SVF).

- Fig. 1: Upward-looking fish-eye lens photograph for the estimation of the Sky View Factor limited by the urban geometry (left) and making only the apparent sky visible (right).

The Sky View Factor is closely related to the aspect ratio. It is the proportion of the sky dome that is "seen" from a surface, either from a particular point on the surface or integrated over its entire area (s. Fig. 1). The calculation of the SVF is focused to determine the street`s geometry for the analysis of this project. These geometric descriptors of an urban street canyon are correlating in a useful way with a number of climatic effects. Both the aspect ratio and the SVF indicate a direct relationship with the urban heat island effect. One of these influences can be shown by different wind regimes or general patterns of air-flow over the urban surface (Souza et al., 2003; Gal et al., 2007, Erell et al., 2011).

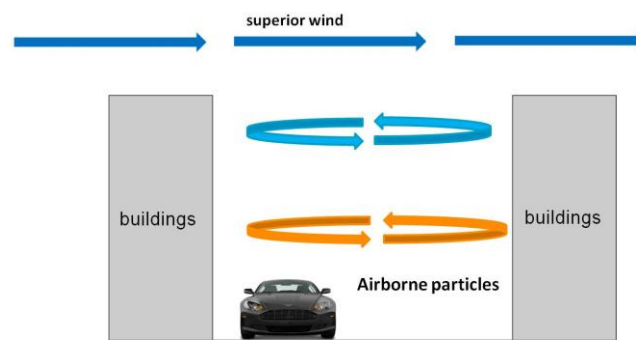
Different numerical models as well as scale-model simulations could show that the skimming flow is always present and that the aspect ratio of the urban street canyon determines the number and strength of the vortices formed within the street. So a single vortex could be formed, with its centre a little downwind within the urban canyon. Another theory suggests that deeper urban street canyons will be able to exhibit two counter-rotating vortices. And this second one definitely could have an influence on the urban air quality near the ground because of less potency in comparison to the upper vortex (s. Fig. 2) (Erell et al., 2011).


Fig. 2: Scheme of an idealized representation of two counter-rotating vortices formed in a deep street canyon by above-roof wind blowing perpendicular to the canyon axis.

Most urban aerosols are anthropogenic in origin. A large proportion of these result from combustion processes (e.g. domestic fuel, industries, traffic), which are typically the main source of particulate matters within urban streets and the urban canopy layer respectively. Several studies show that the particle number concentration at street level is linearly correlated with traffic volume as well as being inversely correlated with wind speed (Henninger, 2011; Errel et al., 2011). So the dispersion of aerosols and pollutants is directed on wind and in particular on turbulence. Depending on the atmospheric stability and the roof geometry clean air may be entrained at roof height and directed downwards into the canyon near the windward wall. At ground level the flow is directed opposite the above-roof wind. Ideally, traffic emissions from the middle of the street are carried to the base of the leeward wall and then sucked upwards by the vortex flow. But if there is the above mentioned second vortex this dispersion is prevented (s. Fig. 2) (Hotchkiss & Harlow, 1973; Yamaritino & Wiegand, 1986; Erell et al., 2011).
Fig. 3: Upward-looking fish-eye lens photograph for the estimation of the Sky View Factor limited by the tree geometry in summer (left) and making only the apparent sky visible (right).

2.2 Permeability of trees

The Sky View Factor could also be estimated for other types of space, whose geometry differs from a linear-type of an urban street canyon (s. Fig. 3). Trees are often employed as shading devices for buildings as well as for pedestrian spaces (Brown & Gillespie, 1995). However, this idealized behavior could not always be

observed in practice for several reasons. One of these is that the branches may still create a substantial obstruction to the sunrays and the tree crown is able to close up broad parts of a street, like it is known by the urban street canyon bounded by the walls of the surrounding buildings (comp. Fig. 1) (Canton et. al, 1994; Erell et al., 2011). Thus, trees have the capacity to filter the air by absorbing a variety of undesirable pollutants. But however, the effect of the trees on air quality within urban streets is not absolutely beneficial (Taha et al., 1997; Erell et al., 2011; Henninger, 2012).

Different wind tunnel studies could confirm results of computer simulations showing that a row of trees planted along city pavements interferes with the formation of the lee vortex. They are responsible for the removal of traffic induced pollutants originating within the street. This results in less dispersion of pollutants and consequently poorer air quality. Again, as it is known for the aspect ratio of street canyons these could be simulated for adjacent trees at street level and lead to the above mentioned second vortex near the ground (s. Fig. 4). It is worth noting that even very porous tree crowns have a big effect on pollutant concentration. Tree crowns should not occupy large street canyon volumes in order not to suppress the ventilating canyon vortex system and the trees height should not exceed the roof level. Otherwise, air exchange is hindered and the concentration of pollutants at street level may rise (Gromke & Rush, 2009; Erell et al., 2011).
Fig. 4: Scheme of an idealized representation of two counter-rotating vortices formed by the densely tree geometry by above-roof wind blowing perpendicular to the street axis.
Fig. 5: How pupils of the investigated school reach the schoolyard; results of an evaluation (n = 291).

3 AIM & METHOD

The research primarily concentrated on the analysis of airborne particles, how they were modified by different times of the day in dependence of the current traffic and how these were influenced by the surrounding buildings and tree geometry. Therefore, exemplarily one investigation area was chosen, which is conspicuous particularly with regard to its temporal traffic density. The so-called area of "Pfaffenberg" is situated in the south-western part of the city of Kaiserslautern, Germany and could be considered as a typical suburban terrain with small single-family houses, blocks of flats and a heterogeneous structure of sealed-up areas in connection with urban green spaces and adjacent forest areas. The measurements were done within and in the nearby vicinity of the elementary school called "Pestalozzi-School". Evaluations of the traffic situation along this street offered that most parents transport their children by car, less pupils are going by bike or schoolbus (s. Fig. 5). So first of all, in consideration of the street system, it is obvious that there is not

enough parking area along the street which leads to "wild parking" and a permanent fight for the best places, resulting in criss-cross parking. This indicates that a high volume of traffic is a directly physical danger to the pupils.

Also visible or smellable respectively was the fact, that most parents did not stop the engine while parking. This resulted in an accumulation of different air pollutants in the exhaust plume. Considering figure 3 and 4 the situation along the street is reflected very well. Especially for the time of spring and summer the densely planted trees cover most parts of the street. A green street canyon arises (s. Fig. 4), which is, depending on the SVF, comparable to an urban street canyon. So furthermore we decided to analyze the local linear emission sources along the "Pfaffenbergstraße". Therefore, air quality measurements as well as the climatological ones were taken by three stations. This methodology made it possible to measure air quality as well as meteorology at three different locations; the first one was directly located on the pavement of the street, the second one in the transition area to the schoolyard and the third one right in the middle of the schoolyard. The aim of this measuring methodology was to determine the temporal course of different air pollutant concentration in relation to the meteorological conditions within the urban green area. Thus it should be possible to prove the daily air quality and how it was influenced respectively dependent of different external influencing factors. Especially from the mentioned second and third measuring device we expected to get an impression of the air quality situation of the schoolyard, offside of the street. Beside the particulate matters (PM10, PM2,5, PM1), carbon monoxide and carbon dioxide additionally air temperature, air humidity, solar radiation, wind speed and direction were measured in 2 m above ground level. The air quality indicators were determined by a suction device even at 2 m a. g. l. First of all, using a 3-D sonic anemometer permitted an accurate reading, especially of the expected thermally caused wind field changes. Of course it was also possible to display the results as a time line or in dependence of wind speed, but it is more favorable in dependence of the wind direction. This enables an exact temporal allocation to the potential sources of emission of the specific air pollutants within and outside the investigation area, e.g. by calculating a trace gas wind rose (Henninger, 2012).
Fig. 6: Location of the investigation area (red line) and the „Pestalozzi School" (buildings marked in red), the traffic system (grey line), the non-parking areas and the three air quality/ meteorological measuring stations (purple-green triangles).

4 AIR QUALITY AND MICROCLIMATOLOGICAL MODIFICATIONS

4.1 In-situ air quality measurements

Getting a first impression and a better comparison depending on the problem of the traffic induced air pollution figure 7 offers the temporal course for the concentration of PM10 from 7.30 a.m. till 9 a.m. regarded as representative for the air quality situation on weekends and holidays. In respect on the German Federal Immission Protection Ordinance (BImSchV) the particulate matter of PM10 should examplarily be used for the quantification of the air quality situation within the investigations area. It is obvious that the suburban character of the investigation area provides a smooth course of the determined concentration by

ΔPM10 = 28.1 µg m-3. This equated course of the particulate matters reflects the solitude of the location sometimes interrupted by shortly increasing concentration due to the routinely consorting bus and some individual traffic as well.
Fig. 7: Temporal course of PM10-concentration [mg m-3] for the street level of the investigation area on a representative holiday between 7.30 a.m. and 9 a.m.
Fig. 8: Temporal course of PM10-concentration [mg m-3] for the street level of the investigation area on a representative schoolday between 7.00 a.m. and 9 a.m.

A completely different air quality situation is offered for weekdays. First and foremost it is obvious that the mean PM10-concentration for the time before school starts (7.00 a.m. till 7.30 a.m.) is by ΔPM10 = 52.2 µg m-3 higher than figured out in the above mentioned course anyhow (comp. Figs. 7 & 8). This could easily be explained by the matter of fact that there are more cars using this street in consequence of the weekdays commuter traffic. Around 7.30 a.m. the mapped air quality situation changes completely. Due to the so-called "open-beginning" of the schools first lesson the "struggle" for ample parking spaces in front of the school buildings starts at this time and the traffic situation is getting worse in this area. This "traffic jam" is replicable in the abruptly increasing PM10-concentration up to 170 µg m-3 (s. Fig. 8).

The mentioned "traffic jam" continues about ten minutes. Now, everyone would expect, that after the traffic has reassured air quality will normalize by distinct decreasing concentration. Unfortunately, the above explained problem of the street/ tree geometry becomes important. Because of the more or less closed tree

crowns the dispersion of PM10 is extremely reduced and it lingers on a high level (ΔPM10 = 121.9 µg m-3) for a longer time.

By 8.00 a.m. a trend of slightly decreasing concentration becomes visible. In consequence of the reduced exchange rate of the air masses within the canopy layer this slow decrease could be explained by the low dispersion rate in the surrounding areas. But comparing the results of figure 8 with the findings of figure 9 introduced a completely new interpretation. A slight time-display to the development provoked by the traffic situation on the street is visible and nearly the same image arises by considering the results of the measuring station within the schoolyard (s. Fig. 9).

Until 8.30 a.m. a smooth course of PM10 is visible by ΔPM10 = 36.2 µg m-3. But afterwards an almost mirror-imaged abrupt increase of the PM10-concentration appears and an equally immediately decrease in air quality within the canopy layer of the schoolyard. Of course this did not reach the high level of the street in front of the school, but by ΔPM10 = 74.4 µg m-3 and a time period of more than two hours before the concentration was decreasing again, but the situation not suitable from the humanbiometeorological point of view. Most notably not considering, that during this time period the pupils were using the schoolyard for the breaks between the lessons.

Now, it must be expected that the air quality development has to be regarded in the context with the situation on the street by the accumulation of the airborne particles. So the question was, how could these particles move so fast from one point to an other? Trying to explain this development a numerical simulation was done.
Fig. 9: Temporal course of PM10-concentration [mg m-3] for the schoolyard of the investigation area on a representative schoolday between 8.00 a.m. and 9.30 a.m.

4.2 Modeling the urban microclimate

Trying to find an answer for the dispersion of the aerosols the investigation area was analyzed due to its microclimatic situation by the simulation model ENVI-met 3.2, because analyzing the meteorological parameters showed, that there is a temperature difference between the street outside the schoolyard and the schoolyard itself.

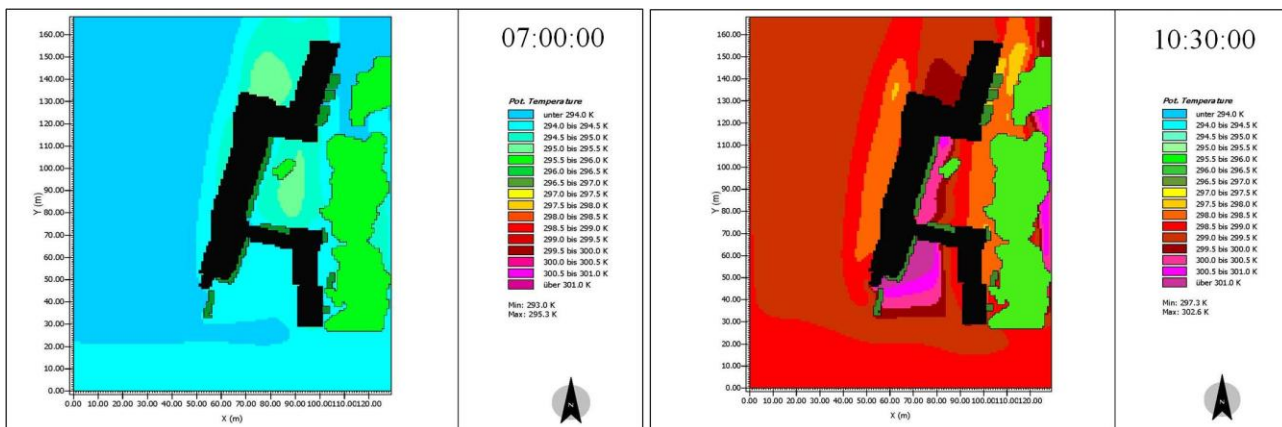
ENVI-met is a CFD application (computational fluid dynamics) comprising a three-dimensional mathematical computer model designed for the specific purpose of analyzing micro-scale interactions between urban design and the microclimate. The model combines the calculation of fluid dynamics parameters (wind flow, turbulences) with thermodynamic processes taking place at the ground surface, like walls and roofs or plants. Using a resolution between 0.5 m and 10 m this enables the model simulating even complicated geometric forms such as terraces, balconies or complex quarters. The model includes the simulation of flow around and between buildings, exchange processes of heat and vapor at the ground surface and the walls, turbulences, exchange on vegetation and vegetation parameters, bioclimatology and particle dispersion (Bruse & Fleer, 1998; s. a. www.envi-met.com).


Fig. 10: ENVI-met simulation of the investigation area shortly before the sunrays directly reach the schoolyard (left) and when the schoolyard is heated up after the direct exposure to the sun (right).

Exemplarily, the results of the microclimatological simulation are shown in figure 10. These confirmed the in-situ measurements. It is obvious that in the course of the day the schoolyard (most parts are sealed by asphalt) could heat up by the direct exposure to the morning sun. This resulted in a "thermal hot spot" where a local convective air flow seemed to occur.

Regarding the near surface temperature and the wind direction, predominantly by the data of the measuring device located in the transition area of the schoolyard, the analysis offers a distinct local wind circulation between the cooler tree street canyon and the "hot spot" of the schoolyard. Evidently, the convective air flow above the schoolyard creates a local thermal area of low pressure, which will be set off by an area of higher pressure outside along the street (s. Fig. 11). This results in a measurable movement of the local air masses within the urban canopy layer.
Fig. 11: Scheme of the determined local micro-scale wind circulation within the investigation area.
Fig. 12: Trace gas wind rose showing the flow of the PM10 [μg m-3] in dependence of the concentration and the direction of their source.

The development of this local microscale wind circulation explain the above mentioned decreasing concentration of PM10 within the investgated area of the street and also the increasing PM10-concentration within the schoolyard (s. 2.2). The determined compensation flow of this microscale air flow transports the airborne particles from the linear emission source into the schoolyard where the pupils are playing during their breaks between classes. This assumption could be proven by calculating a trace gas wind rose. Such a wind rose uses the arithmetic mean of a trace gas concentration for each wind direction sector, a trace gas wind rose can be calculated. Based on this it is possible to display an elevated trace gas concentration for an individual wind direction and it could be mapped to a potential emission sources (Henninger, 2005).

As it is displayed in figure 12 the wind rose indicates an air flow coming from the street, shifting in a small corridor of wind direction between east and south-east respectively, transporting a load of up to 80 µg m-3 of PM10, passing the entrance of the school and reaching the schoolyard later.

5 CONCLUSION

Among others, a steadily increasing individual traffic load by the parents of elementary school pupils could be made responsible for a local degradation of urban air quality within the urban canopy layer. The daily "battle" for the best parking space in front of the school often leads to obvious dangerous situations. However, it could be shown that the traffic peaks of a school day around the school ground in the morning and early afternoon hours did not only pose a physical danger to the pupils, but also present a hidden and therefore not noticed air pollution problem caused by the emission of the vehicles. With the aid of the project "Endangerments on schools" it was possible to show, using the example of the elementary school location of the "Pestalozzi School" in the south-west of the urban area of Kaiserslautern, Germany, that a high volume of traffic is not only directly, but also indirectly able to affect children. Ultimately, the project results should be used to sensitize the population to ensure that for each elementary school in the city of Kaiserslautern an individually created route-to-school-plan exists, which allows the pupils a safe and fast way to school and reaching it, of course, without a vehicle as well.

1 ABSTRACT

The degradation of the quality of the urban environment has a direct impact on the quality of life.This, has led many Member States of the European Union to develop policies for the conservation of natural resources in order to ensure a healthy environment for residents.

The research is referring to the environmental management problems that Alimos faces. Specifically, the research focuses on land use, on the degradation of natural resources and on businesses. Taking into account the EU directives and policies that have been implemented, it attempts an assessment of the current situation.

To conduct the research, a research in situ and a method of personal interviews with the local authorities took place. At the same time, legislations, land uses plans, which have been implemented until now for the regulations of land use and addressing problems, are used.

The research showed that Alimos presents many environmental problems that have degraded the quality of life of its residents. On the other hand, it has the natural resources that are necessary for the economic development and the revitalization of the area. This requires new policies and actions not only on the part of local authorities but also from on behalf of local residents.

2 INTRODUCTION

The twilight of the 21st century finds the majority of human population residing in urban environment. In an environment that has suffered radical and unusual changes and degradation, which necessitates the research that can solve the multiple problems that are resulting. Some of these include poor living conditions as a consequence of unregulated and without schedule building, traffic, pollution, poor and degraded natural areas and other.

The last few years a series of initiatives and actions aiming at solving these issues have been undertaken. The member countries of the European Union such as Greece (EU) were supported in this direction and have made many projects towards the protection of the urban environment.

The present essay is referring to the environmental management problems that the urban municipality of Alimos is facing. It focuses on land use in the building, the degradation of the natural resources and businesses. Taking into account the EU directives and policies so far implemented, it evaluates the current situation in Alimos.

3 CASE STUDIES

3.1 Municipality of Alimos

Alimos is a municipality in the conurbation of the Attica region in Greece. It is located in the southern part of the Attica region and is surrounded by Poseidon Avenue, to the east by Vouliagmeni Avenue. To the north it borders with Paleo Faliro, southwest is limited by Mount Hymettus and to the west is surrounded by the Saronic Gulf (Fig. 1). Alimos covers an area of 7.5 Km.2

According to archaeological findings, the area of Alimos is inhabited since the 23rd century BC and is considered to be the birthplace of the historian Thucydides. Its name comes from the plant alimos (armyrithra) which grew in the area.

The area was recognized as community Kalamakion in 1927 and in 1968 as Municipality Alimos. Initially Alimos was full of pasture land and later, especially the period 40-70, it turned into a residential area. At first cottages were built and later the first businesses along the roads were developed.

The last decades in the area of Alimos there has been a significant residential development. The reasons that led to this were the search for better quality of life in suburban areas, outside from Athens. Alimos possessed proper quality of life due to the short distance from the city centre, easy road access, extensive waterfront

and recreational facilities. This increase of the population has created the need for more services, leading the area to further development.

Fig.1: Municipality of Alimos

Nowadays, the commercial movement of Alimos concentrates particularly in the major Avenues of Poseidon and Vouliagmeni and all the other major roads running through and in many cases diverse it. In the area there are major lighting shops, furniture shops and of other products, thus, residents of other neighbouring municipalities of Attica come in daily for their purchases (MUNICIPALITY ALIMOS, 2011).

3.2 Economic elements

According to the last officially published element by the Hellenic Statical Authority of Greece, during the period 1971-2001 the employment in Alimos has as follows:

- In the primary sector it presents very low percentages of about 2.32 % – 0.29 %.
- The employment in the secondary sector presented progressive reduction from 34.63 % 1971 reaching 16.06 % the year 2001.
- On the contrary, the employment in the tertiary sector, presented small increase. From 59.57 % 1971 it reached 72.31 % the year 2001.

In the area of Alimos business dexterity is developed, big commercial shops and lots of companies do exist. During the last decades, there was an increase in the number of firms (from 1991 – 2010), in contrast to 2011 where there is a steady number of companies due to the economic crisis experienced by Greece (HSAG, 2011).
Fig.2: Number of enterprises in the area of Alimos (ICG, 2012).

The largest number of firms mentions in the wholesale and retail trade. Industry commercial agents and representatives follow in vehicles, motorcycles and auto maintenance and vehicle parts trade. The remaining companies, grocery stores, pharmacies, activities associated with agriculture, and other have low rates (INDUSTRIAL CHAMBER OF GREECE, 2012).

3.3 Redevelopment works

In the area of Alimos there have been a significant number of technical interventions so as to upgrade the area most of whom funded by the EU (www.kps.gr). Particularly, in the Theomitoros street, in Hero Matsi and in Panagouli square. In the Ypsilanti street, there has been a reduction of paving, widening of pavements, manufacturing benches with pergolas, placement photovoltaic and creation of green areas and recreation areas as well.

Also, the Armatolon Hill in the small church of St. Nikolaou was reconstructed with areas of recreation and walk, side walks and playground. Other projects that were conducted in the area are:

- Operation of the first kindergarten station at Old Alimos.
- Operation of the third Centre for Elderly Citizens in Alimos.
- Renovation of the Municipal Theatrical Scene "Karolos Koun".
- Manufacture of flood-preventing projects in the intersection Thoykididou and Megistis as well as in other areas of the city.
- Revision of the General Urban Drawing.
- Paving on the garden of Myrtidiotissas church.
- Manufacture of side walk in the Bath area, in the playground of Kotzia street, in the Nicosia road and in the Z. Romigy road at Pani.

3.4 Road works

The road structures that were made in the past few year in Alimos include asphalting the roads Kilkis, Evia, Cypriote Fighters, Stymfalias, Marathonomachon, Dilippoy, Char. Trikoupi. Also in the new program of the Municipality also other asphalting roads are included, which will totally cost 400000 Euros (MUNICIPALITY ALIMOS, 2011).

As far as transport is concerned, the area of Alimos is served by a network of urban buses that includes 28 lines and 107 stations. Also, Alimos is being serviced by two lines of Tram (Syntagma – Boula, and New Faliron – Boula).

3.5 School infrastructures

The area allocates 28 school units (9 nursery schools, 7 primary schools , 11 high schools and 1 Technical professional High School).

3.6 Sporting facilities

As far as athletic infrastructures are concerned, Alimos has two football fields, basketball and volleyball courts, swimming pool and indoor gym. Also, in the limits of the Municipality athletic associations, as Athletic Club of Sports fans Alimos, Union Trachonon Alimos for the basketball, the Athletic Association Gaia (TAEKBONTO), the Naval Group Kalamakiou and the team Trachonon are activated (Football).

3.7 Other services

In Alimos there are department stores such as LIDL, Carrefour, Jambo, banks, consultancy firms, recreation centres mainly on the coastal front, Greek Post Office, Social Insurance Institution, cultural centre, library, cultural clubs, marina, yacht club, shopping centre and other.

3.8 Open spaces

The more important green areas in the area are the Pani hill and the Kythirion hill. Also, the Municipality claims the space of former Greek Airport for the creation of green areas.

3.9 Tourism

In the area of Alimos hotel units of 2 and 4 stars exist. The tourist movement is strengthened from the existence of beaches, the Marina of Alimos and seawater sport.

Municipality of Alimos			
Category	2**	4****	Total
Hotel units	7	1	8
Rooms	257	29	286
Beds	469	54	523

Table 1: Hotel Potential in the area of Alimos (HSAG, 2010)

According to the statistical data at the time period 2005 – 2009, the area shows an increase of number of overnight stays from 2005 up to 2008, this is followed by a small reduction (Fig. 3).
Fig. 3: Number of overnight stays in the area of Alimos from 2005 to 2009 (HSAG, 2010).

3.10 Land Uses

The area of Alimos is an urban area, which is crossed by big road arteries for the service of its residents and big commercial shops which is hosting.

Based on the extent of land uses, the bigger extent is occupied by the building (building square) with percentage 65.56 %, followed by roads on 18.57 %, green area on 8.59 %, the open area-parking on 4.17 %, sport facilities on 1.21 %, cemetery on 0.83 %, beaches on 0.52 %, Tram on 0.39 %, and finally the waters (stream) on 0.06 %.

Municipality of Alimos		
Land uses	Area (square meters.)	%
Building Square	3796481.002	65.56
Green area	497334.05	8.59
Stream	3698.90	0.06
Sport facilities	69797.30	1.21
Open area – parking	241666.66	4.17
Cemetery	47977.50	0.83
Tram	22632.60	0.39
Beaches	30245.78	0.52
Roads	1075129.81	18.57
Total	5790954.00	100.00

Table 2: Land uses in the area of Alimos (Our data processing is based on data from the Geographical Information Systems)

Fig.4: Land uses in the area of Alimos

The total coastal extend is 240 km2. The 170 Km2 belong in the Greek Tourism Organization, 150 km2 cover the installations of the marina and 20 km2 cover the installations of organised beach. The remaining

70km2 belong in the Municipality for public use facilities, sport facilities, green area and recreation areas and other.

3.11 Building activity in the area of Alimos

According to the statistical data of the Hellenic Statistical Authority of Greece, the area presents an increase of the building activity, mainly after 1945 up to 1960. In the following decades a progressive reduction of the building activity is observed. The residential growth as mentioned above was strengthened by the quest of the residents for a better quality of life and access to the sea when the centre of Athens has been burdened.
Fig. 5: Building area of Alimos from 1920 to 2000 (HSAG, 2001).
Fig. 6: Number of new buildings in the area of Alimos from 2000 to 2008 (HSAG, 2011).

According to the approval of the General Urban Drawing (GUD) the Municipality of Alimos, the urban organisation plan of the area was made for a population of up to 32000 residents for year 1991 (OJHR, 1987) The extension of the planning of city refers to the areas Trachonon Loutro and in the area of at both sides Alimos in Pani, as well as in the creation of 6 additional urban units.

According to the GUD of Alimos, in all his extent as general use is forecasted the residency and in each urban unit it is foreseen the essential social equipment in communal and beneficial operations for the public.

Also, GUP proposes for the area Trachones, the creation of communal spaces round the monuments and its configuration in archaeological park, area of recreation and sidewalk upon special research.

In 1992 a modification was made from the General Urban Drawing for an extension of its limits (OJHR, 1992)

A/A Neighborhood	Mixed density res/HA (1991)	Medium factor of building
1	70	1.40
2	53	1.10
3	55	1.10
4	118	1.40
5	49	1.10
6	17	0.80

Table 3: Neighborhoods, densities and factor of building in the area of Alimos

The extensions are reported in the increase of general residency, free areas and urban green area. It also sets out the land use and the conditions limiting the building outside town plan area of the Municipality of Alimos.

- Specifically, for the urban planning section 1, the average density altered to 50 per / ha and the average rate of building in 1.2.

- In the 6th urban planning section the use of Industrial Park (BIPA) is included – Craft-based Park (BIOPA) to be purified.

- Use of free urban green areas in the property "Geroulanou" with outdoors installations of recreation, where only the elementary manufactures of configuration to serve the public will be allowed.

4 ENVIRONMENTAL PROBLEMS

The survey is based on a series of personal interviews with officers of the municipality and on a survey in situ in order to identify the promblems.The results showed that the area of Alimos presents various problems. Specifically:

- Alimos is intersected by three major expressway avenues. (Poseidon Avenue, Kalamaki Avenue, Eleftherias Avenue). These roads split the city into 4 sections.

- Increased noise pollution do exist in the area mainly in a small distance from the big road arteries.

- Pollution of the atmosphere is presented from the major car circulation. The fact of the existence of many electric beacons at length of the avenues, increases the emissions of the cars in the atmosphere.

- The operation of the TRAM has not provided solutions in the circulatory problem of the area.

- Alimos faces problems with the rainwater pipes which are not sufficient enough for the collection of rainwater, thereby resulting into flooding phenomena in the coastal part of the area. While in the transmission of wastewater problems are being experienced related to the construction and maintenance of the network.

- The area presents problems when rain waters with the domestic sewages are mixed together.

- The coasts of the area of Alimos apart from B´ alipedo belong in Greek Tourist Real Estates, thus resulting that the Municipality does not have the management of the beach.

- A cemetery does not exist in Alimos, therefore as a result the needs of the Municipality are covered by the neighbouring municipalities.

In the area recycling is up to 20 %. 110 tons/day of litter approximately is being recycled, which are being transported in the central station of the municipality and afterwards in the station of recycling. The non recyclable litter is transported in the space of sanitary burial of litter. The recyclable litter are transported on the vehicles of the company of recycling. Thus, the cost of litter transport is reported in fuel of the vehicles and the cost of workers for the collection of litter. It is marked that economic profit for the municipality from the recycling of litter do not exist.

5 MEASURES TO DEAL WITH THE PROBLEMS

In order to deal with the problems mentioned above, there was a suggestion to make some parts of the coastal avenue underground. This demand has been rejected, on the basic argument that there would be a problem with the collection of rain waters that are responsible for the creation of flooding phenomena. The flooding and water management problems has not been tackled more vigorously due to the high cost of construction projects.

According to the opinion of the Director of Technical Services of the municipality, the management of the coastal department of the area of Alimos, should belong in the Municipality. This however requires fights and claims, because it has to reverse a long lasting situation. As far as the southern department of Alimos is concerned, which belongs to the former Greek National Airport, acooperation with the Kallikratic Municipality of Argyroupoli – Helliniko is needed, so as to make a decision regarding its utilization.

The current programs of the municipality are (Municipality Alimos, 2011a):

- The continuation of the asphalting project, the increase of green areas, the renovation of Karaiskaki Stadium's square at Ano Klamaki,

- The Restoration of the old space"Fantasia"by creating green areas, spaces of recreation and promenades.

- The exploitation of ground water horizon for the irrigation of all the green areas.

- Planting of trees on central traffic islands.

- Completion of circulatory study.

- Restoration of streams (Pikrodafni, St. Nikolaos, St. Dimitrios and Lagkadion).

- Study for the creation of a digital museum in the municipality.

- Integration of the Property Trachones in the General Urban Drawing (GUD) for the protection of its natural environment and archaeological areas that it includes (centre of ancient Municipality of Euonymou). Also, the insertion of the area Troumpari in the GUD so as to increase its contribution in areas is important.

5.1 Advantages

In the advantages of Alimos the application of President Decree 254/2004 (OJHR, 2004) is included, that determines the land uses. Positive is also the fact that in the area arbitrary building does not exist, apart from the overshootings with the semi building spaces. At the same time abandoned open spaces and buildings does not also exist.

5.2 Investments

In the area of Alimos the biggest investments do concern in the projects of sewerage – processing of sewages – flood-preventing, and the projects of road construction are following and then the projects that concern the support of human potential.

Approved Projects	Euro
Works of road construction	3492000
Works of sewerage – treatment of sewages – flood – preventing	4189000
Advisory – Information – Support	100000
Structures of support of human potential	1302978
Infrastructures of society of information in the education	127643
Energies of briefing – Enegies of sensitization	38000
Infrastructures of society of infomation in the public administration	225160
Total	9474781

Table 4: Included work in Alimos, per category (www.kps.gr, up to 5/2/2009).

6 CONCLUTIONS

The area of Alimos has developed due to its good climatic conditions that allocate the small distance from the centre of the capital of Greece, Athens. The construction was rapid in the area, however it still continues

on a smaller intensity at the duration of the last decades. In the area there is small hotel capacity for the hospitality of tourists during the summer months.

Features of the area of Alimos are, the beaches which gather a large number of tourists during the summer months and large commercial shopping malls. Thus, the biggest percentage of employment belongs to the tertiary sector of production.

Negative element of Alimos is that it is being diverted by big road arteries that are running through it (Poseidon Avenue, Kalamaki Avenue and Eleftherias Avenue).

The area faces problems of pollution as:

- Air pollution and noise pollution from road traffic
- Lacking in management of liquid waste and rain waters.
- Problems of land use such as, management of the coastal section, the southern section that belongs in the area of the airport and the lacking of proper space for a cemetery.

Also, Alimos faces problems of connection between the coastal forehead and the remainder urban web and secure access of its residents in the beaches of Alimos.

As far as the green areas are concerned, it has sufficient spaces of green as the Pani hill and Kythirion hill, which however are threatened by the building.

The above recorded current situation and problems faced by Alimos, led us to the formulation of proposals for the improvement of the area.

- The area is in need of projects to deal with the problems caused by heavy traffic, and sewerage and rainwater collection.
- The area needs to increase the revenues of the Municipality from the management of the beach, which belongs to the Greek Tourist Real Estate.
- An awareness of the citizens of Alimos is needed so as to participate more actively in the recycling program aiming to increase the revenues of the municipality and its contribution to the environmental protection.
- Despite the building, Alimos has enough green areas, which can be increased by the appropriate utilization of the open spaces.

Finally, we should emphasize that actions are required for the financial support of the Municipality of Alimos, so as to be able to finance the construction of new works to upgrade and ensure a better quality of life.

1 ABSTRACT

Planning is a continuous and dynamic process, which needs to be considered as a part of the whole decision making activity. Although law and regulation fixed procedures, its undetermined duration and the spread in time of its effects make it difficult to manage territorial transformations, in time and space. Moreover, during the implementation process, socioeconomic and environmental changes occur to the context and ask for plan adaptation.

To deal with time-effectivenes, the article focusses on the importance of monitoring since early stages of plannig. To drive the process and modify contents when necessary, monitoring should effectively join planning. Environmental monitoring in particular seems to properly pose the bases for facing this challenge, following 42/01 Directive concerning the environmental effects of certain plans and programmes (Strategic Environmental Assessment Directive).

Changes enacted or simply unwillingly produced by plans or programmes must be kept under control within a common territorial framework. Beyond 42/01 Directive, the article argues integrated monitoring as a frame for testing the sustainability of overall changes induced by decision making at territorial level. It requires the definition of a governance scheme, describing subjects involved, roles and tasks for the implementation phase. The monitoring of a single plan should be considered as a part of the integrated system.

To make integrated monitoring effective, a common knowledge framework is to be defined, at proper territorial level, by public administrations. It must put in common certified data from different sources (context indicators), useful for environmental and territorial descriptions. It must also make metadata available for continuous updating.

Monitoring is a complex process involving planning and environmental authorities, stakeholders and the public. Assuming that participation should follow the whole planning process including the implementation phase, the article explores the potential breakthrough impact of monitoring in empowering participation processes.

Within this theoretical account, the article highlights the potential of integrated monitoring in supporting planning along time and within space(s), in accordance to recent Italian case studies coming from research activity by Poliedra-Politecnico di Milano – in collaboration with the Italian Ministry of Environment, Land and Sea and the Italian Institute for Environmental Protection and Research.

2 RESEARCH BACKGROUND

Poliedra – Politecnico di Milano since 2008 supports the the Italian Institute for Environmental Protection and Research (ISPRA) in a research activity on monitoring in Strategic Environmental Asessment (SEA) funded by the Italian Ministry of Environment Land and Sea. The activities are to be intended as a part of the whole themes covered by the State-Regions-Autonomous Provinces Meeting Table on SEA.

In a first phase, until 2009, a core set of indicators for SEA and a methodology for monitoring plans and programmes have been provided.

In a second phase, from 2010 to 2012, a testing activity of proposed methodology has been put in place in Italian Convergence Regions, through a careful selection of case studies.[1] It led to the definition of "Operational and methodological elements for SEA monitoring".[2]

---

[1] Following plans have been selected for testing:
•   Apulia Regional Coastal Plan (safeguard of Apulian coasts. All local plans will have to comply with its contents for a territorial strip of around 300 metres from the coastline)
•   Urban Municipality Plan of Monopoli (Apulia Region)
•   Territorial Province Plan of Caserta (Campania Region)
•   Urban Municipality Plan of Mercato San Severino (Campania Region)

At the same time, the Environment Agencies Network[3] continued working on the updating of the core set of indicators for SEA.

This paper represents a critical overview of research outputs, reflecting in particular on the role of monitoring for strengthening the inter-linkages between planning and environmental assessment.

3 DYNAMICS IN DECISION MAKING: GOVERNING COMPLEXITY

Decision making process can be described as composed by a multiplicity of plans and programmes characterized by procedural autonomy. They show own peculiarities relating to several aspects, which can be summarized as follows:

- Territorial scale and reference sector: every plan involves a certain territory. The same territory can be concerned by several sectorial and territorial planning instruments, such as regional, county and local plans, although through different roles, duties and scales;

- Implementation rules and tools: planning implementation can be direct – through tenders, public announcements, etc – or it can imply subsequent planning levels with specific implementation plans or programmes;

- Times: every plan has its own timeline. Furthermore, its influence and foreseen implementation tools can overpass expected deadlines and delay for an unpredictable time;

- Actors: plans concerning the same territory partially involve common actors and stakeholders, depending on the reference sector of the plan and on its territorial dimension. For this reason, participation activities should be properly structured, and should follow the whole decision making process chain.

To face real time planning and to deal with uncertainty, planning and evaluation activity are to be considered within their comprehensive container, the decision making process. It is dynamic by nature and links plans, policies, programmes and related implementation tools into a territory–tied system. The decision making as a whole deploys effects, both planned and unforeseen, on the territory it relates to.

This assertion partially shifts the attention from the long time often needed by planning and decision making process to become effective. Rather, it leads to concentrate on the territory planning refers to and on its relationship with the governing instruments. In this view external elements affecting concerned territory are to be considered for reaching further decisions.

In such a dynamic interaction, the assessment of territorial effects produced by a single plan or policy seems to be puzzling and particularly demanding.[4] The 42/01 directive introduces the obligation for plans and programmes to monitor the likely significant effects induced on the environment in areas affected by their implementation, even those unwillingly produced.

This sentence, simple and unquestionable in theory, implies several difficulties in practice.

An environmental context is part of a dynamic system. It undergoes continues transformations. It is really difficult to understand which part of such transformations can be ascribed to the implementation of a single plan addressing a certain territory. It is quite demanding even for projects subject to Environmental Impact Assessment, but in this case, depending on the type of works to assess, there can be observed effects or impacts directly produced by their development.

Reflecting on the planning process, this challenge requires even more efforts to be adequately engaged. The research activity carried on in this field underpinned at least three elements to be taken into proper consideration.

- Urban Municipality Plan of Lamezia Terme (Calabria Region)

[2] http://www.va.minambiente.it/monitoraggio/monitoraggiovas/costruzionedelsistemadimonitoraggiovas.aspx
http://www.isprambiente.gov.it/files/via-vas/indicazioni_per_il_monitoraggio_nella_vas_def.pdf

[3] The Italian Institute for Environmental Protection and Research works at National level constantly relating to Regional Agencies for the Environmental Protection within the so-called "Network of Environmental Agencies". They created in 2011 a specific working group on SEA monitoring.

[4] In the article, the word plan will stand for both plans and programmes

The first one looks at the relationship among decision making, planning process and the territory they relate to. Once defined the scale of planning, the whole planning and policy instruments involving that territory should be taken into consideration for monitoring the environmental cumulative effects induced. In this vision, concerned territory is the focus upon which changes shall be continuously monitored and described through proper shared data and indicators.

The second element deals with planning processes involving a certain territory and their assessment. By law, environmental assessment procedures must be referred to a single plan, programme or project. But to proper pose the basis for adequate monitoring of their effects common provisions should be put in place and shared at territorial level.

The third one reflects on the need of defining environmental frames. They should be lens through which look at territorial changes and establish sustainability goals. The research in this sense underpinned the crucial role of sustainability strategies for driving planning and assessment processes. To be effective, they should be participated and shared at proper territorial level.

Synthesizing, territorial and environmental dynamics should be interpreted per sè, delegating to the single planning component the demonstration of its contribution to changes underway. This step could bring to the full application of the strategic spirit of the SEA, unburdening the single planning and assessment process from context based analysis.

Focussing on plan or programme contents, plan contribution to the occurring transformations is to be continously monitored and assessed. Assessment outputs could allow enlightening feasible adjustments during the implementation for reaching territorial and environmental goals.

Environmental assessment, even further when strategic, should become in this frame a picklock through which integrate and critically review the implementation by monitoring its real effects.

3.1 Sustainability in planning: giving substance to evaluation

An integrated approach for framing all decision making elements is required to move towards sustainability. Italian law, by legislative decree 152/2006 and further amendments (framework law on environment), betokens sustainability strategies as common frameworks for environmental assessments at all level.[5]

By fixing their role, the legislator took the trouble to coordinate problems at different institutional levels.

Also, it challenged the formal approach to environmental assessment, overwhelmed by procedure, which is spreading among public entities in charge of the assessment. Furthermore, it represents an attempt of shifting questions arising from the issue of value from the single assessment instrument to a more comprehensive territorial level. In this sense, environmental assessment has a ground for learning by planning theory, where universal paradigms and approaches has been in time put under discussion.

The development of planning theory has not been about the adoption of a central paradigm, but about the gradual emergence of a more contested territory, where overarching theories have failed to convince the academic community that they are as universally relevant as they might claim. (Richardson 2005, 343)

Following this argument, the disappearance of universal approaches should lead to a more context-based inspiration for environmental assessment and planning. Also, it has to engage with competing multiple rationalities and with conflicts arising from the different values they represent and bring into the policy making arena. A tentative and collective ongoing process, led by the so-called adaptive management (Holling 1978). Intended in a wide sense, it allows establishing an iterative territorial learning process enriching knowledge and delivering short term outputs for management.

Therefore, a sustainability strategy shall be territorial, or rather concerning a proper territorial level, to be defined case by case. Its drafting process shall involve formal actors, stakeholders and the public to share a common vision on how to govern that territory and its complexity. The sharing does not exclude conflict. As

---

[5] Art. 34, legislative decree 152/2006 and further amendments: "Sustainability strategies are intended to frame environmental assessments foreseen in this decree. Such strategies, coherently defined at different territorial levels, ensure the dissociation between economic growth and its environmental impact. They have to be carried on through citizens' and third sector participation as representatives of different requests. They also guarantee the respect of conditions of ecological stability, biodiversity safeguard and the satisfaction of social needs linked to the development of individuals' potentials as demanding premises for competitiveness and job growth."

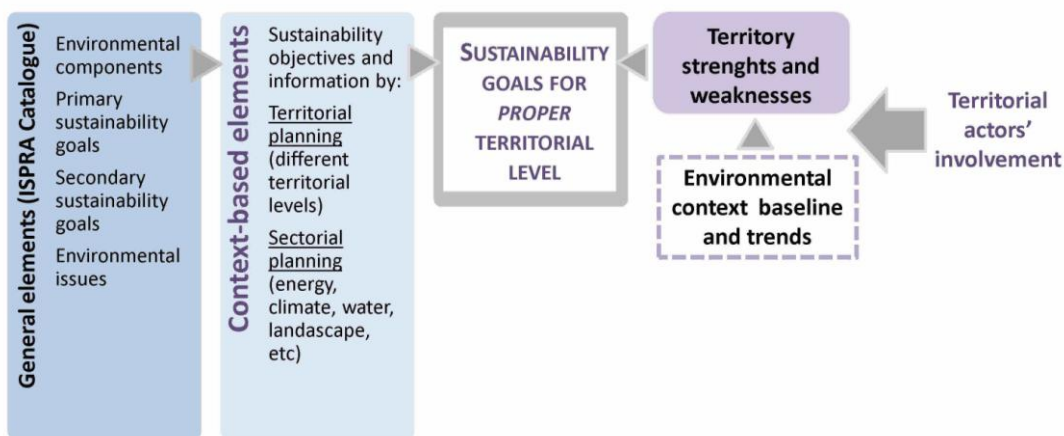
an arena where different values are put in place and represented, even though differently explicited, the strategy should negotiate some common goals. As sustainability general objectives have been defined at least at European level, the negotiation process should select the general aim fitting with the local context concerned. In other words, aims matching local issues, seen as both context strength and weaknesses, should be defined (fig. 1).


Fig. 1: definition of sustainability goals at territorial level

Once sustainability objectives have been selected, proper data and information shall be provided for monitoring their achievement. This means, at once, monitoring context changes through defining a baseline and the performance of decision makers towards sustainability. This also means thinking about enivronmental assessment as a tool for improving the chance of achievement fixed goals. This latter sentence implies a common challenge for planning and environmental assessment, which would delegate to sustainability strategy the background activity, common to all decision making instruments at territorial level.

Sustainability strategies are in this view the room where defining, coordinating and testing decision making implementation process (through plans, programmes, projects and related environmental assessments). They should make objectives available, as well as indicators and data (historical series, where possible), credible targets, information and communication protocols to be shared by all instruments.

The updating of the baseline, through monitoring of context changes and plans effects, creates a territorial-based knowledge continuously fostered by monitoring activity (fig.2).
Fig. 2: Sustainability strategies, monitoring and shared knowledge: framing decision making process

The shared knowledge basis aims at supporting planning and environmental assessments, providing a reliable framework upon which starting reasoning about the contribution of the single instrument to common

goals and occurring changes. It also gives the floor for properly assess cumulative effects and to re-orient the strategy on real time. If the territorial vision is put under discussion, then the overall strategy should be revised. Consequently, and in a second phase, the single instrument should acknowledge revisions..

It seems to be describable as a matter of scale of governance: the strategy orients decision making process as a whole on a limited territory, interiorizing some values and conflicts by its participative process, as well as giving priorities and adequate tools for describing and fulfilling them. Disclosing in advance these crucial elements, the single plan or project and their assessment could "limit" to frame their contents under the shared vision, describing how, in qualitative and quantitative meaning, they contribute to its accomplishment.

Even though in Italy the general approach is fixed and shared by legislation, the role of sustainability strategies in practice is very narrow or fragmented.

It seems anyway a fruitful path towards a non-formal integration between planning and assessment. Sharing the background at the root could allow focussing within the planning process on integrating tools and approaches and making them dialogue at the proper territorial scale.

It is a step forward Therivel's decision makers "thinking SEA" (Therivel 2012, 263), as it applies to the sustainability of decision making process as a whole and does not infers the uselessness of environmental assessment procedures. Rather, it implies the role of the territorial arena, to which the sustainability strategy refers to, in marking the opportunity for constructing environmental (and social) subjectivities and qualifying related planning and assessment system.

3.2 Monitoring and knowledge

The knowledge basis set by sustainability strategies is fed by monitoring. Its effectiveness is crucial firstly by the self-reference point of view, as effective monitoring of environmental effects induced on a territory. Furthermore, it is essential for drawing reliable scenarios for forthcoming decision making.

Monitoring and research programs must be designed not just to advance general understanding, but for their relevance to informing potential future decisions. (Parson 2001, 348)

According to Parson, policies (and therefore plans) should be informative. They should, among other goals, design decisions supposed to perturb environmental systems to generate a signal and be sustained for long enough to observe a response. Such observation implies and requires the definition of a monitoring system, intended to support and increase the informativeness of policies.

To follow this argument, institutions need to show the ability of sharing their own, often locked, knowledge, assimilating new knowledges deriving from different actors, both institutional and non-institutional. They also should demonstrate flexibility to respond to such new fragments or forms of knowledge. Finally, they need to assemble contributions coming from all actors into a common knowledge framework. These steps and abilities could allow policies acted by institutions to become informative, as Parson suggests.

To make the system work, the definition of rules and mechanisms for exchanging knowledge can't be underestimated. They should mostly be selected through participative process accompanying the definition of the sustainability strategy.

The knowledge basis deriving from this approach – defined within the research shared knowledge basis – aims at supporting planning and environmental assessment processes. It works for increasing the quality level of assessments and planning, ensuring homogeneity and comparability. At the same time it aims at supporting public institutions in their demanding role of governing complexity on their territory. Far from being the solution, it must be intended as a tool for enriching and giving depth to analyses and evaluations.

The shared knowledge basis is a framework which can guarantee coherence to planning and assessments at different scales, avoiding duplications and waste of public economic resources.

In this view, strategic environmental assessments and related plans can share within the basis context analysis, coherence evaluation, environmental objectives and indicators, etc. Their duty is to adapt such common elements to their own contents and to transmit them to subsequent levels of project and assessment (Environmental Impact Assessment and Appropriate Assessment). The monitoring results coming out from every step of this structure should be able to feed the shared basis, in a process of territorial learning which main aim is to contribute to the spreading and sharing of produced knowledge.

Aware of the demanding challenge proposed, the research experience described in the following pages represents a first step conducted in Italy in this direction, oriented towards a problematic institutional integration attempt, involving national, regional and municipal level.

3.2.1   Framing environmental assessment: the ISPRA Catalogue

Italian framework law on environment establishes a direct involvement of Environment Agencies in monitoring activities.[6] Within the institutional framework set by the Ministry for the Environment, Land and Sea, the Italian Institute for Environmental Protection and Research, supported by Poliedra – Politecnico di Milano, started thinking about the definition of a core set of indicators for SEA.

After a two-year work, a so-called catalogue has been produced.[7] It aims not only at fulfilling the basic institutional request. Indeed it has been shaped for framing environmental assessement in a wider sense, waiting for the approval of national and regional sustainability strategies (Fiorletti 2012).

To define priority objectives, the European Strategy for Sustainable development (European Council 2006) has been analysed in order to extract strategic themes (climate change and clean energy, conservation and management of natural resources, sustainable production and consumption, sustainable transports, public health, cultural resources and landscape).

Following Eurostat scheme, strategic themes have been linked to primary sustainability goals, defined by the integration of EU sustainable strategy with the Italian Action Strategy for Sustainable Development (Ministero dell'Ambiente e della Tutela del Territorio 2002) and other strategic documents.[8]

According to sectorial European documents (Directives or Communications) and to national legislation, the secondary objectives have been defined, directly related to the priority ones, focussing on environmental issues, intended as specific environmental concerns to be properly reported at different territorial levels.

Every environmental issue is described by at least one context indicator. Every indicator is accompanied by a meta-information form, providing a description and details on the availability of data for population and updating among other characteristics.

Criteria have been defined for selecting appropriate indicators. Particularly relevant has been the data availability at national and regional level. Further implementation has been provided at municipal level through the testing activity on the Convergence Regions. The indicator significance towards the related environmental issue has also been ranked, as well as its level of updatability, the availability of historical series, the "scalability" of data. This latter criterion is particularly relevant and demanding at institutional level. It infers the willingness of all institutional actors involved in planning and environmental data production to make their knowledge available for guaranteeing the data covering at different territorial levels.

This still ongoing process led to the definition of 72 context indicators, describing 52 environmental issues. 53 meta-information forms are at the moment available. The updating and enrichment of the Catalogue, both for objectives and indicators, have been introduced into the formal duties of the Environment Agencies Network.

The Catalogue contents are supposed to be adjusted case by case for being used at territorial level, guaranteeing a common frame for comparing trends and situations. It undoubtely is a long and complicated track, but the layout has been traced.

Several Regions participating to the the State, Regions and Autonomous Provinces Meeting Table on SEA did share and acknowledge Catalogue approach and contents. Campania, Apulia, Emilia Romagna, Piemonte and Marche, among the others, did start the construction of their own regional catalogue for environmental

[8] the Sixth Environment Action Programme (European Commission 2001), the European Landscape Convention, the European Strategy on Biodiversity (Biodiversity 2020) and the Italian National Strategy on Biodiversity

assessments. In some cases, the definition of such catalogues has been encompassed within european structural funding activities (Cossu e Kohan, 2012).

4 INTEGRATED MONITORING FOR PLANNING

The proposed approach conceives the monitoring of a single plan as part of a comprehensive activity – an integrated monitoring system – falling within the decision process and the sustainability strategy defined at territorial level.

Every plan must be part of an integrated monitoring system aimed at estimating the achievement of sustainability goals, by demonstrating its contribution, both positive or negative.

In other words, monitoring activity of a single plan should enlighten through performance indicators its influence on changes underway, described by the movement of context indicators. Monitoring must accompany the plan all along the implementation process.

The integrated system is also a tool for the plan and for its SEA for framing subsequent monitoring of projects foreseen by EIA and Appropriate Assessment. It simplifies monitoring activities, making available reference objectives, indicators and data, and allowing a resource efficiency review.

From a methodological point of view, the whole monitoring process can be described as a three phases process (Laniado, Cossu, e Vaghi 2009), to be carried out during the plan implementation, whose results are described in monitoring periodical reports (fig.3):

- Analysis: acquiring information, calculating indicators and comparing them to the foreseen trends of environmental sustainability indicators and objectives, in order to verify any existing gap;

- Diagnosis: describing the reasons of the gaps identified (either due to unexpected changes in the external scenario or to problems in the implementation of the plan);

- Therapy: developing proposals for the re-orientation of the plan (concerning objectives, actions, conditions for implementation, timelines, …) in order to make it consistent with sustainability objectives.

To allow monitoring to fully play the proposed role, some basic conditions are required. It must be designed to be a decision support system to be structured and managed through a careful definition of actors, roles, rules and instruments for their involvement (monitoring governance). Moreover, it must follow the plan enactment all along its life cycle, verifying at the same time the effects induced on the territory and the achievement of sustainability goals. Finally, adequate information on monitoring activities shall be provided, in terms of modalities, results and call for remediate actions when necessary.

The design of an integrated monitoring system is based on the definition of two main elements. The first one, highly technical, relates to the definition of indicators. They should not be defined per sè and should not lead to infinite lists of good indicators. Rather, they should be limited in number but accompanied by all information needed for their continuous updating and for the data exchange among different insitutions and territorial levels. Both context indicators and plan indicators should be defined, estimating the direct effects of plan enactment on territory. Context indicators are directly related to those made available from sustainability strategy for concerned territory.

A second element is necessary for monitoring effectiveness and deals with relational sphere. The monitoring governance has to be defined, establishing duties and roles of all actors involved, in addition to mechanisms and rules relating to timelines, resources, reporting, exchange information protocols, participation instruments.

From the technical point of view, the definition of an integrated monitoring system can be developed through some generalizable phases.

In a first step, given the background information by the sustainability frame (objectives and context indicators), the linkage between the execution structure of the plan, its actions and selected sustainability goals is to be drawn. The analysis has to be carried on through the estimation of effects produced on every objective. Every effect should be described to allow recognizing the ones to be kept under observation and to lead to the definition of one or more indicators – process or contribution indicators – to this purpose.

The research underpinned the potential of graphs in supporting the explicitation of different kind of nexus between actions, effects and objectives. It also aided in the translation of such relationship into indicators by representing entity and tipology of the effects to be monitored and by evidencing mutual relations.

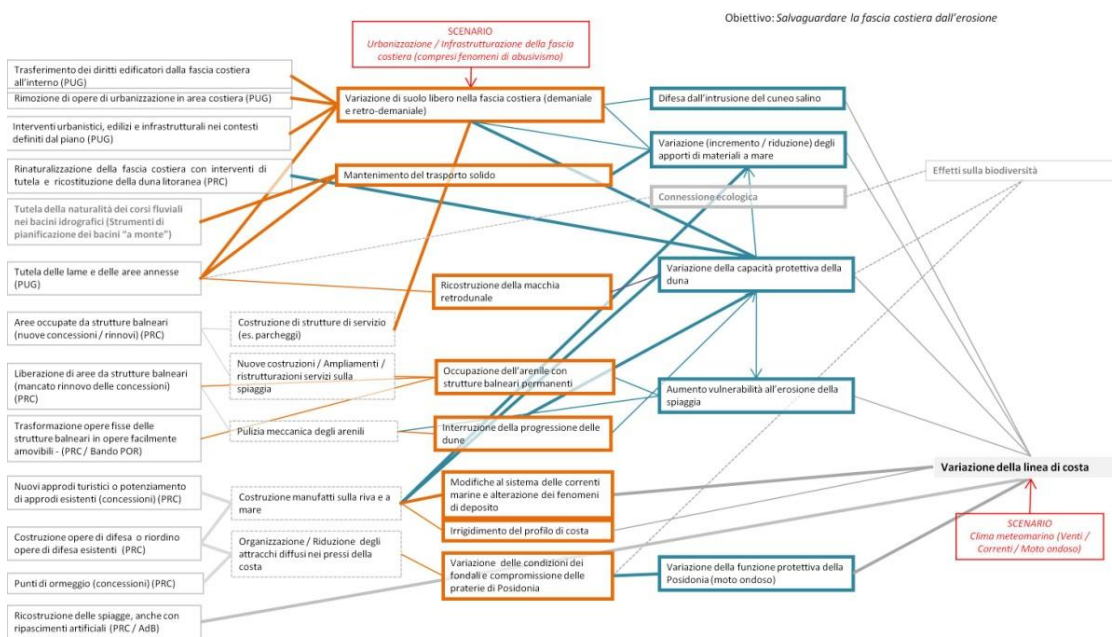
It allowed visual returning of complex causal relationships and representation of cumulative effects, both direct and indirect, of more than one action on the same goal (fig. 3).


fig.3: graph for to defining performance indicators (process and contribution) in the integrated monitoring system proposed for the Apulia Regional Coastal plan

Similarly to the exposition on environmental effects, graphs have been used for defining indicators. To every action one or more process or contribution indicators have been linked. The linkage between performance indicators and context ones is also explicited.

Scenario elements, such as informal settlements, must be been taken into account for properly assess the potential responsability of all decision making elements in occurring territorial changes.

4.1 Time and space. Exploring and keeping plan implementation under observation

An integrated monitoring system must embody all aspects concerning the effects induced by decision making elements active on a certain territory (spatial dimension) all along the decision making life cycle (temporal dimension). This requirement translates into the need of defining on one hand the territorial dimension of the plan to be monitored to find out all the plans, programmes and projects in force on the same area. On the other hand, it requires the punctual description of phases and implementation tools to properly define expected monitoring outputs by any of them.

The spatial dimension is crucial when working on an integrated system. It selects the elements of decision making process which will enter the system, defining their role and contribution, directly depending on their territorial dimension.

Within the temporal dimension nature and potential of indicators are to be considered. Both process and contribution indicators follow the enactment of the plan. The difference between them relates to the availability of reliable data during the implementation process. Information will usually become more useful and precise with the full accomplishment of the plan. Otherwise, to properly detect unwanted effects it is necessary to identify at an early stage potential negative impacts. For this reason, indicators change during the life cycle of the plan, aknowledging the progressively more detailed available data.

In a first phase, if necessary, process indicators can be used for estimating potential effects by first information available. They often can not be directly linked to the environmental objectives in terms of induced effects, but can act as a proxy. As information gets more reliable, contribution indicators can be defined, describing qualitatively or quantitatively the role of the plan in achieving sustainability goals.

This dynamism in monitoring structure implies the necessity of continuous adjustment of its contents. While defining clear mechanisms since the designing phase, peculiarities in enactment process must be taken into proper account (fig. 4).
fig.4: integrated monitoring system for the Structural Municipal Plan of Lamezia Terme

4.2 Actors, rules and conditions for monitoring effectiveness: "the governance"

Monitoring should allow institutional and non-institutional actors to express their own opinions and positions about the implementation through guaranteeing adequate environmental information. Active forms of reporting are all to invent in this sense, and crucial.

The belief is that, by implementing such principles of " good governance", SEA may provide a useful meeting point between top-down and bottom-up approaches to sustainable development (Scott 2011, 69)

Technical structure alone can't guarantee monitoring effectiveness. Relational dimension needs to be properly considered to support the encountering of top and bottom and to deploy the whole potential of monitoring in intercepting and properly responding to fast changes.

The management of such a complex system demands the early definition, since the planning phase, of the actors involved and their respective roles; of rules and mechanisms necessary for performing such roles; of human and economic resources available and needed; of phases and timetables of the implementation process with specific time frames for reporting activities; of feasible tools for supporting participation of the public, environmental authorities and stakeholders, foreseeing appropriate paths when viable. Finally, it must enounce the way in which remedial actions should be undertaken when necessary.

This collection of information and decisions gives the opportunity to the technical structure of the system to stand and to avoid its transformation into an elegant proof of concept. Every governance element shall be defined and adjusted case by case.

Research activities showed the problematic nature of the relational dimension. The reluctance of public administrations involved did not allow defining a real governance system. Only few suggestions where sketched out and put before their attention, particularly focussing on potential actors to be involved and on their role. Only in one case, the sensitiveness of planning authorities towards monitoring and environmental issues did allow going beyond formal acceptance. Where awareness of problems, good disposition and consciousness of monitoring potential are provided, ground-breaking spaces open up. The work forward has to unavoidably deal with this dimension.

5   CONCLUSION

To deploy its potential, monitoring requires the clear definition of its governance. It seems to be a wider issue, overpassing planning and assessment borders, while entailing institutional and administrative layouts. In the near future, this seems to be the prior sphere for working, aiming at diffusing a real monitoring culture, as a prodrome of real – time responding planning.

Adaptive management is needed to make it possible. The monitoring culture should teach how to learn by mistakes and inscribe into territorial descriptions performances of plans and programmes. That means recognizing responsibilities and diffusing related information.

It also implies a completely different relationship with the public, transforming the actual approach to participation, seen as an plan-related tool, strictly limited in time and space. The role of sustainability strategies is crucial in this challenge, nor is doubtable the potential role of environmental assessment in supporting transparency and participation to the decisions.

Nevertheless, a forgotten peculiarity still waits for proper consideration. The updating of plans due to their real effects is a clear role ascribed by law to SEA. It opens the path to an overturning of separated logics actually underlying planning and assessment activity.

1 ABSTRACT

Given this competitive and uncertain environment, developing cities need to be disciplined in achieving targets, utilizing limited financial and human resources in the most effective ways. At the same time, capital available to any given city is highly elastic, flowing to cities that show potential, and have well thought out urban futures. Since decision making and planning processes take relatively long time before becoming effective, CDS (City Development Strategy) is an action plan for when decisions need to be immediate, and it is a plan for equitable growth in cities, developed and sustained through participation, to improve the quality of life for all citizens. An effective CDS process can both attract capital and discipline its use. The CDS activity is both a process and a product which, taken as a comprehensive program, identifies ways of enhancing a city`s competitiveness, livability, management, and financial solvency. It includes a process to engage a wide coalition of local leaders to help strengthen the city`s strategies and plans, reviewing its challenges and opportunities. Since one of the requirements for the preparation and implementation of the CDS program is a desirable urban management system that it lead to achieve CDS goals, this research is going to investigate the CDS program was prepared for Qazvin city, in order to assess the deference of the Qazvin management system with good governance approach- as a basis to develop and implement CDS programs- So by using questionnaires, interviews and reviews of documents, urban management system of Qazvin city will be evaluated in terms of having good governance criteria. The one hand this essay describes the process, characterize and outline of the CDS and the other hands evaluate urban management systems of Qazvin city with requirements of CDS.

2 INTRODUCTION

City Development Strategies (CDS) are an approach to city-based strategic planning. City Development Strategies (CDS) have become part of the lexicon of urban development used by cities, donors, and international agencies since the late 1990s. What is being referred to be not a tightly defined planning methodology but rather an approach to strategic planning at the city (or in some cases regional) level which manifests certain general attributes (ECON Analysis and Centre for Local Government, 2005). "A City Development Strategy…focuses on the city as the unit of analysis with the understanding that cities contribute to national welfare, are an integral and often major part of the national economy, and with assistance in reforms, adjustments and investments, can be made to increase both local and national output" (World Bank Memo).

As a broad approach, CDS has been characterized as the confluence of three 3 organizational approaches:

- The World Bank – with a particular focus on local economic development, poverty alleviation, enhancement of the environment, and reform of city finance and overall management

- UN Habitat-UNDP – promoting city consultation as a means of reforming urban government as part of wider processes of stakeholder participation

- The Japanese Government – contributing experience in city planning which had conventionally been interpreted as spatial or physical rather than economic or social planning (Development Planning Unit, 2002).

3 THE CDS PROCESS

The building blocks in putting together a CDS can be viewed as forming a cycle (fig. 1). In designing the CDS, Cities need to be aware there is no single starting place that has been used for CDSs. Some cities have commenced with comprehensive assessments; others with extensive consultation and participation; some

cities have started a CDS with a consultative process to agree upon city visions. Whatever their preferred starting point, Cities will need to complete all of the building blocks at some stage in preparing their CDS. Following the guidance on the "building blocks" will ensure that Monitoring & Evaluation is incorporated into the process of preparing the CDS This guidance framework provides modules covering each of the five CDS building blocks:

- Assessment
- Consultation and Participation
- Visions, goals and objectives
- Action plan and implementation
- Institutionalization

Fig. 1: The building blocks in the CDS process

3.1 Assessment

The Assessment Phase of preparing a CDS is essentially about asking the question "where are we now"? It is the stage at which a City assesses its current situation, and where its leaders, managers and citizens explore important problems or issues where the city has limited or unreliable baseline information. In some case the initial assessment is broad ranging, covering a series of city development challenges. In other instances, CDS initial assessments focus on quite specific challenges or opportunities where the city lacks accurate baseline data (e.g., the drivers of demographic change, the creation of employment, the state of the environment).

3.2 Consultation & Participation

Community (or "stakeholder") Consultation and Participation is a feature of every CDS process. Consultation and Participation activities are about getting people involved in the strategic planning process – finding out what they know about the city, what different groups contribute to city development, what suggestions/ideas they have for the future development of the city, and what their priorities are for reform. In many cities, the CDS process provides a unique opportunity to engage with key stakeholders to develop a shared vision and set of priorities for city development. Effective consultation and participation can also ensure that the CDS has strong "buy-in", which help to facilitate implementation activities.

3.3 Vision/Goals & Objectives

At the core of the CDS process is the task of determining a vision for the development of the city and a clear set of goals and objectives. Establishing a vision, goals and objectives means asking: "where are we trying to get to?" in the short, medium and long term.

This module focuses on the M & E[1] issues associated with defining the vision, goals and objectives of the CDS. The following modules focus on the M&E issues relevant to the development of more detailed action plans and implementation schedules.

---

[1] Monitoring & Evaluation

REAL CORP

3.4 Action Plan/Implementation

The CDS Action Plan typically sets out the range of activities (projects, programs, investments, etc.) that will be required in order to achieve the CDS objectives. Realizing the long-term vision for the city invariably implies a large number of activities, interventions and investments. In many cases it also implies significant institutional reforms. It is therefore important to differentiate between actions in the short, medium and long term. In the short term, action plans should be realistic and take resource and capacity issues into account.

3.5 Institutionalization

A city development strategy is of limited value if it is not 'institutionalized', that is, integrated into the city's routine operating procedures and systems (both existing systems and other new initiatives under development). This includes: other strategic planning initiatives, land use planning, budgets, expenditure and investment plans. These are often mandated under national legislation. If the CDS is to maintain its relevance, these initiatives need to be taken into account when preparing the CDS. Furthermore, the results of the CDS process (priorities, action plans, etc.) need to feed in to the cities routine operating procedures and systems (The Cities Alliance, 2005).

4 SUMMARY OF M&E ISSUES

M&E of the various phases of CDS preparation and implementation will help to ensure that:

- All the necessary building blocks are in place
- Assessments, consultation, formulation of a vision, goals and action plans, and strengthening of institutional arrangements have all been carried out thoroughly and in a manner most likely to lead to successful implementation of the strategy.

M&E need to be considered at and incorporated into all stages of CDS preparation so that stakeholders can agree on the questions that need to be asked as work proceeds, who is to be responsible for asking those questions and analyzing the answers, and how the information collected from M&E will be used to correct any deficiencies in the process (The Cities Alliance, 2005).

5 CDS THEMES

CDSs generally explore a number of issues/themes. While all CDSs will have a focus on reducing poverty, Cities may present this commitment quite differently in their strategies. The emphasis on different themes will vary from city to city, and may change over time. The 'thematic' approach to developing CDS M & E encourages cities to focus on the most important outcomes they expect from the CDS. Following the guidance on the themes will ensure that cities have prepared the basis for M&E for the proposed outcomes of the CDS.

While the objectives of individual CDSs differ there are some common "groups" of themes in CDSs internationally. To illustrate how M&E can be integrated into the themes of a CDS we have used a thematic grouping developed by UN-Habitat for developing urban indicators. The five themes are:

- Shelter
- Social development & poverty reduction
- Environmental management
- Economic development
- Governance

5.1 Shelter

Most City Development Strategies include a focus on improving housing, including reducing the proportion of the population living in slums and informal settlements. This module has been developed to help cities to integrate M & E of shelter issues throughout the CDS process (from initial assessment through to implementation, institutionalization and ongoing review and renewal).

5.2 Social Development & Poverty Reduction

Measures to promote social development and reduce/eradicate poverty are a feature of every City Development Strategy. This theme covers a broad range of range of issues, community aspiration and activities and interventions by local government authorities. The social development and poverty reduction elements of a CDS may include objectives and actions relating to public health, education, demographic change, crime and security issues, conflict resolution, and a range of other issues.

5.3 Environmental Management

Addressing environmental issues and strengthening environmental management is a feature of many City Development Strategies. This includes a range of issues, including many that have a direct bearing on other CDS objectives (e.g., poverty reduction and economic development). These include: water quality & water pollution, waste management, managing public lands, air quality and local air pollution, natural disaster risk management, energy efficiency and climate change, access to public transport, and managing natural and cultural heritage.

5.4 Economic Development

Economic development features in most City Development Strategies. Enhancing and sustaining economic development includes are range of inter-related issues including: generating employment/reducing unemployment, supporting small business and micro enterprises, vocational training, infrastructure development, access to capital, exploiting competitive advantages, and promoting information exchange and partnerships between the private and public sector. Some CDS include wide-ranging assessments of the drivers of economic development, whereas other cities have used the CDS to focus on key trends (e.g., public private partnerships) or sectors of the economy (e.g., manufacturing, tourism).

5.5 Governance

In setting out a vision for future, City Development Strategies invariably address the governance and management of city and various aspects of public sector reform. The overarching themes here often relate to promoting efficiency, transparency and accountability. More specifically, the governance elements of a CDS can encompass a broad range of issues including: strengthening local democracy (local elections, stakeholder consultation and participation), restructuring local government institutions (especially managing decentralization of service delivery), improved budgeting and financial management, tackling corruption, improving government procurement practices and various forms of capacity building and training for local government employees (The Cities Alliance, 2005).

6   OUTPUTS OF A CDS

These are:

- A collective vision and strategy for a city, to act as the foundation for economic growth and introduce strategic thinking into city development, institutional, and financial plans
- Defined priorities and action plans, to promote economic change and assist stakeholders in determining development priorities and resolving issues related to inter-sectoral priorities and investment programming
- Development strategies that promote economic growth and address poverty reduction
- Defined policies that lead to an improved investment climate.

In summary, a CDS should have clearly defined aims and outputs, be based on an agreed program logic, incorporate a performance management and evaluation system, establish effective processes, and focus on appropriate outcomes and implementing mechanisms. The ultimate goal is for the city to create the internal institutional and political capacity to innovate and respond to the rapidly changing economic and social realities of today (www.adb.org/Documents/Books).

7   CONSTITUTION OF A GOOD STRATEGY

Characteristics of effective CDS processes, outputs, and outcomes are:

- The CDS is internally consistent. For example, strategic thrusts follow from the Vision and SWOT.

- A limited number of strategic thrusts are put forward, the product of tough choices. Nothing is of equal importance.

- The strategy is realistic, but challenging.

- The strategy has a high probability of producing results, consistent with the Vision.

- Achievement is measurable, and is measured, using lean, powerful, results oriented indicators.

- Strategic thrusts are cross-cutting, involving a variety of modes and agencies.

- Responsibility for implementation is clearly defined, against definitive targets and timelines.

- Incentives are in place to drive performance. These can take a variety of forms, e.g., financial, awards, and community recognition.

- Flexibility exists within the strategic framework to adapt and change tactics as conditions change, but the Vision normally remains constant over the medium run.

- Priorities reflected in budgeting and investment strategies (Cobbett, 2006).

8 VARIATIONS IN THE CDS PRODUCT

Variations in the CDS product related to:

The Stage of Development of the City: A CDS for the City of London will be different from that for a city characterized by poverty, under- and unemployment, and obsolete and uncompetitive economic activities. Obviously the nature of a CDS will also be function of the specific nature of the economic bases, opportunities and threats characterizing a city.

The Stage of Development of the CDS: Many CDSs start off as a strategy to address a particular sectoral issue or improve city service delivery (which is not really a CDS, but what can be called a proto-CDS), and progress to broader governance and economic issues (which is a CDS). Sector specific strategies can be used (and are in effect so used) to "pilot" the participatory process and allow a city to confidently engage broader and more fundamental developmental issues.

The Scale of the Problem or Size of the City: What is possible in a small city or town may not be attainable in a mega-city where there are many conflicting interests and a range of problematic issues.

Variations in the Driving "Needs" of Development: CDSs for East Asian cities may be focused primarily on economic development and positioning in global markets, whereas many CDSs in Africa and South Asia may focus firstly on poverty alleviation and municipal service delivery (GHK Group of Companies, 2000).

9 CHARACTERISTICS OF GOOD GOVERNANCE

Good governance approach has been emphasized in the process of CDS implementation. Improving urban management is a key issue for controlling urban poverty and managing opportunities that decentralization and globalization have created. Because of this, the main goals of CDS has based on improving urban management system by establishing good governance to response their goals and emphasizing it as pre-requisite for achieving other goals (economic development and poverty reduction). (kamelrahimi, 2012)

Good governance has 8 major characteristics. It is participatory, consensus oriented, accountable, transparent, responsive, effective and efficient, equitable and inclusive, and follows the rule of law. Good governance is responsive to the present and future needs of the organization, exercises prudence in policy-setting and decision-making, and that the best interests of all stakeholders are taken into account.

Rule of Law: Good governance requires fair legal frameworks that are enforced by an impartial regulatory body, for the full protection of stakeholders.

Transparency: Transparency means that information should be provided in easily understandable forms and media; that it should be freely available and directly accessible to those who will be affected by governance policies and practices, as well as the outcomes resulting therefrom; and that any decisions taken and their enforcement are in compliance with established rules and regulations.

Responsiveness: Good governance requires that organizations and their processes are designed to serve the best interests of stakeholders within a reasonable timeframe.

Consensus Oriented: Good governance requires consultation to understand the different interests of stakeholders in order to reach a broad consensus of what is in the best interest of the entire stakeholder group and how this can be achieved in a sustainable and prudent manner.

Equity and Inclusiveness: The organization that provides the opportunity for its stakeholders to maintain, enhance, or generally improve their well-being provides the most compelling message regarding its reason for existence and value to society.

Effectiveness and Efficiency: Good governance means that the processes implemented by the organization to produce favorable results meet the needs of its stakeholders, while making the best use of resources – human, technological, financial, natural and environmental – at its disposal.

Accountability: Accountability is a key tenet of good governance. Who is accountable for what should be documented in policy statements. In general, an organization is accountable to those who will be affected by its decisions or actions as well as the applicable rules of law.

Participation: Participation by both men and women, either directly or through legitimate representatives, is a key cornerstone of good governance. Participation needs to be informed and organized, including freedom of expression and assiduous concern for the best interests of the organization and society in general (UNDP, 1997)

10 URBAN MANAGEMENT SYSTEM IN QAZVIN

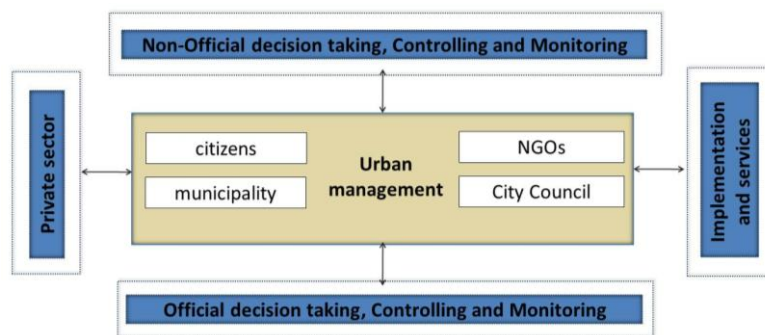
City councils establishment in Iran is an important step moving from a centralized system to a decentralized planning system and urban management based on citizen's participation (Momeni et al, 2011). Management system of Qazvin city municipality is based on Council-Mayor model. In this pattern, mayor is elected for 4 years by city council. Also the members of city council are elected by people directly. This municipality is formed of some dependent organizations that consist of transportation, green space, terminals, fire station, waste recycling, urban renewal and etc (Qazvin municipality portal, 2011) . generally, four main functions of municipality are classified in services, reclamation, supervision and social welfare. In generally, the elements related to urban management structure are classified in official and non-official decision taking, controlling and monitoring, private sector, implementation and services (kamelrahimi, 2012) (fig 2).


Fig. 2: The relation of elements in urban management of Qazvin

11 THE CDS OF QAZVIN CITY

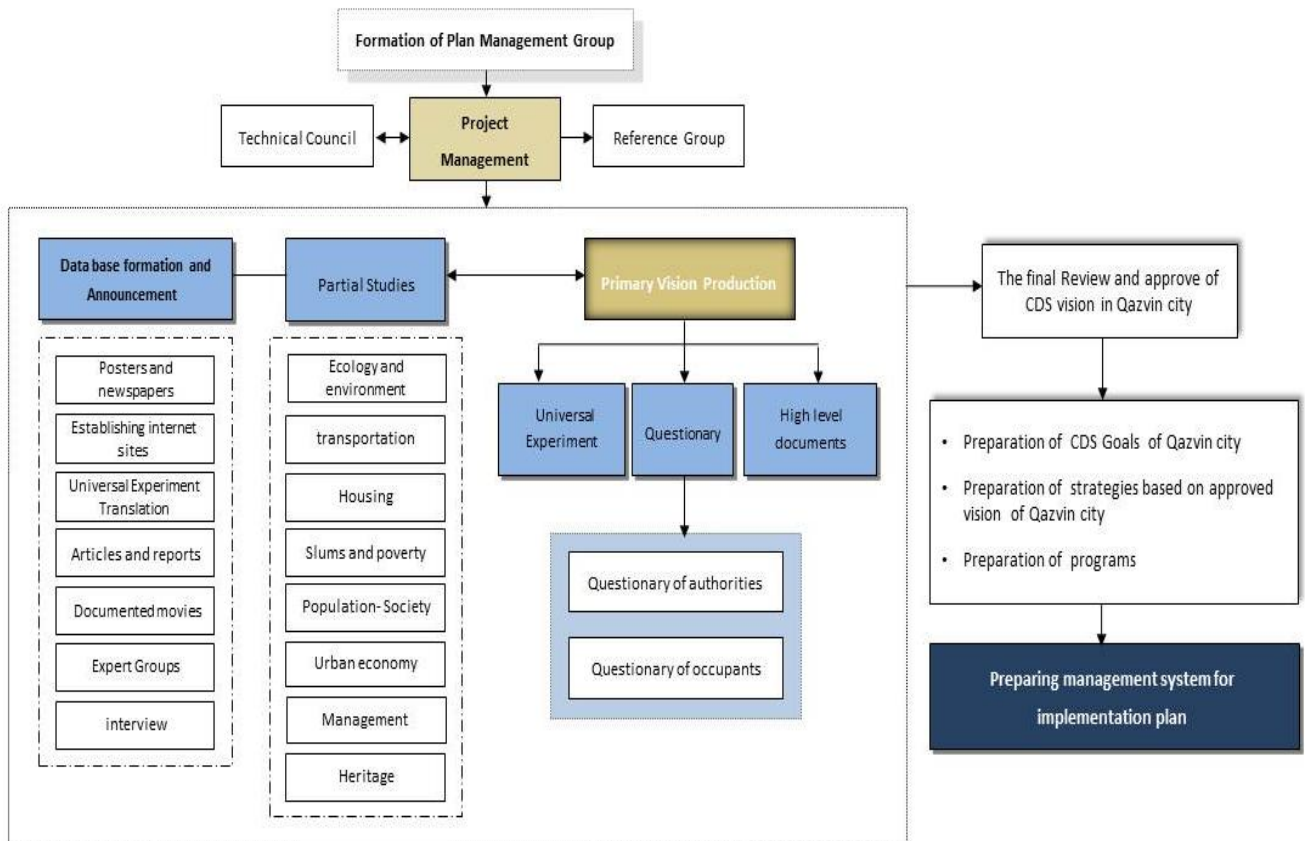
In the process of Qazvin CDS, first the vision of city development is produced by incorporating peoples and groups opinion that have affected on the plan in national, regional and urban levels related to Qazvin city, then this vision is approved by urban management system. The next step is going to analyze, classify and prioritize the strength, Weakness, threat and Opportunity in the city and produce the final vision and goals from their results. At the final stage, development strategies of Qazvin are established is shown in fig. 3 (Barati, 2009).


Fig. 3: The process of preparation of Qazvin CDS

12 EVALUATION OF QAZVIN CDS WITH GOOD GOVERNANCE CRITEIA

Analysis of Qazvin management system criterion was led to vision based on difference of urban management structure in status quo and optimal and suitable status of urban good governance- as pre-requisite of implementation of CDS.

In order to evaluate Qazvin CDS, 8 good governance criterions were extracted from theoretical framework studies. Then some sub- criteria based on good governance criterions were defined in order to deign Questionary. 250 questionnaires were filled from occupants and authorities that result of questionnaires analysis were shown as table 1.

Governence criteria	Weight	Sub- criteria	Criteria Score
Rule of law	5	Against the interests of the general and specific	33 %
Participation	7	Role of the private sector (Developers) in urban development plans	26 %
Transparency	7	Free flow of information	30 %
Responsiveness	9	Role of civil society in urban development	31 %
Effectiveness and Efficiency	9	Management, political, social and economic systems	39 %
Accountability	5	Organizational, administrative and implementation resources	37 %
Consensus oriented	7	Civil rights	28 %
Equity and Inclusiveness	5	Urban and social	36 %

Table 1: The rating criteria for each measure based on points derived from completed questionnaire

After assigning weights to each criterion – based on the Delphi method – in the score for each criterion, we can be compared the criterions with each other and by this way, the worst and the best in terms of proximity to urban good governance identified. Based on the results of the questionnaire can be seen that all criterion after applying weight (Table 2), they are accounted a score of less than 40 %. As can be seen in the chart, the

lowest and the highest score were participation and efficiency. So based on finding of the research can be realized the Qazvin management system has many different to City Development Strategy to implement.
Fig. 4: Compare the criteria of good governance in the Qazvin urban management after applying of the weights of each criterion

13 CONCLUSION

The institutionalization of CDS makes urban management more comprehensive, outward looking, and inclusive of all important segments of the society. CDS will help the municipality establish goals and set priorities, and will assist in linking a long-term view of the city's prospects with short-term actions.

Under the CDS, the city is encouraged to look at workable institutional options under their new autonomy so that they can effectively address constraints to their development. Summarily, a city's institutional action plan where internal policies of the city become enabled and supported by external policies instead of being restrained and hindered by it is sought. Local governments alone cannot turn a city around. They control a miniscule portion of capital available for city building, and often an even smaller percentage of talent in urban innovation. Although important as catalysts to take action, and representatives of the public interest (in theory, at least), local governments must work in partnership with private and civil society interests to change a city's developmental direction.

Evaluating of the level of good governance criterion and urban management system in Qazvin show large differences between the criteria of the optimum levels as a main pre-requisite for the implementation of Qazvin's city development strategy (CDS).These deference is a main problem to implement this plan. No doubt, insist on taking this approach in urban management system in other cities CDS will not success. Because good governance criterion is necessary before adopting CDS approach and conduct to good governance ought to consider for achieving goals and principles of the program.

Flooding, Vulnerability and Livelihoods of Low Income Coastal Settlements in Lagos

Oluwafemi Olajide, Suzanne Speak, Taibat Lawanson

(Oluwafemi Olajide, School of Architecture, Planning and Landscape, Newcastle University, Newcastle upon Tyne, UK, oluwafemi.olajide@ncl.ac.uk)
(Dr. Suzanne Speak, School of Architecture, Planning and Landscape, Newcastle University, Newcastle upon Tyne, UK, s.e.speak@ncl.ac.uk)
(Dr. Taibat Lawanson, Department of Urban and Regional Planning, University of Lagos, Nigeria, tolawanson@yahoo.com)

1 ABSTRACT

The paper examines livelihoods vulnerability of low income settlements in Lagos, Nigeria to the incidence of flood. It utilizes both primary and secondary data. The primary data includes household survey and qualitative interviews of both household and key informants. While secondary data include literature review of various publications, including government publications. Focusing on individual, household and community vulnerabilities, the paper explores literature on vulnerability, livelihoods and flooding. This paper uses Sustainable Livelihoods Approach as analytical framework to understanding livelihoods vulnerability of two low income settlements in Lagos to the incidence of flooding. The framework enables a holistic appreciation of how household's assets are affected by flood incidence. More specifically impacts of flood events, and factors that intensify the impacts on livelihoods assets of the urban poor are examined. The need to focus on assets arises because assets is the bedrock upon which livelihood is based. Building on the literature and empirical data from Lagos perspective, this paper indicates that the effects of floods on urban poor livelihood are multifaceted but interrelated. It was discovered that though, flood is a natural phenomenon caused mainly by natural events. However the incidence of flood and its associated risks have been exacerbated by human induced activities. Vulnerability of Lagos to flood hazards is a function of various biophysical, topographical, climatic and socio-economic factors. These are manifested in its location (coastal), population density (densely populated and mostly overcrowded), infrastructure provision (often inadequate and poorly maintained), socio-economic characteristics (predominantly poor), and settlements morphology (predominantly unplanned and haphazard). It was further noted that uncoordinated urban expansion into flood prone areas, and increase in the intensity and volume of rain are also contributory factors to incidence of flood hazards in Lagos.

2 INTRODUCTION

Historically, coastal area has traditionally attracted human population as a result of its potential for resources and commerce opportunities. However, it also exposes dwellers to environmental hazards. Costal settlements are particularly vulnerable to climate change-related risks such as sea level rise, flooding among others. Long before now, various studies across the world have suggested that climate change is likely to cause shifts in the global pattern and intensity of rain fall, and thereby, in some regions, increasing the exposure of many people to severe flooding (Vogel, 2000; Few, 2000; Spurgeon et al., 2009). Current global happens as regards flooding have, in fact, come to validate the prediction of these studies (IPCC, 2009).

Cities in developing countries are essentially vulnerable to climate change impacts especially flooding (Vogel, 2000). Flood risks are increasing and worsen the risks already faced by poor and vulnerable people in developing countries (IDS, 2012). Climate change and its associated impacts, particularly flood events have been increasingly felt in the recent years. The vulnerability of cities in developing countries has similarly increased because of the unpredictable and risks associated with flood events. It is evident that climate change has, indeed, increased the risk of flooding, especially, in coastal cities. While coastal cities are generally vulnerable to flood risk, low income settlements and urban poor within such location are more vulnerable because they lack adequate capacity to cope with the associated risks.

With the continuous increase in urban population, flood disasters are increasingly occurring in urban areas, resulting into negative impacts on the livelihoods of the urban poor (Alain et.al., 2008). As noted by Olorunfemi (2011), flood is one of the most occurrence environmental hazards, globally, causing huge annual losses to urban livelihoods. Urban poor, particularly those in informal settlements, are vulnerable to flood risk because of where they live, and the conditions of their settlements and dwellings. Urban poor are the most likely to live in risk prone areas. The quality of their housing is the poorest and least resistant to

extreme weather events. They also lack the resources, and often the information to respond in ways to mitigate their increasing vulnerabilities and associated losses (Feiden, 2011: 1)

Globally, the number of people killed or adversely affected and the number of livelihood damaged by floods have been on the increase (Olorunfemi, 2011). A large proportion of these impacts are felt, mostly, in urban areas of low and middle-income countries. For instance in Nigeria between 1983 and 2009 as indicated in EMDAT disaster database cited in Olorunfemi (2011) over three million people in selected urban areas in Nigeria, Lagos inclusive, were affected by floods.

The effect of climate change-related risks, particularly flood, are already manifesting in Lagos. In the past few years almost every part of Lagos has experienced, and has been affected by flood incidence. However, low income settlements are disproportionally affected by the incidence of flooding due to their multiple forms of vulnerability and multiple sources of deprivation. This paper therefore, through the lens of sustainable livelihood framework, examines how livelihoods of the urban poor in Lagos, Nigeria are affected by flood events and what compound their vulnerability to these events. To achieve these, two low income and flood prone areas in Lagos, Ajegunle and Aboru in Kosofe and Alimosho local govenement areas respectively, were used as case studies

3 LITERATURE REVIEW AND CONCEPTUAL ISSUES

3.1 Understanding Vulnerability

Globally, vulnerability is receiving increasing attention, although little consensus exists about its meaning and usage (Brooks, 2003; Fussel, 2007; Adger, 1999). The concept of vulnerability emerged from the dominant approaches to natural disasters in the 1960s, which focused mainly on investigating hazards as the causes of disasters (Schilderman, et.al., 2004: 415). Ever since then, the concept has been applied in various disciplines, and has been conceptualised from different perspectives depending on the disciplines where it is applied, the authors and the focus of the authors' application. Though, it is not the focus of this paper to engaging with review of these numerous conceptualisations. However, it briefly draws on three perspectives-biophysical, social and integrated approaches in explaining and understanding vulnerability. Thereafter, in the methodology and analytical framework, and analysis sections, it focuses on livelihoods perspectives in understanding the effects of, and vulnerability of urban poor to, within the context of Lagos, floods' events.

Biophysical definition of vulnerability, rooted in risk-hazard approach is widely applied in the field of disasters. It is particularly used in assessing the magnitude of damage experienced by a physical system or unit of a system as a result of an exposure to hazards (Burton et al., 1978; Kates, 1985; Brooks, 2003; Jones and Boer, 2003; Allen, 2003). From social perspective, vulnerability is rooted in political economy, and it is widely applied in poverty and development studies. According to Adger and Kelly (1999: 253), vulnerability is „the state of individuals, of groups, of communities defined in terms of their ability to cope with and adapt to any external stress placed on their livelihoods and well-being". This approach is particularly concerned with how the socio-economic and institutional characteristics of individuals or communities expose them to risks resulting from climate change hazards. Hence, it holds that vulnerability is largely associated with the peculiar characteristics of the society, as defined by social and economic classes, poverty, inequality, exclusion, gender, age and access to resources.

An integrated approach however, adopts a multidisciplinary approach by combining biophysical and social approaches to explaining vulnerability. Based on this approach, Cutter (1993) defines vulnerability as „the likelihood that an individual or group will be exposed to and adversely affected by a hazard. It is the interaction of the hazards of place with the social profile of communities." In the context of climate change, IPCC (2001: 995) defines vulnerability as the extent to which a natural or social system is susceptible to sustaining damage from climate change. Also UNDP (2004) refers to vulnerability as „a human condition or process resulting from physical, social, economic, and environmental factors which determine the likelihood and scale of damage from the impact of a given hazard"

Vulnerability can be expressed as the degree of loss resulting from interactions between occurrence of a natural phenomenon and individuals or communities characteristics (Jha et al., 2012: 175). Turner II. et al. (2003: 8074) hold similar view that vulnerability is the degree to which a system, subsystem, or system component is likely to experience harm due to exposure to hazards, either perturbations or stresses". The

degree of anticipated or experienced damaged is however, a function of the character, magnitude, and rate of climate variation to which a system is exposed, its sensitivity, and its adaptive capacity (IPCC, 2001: 995).

As noted by Sherbinin et al. (2007) vulnerability is generally identified in terms of three elements: i) system exposure to crises, stresses and shocks; ii) inadequate system capacity to cope; and iii) consequences and attendant risks of slow system recovery. This understanding according to Roy et al. (2012: 11-12) suggests that most vulnerable people or locations are those with most exposure and sensitivity to stresses and with weakest capacity to respond and recover, as a result of factors governing their local and wider contexts. In the context of increased hazards and livelihoods vulnerability, as noted by Wisner et al. (2004: 12) vulnerable groups are those who find it most difficult to reconstruct livelihoods following disaster, and this in turn makes them more vulnerable to the effects of subsequent hazard events.

From which ever perspectives vulnerability is defined or understood, the common thing is that it poses a major threat to physical, social and economic development of individual and community at large, particularly, those groups identified as vulnerable. In the light of this, poor people are especially vulnerable to incidence of climate change hazards, including flooding, because they have few resources, and thus, have limited capability to cope with such hazards whenever they occur.

3.2 Vulnerability, Floods and Livelihoods

For the first time in human history, in 2008, half of the world's population lived in urban areas (UN-HABITAT 2008). UN-Habitat and World Bank projections have it that by years 2030 and 2050 about 60 and 70 percent, respectively, of the world's population will live in urban areas and they will have to cope with challenges of climate change and its associated effects (UN-HABITAT, 2008; WDR, 2010). Flood hazard is one of such effects.

Vulnerability to flood events is increasingly becoming rampant globally. However, rapidly growing low income settlements essentially in developing countries are particularly vulnerable to impacts of flooding (Jha, Bloch and Lamond, 2012). Spatial, physical, and socio-economic characteristics of these settlements, particularly in developing countries, which are characterised by precarious conditions, unprecedented urbanisation and population increase, make them more vulnerable to incidence of flood risks.

Various researches Parnell et al. (2007); WGCCD (2009); WDR (2010) have estimated that, in developing countries, about 95 percent of urban population growth and urban expansion takes place in informal settlements with low-quality and overcrowded housing, and inadequate urban facilities and services.Therefore, from developing countries experence, urbanisation, in a way, is associated with unprecedented urban spatial expansion, involving settlements growing outwards beyond their normal boundaries, including flood prone areas, in order to accommodate population increases. Generally, as noted by Satterthwaite (2011), urban expansion alters the natural landscape, land uses and land cover, and water flows. Uncoordinated and unplanned high level urban expansion into flood plains and water catchment areas, typical of informal settlements in developing countries, are increasing the incidence of flood risks. Wheater and Evans (2009) equally agreed that land use change and unprecedented urbanisation are contributory factors to floods' incidence. They noted that:

The changes in land use associated with urbanization affect soil conditions and the nature of run-off in an area. Increased development of impermeable surfaces leads to enhanced overland flow and reduced infiltration. It also affects the natural storage of water and causes modification of run–off streams (Wheater and Evans 2009)

The increase in urban population resulting from both natural population increase and rural-urban migration has led to an increase demand for land, housing and other resources which are needed for sustainable human living (Olima, 1997). Unfortunately, government at all levels in many developing countries lack capacity to adequately meet these demands. The urban poor generally lack or have limited access to service land, social housing and other livelihood assets. The outcome of the inability of government to cater for the needs of, ever increasing, urban population have led citizens to build illegally or informally, and live under very poor environmental, social and housing conditions (UNECE, 2009).

Interaction between high demand and limited supply of service land and housing to accommodate the continuous urban population increase has, obviously, resulted into uncoordinated and uncontrolled urban expansion especially within the periphery areas of cities in developing countries. The outcome of this

process is that cities are now expanding from core areas unto marginal areas, ecologically fragile sites and hazardous locations such as flood plain, swampy areas, and canal setbacks, where they are expose to flood risks (Satterthwaite, 2006). People, especially urban poor, usually choose such locations because they are mainly the only places affordable to them in the absence of service land. These locations naturally expose the dwellers to various environmental hazards, which threaten their health, well-being and overall livelihoods (IIED, 2001).

In addition to urbanisation and uncoordinated urban expansion to flood prone areas, vulnerability to flood hazards is particularly intensified where combinations of inadequate and poorly maintained infrastructure, low-quality housing and low capability of the urban poor intertwine (World Bank, 2008). The fact that urban poor are typically accommodated and work in informal settlements, often densely populated, with poor construction materials and poorly constructed housing, and lack of access to adequate urban infrastructure facilities make them and their livelihoods more vulnerable to flood risks.

Though flood is a natural phenomenon caused mainly by natural events. However the incidence of floods and its associated risks have been exacerbated by human induced activities. Human activities such as deforestation, wetland reclamation, greenhouse gas emission, poor planning, improper development, and poorly-designed infrastructure particularly, drainage systems are capable of increasing flood events and vulnerability to the associated risks. What is important to note here is that vulnerability to flood events is caused by both natural and human induced activities. While flood originates from natural activities, human induced activities increase its potential to causing damage to physical, natural, and socio-economic environments.

4   METHODOLOGY AND ANALTICAL FRAMEWORK

This paper uses Sustainable Livelihoods Approach as analytical framework to understanding livelihood vulnerability of selected low income settlements in Lagos to the incidence of flooding. More specifically impacts of flood events and factors that intensify the impacts on livelihoods assets of the urban poor are examined. The need to focus on assets arises because assets, on the one hand, are the bedrocks upon which livelihoods are based and, on the other hand, assets define people's capabilities to cope with vulnerabilities (Sen, 1997; Bebbington, 1999). There is a close relationship between vulnerability and assets. The more assets people have, the less vulnerable they generally are; the greater the erosion of people's assets, the greater their vulnerability (Moser and Satterthwaite, 2008: 7). Within livelihoods context, asset is generally defined as stock of natural, physical, human, financial and social capitals, which are used directly or indirectly by individuals and households to making livelihoods. As noted by (Moser and Satterthwaite, 2008) these assets can be acquired, developed, improved and transferred across generations. They can also generate flows or consumption, as well as additional stock (Ford Foundation 2004: 9).

The Sustainable Livelihoods Approach (SLA) provides a framework for research which summarises many of the concepts related to the livelihood assets and livelihood vulnerability (Chamber, 1989; Chambers and Conway, 1992; Chamber, 1995; Carney et al., 1999; Lyons and Snoxell, 2005; Kantor and Nair, 2005). This framework enables a broad range of quantitative and qualitative research design and data collection methods. Consequently, for the purpose of this research, both quantitative and qualitative data collection methods, which included household survey, households' in-depth interview, key informants' interviews, direct observation and published documents, were used. The study was undertaken in Lagos. Specifically, two (2) low income settlements (Ajegunle in Kosofe local government area and Aboru in Alimosho local government area) with high incidence of floods, as identified by Lagos state ministry of Environment, were selected for further empirical study. In each settlement, a total of 100 questionnaires were randomly administered to households' heads giving a ground total of 200 questionnaires in both settlements. In addition, a total of 10 interviews including both households and key informants interviews were conducted in both settlements. The use of multiple methods, no doubt, provided valuable information on vulnerability and impacts of floods on livelihoods of the urban poor in Lagos.

5   VULNERABILITY OF LAGOS TO FLOOD HAZARDS

Vulnerability of Lagos to flood hazards is a function of various biophysical, topographical, climatic and socio-economic factors. These are manifested in its location (coastal), population density (densely populated and mostly overcrowded), infrastructure provision (often inadequate and poorly maintained), socio-economic

characteristics (predominantly poor), and settlements morphology (predominantly unplanned and haphazard).

Lagos, the largest conurbation in Nigeria and one of the largest in sub-Saharan Africa is located in the rain forest of Nigerian coast which lies within latitudes 6°23'N and 6°41'N and longitudes 2°42'E and 3°42E. Lagos state covers an area of 3,577.28 km², the smallest but the most populated urban agglomeration in Nigeria. Lagos has a population density of 4,906.78 persons per square kilometre. However, the situation is worse within Lagos metropolis, which accommodates most of the low income settlements and urban slum. Lagos metropolis is the continuous urbanised area of Lagos state, which consists of 16 local government areas out of the 20 local government areas of Lagos. It covers about 37 % of Lagos state landmass and accommodates about 80 % of the population with a population density of about 1,308 per square kilometre, but in heavily built-up areas the average population density is as high as 20,000 per square kilometre. The occupancy ratio is 8 – 10 persons per room with 72.5 % of households occupying one-room apartment.

Lagos environment is characterized as coastal with wetlands, sandy barrier islands and beaches. Water is the most significant topographical feature in Lagos State. Water bodies (sea, lagoons, rivers, creeks and swamps) cover about 40 % of the total landmass. Most of the land areas in Lagos State have an elevation of less than 15m above sea level. The land surface generally slopes gently downwards from north to south, and is particularly low-lying and flat in Victoria Island, Lagos Island, Ikoyi, and Apapa. The elevation of the built up area of the city ranges between 1m in the coastal areas to about 75 meters above sea level at its northern fringes. The climate in Lagos is tropical with two main seasons- the rainy and dry seasons, which usually lasts from April to October and November to March respectively. Floods usually occur during the rainy season, which are aggravated by the poor surface drainage systems of the coastal lowlands.

In addition to the physical and topographical feature of Lagos, change in global and local climatic factors have also been attributed to the increased incidence of flood hazards experienced across Lagos in the recent years. Long before now, various studies across the world have predicted that climate change is likely to cause shifts in the global pattern and intensity of rain fall as well as sea level rise. Lagos is not immune against these predictions. It is, in fact, predicted that it will have its own share of the associated impacts. Based on Nigerian Meteorological agency projections (NIMET) and the Intergovernmental Panel on Climate Change (IPCC), recent research findings relating to climate change induced hazards, particularly sea level rise and flooding, predict that Lagos is likely to be one of the most negatively impacted conurbations in Nigeria as a result of its low lying and costal location with a high concentration of population and economic activities (Spurgeon et al., 2009). Evidences have clearly shown that the frequency and severity of floods disasters in Nigeria generally and particularly in Lagos over the years have increased considerably. The current increase in flood incidence and its associated risks, experienced across Lagos, have been attributed to the global sea level rise and increase in the intensity and volume of local rainfall. For instance, in early 2011, the Nigeria Institute for Oceanography and Marine predicted a significant increase in the volume of rain especially in the Southern part of the country (Nigeria) where Lagos is located. The volume of rain fall was predicted to be between of 1200 and 2700mm as against 300 and 1100mm in the North.

Tunji Bello, Lagos commissioner for environment in his comment as reported by Vanguard new paper on July 15, 2011 states:

The intensity of rain has increased and the water level has risen incredibly so that the channels that are meant to discharge water from the roads and drainages are completely locked because of the high tide and because both the Atlantic Ocean and Lagoon that receive water from the channels have risen more than usual.

In the past few years, flooding has become a common feature in Lagos. Recent flood occurrences of years 2010, 2011 and 2012 point to the fact that the situation is getting worse. Flooding has, indeed, been identified as one of the major obstacles to sustainable development in Lagos especially among urban poor (Ministry of Economic Planning and Budget, 2004). It is paradoxical, as noted by Adelekan (2010: 440), in the last ten years that the frequency of rain days per annum has reduced in Lagos whereas the severity of rainstorms has increased and therefore resulting into more flood hazards with devastating effects on the residents' livelihoods, particularly the low income. It is projected that there will be a further increase in rain intensity which will result into more storm water. This is expected to have further implications on livelihoods sustainability of the urban poor.

Furthermore, as exemplified by Lagos situation, a host of other factors have been attributed to the continuous vulnerability of cities in developing countries to flood hazards. The factors as noted by various researchers Bull-Kamanga et al. (2003); Lavell et al. (2003); Adelekan, (2010) include- unprecedented urbanisation resulting into uncoordinated urban expansion, particularly into flood prone areas; overcrowding; informal land occupation; poor waste management; disruption of natural drainage channels; inadequate infrastructure, particularly drainage system; poor maintenance of the existing infrastructure; poor housing quality; poverty and weak institutional capacity. In actual fact, urban poor are caught within the webs of these multiple factors because they are the most likely group to experience multiple of these factors simultaneously. At this point it is important to emphasised that all these factors- biophysical, topographical, climatic and socio-economic factors combined to exacerbate vulnerability of Lagos' urban poor to flood hazards

6 LIVELIHOODS VULNERABILITY AND IMPACTS OF FLOOD IN LOW INCOME SETTLEMENTS

Flooding has been identified as one of the major natural hazards which disrupt the prosperity, safety, infrastructure, livelihoods and wellbeing of human settlements, particularly in developing countries, and by implication prevents poor households from moving out of poverty (ActionAid 2006. 134). It further noted that flood has multiple effects on livelihoods of the urban poor:

Flooding has enormous effects on the poor people in African cities. It affects people's health through waterborne diseases, damage to food; it destroys income and causes further deterioration of sanitation, increased exposure to disease and temporary reduction of access to health care facilities. Many schools are closed during flood periods and children have their education interrupted. Some people may not be able to get to work for long periods and suffer loss of income and possible losses of jobs. Flooding thus greatly aggravates poverty (ActionAid, 2006: 7)

In understanding urban poor's livelihoods vulnerability to flooding hazards, as relate to the selected low income settlements, the analysis therefore, focuses on the effects of flood on livelihood assets of the respondents. This paper however, indicates that the effects of floods on urban poor livelihood, in Lagos, are multifaceted but interrelated and cover wide range of livelihood activities and assets.The details of the effects are subsequently discussed.

6.1 Physical Vulnerability – Impact on Physical Assets

The most visibly devastating impact of flood is the damage to physical structures. At the community level, the physical vulnerability is manifested in the destruction of basics infrastructure. As noted by Jha et al. (2012: 161) large scale flooding can cause damage to community infrastructure, particularly roads, which are often the major way of accessing flood affected communities. As revealed by this study, effects of flood on physical assets of low income settlements in Lagos is manifested in physical damage to buildings and community infrastructure (both socio-economic and physical infrastructure), total collapse of buildings, damage and loss of households' productive and non-productive assets. Majorly, households' assets damaged by floods as reported by many respondents included: televisions, beds, chairs, radios, clothes, refrigerators, freezers, carpets, generators. Community infrastructures, including roads, electricity poles and drainage as well as public buildings were reportedly damaged by floods. For example, in Ajegunle, the only public secondary school was severely affected by the October 2010 flood incidence. As reported by residents, the flood did not only damage the school's properties but took over the school completely and displaced both the staff and students. The impact led to disruption of academic activities for more than three weeks before the students were eventually relocated to another school in a relatively distance community (Ketu).

Of course, the relocation of the school has effects on both human and financial assets of the residents. Many respondents interviewed complained of the additional burden the relocation has placed on their, already, inadequate income resulting from increase in transportation cost of school children. Attendance and safety of the students were also areas of concerns for parents. Due to delay in transportation and terrible traffic situation they have to contend with, many students resume late. Some parents complained that sometimes they are unable to afford transportation cost. In such situation, the affected students are made to stay at home.

…….*whenever I or my wife cannot afford to give them transport money; we make them sit at home. Though we are all not happy about it but what can we do?*

The current location of the school means that majority of the students have to cross busy expressway (Ikorodu road) twice on daily basis when going to, and coming from school. It was noted by one key informant: 'the community has lost about seven children, which I know off, in the process of crossing the expressway". This equally has implication for students' attendance. For instance, one female respondent, a widow who has a child in junior secondary school one (JSS1) expressed:

"My boy does not attend school any time I do not have enough money or time to take him to school and also to pick him in the afternoon. For now, I cannot allow him to cross that express alone. I cannot even entrust him with anybody.....I do not want him to join his father too soon. He is the only one I have got, he is my future."

Despite these terrible experiences, Up until the end of 2012 when the study was completed, the school premises was still deserted and overgrown with weeds without hope of when it will be rehabilitated. Also as at the time of field survey, it was observed, in both case study settlements, that many of the damaged infrastructures were yet to be replaced or repaired. This observation was equally corroborated by many respondents. As one of the key informants in Ajegunle said:

"The flood that happened in October 2010 attracted many government officials, including president and Lagos state governor. They came to assess the situation... They sympathized with us and promised to help. We have seen more promises that action."

Another resident interviewed in Aboru expressed:

"More than there (3) weeks now, since some electricity poles got damaged by flood, we have not had electricity in my area and up till now nobody is say or doing anything, that I know of, about replacing them."

Though it was noted that before the incidence, power supply was not regular but residents still manage with the irregularity, whenever it is available. But now, they have to cope with the total blackout without the hope of when the power will be restored. No doubt the situation has implications on the income of the residents; particularly those who operate home based enterprise and artisans who rely solely on electricity for means of productions.

6.2 Human Vulnerability – Impacts on Human Assets

Human assets-related impact and vulnerability is characterised by loss of human life and social networks, and ill health and injury. Loss of human life does not only bring psychological and emotional pains to people who lost loved ones but also can lead to economic and financial vulnerability in the case of losing the bread winner of the household, and increase in medical bill of the household. Furthermore, floods could lead to incidence of disease which potentially could lower ability to labour and also reduce individual and household income.

International Institute for Sustainable Development (2003) states that:

[......] health impacts pose a double jeopardy for poor people's livelihoods: the contribution of key productive members of the household is lost and the cost of health care is expensive and time consuming (IISD, 2003: 15).

The above quote is an indication that ill health and injury, on the one hand, lowers human capability to labour, particularly when it affects households' workforce, and hence reduces household income and on the other hand cost of treatment would increase household expenditures. The severity of impact of ill health and injury on household is a function of the extent to which the affected members contribute to the socio-economic functioning of the household (Jha et al., 2012).

As revealed by this study, during flood and immediately after flood incidence which usually last for about five months from May to July, reaching its peak in July with a little break in August and later to pick up between September and October, environmental sanitation is a major problem for the residents, resulting in high rate of diseases. This experience continues for some times, even, after flooding periods. Common diseases experienced during these periods, as indicated by many respondents, include: diarrhoea, malaria, typhoid, cough and cold. About 82 % of the respondents indicated that at least one member of their household has experienced sickness, during the floods, which sometimes disturb them from carrying out their normal activities, including income generating activities. The study also revealed that, during flooding,

there is usually high incidence of disease outbreak among residents. As stated by one respondent who sells local herbs in Ajegunle:

„Any time we experience flood here, there is usually high demand for herbs and treatments associated with water-borne diseases"

High incidence of disease outbreak experienced during flood hazards has been attributed to environmental pollution and increased underground water contamination that usually occur during flooding, as significant proportion of the residents either rely on well, boreholes or water vendors for their main source of water for drinking and domestic use. The situation is further exacerbated by overcrowding, which aids easy spread of communicable diseases.

Disruptions to academic activities were also reported by respondents across the study areas. It was reported that as a result of July, 2011 flood both primary and secondary school students, across the state, were ordered by government to stay away from schools in order to prevent further lost of lives particularly school children. As reported by many respondents, even after the order was over, for weeks, as a result of the magnitude and devastating effects of the flood, some schools remained shut while some remained not conducive for academic activities.

6.3 Financial Vulnerability- Impacts on Financial Assets

Directly and indirectly, flooding can have a range of negative effects on businesses and economic activities. As noted by Ingirige and Wedawatta (2011) theses effects may include damage to premises, equipment and fittings; loss of stock; reduced customer visits and sales. To this end, flooding has been identified as one of the major factors preventing urban dwellers, especially in Africa, from escaping poverty as a result of its effects on the economy as well as damaged to home, livelihoods and infrastructure (ActionAid, 2006). Replacing community damaged infrastructure resulting from flood events, as well as assisting flood victims has financial implications for government. Individuals also bear the financial brunt of their losses during flood hazard. This situation, as noted by Jha et al. (2012) puts additional burden on both government and individuals' budgets, and as well reduces their economic capability to cope with shocks, in turn adding to the already vulnerable situation.

It was observed that, though, before the experience of the recent flood hazards that occurred in Lagos in years 2010, 2011 and 2012, the residents were generally economically vulnerable. Being essentially low income settlements, the majority (71.4 %) of the residents rely on informal economy with irregular and inadequate income, for their daily survival. However, as expreesed by many respodents, their financial conditions were exacerbated by the experience of flood hazards.

It is important to note that, as observed by Jha, Bloch and Lamond (2012), it is particularly difficult to get accurate data to quantifying, in monetary term, the ripple effects of flood events on the economy and impacts on infrastructure. This statement is true for the current study. Though, it was difficult for the residents to value the actual financial loss to flood but as revealed by the respondents, economic cost of their loss is manifested in damage and loss of household properties, and disruption of economic activities. A large proportion (67.4 %) of the respondents confirm that they have lost properties, which they are yet to recover, to floods while (53 %) states that, in some cases, business activities of at least one members of their households have been disrupted by floods resulting into loss of time and money. One male respondent in Aboru expressed:

„I cannot say this is the total amount of what I lost to flood between last year (2011) and this year but, the point is that many of my properties, I mean my household items, were damaged, and I am yet to replace most of them because I have no money to do so."

Statement of another respondent in Ajegunle corroborated the above quote:

„I do not know what to do neither do I know where to move to, everything I have laboured for over the years, including my certificate have been lost to flood that ravaged last two weeks. Now I am empty, left with nothing…..I am practically back to square one, where do I even start from."

It must be noted that the above statements are not peculiar to these respondents; rather they a common experiences among the residents as revealed by this study. Though, it must be emphasised, flood is a

seasonal event but its associated loss on poor households' livelihoods is often enormous and difficult to cope with.

7 CONCLUSION

The aim of the paper was to contribute to understanding of the vulnerability and impacts of flood on the livelihoods of the urban poor in Lagos, Nigeria through the lens of sustainable livelihood framework. Building on various literature and empirical study, the paper reveales that vulnerability and impacts of flood on urban poor in Lagos are mostly related to physical, human and financial/economic assets. Arguably, these nature of vulnerabilities and impacts are not limited to the residents of the case study settlements but virtually all low income settlements in Lagos experience similar occurrences as shown by the study conducted by Adelekan in 2010 in four other low income settlements (Makoko, Ilaje-Bariga, Ijora-Oloye and Marine Beach Apapa) in Lagos.

Generally, it was discovered that though, flood is a natural phenomenon caused largely by natural events. However the incidence of floods and its associated risks have been exacerbated by human induced activities. Human activities such as deforestation, wetland reclamation, green house gas emission, poor planning, improper development, and poorly-designed infrastructure particularly, drainage systems are capable of increasing flood events and vulnerability to the associated risks. It was further noted that increase in the intensity and volume of rain fall have been attributed to the increase in flood events. In addition to these, vulnerability to flood hazards is particularly intensified where combinations of urbanisation and uncoordinated urban expansion to flood prone areas, inadequate and poor maintained infrastructure, low-quality housing and low capability of urban poor intertwine.

In Lagos, impacts of flood events and factors that intensify vulnerability to flood hazards manifest in different forms. This paper has discussed in detail the magnitude of the effects of flood on the livelihoods of informal settlements dwellers from Lagos experiences. It establishes that effects of flood, on the livelihoods of Lagos urban poor, are enormous and thereby worsen their already vulnerable and impoverished conditions. Though, in Lagos, flood hazard is a city-wide experience as a result of its costal location coupled with uncoordinated urban expansions to flood-prone areas as well as inadequate drainage facilities. However, urban poor are disproportionally vulnerable and affected by the impacts of floods hazards because they already experience multiple deprivations and exclusions in their livelihoods. These are manifested in their low and, often, inadequate income, poor environmental conditions, overcrowding, inadequate access to infrastructure, hazardous and precarious locations among others. These deprivations are experienced simultaneously by urban poor in Lagos. The risks associated with flood hazards therefore hit them hard, and do not only exacerbate their already poor conditions but also hinder their capabilities to move out of poverty.

Unfortunately, as it is at the moment, urban poor do not have adequate capacity to positively change the causes of most of these vulnerabilities. Likewise, on the long term, they do not have capacity to adequately cope with the impacts and loses associated with flood hazards. Against, these backgrounds, government must develop a holistic planning and engineering solutions to curbing future occurrence of flood hazards. It is acknowledged that the focus of this paper is limited to the impacts of flood hazards on the livelihoods of the urban poor and factors that intensify such impacts. Therefore, the paper does not claim to have developed solution to the incidence of floods in Lagos. This, obviously, is a focus of another study, which the authors intend to undertake in the near future.

French Planning System Paradox

Jean-François Guet, Sylvain Petitet

(JF Guet, Architecte et Urbaniste de l'Etat, CERTU, jean-francois.guet@developpement-durable.gouv.fr)

1 ABSTRACT

French planning system have been deeply renewed since the planning act of 2000 usually called loi SRU (loi sur la solidarité et le renouvellement urbains) and some very interesting innovations have been set. Years after years, this renewall has been enriched, especially by the Grenelle de l'Environnement which has been one of the master law of Nicolas Sarkozy's presidency. Lots of new topics are now compulsary at each level of planning : climate change, energy, carbon emissions, urban sprawl and so on. So today, the french planning system aiming to political and technical perfection has became hawfully complex, dangerously unstable and disconnected of land market and building business realities. The reason why such a perfect system does not work as well as planned comes from three unvariant principles which have been edicted by the first french planning act of 1967.

- planning system supposed to manage land use ignores land market and building market rules,

- planning system supposed to be organized from top (regional and city planning) to bottom (local plans and urban design) is in fact only dedicated to individual building licences,

- planning system supposed to organize framing major public decisions concerning cities and communities future has to take, day after day, into consideration such decisions which are taken independantly.

After a short description of the french planning system, this paper proposes to describe and illustrate system dysfunctions. The conclusion aims to open the debate about stakes of integration and synchronisation of regional and urban planning in a sustainable urban development context.

2 INTRODUCTION

Despite many significant reforms since the Urban Solidarity and Renewal Act (loi Solidarité et Renouvellement Urbain) in December 2000 to the Law on National Commitment to the Environment (loi Engagement National pour l'Environnement) in July 2010, the legal framework of urban planning in France set by the Law on Land Use Orientations (loi d'Orientation Foncière) of December 1967, retains three invariant principles tending to neutralize the operational scope of urban planning documents. While elected officials and citizens get involved passionately in the preparation of these documents, parliament continuing to add or enrich urban planning legislation, system is organized so that decisions relating to sustainable urban development continue to take "elsewhere". The purpose of this paper tries to give new understanding of the evolution of urbanization in France.

Since the beginning in 1967, french planning system has been based on two scale level of plans :

- metropolitan area : strategic plan called SDAU (Schéma Directeur d'Aménagement et d'Urbanisme) : perimeter based on local cities grouping,

- city area : local plan called POS (Plan d'Occupation des Sols): supposed to be compatible with the SDAU, perimeter following city border.

Establishing these plans was not compulsory.

These two planning documents contents were quite similar :

- presentation report which describes the area and urban development trends

- zoning plan and rules

- attached files

From 1967 (land use act) to 1983 (decentralisation act) planning documents have been elaborated and acted by local state offices managed by the prefect. From 1983 to 2000 (solidarity and urban renewal act) document have been still elaborated by local state offices but act by cities grouping councils for the SDAU

and by city council for the POS. During these times, several sectoral plans have been established aiming to support sectoral policies. The mains sectoral plans were :

- mobility : PDU (Plans de Déplacements Urbains) estalished by the law on inland transports orientations (Loi d'orientation sur les transports intérieurs) acted in december 1982;
- housing : PLH (Programme Local de l'Habitat) established by law on city orientations (loi d'orientation sur la ville) acted in july 1991.
- water : SAGE (Schémas d'Aménagement et de Gestion des Eaux) established by law on water (loi sur l'eau) acted in january 1992.

These plans have been elaborated by specific cities grouping. SDAU and POS were supposed to be compatible with the SAGE. PDU and PLH were supposed to be compatible with the SDAU (if they exist). POS were supposed to be compatible with PDU and PLH as well. Many sectoral plans have been established at different large scales introducing an awful complexity into the system which was more and more fragile.

So, the Urban Solidarity and Renewal Act (loi Solidarité et Renouvellement Urbain) estalished in December 2000 two new planning documents : at the metropolitan scale, the SCOT (Schéma de COhérence Territoriale) and at the local scale, the PLU (Plan Local d'Urbanisme). Establishing these plans is now compulsory except for small rural communities. Introducing coherence into the system, elaborating plans including PDU and PLH, is now based on the same systemic concept following the principles of the "project approach" as it is practiced in the industrial sector, ie on the Systemic following sequence:

- Inventory (including environmental issues)
- Diagnosis
- selection of goals
- Action Plan
- Operational implementation
- Results (assessment)

Each element of this chain asks the previous under otherwise constant evolution, forming many loops in perpetual movement. The interlocking scales and the relationship of compatibility between all the plans, especially SCOT and PLU, brings high complexity to a system composed by many sub-systems also in permanent evolution.

2.1 The SCOT :

It takes place of the SDAU. If SCOT limits and elaborating process are similar than SDAU, the file contents is very different. First of all, the zoning plan are abolished. A major failure of SDAU zoning plans was the excess of precision, sometimes similar as precise as a local zoning plan. In a SCOT, no map takes place of this zoning plan. Its a true way of progress and new tools and methods of mapping are to be conceived and improved.

Now the file is organised in three chapters:

- presentation report including an important chapter on environmental issues to be taken into consideration and describing incidences of the plan on environment. It presents a diagnosis and justify goals.
- urban sustainable development plan (PADD, Plan d'Aménagement et de Développement Durable)
- guideline

Local authorities have to organise public debates and consult inhabitants from the beginning to the end of the process.

2.2 The PLH :

The main goal of such plans is favouring mixity and diversity of housing. PLH is also a 5 years contract between local authorities and state to finance social dwellings building. That's the reason why the P of PLH means Program. It's also a reason why no public debate has to be organised.

A PLH file contents:

- inventory
- diagnosis
- selection of goals
- action program

Evaluating the first generation of PLH shows that in fact neither diagnosis nor action plan were really shared by local authorities and state services. PLH are mostly conceived by private housing planning companies which work for a long time on housing problems ans policies for local authorities and housing public companies as well.

2.3 The PDU :

The main goal of such plan is limiting car traffic by favouring alternative means of transportation. PDU concerns all means of transportation and SRU law adds parking planning and goods trafic planning as well.

A PDU files contents:

- inventory of traffics
- diagnosis
- selection of goals
- action plan
- assessment indicators

The Action Plan runs 5 years. Local authorities have to organise public debates and to consult inhabitants from the beginning to the end of the process. Assessing the first generation of PDU shows heavy trends:

- mobility increasing : car traffic still increasing, public transportation increasing after declining but the repartition of traffics still profits to car
- public transportation networks developing especially with new tramways which bear now a very positive image of cities and can be considered as contributing to creative economy
- alternative meanings of transportation networks, especially cycling and walking paths.

2.4 The SAGE :

A SAGE file contents :

- presentation report
- maps and graphics.

The report presents :

- analysis of the existing situation of the aquatic environment and a census of the various uses made of water,
- analysis of the main perspectives of development,
- the indication of the possible consequences on public decisions in the field of water.

Graphic documents show :

- the distribution of the resource surface and groundwater, including an indication of quantitative and qualitative objectives,
- the location of the main economic and social activities and public facilities existing or general interest, the bathing areas, the areas of abstraction and discharge,

- the main natural aquatic protect facilities,
- major migration routes of fish species,
- protection zones of drinking water catchments.

SAGE may include requirements on the Water Police and the protection of catchment areas. These requirements are compulsory taken into account in the PLU.

2.5 The PLU :

PLU takes place of POS. Process is quite similar than POS but much more simple but its content is very different:

- presentation report including an important chapter on environmental issues to be taken into consideration and describing incidences of the plan on environment. It presents a diagnosis and justify goals.
- sustainable development plan (PADD, Plan d'Aménagement et de Développement Durable),
- urban design guideline (Orientations d'aménagement),
- zoning plan and building rules
- attached files (public networks)

Local authorities have to organise public debates and to consult inhabitants from the beginning to the end of the process. PLU have to be compatible with SAGE, SCOT, PLH and PDU.

3 URBAN PLANNING AND LAND POLICY : IGNORANCE ESTABLISHED

Curiously, the word "planification" (planning) does not belong to the vocabulary used by the Town Planning Code (code de l'urbanisme), the legislator may be repugnant to use a word and also a concept coming from the Soviet conception of economy. Another curiosity, the articles establishing planning documents mention territory, space, ground, soil but the word "foncier" (land) is missing. None recall that land is the raw material for urban development. None indication of the need for the competent authority to develop and implement a land policy based on public policy. The complexity of the legal instruments of this policy is a convenient alibi to avoid to use it. This refers to the disillusioned remark Pisani Edgar: "I have long believed that the land issue was legal, technical, economic (...) I slowly discovered that it was one of the most significant political problem. "

Moreover, it is not explicitly stated that, in part, the aim of the town planning code is to frame and thus to limit the property right which is "inviolable and sacred" as enrolled in the 17 th article of the Universal Declaration of Human Rights appended to the Constitution of the french Republic because of the "public need" to implement local policies of urban development. So, it is interesting to notice that, since opening in July 2008, the Constitutional Council referral under Question of Priority Constitutionnalité, several articles of the town planning code were canceled, others confirmed.

Finally, despite numerous evocations, including national debate of the "Grenelle" for environment started in september 2007 and concluded by Law on National Commitment to the Environment (loi Engagement National pour l'Environnement) in July 2010, there is still no mention of financial gains generated by the constructability of a plot of land previously unbuildable, which multiplies its value by 30 and, in some sectors, by 100, thus forming a right (virtually) acquired for the lucky owner. So no mention of rules to share that gain with the public authority which has offered such rights and gains, noticing that only a part of financing the public networks and equipments required by new buildable areas is, under conditions, attributable to petitioners. Considering the financial stakes, the competent public authority, most of the time the mayor himself, and is mechanically pressurized by landowners especially in small municipalities. Conversely, if in return, the changes likely to reduce or even remove existing rights of building under new rules approved by the local authority, are not compensable.

In summary, although it is obvious that the land is the raw material of urban development, french texts governing planning documents still do not state the obligation to link land policy and urban planning. Therefore, the purpose of planning documents, and PLU in particular, seems to be limited to state the

boundaries of buildable areas, and thereby to the unjust enrichment of happy landlords. Here is one of the causes of urban sprawl in France, maybe the main one.

4 URBAN PLANNING: THE INVERTED PYRAMID

Since the publication in December 2000 of the Urban Solidarity and Renewal Act, the content of planning documents, SCOT and PLU continues to increase over laws that focus sometimes on environment, sometimes on agriculture, sometimes on transport and mobility, sometimes on housing, to name only the main ones. Each of these themes refers to a sectoral policy formalized by plans of greater significance with which planning documents must contend. The Grenelle de l'Environnement has accentuated this trend adding regional plans for climate, air and energy (Schéma Régional pour le Climat, l'Air et l'Energie) ; and regional plans for ecological corridors (Schéma Régional des Continuités Ecologiques). However, that the town planning code grows, its articulation with other codes is rarely specified. Thus, a few years ago, it was that the planning documents (SCOT and PLU) should be consistent with the plans for water management (Schéma d'Aménagement et de Gestion des Eaux) as stipulated in the Environment code but not the town planning code, forgetting repaired by the law for town planning and housing (loi Urbanisme-Habitat) acted in july 2002. It seems that the list of regional plans and departmental plans to take into account the SCOT and PLU is not clearly stopped: quarries, waste etc ... Thus, one could consider that a PLU is the simple declination of all sectoral policies supra-municipal, at the scale of the municipality.

In addition, compared to a POS, the content of a PLU has grown considerably since the publication of the SRU. The presentation report now includes an important chapter on environmental issues to be taken into consideration and describing incidences of the plan on environment. It contains two more elements: a sustainable development plan (PADD, Plan d'Aménagement et de Développement Durable) and an urban design guideline (Orientations d'aménagement). As if the PLU were a local bible to organize daily citizens's life, the municipality is thus commited to design an ideal urban future in a strict legal framework abundant and complex.

But the daily use of a PLU, in fact its one true purpose, is limited to the supervision of individual permissions: development licenses, building permits, demolition permits. In this regard, it should be noted that this is the number of building permits issued each year (between 5 and 10), who led the state town planning office to convince a municipality to initiate the process of establishing a POS. Thus, the useful part of the PLU is limited to regulation and zoning plan. In this, the French urban planning adheres to established legal principles in the United States in the late nineteenth century, first to preserve the rights of third parties with respect to new construction projects. In this regard, it should be noted that the principle of "one function, one area, one regulation" is derived from the Athens Charter which required the separation of flow and functions "live, work, leisure". The zoning of the local plans (POS, now PLU) could already take into account the diversity of urban functions and it was most often the case in dense urbanized areas but outside the centers of cities, centers zoning mainly continues to be strictly monofunctionnal. Thus, local plans (POS, now PLU) determine, at the scale of the plot, a legal framework, more or less detailed, more or less restrictive.

This setting to the plot, refers ipso facto to individual strategies of landowners who have two constitutional freedoms:

- except expropriation cases related to easements, landowners have no obligation to sell their property,
- except in special cases related to public safety, property owners have no obligation to carry out building.

Faced with the principle of reality, local development plans, in order to meet the needs of the municipality, shall provide wide buildable areas, taking into account land retention observed locally. Thus, in the 90s, outside the metropolitan centers, in many cases the buildable surfaces offered by a POS was permitting to double legally the urbanized surface of the city. Some surveys have shown that, at the usual rate of land consumption, the stock of buildable land was able to face to the demand for 50 years. Two consequences of this practice as old as french local planning :

- Difficulty in correctly programming public investments, especially roads and other public networks. Therefore difficulty to properly allocate the costs of such public investments to the petitioners.

- Difficulty in applying the principle of continuity with the existing urbanization which results in the formation de facto private land reserves.

Municipalities are "condemned" to develop planning documents "perfect" without the means to ensure their implementation in time and in space.

Everybody now can understand the importance of examining requests for individual authorization. The mayors are very attached to their power which they often practice in a very personal way, sometimes discretionary, and the PLU is for them a tool to help the decision reviewable and modifiable as needed for individual demands. Last years, true "standing committees for building permits" have been multiplied which, in defiance of all rights, behave like juries of architecture, requiring as much modifications as necessary to please them. Neither professionals nor petitioners complain of this abuse of power preferring getting slowly their permit than forming a litigation. In another opposite way, professionnals use to negotiate with the municipality in order to impose their projects sometimes getting significant modifications of the rules. This absence of separation of powers could be a question of constitutionality potentially explosive.

In summary, urban planning documents have one, and only one purpose, supervising individual authorization requests. If they do not allow a project supported by the municipality or group together, they are changed or revised accordingly.

5 PLANNING AND PROGRAMMING: THE INVERTED HIERARCHY.

In its wisdom, the legislature took into account, from 1967, the need not to paralyze life in the territories by submitting town planning to projects programming, ie giving legal precedence to projects as they are recognized as general interest (Projet d'Intérêt Général) or as public utility (Déclaration d'Utilité Publique). Legislation provides appropriate devices to make plans compatible with projects under the responsability of State. Thus, despite the excellence of french system of territorial planning, it is common to observe that the major development projects, including transport infrastructure projects, are designed independently of urban planning since, ultimately, these plans should take into account these projects.

This dichotomy is reflected in the organization of public bodies : the services assigned to urban projects programming are different than services assigned to town planning. The State, supposed to be "exemplary", for significant projects (highways and transport infrastructure; polarization of hospital equipments; development of universities; national research centers such as ITER in Cadarache) studies are designed and discussed independently of urban plans that will, in time, set compatibility with these projects. This applies to projects of public facilities under the jurisdiction of the Regions (High Schools, etc..) And Departments (colleges, nursing homes, etc.).. For exemple, the component "school facilities" is mostly missing in SCOT in spite of the link between school equipment and urban mobility and dwelling choices of concerned families. Curiously, this legal fragility of SCOT has not yet been used in litigation.

In addition, projects of designing or refurbishing or adapting public space (including roads and public networks) are mostly not subject to any authorization procedure as soon as the contracting authority owns the land what is the main case in a city. If acquisitions are needed, it will suffice to rank on the list of reserved areas into the PLU, and apply for declaration of public utility. Architects are rarely involved in such projects despite many exemples of good practices (redevelopment of the quays of Bordeaux or the Place Stanislas in Nancy). Thus, between scarification incessant, inappropriate flooring materials, signage and advertising, risky choice for urban furniture, the public space of many French cities seems to come to itself, especially outside the centers of the cities. This confirms that french code of urbanism does not address urban design, but only the right of building.

Finally, many development projects and construction borne by private owners as joint or group of municipalities judge abruptly priority if of general interest as they have not been taken into account in the PLU. Regardless, it is sufficient to initiate an amendment or revision of PLU. For instance, the classification of the Canal du Midi as a World Heritage Site in 1996, abruptly sharpened appetites of marinas developpers who tried to seduce the elected representatives of the municipalities concerned, fortunately with a very uneven success, Without prejudice to the desirability of these projects, this is a good pattern to justify the development of an instrument to ensure consistency of planning documents, SCOT and PLU; and to ensure a reasonable planning and development of the Canal, especially its surroundings. In this respect, it may appear

as a responsibility of the State to preserve this part of the "national territory, the common heritage of the nation".

In summary, the bodies responsible for the decisions that affect urban development in a territory are not the bodies responsible for the preparation of planning documents. As necessary, such decisions have to be taken into consideration by town planning documents, eventually by legal requirement. Actually town planning in France has to be compatible with projects and not the reverse.

6 CONCLUSION

Logically, the three invariant principles outlined above form system: disconnecting the urban planning of land policies on the one hand and programming of public and private investment on the other hand, limiting the subject matter of documents Planning for the establishment of a legal framework for permissions, appears hollow and reverse production system of urbanization in France. It is based fundamentally on respect for private ownership of land, on the individual rather than institutional initiative on personal enrichment rather than collective value creation. There is no "invisible hand" to organize and protect this system, if not the market.

1 ABSTRACT

This paper describes possibilities and examples in which augmented reality solutions can be implemented in planning and participation processes, based on an analysis of the results of the project "ways2gether – Target-group-specific use of augmented reality and web 2.0 in participative traffic planning processes". An augmented-reality-demonstrator based on the free metaio Mobile SDK was developed as part of the project ways2gether. This new communication and information tool was practically evaluated in three test cases to show the benefit in planning and participation processes in transport planning.

The actual possibilities and challenges in implementing augmented reality in planning processes are discussed, the technical background and a possible workflow for the integration of augmented reality solutions in planning processes are described and finally the benefits and difficulties in using augmented reality in participation processes are explained based on the results of the test cases.

2 AUGMENTED REALITY AND PLANNING

Augmented reality (AR), a term that has been increasingly used since the 1990s, refers to one's own perception – mostly visual – being enhanced through computer-generated information. This can be achieved in a variety of ways, though common to all systems is that virtual reality and reality are combined and overlaid. Another shared characteristic is also that these systems operate interactively in real time and three-dimensional information is provided (Azuma 1997).

The planning sector is becoming increasingly more interested in these instruments, with the opportunity for many planning fields to provide on-site geo-referenced information proving to be an especially interesting expansion of their repertoire of methods. The field of mobile augmented reality is particularly interesting for planning and participation processes thus an additional requirement is that the AR environment has to work on mobile devices.

Due to the increasing number of mobile devices that have a camera, data connection, GPS sensors on board and sufficient computing power, mobile augmented reality applications are becoming more and more interesting for a broader public. The dissemination of (powerful) smartphones and tablets as well as the possibility to use third party applications on mobile devices has caused a visible trend in augmentation in recent years. Augmented reality is seen as an important tool in planning processes, especially in participation processes, to improve communication with "non-planners". Planning information can be shown location based, three-dimensional, and in the context of the "real world" on mobile devices (c.f. Azuma 1997, Azuma et al. 2001, Tönnis 2010, Carmigniani, Furth 2011).

2.1 The use of AR in planning and participation procedures

Current and future uses of augmented reality include the provision of three-dimensional information, such as navigation, marketing, and location information, as well as in the gaming and entertainment industry, assembly, the medical field, or real estate which can be supported by AR information. AR has also been used in advertising, where webcams are attached to PCs and the camera images were overlaid with objects usually supported by QR Codes. AR is also used in sports broadcasts, for example in soccer and ski jumping, where the offside line or the current maximum jump-distance appears virtually.

Even the planning and architectural sector is using augmented reality more and more. Currently the majority of AR applications are being used to provide location-based information. There are some (individual) projects which use three-dimensional AR renderings or provide three-dimensional information, such as

"Smart Vidente", where electric or gas lines in the underground are shown with a special mobile device (Junghanns S., 2008). Other examples, like the "Archeoguide" (Augmented Reality based Cultural Heritage On-site GUIDE), which shows multimedia information such as historical buildings, need special mobile devices (Vlahakis V., et al. 2002).

The other approach is to use common mobile devices such as smart phones or tablet-computer to provide three-dimensional information. The most popular AR browsers such as Layar, Wikitude or Junaio work on regular mobile devices.

The third approach is to use tailored apps on regular mobile devices. One example is from ovos, who developed their own app for the Seestadt Aspern in order to view the master plan on mobile devices (www.ovos.at.) You can view the future city from five different viewpoints which are defined by LLA-markers. However, you are fixed to the point where the LLA marker is set and are unable to move freely within the model.

The ways2gether project focuses on the use of common mobile devices, such as smartphones or tablet-computers, to reach a broader public. We also wanted to make it possible to move freely within the AR model.

For the development of the app we analysed different planning and participation processes in order to point out different possibilities for using AR (Reinwald et al. 2012). In short, the analysis showed a broad spectrum of possibilities in which AR can be implemented, from the possibility to use AR apps for information and consultation to the visualisation of drafts, different versions or final designs. For the ways2gether project we mainly focused on the augmented visualisation of drafts and final designs.

2.2 The project ways2gether

The assumption that by using AR it is possible to make planned changes visible and reduce barriers caused by a lack of three-dimensional imagination (c.f. Zeile 2010) was the starting point for the project "ways2gether – Target-group-specific use of augmented reality and web 2.0 in participative traffic planning processes".[1]

The idea that augmented reality has the potential to improve a participation process and make it more efficient (c.f. Nash 2010) was also a driving factor to start research in this sector. We also expected that new target groups, for example teenagers who are rarely interested in participation processes or people having little time to take part in participation processes due to care obligations, can be reached with these instruments (c.f. Jauschneg, Stoik 2012).

The following article is based on the results of the project ways2gether, which focuses on the reduction of barriers in terms of communication and accessibility in participative planning processes through a specifically tailored augmented reality application (more information on www.ways2gether.at).

3 CHALLENGES TO IMPLEMENT AUGMENTED REALITY IN PLANNING AND PARTICIPATION PROCESSES

The potential uses of AR systems are as described in chapter 2.1 manifold. In the following chapter the requirements and challenges implementing augmented reality solutions are described.

3.1 From reality to augmented reality

To illustrate augmented reality on mobile devices various system components are required. In short, it takes the reality, the built environment, a mobile device with a camera, a three-dimensional plan, as well as software that makes the overlay (see Figure 1).

Figure 1: From reality to augmented reality

In detail, this means that by using the camera image, the real situation is recorded and by means of a tracker system (GPS, position sensor, compass) the exact spatial position and the direction of view of the mobile device is determined. This information is processed in an application and a three-dimensional rendering of the model is generated. Using an AR-browser the 3D rendering is shown on the display together with the camera image (see Figure 2).
Figure 2: Components of the ways2gether AR system

3.2 Requirements and challenges concerning AR instruments in planning

In order to use AR instruments in planning, additional requirements have to be considered concerning usability, immersion, workflow and accuracy. For the development of the ways2gether app the requirements for an AR system which can be used for planning and participation processes were analysed in expert interviews and by literature research. The analysis shows that the effort for the operation and maintenance must be low for the process facilitators, planners and people who take part in participation procedures.

Whether or not AR is accepted as a tool for planning and participation procedures depends on how easily the AR system can be used.

From the perspective of planners and facilitators, the workflow within a planning process and the consideration of (currently used) data interfaces are of particular importance to the AR instruments. To ensure AR's efficient use in planning and participation processes, the extra effort and the necessary technical skills for planners are to be kept as low as possible. From a technical perspective, challenges are presented especially in relation to GPS accuracy, partially developed software products as well as limitations in the processing power and visualization possibilities (graphics performance) of the mobile devices.

Development in the smartphone and tablet sector is rapid, with new hardware and software products which better meet the high demands of mobile AR tools continuously being introduced on the market. The central challenge in adapting the ways2gether app is – and will remain for the foreseeable future – the inaccuracy of the GPS system, as deviations of up to 7-8m are possible. The restricted level of detail and the limited immersion of the model are a problem.

4   THE WAYS2GETHER APP

The AR framework used for the ways2gether project is based on the metaio Mobile SDK by metaio GmbH (http://www.junaio.com), which includes a 3D rendering engine and can be integrated into your own app. The ways2gether app (see Figure 3) runs in an IOS environment on iPhones and iPads, and is available through the Apple App Store (https://itunes.apple.com/de/app/id515300116?mt=8).

Figure 3: Screenshot of the ways2gether App – on left site the map overview that shows the Seestadt Aspern test case, on the right site the AR-viewer that shows the Seestadt Aspern 3D model.

The ways2gether app is divided into two main components. First there is the map view that provides the user with an overview of all available points of interests (POI) around him. This map view offers the users the ability to drag and drop a specific POI to the users current location, so they can easily visit the selected 3D model without having to go the actual physical location of the POI. Secondly there is the AR viewer, which is a component for visualizing the 3D model connected to each POI.

4.1 Test cases

Three test cases were performed as part of the project: in Wallensteinstraße in Vienna, in Aspern, an urban development project in Vienna, and in Hartberg, a town with 6,500 inhabitants in the province of Styria. The aim here was to test the developed app in the real world, reach different target groups and use the instrument

in various planning and participation processes. The test cases were to cover research questions both in the field of technical development as well as in planning and participation procedures.

The central question for the tests was what are the advantages and disadvantages of using AR. A qualitative and quantitative approach was chosen to analyse the implementation of AR from different perspectives and different settings were chosen regarding the type of area (rural/urban, within a built area/new planning) or the aim of the participation process (presentation of results/consultation/information).

The test itself was conducted using a target and control group setting. One group used the ways2gether app, the other used printed 3D renderings and/or 2D plans to evaluate the planned design. The participants were then asked to fill out a questionnaire, which was quantitatively evaluated. The use of the app and the discussion within the groups were observed and group discussions with facilitators were conducted. The central task of the test cases was also the further development of the ways2gether app and especially to analyse the work-flow.

5 A POSSIBLE WORKFLOW FOR THE INTEGRATION OF AUGMENTED-REALITY SOLUTIONS IN PLANNING PROCESSES EXPLAINED USING THE EXAMPLE OF A TEST CASE

For a successful integration of augmented-reality models in planning processes a specific workflow is needed which considers interfaces, special requirements of the augmented-reality framework as well as the "regular" workflow within a planning and participation process (c.f. Kallenberg 2011, Schultheiß 2011). Central tasks for successful integration include the development of the 3D model and the transfer into the augmented-reality environment. Limitations in mobile AR frameworks mean that the design process necessary for 3D models to achieve the required complexity is quite complicated. Once the ideal complexity has been reached, textures on the model's surface are necessary in order to enhance the user's experience. Additionally, the workflow of the 3D model regarding the export in the OBJ format and the implementation in the augmented-reality framework is crucial.

5.1 Challenges in creating 3D models for augmented-reality test cases on mobile devices

Several challenges have to be overcome in the design process of augmented-reality test cases. The main challenge in this process is definitely the development of the 3D model itself. When developing the 3D model it is very important to keep the model as simple as possible. The metaio Mobile SDK has limitations with regards to complexity of objects in 3D models. Depending on the device (iPhone4S, iPad3, etc.), only a specific number of faces – a face being a closed set of edges which make up a model's surface – can be processed. Different tests done within the ways2gether project confirm the maximum number of faces for the iPhone4S is approximately 8,000 faces, while the maximum number of faces for the iPad3 is approximately 20,000 faces.

First, planners need to ask themselves what kind of audience they want to reach. If the focus is set to the general public then it is recommended to choose a lower level of complexity for the model because the average mobile device only has a moderate computation power. However, if the focus is to impress investors by introducing a new prestige project, then the latest generation of devices can be used and a higher level of complexity can be selected.

There are two kinds of environment scenarios in which the augmentation can take place. It can take place in an urban area, e.g. where a pavement is going to be enlarged (which was the first test case in the ways2gether project done in Wallensteinstrasse) or it can be done in a new undeveloped area, e.g. where a new city district is going to be constructed (which was the second test case in the ways2gether project done in Aspern).

In regular planning processes 2D plans and 3D models are created. If the model or plan has already been created then we need to differ between three starting scenarios:

(1) Only a 2D floor plan has been created, so it is necessary to build the third dimension by hand, as described in more detail in 5.4.

(2) A 3D model has already been created, however the 3D objects inside the model are too complex, e.g. too complex buildings facades. In this case it is unfortunately necessary to reduce the level of complexity by hand, which is indeed a time-consuming task. This scenario is described in more detail in 5.5.

(3) The 3D model fulfills the necessary requirements for augmented reality on mobile devices, which represents the best case and the 3D model can be used without additional expenditure.

At the moment mobile device hardware is definitely the bottleneck for applications using augmented-reality. However, as already mentioned in 3.2, this sector is driven by a high rate of development and perhaps the challenge concerning the usage of realistic details in 3D models on mobile devices can be overcome in a couple of years.

5.2 Tools for the development of AR suitable 3D models

We decided to use Google Sketchup Pro for three reasons:

(1) Google Sketchup Pro can be handled quite easily by people with little to no designing skills. In contrast, acquiring fundamental skills for professional 3D design software such as Blender would take several weeks.

(2) The metaio Mobile SDK requires 3D models in OBJ format. Google Sketchup Pro supports the export of 3D models in OBJ format, so the models can be directly used for the augmented-reality test case.

(3) Google Sketchup Pro can import models in different formats, such as DXF and DWG created by common CAD software, like AutoCAD.

Additionally, Google Sketchup Pro is becoming more and more popular in the (3D) planning sector because it can generate simple and nice looking models within a short time.

5.3 Exporting the 3D model to the required 3D format

Depending on which kind of AR-framework is used, the model needs to be exported in a specific format. At the beginning of the ways2gether project, different AR-frameworks were evaluated (c.f. Reinwald, Murg, Damyanovic 2012) and the metaio Mobile SDK (http://www.metaio.com) was eventually chosen because it was the only framework which fulfilled nearly all of the requirements, such as fast and stable visualization of 3D models, a stable implementation of the device localization, LLA-code recognition (a GPS independent localization feature), and in-app integration – and all for free. The metaio Mobile SDK requires 3D models exported in OBJ-format for static content and 3D models exported in M2D-format for dynamic content, e.g. animated objects.

5.4 Floor plan to 3D model

2D floor plans are not the best starting point for the design task as it could take a great deal of time to build the floor plan up to a 3D model. We experienced this first hand during the ways2gether project when creating the Aspern test case. The planners could only provide a 2D floor plan of the street section which needed to be designed for the test case. This meant it was necessary to build the third dimension by hand, which took several hours. It is always recommended to use a 2D floor plan containing already closed polygon geometries. These geometries can be easily built into the third dimension, which saves valuable time and further costs.

5.5 Reducing the complexity of 3D models

If planners provide high complexity 3D models it is necessary to reduce the complexity to keep the graphic refresh rate running smoothly. There are different reasons for high complexity in 3D models:

(1) The 3D model is much too large, in which case unimportant parts of the 3D model should be removed.

(2) The model's objects are too complex, e.g. buildings with a highly complex facade. The complexity of these objects could be reduced by using special software; otherwise this task needs to be done by hand which is a time consuming process.

(3) The 3D model contains objects that are not really necessary for the augmented reality test case, e.g. electric lines or water pipes that may be hidden behind walls or under the ground. In this case all unnecessary objects should be removed from the model.

5.6 Adding textures and details to the 3D model

To improve the experience of a test case appropriate looking textures should be used. For example, brick-textures should be used for brick walls, bitumen-textures should be used for bitumen roads and glass windows should be translucent (see Figure 4). Moreover, the effect of furniture should not be

underestimated. As shown in Figure 5, it does increase the experience of the augmentation, while also providing an indication for the user so he can estimate the size of objects, e.g. buildings, street width etc. more easily.
Figure 4: Google Sketchup Screenshot of the Aspern Seestadt – on the left site without textures and on the right site with textures and additional decorative items, to give depth and scale

Figure 5: Google Sketchup Screenshot of the Aspern Seestadt – street view

5.7 Setting up the augmented-reality test case – export of the model in the AR framework

Due to the integration of the metaio Mobile SDK, setting up the augmented reality test case in ways2gether is quite an easy task. There are only a small number of files necessary that are grouped together in a repository on a FTP-server. Only a small number of files stored in the same directory on the FTP server are necessary. As shown in Figure 6, three files build the ground setup for an augmented-reality test case. Every test case is separated into a single directory. In the file Aspern.config.txt (marked by the red frame), basic configurations are stored, such as the model's location, orientation, and heading. The files surrounded by the green frame, Aspern_JRS_orig.mtl and Aspern_JRS_orig.obj, contain information about the 3D model itself. In addition to these three files, textures used in the 3D model also need to be located inside the directory.

The ways2gether app needs a mobile data connection in order to update new augmented reality test cases. After finishing the update process, there is no further need for mobile data connections as long as no new augmented reality test cases are needed.
Figure 6: Example files of the Aspern test case used in the ways2gehter project

6 DISCUSSION – THE USE OF AUGMENTED REALITY IN PLANNING AND PARTICIPATION PROCESSES

The initial results of the test cases show a differentiated picture,[2] with around 230 people taking part in the test cases overall. The possibility to be quickly immersed in the situation appears to be an advantage of the augmented reality app. People who are not involved much in creating plans or only rarely read plans in particular can quickly imagine the situation in reality.

Figure 7: Test of the ways2gether App in Seestadt Aspern, Vienna

6.1 First results of the test cases

Augmented 3D visualizations have the advantage that spatial relationships are visible immediately. Thanks to augmented reality it is no longer necessary to explain the difference between the reconstruction represented by objects in the 3D model and the already existing environment. It also helps to overcome language barriers because the model is for the most part self-explanatory. The possibility to view the object from all directions and to move freely within the model is especially seen as an improvement in contrast to traditional renderings presented on paper. In traditional renderings on paper the perspective which is chosen is usually the most attractive. By using an augmented-reality app where you can navigate freely, the possibilities for manipulating perspectives are reduced. The augmented reality app can also provide a better indication of the height of buildings or different ground levels. The option to view objections from a child's perspective was a very interesting feature for most people. In the child's perspective mode the height of all objects inside the 3D model is doubled and by activating this feature the user can put himself into a child's perspective in order to better understand which visual barriers a young child (between seven and ten years old) has to deal with every day. Additionally, the use of iPads was a strong magnet for many teenagers and young adults who otherwise usually are not represented in participatory processes. This younger group reported that the use of new technologies was definitely a motivation for their participation.

6.2 Accuracy of positioning

Urban street canyoning in particular causes a higher inaccuracy of the GPS signal, which influenced the positioning of the 3D object decisively. Metallic elements such as tram tracks, window frames or passing cars influenced the accuracy of the compass which in turn influenced the orientation of the 3D model. When it comes to projects in already built environments it is especially important that the model fits very well into the existing reality otherwise it may lead to misunderstandings among the users.

The implementation of LLA codes – QR (Quick Response) codes containing the latitude and longitude of the current position was tested in order to improve the accuracy of the device's postion. By using LLA codes the device's location can be determined within one-meter accuracy. However, due to the usage of QR codes, the key advantage of the augmented reality app – moving freely within the model – is lost because the user is tied to the location of the QR code.

---

[2] To evaluate the ways2gether app, a comparison of means (t-test) was applied. One group used analog plans, the other the AR app. Part of the results of this evaluation is documented in another CORP paper by Martin Berger, Mario Platzer, Christoph Schwarz, Thomas Pilz (2013) Neue Instrumente der Partizipation: Vergleich von Augmented Reality und Perspektiveskizzen im Rahmen des Shared Space Projektes Alleegasse in Hartberg.

A manual control unity was also integrated into the app during the development process so the user could manually modify the three axes of the model, whereby the model could be located more precisely. This workaround still allows the flexibility to freely move within the model. The disadvantage is that a strong three-dimensional imagination is required and the functions of the augmented reality app need to be known in detail. In the test cases for the project therefore guided tours were conducted in small groups with a maximum number of five participants. During these tours a trained person calibrated the model exactly by hand and afterwards the iPad was handed over to the participants.

When it comes to decision-making processes in particular a high accuracy of models and a precise positioning are necessary. It is expected that the usage of special digital video process algorithms, such as edge detection, will prove to be an improvement since the accuracy of GPS systems cannot be greatly increased in the foreseeable future,. Metaio is currently working on a semi-automatic snap-in (snapping) mechanism presented on the insideAR2012 (c.f. Metaio snap-in 2012) that could help to fit the model to its designated location. This feature works with object recognition using the camera of the mobile device. Once a manual setup of the 3D model is done by a user, the model will be automatically located in the correct position and this manual set up can be stored permanently so it is only necessary once.

6.3 Accuracy of the model

Due to current technical limitations, only a low level of immersion – how "real" the virtual world feels – is possible. Some participants in the test groups were a little bit disappointed about the low-detailed objects inside the 3D model because they were already used to the photorealistic renderings used for 3D movies or in computer games. The restriction of the used augmented reality framework regarding the amount of displayed faces and the absence of shadows inside the model reduces the immersion. However, test cases have also shown that the disappointment regarding the quality of representation is, in most cases, only experienced by people who already work in the planning sector.

It is also important to mention that for presenting first drafts – which is often necessary in participation processes – a more reduced schematic representation is necessary to give the impression that changes are still possible and suggestions and feedback are valued and will be taken into account.

6.4 Workflow

As mentioned in 5 there are a number of steps necessary to go from conventional plans or 3D models to the final augmented reality test case. It has been shown that the basics for an augmented reality model can be developed with existing and popular programs. The earlier in the planning process the decision to use an augmented reality model is made, the more easily it can be integrated into regular planning and participation processes. Augmented reality instruments can be used in many phases of the planning process, from the presentation of the first drafts up to the visualization of results.

The Austria-wide (and probably European-wide) first concretely applied test of an augmented reality app in the field of planning tested under real conditions has shown that these tools have great potential to increase the quality of participatory processes. Moreover, the augmented reality app is a helpful tool set and could help to expand the visualization and the presentation of results in planning. The app can also be used as an additional tool to extend the visualization and result presentation in planning.

Geographic Information System for Land Acquisition Process: A Social Need for Road Infrastructure Development in India

Bikram Kumar Dutta

(Bikram Kumar Dutta, Regional Planner, Associate Manager, IL&FS, L-30,Delta II, Greater Noida, bikramdutta@hotmail.com)

1   ABSTRACT

India is a developing country and it requires fast space quality infrastructure development, which is the need of current times. For any development, land is required and the land belongs to the people. Government is acquiring land for public purpose for the development of National Highways through National Highway Act of India 1956. Acquisition of land for public purpose displaces people, forcing them to give up their home, assets and means of livelihood. The Government of India (GoI) recognizes the need to minimize large scale displacement to the extent possible and, where displacement is inevitable, the need to handle with utmost care and forethought issues relating to Resettlement and Rehabilitation (R&R) of Project Affected Families (PAF) and formulate R&R Policies (NRRP 2007). But the ground reality differs from R&R policy. For assessment of land details are recorded in a system which is more than two hundred years old. This conventional system is not fulfilling the changing demands of time and ground truthing of space. The upcoming technologies such as Geographical Information System (GIS), data warehousing and web based information dissemination shall be very much helpful in land records management for decision making, strategy planning and predictive modeling. The use of these technological leverages can make land records management efficiently.

Since time immemorial, it has been a constant endeavour of human being to pursue various aspects of life with ease. In the present era of high-end computing, this endeavour of simplifying things is well achieved by an effective tool like GIS, when applied to, as complicated a process as land acquisition. Unlike the conventional procedure of simultaneous handling of various maps such as village cloth maps, engineering drawings and Layout plans etc., which are of different scale, GIS helps to prepare the maps and peruse the maps of multiple types at the same instance through registration of geographic coordinates. The concept of layer mechanism and subsequent superimposition one above the other is used so as to store both non-spatial and spatial data in different thematic layers. GIS technique has determined a fair and accurate location of linear alignment of proposed road corridor from current highways and to manage cadastral information which has to be obtained by satellite imagery, land records, Physical survey and land parcel creation more proactively by Overlay Analysis in accordance with name of the village and plot number basis. For the planners this entire process is made available at fingertips at the Personal Computers (PCs) without unfolding the age old cloth maps. The major hindrance in acquisition is calculation of proposed required area from a specific parcel or environmental sensitive areas, defense lands, alteration of topography etc. Through this approach an effort is made to analyse the various causes of mismatch between the map area and the old-recorded area and also the present manual system of superimposition of maps. In this context this paper describes a proposed automated process of land acquisition through Geographic Information System there by reducing the malpractice of resettlement and rehabilitation issues particularly in road development project in India.

Keywords: Geographical Information System, Land Acquisition, Land Parcel, Data Warehousing, Web based data Information system, Overlay Analysis.

2   HISTORY OF LAND RECODS

The Process of Land Records Management in India is very old. The Arthsastra is supposed to be the first Indian work to mention of the village officers known as "gopa" maintained records on village fields, transfers, due taxes, etc. but that was in a very rudimentary level. Attempt to reform the system was first made by Sher-Shah-Soori (Ruled from 1534-1545) whereby land was categorized, measured and a schedule of crop rates fixed. The system was reformed during Mughal King Akbar regime (Ruled from 1556-1605) by adviser Todar Mal. The subsequent colonial rule by the British implemented the system on scientific lines whereby large scale cadastral surveys were conducted to demarcate the boundaries and extent of each individual landholding, Soil fertility to levy revenue from landholders of each and every village. A "Patwari or Revenue Officer" was responsible for collecting agricultural revenue, reporting the transfer or transition information, maintaining pedigree database and managing land records of the area of his jurisdiction that is

known as a Patwar circle. After passing about two hundred years the system retain the same character and only minor changes have been made according to the needs of the time.

3 OBJECTIVES OF THE STUDY

- Understand existing land record system of India
- Identify Land acquisition act in the case of development of National Highways,
- Methodology for collection of land records
- Steps for preparation of land acquisition plan
- Suggest procedure for developing a computerized Land Records in Road Project Interface
- Information Management System and its implementation plan, for decision making and strategy planning.

4 LAND RECORD SYSTEM OF INDIA

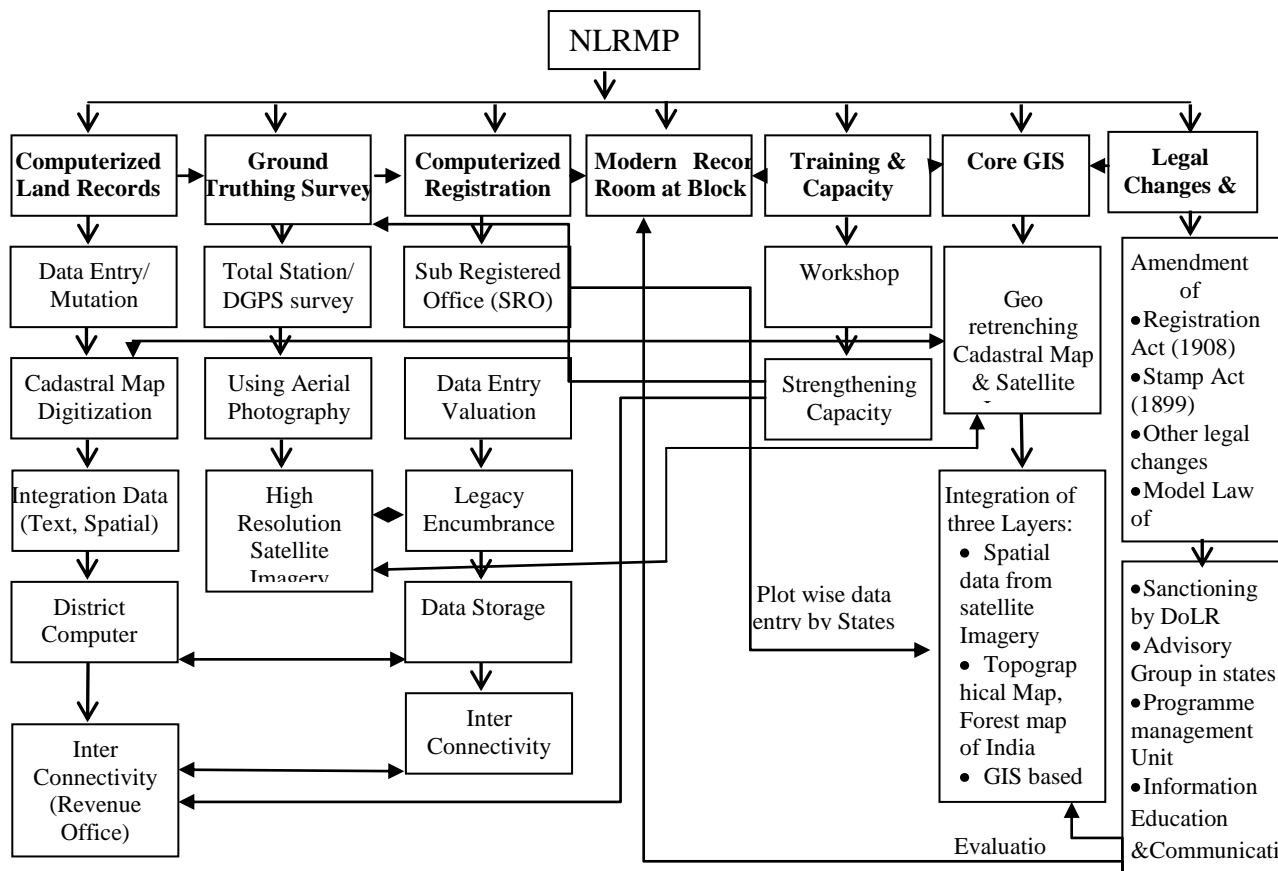
Land record system is at transition stage from 200 year old land record system to more advance computerization systems now. The Computerization of Land Records (CLR) was started in 1988-89 with the intention to remove the inherent flaws in the manual system of maintenance and updation of Land Records. In 1997-98, the scheme was extended to tehsils to start distribution of Records of Rights (ROR) to landowners on demand. So far the scheme has been extended to 582 districts and 3286 tehsils. Computerized copies of ROR are being issued to landowners from 1976 tehsil/taluks across the country. This project can safely claim to be the first successful initiative of e-Governance in India, at the grass-root level. The focus of the entire operation has always been to employ state of the art information technology (IT) to galvanize and transform the existing land records system of the country.


Fig 1: Basic System Architecture towards NLRMP

The Government of India has decided to implement the Centrally-Sponsored scheme in the shape of the National Land Records Modernization Programme (NLRMP)[4] by merging two existing Centrally-Sponsored Schemes of Computerization of Land Records (CLR) and Strengthening of Revenue Administration and Updating of Land Records (SRA&ULR) in the Department of Land Resources (DoLR),

Ministry of Rural Development[1]. The integrated programme would modernize management of land records, minimize scope of land/property disputes, enhance transparency in the land records maintenance system, and facilitate moving eventually towards guaranteed conclusive titles to immovable properties in the country. The major components of the programme are computerization of all land records including mutations, digitization of maps and integration of textual and spatial data, survey/re-survey and updation of all survey and settlement records including creation of original cadastral records wherever necessary, computerization of registration and its integration with the land records maintenance system, development of core Geospatial Information System (GIS) and capacity building. The following is an outline of the components and activities to be taken up under the NLRMP.

5 IDENTIFICATION OF LAND ACQUISITION ACT IN THE CASE OF DEVELOPMENT OF NATIONAL HIGHWAYS

The importance of land requirement in development projects needs no introduction. The ownership of such land may vest with the Government or any private person. For linear pattern projects such as the construction of roads, canals, pipelines, etc., minimum horizontal strip of land is required for acquisition. The land acquisition is generally spread over administrative boundaries of different districts. This necessitates co-ordination between the concerned administrative units. Further, another general feature observed is of encroachment along such linear projects. In this project, on examination it has been observed that such encroachment (Government Land) has been prominent at settlement stretches along the corridor. Such encroachments will be cleared due to requirement of land for the project corridor improvement.

Acquisition of Private Land: However, for the legal private property holders, the acquisition of the land would be taken-care of under the aegis of the Land Acquisition Act 1894 (amended 1984) (L.A Act)[2]. The L.A Act is applicable to all parts of India, but Land Acquisition by this process is lengthy. So for faster land acquisition National Highway Act of 1956 has introduced. Under the provisions of this act, the Government or any department of the Government can acquire land from the people for public purpose.

Legal Framework for Land Acquisition: With the increase of movement of traffic on account of industrial advancement it was found necessary that important highways of the country be developed and maintained by the Central Government. To achieve this objective The National Highways Bill, 1956 was introduced in the Parliament. The Land Acquisition (LA) for this project is to be undertaken in accordance with the provisions of this act. The following are the major provisions of the act for the land acquisition:

Section 3A: Provides for notification to landowners (Notification should be published in two daily newspapers; one in the regional language and the other in English. The same should be published in the Hindi Government Gazette) about the interest of the Government to acquire the notified land;

Section 3B & 3F: Provides power and right to the person authorized by the central government to make inspection, survey, measurements, valuation or inquiry;

Section 3C: Permits landowners to express their objections against such land acquisition;

Section 3D: Declaration of acquisition if no objections has been made to the competent authority;

Section 3E: Provides power to take possession of land once the amount determined by the competent authority has been deposited under sub-section (1) of section 3H;

Section 3G: Allows the competent authority to decide on the compensation to be paid;

Sections 3H: Provision for deposit of payment determined under section 3G in the manner as may be laid down by rules made in this behalf of the central government and

Under Section 3J: As per the provision of this section nothing in the Land acquisition act 1894 shall apply to an acquisition under this act.

6 METHODOLGY FOR COLLECTION OF LAND RECORDS

In order to determine the extent of private property that will be acquired under the project, it is requested the respective District Magistrate of the district to arrange through the concerned revenue officials to provide the Revenue maps of all the villages through which the corridor traverses. The concerned officers from the Revenue Department of different Talukas/Tehsils of respected District were then approached to obtain a copy of the village maps with the demarcated individual plots. The widening plan developed as part of the

Feasibility study was superimposed on these village maps to identify the individual plots that are being affected. The plots numbers of these affected plots were provided to the Revenue Officer for verification of plot numbers and provide the land records for each of them. All this has been compiled as part of the Land Acquisition Report, an independent document prepared for the project.

7 STEPS FOR PREPARATION OF LAND ACQUISITION PLAN

Summary of procedure adopted for land acquisition plan are followed:

Step-1 (Project Initiation): The user agency shall issue letters to Concerned District Collectors, acknowledging them about the project and also ask for providing necessary documents to the user agency. District Collectors have issued letters to Tehsildars, who consecutively directed Revenue Officer to provide respective Village Maps, Revenue Records and Cost of Land to the User Agency for preparation of LAP.

Step-2 (Identification of Villages): The user agency shall identify the villages through which the project corridor is passes.

Step-3 (Collection of Revenue Maps): After the identification of villages, the user agency shall approach respective Revenue Officer for collecting Revenue Maps

Step-4 (Overlapping of Revenue Maps): Once after gathering Revenue Maps, the proposed widening plan would be overlapped or superimposed on the Revenue maps with the help of software packages.

Step-5 (Identification of Affected Plots): The exercise of overlapping could bring out specifically the affected plots. Such affected plots have been market out.

Step-6 (Demarcation): After identification of affected plots, the specific area of the affected plot could be demarcated.

Step-7 (Collection of Land Records): On demarcating the affected area, land records would be collected from Revenue Officer. This could fulfil the requirements of 3A.

Step-8 (Compilation): After collecting land records for all the plots from respective Revenue Officer, the same has been sorted out for affected plots.

Step-9 (Final Land Acquisition Plan): All the information collected from Revenue Officer has been worked out with respect to proposed widening plan there after the final land Acquisition Plan was prepared.

8 FRAMEWORK FOR DEVELOPING COMPUTERSIDED LAND RECORDS IN ROAD PROJECT INTERFACE

In conventional system, query of land records is laborious, time consuming and revolves round a single person (Patwari) that is why integration of geographic data and their pertinent alphanumeric data is indispensable to develop and maintain a comprehensive Land Records Information Management System (LRIMS). The geospatial techniques of the present information age can prove to be very useful to transform the conventional system into an efficient, easy-to-use, updatable, remotely accessible and above all practically applicable LRIMS. The proposed system will not only be useful for the revenue department regarding Information updating, query, reporting, customization, leakage detection and predictive modeling but will also beneficial for other system stakeholders regarding the identification of legal precinct of their respective lands. For land acquisition plan in road infrastructure man machine interface model makes data capturing, ground truthing, plot details, land parcel details and acquisition plan more accurate and less time consuming. As NRLIP is only used for land records and revenue collection but through interface of different stakeholders and department of India LRIMS may role pivotal for decision making process as under:

LRIMS in Road Proiect

Base line information Module: The base line information module basically comprise of map, graphic, raster image, base line information, attribute data related to spatial information in one platform i.e. Geographic Information system (GIS)[3]. The module will have the have capabilities of querying building, presentation of the result of the query in both graphical and tabular presentation through overlay analysis. The information system will have zooming facilities starting from 1:1or 2 million scale and zooming up to 1: 500 scale depending upon the resolution imagery and the level of study (Figure:3)

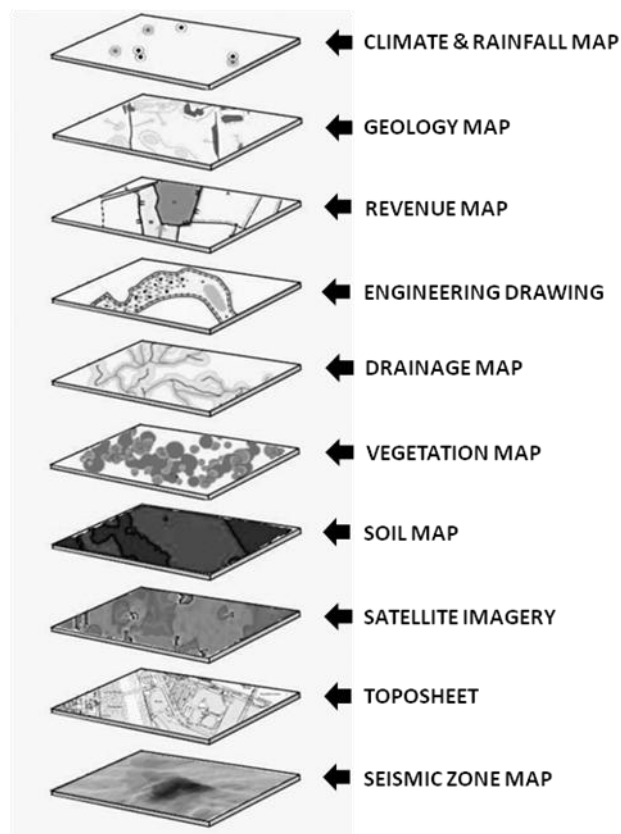
CLIMATE & RAINFALL MAP
GEOLOGY MAP
REVENUE MAP
ENGINEERING DRAWING
DRAINAGE MAP
VEGETATION MAP
SOIL MAP
SATELLITE IMAGERY
TOPOSHEET
SEISMIC ZONE MAP


Figure 3: Baseline Information Mapping

The information content of this module will be cadastral map showing details of each land parcel with physiography, Demography, Landuse, Physical and Social infrastructure, sensitive location, housing, open areas, transportation (road, rail, waterways), utilities (water supply, electricity), hot spots, location of

monuments, polluted stretch, problem areas, tourist spots, pilgrim areas, tribal settlement, earth quack prone areas and environmental status and their details etc.

Organizational Interface Module: Broadly speaking in Indian scenario the development, management and decision making bodies for road sector are Ministry of Road and Transportation (MoRTH), National Highway Authority of India (NHAI), Public Works Department (PWD), Rural Road (MDR), Border security Force (BSF). But these bodies are individual. This module will have three sub modules with highway, state roads and others roads. This module will contain alphanumeric data like Jamabandi, Khasra Girdawari, Pedigree Sheet. The basic booklet to be incorporated in thin module will be Government notifications, norms, infrastructure development standards various gazetteer, guidelines and directions published by Government.

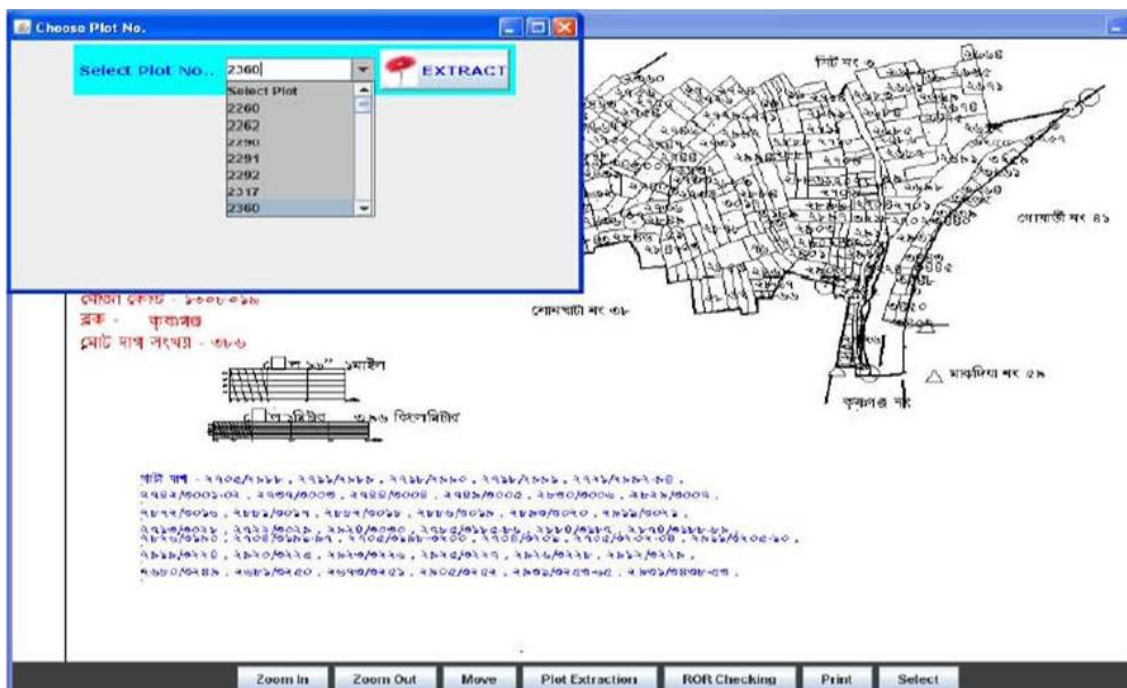
Public Participation Module: Public participation is one of the major tasks in land acquisition process. Sections 3A to 3H are involved with different stakeholders. The module will act as a platform for sharing the plan and progress of land acquisition in this computerized interface. This module will contain land parcel details, status of acquisition process, disbursement of compensation and public grievances.


Fig 4: Public participation Module

The system management and maintenance module: The module deals with the maintenance and management of the LRIMS in Land Acquisition system itself. It is basically a user management module. It deals with the various authorization for access, viewing, updation, modification of data, information etc. The user management function may add and delete users for the system and moreover the module-wise authorization will also vary. The data, graphic and map updation may authorized to different user to update the baseline and other information. The system management will be at block level, district level and state level. The average users will only be able to use data, analyse and compare the data but could not be able to revise, add, delete or modify.

9   INFORMATION MANAGEMENT SYSTEM AND ITS IMPLEMENTATION

Integration of Field Measurement Books (FMB) and alphanumeric data is indispensable to have a full-fledged LRIMS. The technologies like GIS, spatial data warehousing and web are very mush helpful to generate a complete LRIMS. All Block offices will have right to update the information as well as to keep a track of ownership, crop yield and revenue and as well as land acquisition status on it. With the aid of these recent technologies all the land record information will be under fingertip (click of mouse). The implementation of this interface will help:

A gateway to dynamic planning: A developing country like India which is in the transition stage of office automation this information system will act as platform of integration of traditional data and information system and the modern and dynamic GIS based information system.

Efficient data management: Land acquisition exercise needs a wide range of data and information. In GIS platform every data and information are stored in different coverage. It helps in integration and differentiation of graphic and data base information with the data table and text.

Tools for data analysis: This information system has the capability of performing the user – based data query. The types of data analysis used by infrastructure planners, developer, decision maker, land owners will be different from the academician, general public. Ever user will retrieve, plot, and analyze the data as per the requirement.

Transparent planning: With the dynamic nature of the information flow the planning, monitoring and management exercise will be more transparent.

Active public participation in planning: the proposed information system will be web based and it would not be software biased. Information Technology could be opened with any operating system. As all the information are easily available the people will be able to take active participation in the land acquisition and developmental activity.

10 CONCLUSION

Modern GIS integrates various kinds of advanced, dynamic, multi-layered, time series data and graphical information which transform the tedious data analysis job to a faster, dynamic and realistic exercise. Regular updation of information makes the monitoring and management of land parcel in records more transparent and realistic approach towards road development. This information system can be used as a tool for road development as well as it can also be a useful support system for change of ownership, land value evaluation and ultimately land acquisition.

1 ABSTRACT

In recent years, the way we communicate and exchange information has undergone tremendous changes. Among other aspects, this is triggered by rapid advances in modern ICT. Meanwhile, communication processes, which are increasingly Web 2.0 mediated, enable reflective and participatory practice, and the use of geomedia (i.e. supporting geovisualisation and geocommunication). Besides, influencing work life and private life, this has also impact on the field of civic responsibility (a core element to democratic societies). A prominent example therefore is the involvement of citizens in urban planning processes. For participatory urban planning the use of Web 2.0 tools, closely linked to geomedia use, opens up a wide range of opportunities in all planning process steps. This encompasses activities related to providing information, consultation, collaboration, and taking part in decision making.

The handling of geomedia – and thus being able to contribute to urban planning processes – requires for particularly skilled citizens, who currently are mostly missed in society. While school education has recently started to consider geomedia competencies as an essential topic, opportunities for such empowerment for adults barely exist. However, to allow planning processes to benefit from ICT and geomedia use, suitable activities in the field of adult education and learning need to be established. Facing this gap, this paper discusses the topic of how adults can become spatially prepared, i.e. how adults' geomedia skills can be developed and strengthened with the intention to permit them to participate in urban planning processes.

2 INTRODUCTION AND BACKGROUND

Today, cities and urban areas get increased attention all over the world. Topics such as rapid urbanization (e.g. Sao Paulo, Brazil), discussions about smarter cities (e.g. Amsterdam, The Netherlands), the need for green cities (e.g. Chicago, USA) and sustainable cities (e.g. Vancouver, Canada), as well as urban deconstruction and reconstruction (e.g. shrinking cities like Leipzig, Germany) provide various challenges for urban planning.

Urban planning, i.e. city planning, is a special branch in the spatial planning domain. It is concerned with settlements and related spatial arrangements, and determining the conditions for the location of structures in urban space. It is widely acknowledged that successful urban planning processes generate economic growth, social and environmental harmony, political advances as well as scientific progress, while missing, poor, or unfavorable urban planning causes social exclusion, poverty, uncontrolled urban sprawl, and environmental problems (UN-HABITAT 2008; URL 1).

Carried out by experts such as (urban) planners, architects, and geographers, urban planning makes use of particular frameworks such as the strategic planning process. These processes consist of several steps corresponding to generic problem solving procedures: They begin with problem definition, involve various forms of analysis, and finally move to prediction and solution design. To solve the problem they also take into account and evaluate alternatives (Hall 2002).

Over the years the way spatial planning processes are conducted changed. Randolph (2004:16) points out: "(…) public participation grew in the 1970s, communication became the emphasis in the 1980s, and the 1990s saw more collaborative approaches involving stakeholders and partners reasoning together."

Thus, pivotal elements, which meanwhile are increasingly linked to urban planning processes, and which open up numerous opportunities are

(1) the involvement of the general public (public participation);

(2) the integration of modern information and communication technology (ICT), i.e. Web 2.0 tools; and

(3) the use of geomedia.

2.1 Public participation and (urban) spatial planning

Today public participation is broadly accepted as a paradigm in support of sustainable spatial planning as well as urban planning. Due to the specific circumstances found in cities, urban planning, more than other planning branches, relies on collaboration between various groups. This encompasses people in authorities, planners, and the general public (Jiang, Huang & Vasek 2003). Advantages refer to give consideration to the multifaceted and oppositional demands made by a growing and highly-divers city population, to become aware of existing conflicts, and to make better-informed and well-grounded decisions.

In doing so, it has proved especially advantageous to involve citizens in all tasks and steps appertaining to urban planning processes: Throughout the entire process citizens can be allowed to contribute, comment, amend, and evaluate information (Jankowski 2009; Renn et al. 1993). Following the so-called ladder of participation this can take on different levels: level 1: inform; level 2: consult; level 3: involve; level 4: collaborate, and level 5: empower (IAP2 2007). In consequence, many urban planning initiatives and projects see citizen participation to be a pivotal element (see e.g. URL 2).

2.2 Public participation and the development of Information and Communication Technology (ICT)

Due to the rapid advance in ICT in recent years, tremendous changes were generated in the way the general public can become involved in planning projects (Ramasubramanian 2010). As presented in Table 1, therefore digital media provide various opportunities (Da Trindade & Wehrhahn 2010; Milovanovic 2003).

	One-way communication	Two-way communication			
	Inform	Consult	Involve	Collaborate	Empower
Objectives	To provide the public with balanced and objective information to assist them in understanding the problem, alternatives, opportunities, and solutions.	To obtain public feedback on analysis, alternatives, and decisions.	To work directly with the public throughout the process to ensure that public concerns and aspirations are consistently understood and considered.	To partner with the public in each aspect of the decision including the development of alternatives and the identification of the preferred solution.	To place final decision-making in the hands of the public.
Techniques	Fact sheets Open houses	Public comment Surveys Public meetings	Workshops deliberative polling	Citizen advisory committees Consensus-building Participatory decision-making	Citizen juries Ballots Delegated decision
ICT Example	(Basic) Web sites	On-line polls	On-line discussion forums	On-line services, forms & documents in electronic form	On-line decision making support systems

Table 1: Spectrum and technics of public participation (Hennig & Vogler 2011)

Benefits of incorporating modern ICT in planning are numerous and well-known. Some examples are: a large number of people can get involved in discussions, the exchange of ideas, and in opinion surveys without attending meetings personally at fixed times (bad timing) and fixed locations (far away; bad connection to public transport etc.); the speed of communication between the interested persons can be increased; and the quality of communication can be improved given that quiet, reserved, and less eloquent persons get the possibility to contribute. As highlighted by Jiang, Huang & Vasek (2003) and Milovanovic (2003), better planning results emphasize the positive effects of using according tools. Hence, for planners demand is growing to apply new communication tools allowing for public involvement via Internet (Devisch 2008; Evans-Cowley 2010).

2.3 Geomedia, geovisualisation and geocommunication

Owing to the spatial reference of its objectives, the use of geomedia always plays a central role in spatial planning, in which it considerably improves decision-making (von Haaren 2004). In the context of public

participation the use of geomedia must be underlined as important media for visualization and communication, i.e. geovisualisation and geocommunication (Sieber 2006).

Broadly defined, geomedia denotes any digital information or media that provides a spatial reference. This spans a wide range of representation forms including simple verbal descriptions (e.g. route descriptions), complex digital maps (web maps, digital globes), and spatial data. Further, it comprises location based services and location based communication via spatialized social media platforms (Gryl et al. 2010).

Geovisualization refers to a set of tools and techniques that support spatial data analysis through the use of interactive visualization. By this means, geomedia is communicated in ways that, when combined with human understanding, data exploration and decision-making processes are assisted. Particularly relevant therefore are interactive digital maps: While traditional, static maps (i.e. analog or paper maps) have a limited exploratory capability and the graphical representations are inextricably linked to the data beneath, owing to the use of appropriate functionalities interactive, digital maps allow for extended ways to discover the visualized map content. This relies e.g. on the ability to explore different layers, to navigate a map (zoom, pan), and to change the visual appearance of a map (Jiang, Huang & Vasek 2003; Jiang & Li 2005; MacEachren et al. 2004; MacEachren & Kraak 1997).

Geocommunication is characterized by the use and combination of different types of multimedia elements (text, photo, image, animation, audio and video file etc.) as well as geomedia. In doing so, geomedia is accompanied by explanations and multimedia elements in order to clarify the presented content and give context (Hennig, Vogler & Jekel 2011). At that, a high number of users can collaborate in production and consumption of according features (so called collaborative mapping), employing interactive functionalities provided by computer-based tools (Brodersen & Nielsen 2006; Jobst 2009).

Tools leveraging the power of geomedia (i.e. geovisualisation, geocommunication) in the scope of participatory planning are numerous. Applications used are e.g. simple web mapping tools (allowing for collaborative mapping; e.g. Google Maps, Bing Maps, ScribbleMaps, ArcGIS online, Open Street Map); PP GIS (public participation geographic information systems) developed to benefit from user generated content (i.e. volunteered geographic information); specific social media platforms (allowing for discussions between different actors using text, geomedia and multimedia in a combined way); and geoportals (user interface to spatial data infrastructures; INSPIRE, Open Government Data).

2.4 Arising needs in the framework of public participation, modern ICT and geomedia use

Due to the above outlined changes (concerning public participation, modern ICT, and geomedia use) the spatial planning domain faces several challenges: (1) to elaborate suitable methods and techniques to support participation; (2) to provide appropriate software applications; (3) and to meet the demand for adequately prepared citizens being able to participate in planning processes leveraging ICT and geomedia. Even though in recent years, great attention was paid to the first topics, the last one often and still is left behind.

While pupils through changing school curricula including new teaching concepts and materials are more and more empowered to competently use geomedia, a gap exists on strengthening adults' geomedia skills. However, adults are generally the ones asked to contribute to and to participate in spatial planning processes – as well as to other civic responsibility tasks. In this context, there are still many open questions: 1) How spatially enabled is our society (focusing on Austria)? 2) Which skills are needed to handle geomedia competently (i.e. regarding participatory planning)? 3) How can the public become spatially prepared, i.e. how can adults become skilled geomedia users?

The work presented in this paper is based on experience gained in two projects: "Geomedia 50+" and "AccessibleMap": The "Geomedia 50+" project was carried out in cooperation with the program "University 55-PLUS" (Paris Lodron University of Salzburg; URL 3) and the European network "digital-earth.eu" (URL 4), which supports the exchange of experience and the elaboration of adequate teaching materials. This project focused on specifying competence needs to allow for skilled geomedia use; assessing experience on geomedia use on the part of the general public; and designing an appropriate workshop (including courseware) to endow adults with geomedia skills. The "AccessibleMap" project funded by the Austrian Federal Ministry of Transport, Innovation & Technology within the Benefit program (URL 5) aimed at developing and improving the use of interactive, dynamic web maps according to the requirements of the visually impaired people as well as the elderly.

3   SKILLS ENABLING GEOMEDIA USE

Geomedia empowerment of adults asks for a general understanding of therefore required skills. During the workshop "Geomedia 50+" (first lessons) according aspects were revealed through group discussions with and observation of participants using geomedia and modern ICT. This, on the one hand, allowed for identification and categorization of necessary skills. On the other hand it provided insight into the existing level of geomedia skills amongst the participants. Box 1 gives an overview about selected socio-demographic characteristics of the workshop participants.

Number of participations: 19 (13 finished the course including performance record)

Gender distribution: 14 male and 5 female participations

Education level distribution: 2 hold a Phd degree, 2 hold a diploma's degree (equiv. to M.Sc.), 2 hold a secondary school leaving certificate equiv. to high school, 13 hold a secondary school leaving certificate equiv. to junior high school

Age distribution: 55 to <60 years: 5; 60 to <65years: 4; 65 to > 70 years: 7; 70 to >75 years: 2; 75 to >80 years: 0 and older than 80: 1

Box 1: Selected socio-demographic information on the workshop participants

3.1 Geomedia skills

The competencies needed to allow skilled geomedia use are numerous. Due to the information collected in cooperation with the workshop participants, these skills can be grouped under three categories:

- skills relevant to handle geomedia (produce, use, share, reuse etc.),
- skills relevant to use common Web 2.0 tools, and
- basic (digital) cartographic skills, i.e. knowledge.

These categories and the associated skills are presented in Table 2 and outlined shortly in the following.

Geomedia skills and related tasks & topics

Geomedia skills and related tasks & topics	
ICT / Web 2.0	Register and login
	Publish, share, embed (using different web 2.0 applications)
	Work in a cooperative way
	Use of multimedia (find/create images, URLs, video/audio files; insert, embed, share, these)
	Internet safety issues including topics such as intellectual property rights, and data privacy
Geomedia abilities (focusing on web mapping tools)	Use digital maps (find, open, zoom, pan, explore)
	Create maps and features (markers, lines, areas)
	Add further information (using information windows)
	Handle data files (import, export, transfer)
	Output maps (print, save, export, embed)
	Re-use data (find data, assess data, integrate data)
Geomedia capabilities	Cartographic design: adequate symbology, map picture, background map, use of multimedia
	Multimedia use (transfer data, post, comment)
	Critical reflection on the power of maps

Table 2: Categories and associated skills related to competence needs concerning geomedia use

Non-professional geomedia handling – as it is the case within the framework of participatory planning – bases, among other things, on the use of different types of Web 2.0 tools.

First of all, Geomedia handling asks for the ability to manage web mapping tools and other tools related to geovisualisation and geocommunication. Users must be able to find and open maps, explore maps (by the help of using navigational tools, legends, context information available in information windows or balloons etc.). Beside these basic tasks, users should know how to create own maps and data, i.e. map features (point, line, area), how to import and export data (concerning topics such as data file formats, converter tools), how to add multimedia information (using e.g. information windows, inserting links and images), and how to output and re-use data and maps.

Besides web mapping tools, social media tools (e.g. blogs, forums, social media platforms etc.) play a pivotal role. These Web 2.0 applications allow for publishing and embedding of map objects as well as commenting and discussing on the (geovisualised) content. They require from the users to be familiar with the basics of the principal Web 2.0 philosophy and its main concepts: user collaboration, participation, and interaction. Hence, being able to conduct tasks related to social networking services (SNS) is a prerequisite (Ebersbach, Glaser & Heigl 2011; Richter & Koch 2008): It includes (1) identity management (creating a user profile including access rights; group memberships etc.), (2) expert finding (using different search criteria such as name, interest, company etc.), (3) context awareness (awareness of a common context with other people; essential for successful collaboration), (4) contact management (maintenance of the personal digital network), (5) network awareness (awareness on the activities and status of the members of the personal network and on current changes), and (6) exchange (directly e.g. by instant messaging or indirectly e.g. via bulletin boards).

The purpose of communication is to effectively send a message to the receiver rather or the (map) reader. In doing so, information must be transmitted in a way that people without great knowledge of a subject can perceive and understand the presented subject and can create a pertinent idea of it. To facilitate this, the used media must show and/or explain an object or phenomenon in a vivid and reasonable manner. Use and design of either a single communication medium or a combination of several diverse media is generally based on the functions that the media has to accomplish/fulfill in the communication process (see e.g. Hake, Grünreich & Meng 2002). This requires certain skills and knowledge on cartographic design and multimedia use.

3.2 Level of geomedia skills

Concerning the above mentioned skills (see Table 2), users' knowledge and background vary strongly. This also relates to general computer, Internet and ICT use experience.

A certain level of basic ICT skills (including computer and Internet use skills) constitute the fundament for any competent geomedia handling. It encompasses the use of data, applications, and devices (Möller 2006). While today's young people are described as digital natives (URL 6), most adults lack such native understanding of ICT, Internet, and computer use. Moreover, related skills vary considerable among adults. If not using ICT as part of their working life, these users – particularly the elderly – often show weak or no ICT background at all. Thus, for instance, through surveying and observing the workshop participants it become obvious, that most of them face serious problems in registering for web applications (login), searching the Internet, embedding multimedia elements (e.g. images), and inserting hyperlinks. This is even more true for aspects concerning the use of geomedia. Besides experience to plan a route (using e.g. Google Maps), participants, more or less, were not at all familiar with geomedia handling.

4 CONSEQUENCES AND SOLUTIONS FOR PARTICIPATORY URBAN PLANNING

While participatory urban planning benefits from geomedia use, not only the data and the associated tools are a subject of interest. During the last years they deserved great attention in the context of discussions about spatial data infrastructures (SDI), Open Government Data etc. However, it is not enough to provide user-centered tools and applications if users miss the required skills. Hence, it is equally relevant to enable the public to competently handle geomedia in order to bear their civic responsibilities and duties.

For this, interested persons request support. Solutions accompanying the particular planning process are e.g. (1) help, additional information, and tutorials, (2) e-learning material, (3) webinars, (4) blended learning initiatives, and (5) face-to face workshops, which might integrate all mentioned aspects if needed.

Here, to realize adequate solutions, approaches on GI-education as well as adult education and learning deliver suitable background information. A practical example on how to integrate according topics for adults' geomedia enablement is given by the particularly designed workshop "Geomedia 50+".

4.1 Relevant education and learning approaches

4.1.1   GI -education

To endow spatial literacy a number of educational approaches, which are summarized under the umbrella-term GI-education, exist. Until now, they mainly focus on secondary and higher education. In this context, two diverging conceptual approaches can be outlined, namely "Spatial Thinking" (NRC 2006) and "Spatial Citizenship" (Gryl & Jekel 2012).

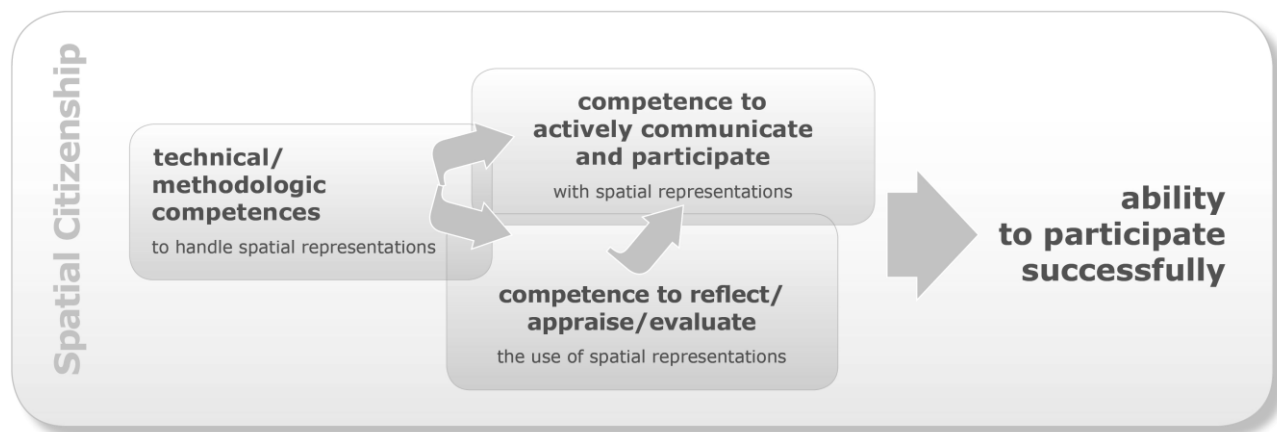
The "Spatial Thinking" approach centers on building up GIS skills and aims at enhancing geomedia abilities in order to face an increasing need of GIS professionals in the current and future working environment. In contrast, the "Spatial Citizenship" approach conceptually argues from an everyday life perspective. It targets at fostering geomedia skills to enable everyone to successfully become part of today's emerging spatially enabled society. Relying on social and social geographic theories (see e.g. Werlen 1993) as well as contemporary citizenship education purposes (see e.g. Bennett, Wells & Rank 2009), the "Spatial Citizenship" approach emphasizes three dimensions (see Fig. 1): 1) basic skills in geomedia handling, 2) competencies allowing for a critical reflection on the power of spatial representations such as (digital) maps, and 3) the competence to communicate with geomedia. This shall ensure to have citizens disposing of relevant abilities and capabilities for a critical, reflective, and emancipatory handling of geomedia in modern geocommunication environments. On the basis of this everyday life embedding, and its focus on (post)secondary education, the "Spatial Citizenship" approach provides a reasonable framework for adult education initiatives concerning geomedia use.


Fig. 1: The concept of "Spatial Citizenship" (Gryl & Jekel 2012)

4.1.2   Adult education and learning

Adult education and learning is considered a strong link in the lifelong learning chain. Recently, it is widely discussed across Europe and steadily gaining importance as it is deemed to have high social and economic significance: It is acknowledged that learning brings equally important benefits for adults' social inclusion, personal fulfillment and development as well as well-being. It enables people to secure an active and constructive role in their communities and in society at large, and can help reduce poverty, health costs and the incidence of criminality (European Union 2006; European Union 2012).

Meanwhile, extensive practical experience and theoretical background on adult education and learning is available (see e.g. Arnold & Pätzhold 2008). General consents exist that adult people learn in a different way from young people: For adults implicit learning plays a central role. They can easily connect new content to already existing knowledge and in consequence have less problems assessing and/ or linking complex topics. Problems are caused by learning under time pressure. Hence, to improve learning outcome it is helpful to give enough time and to recapitulate learning content (BMASK 2010). Ultimately, high quality and attractive adult learning initiatives are most successful (European Union 2012).

As overall concept, support of self-directed learning is essential in adult education and learning. Advantages are numerous: It gives the individual learner greater freedom of choice, it is flexible and it is, by definition, specifically tailored to what learners need (URL 8). Thus, responding to key responsibilities relevant for educators self-directed learning shall target at (1) enabling learners to make informed choices about their development; (2) providing support on an individual, personal level, responding to specific requests for help, (3) providing a range of materials and resources learners can choose those best suited to their personal development needs, and (4) coaching, guiding and assisting learners in using resources and materials to their best effect (URL 8). A selection of principles significant for adult education and learning is listed in Table 3.

Categories	Examples
Action-oriented	Use, tie in with knowledge and abilities of the participants Knowledge on facts and situations Participants ability to decide and judge
Situation-related	Move towards context of everyday life activities Show relationship to everyday life Produce context Experience of the participants
Experience-oriented	Having participants contributing to the course (as co-designer, co-planner)
Science-oriented	Accordance with scientific knowledge
Exemplarity	Course topics as example for other facts and issues Show opportunities for transfer of learning Comparison to other situations

Table 3: Selection of principles significant for adult education and learning (Arnold & Pätzhold 2008; BMASK 2010; European Union 2006)

4.2 Practical example: "Geomedia 50+" – a workshop to build up adults' geomedia skills

The workshop "Geomedia 50 +" (thematically focusing on topics related to Austrian urban areas) was designed and developed based on approaches on GI-education and adult education and learning. The specified list of geomedia skills (see Table 2) was taken into account for the preparation of courseware, the selection of tools, and the elaboration of workshop structure. Selected aspects highlighted in the following sections might provide some guidelines or suggestions on how to face the problem of enabling adults who lack necessary skills to participate in spatial and urban planning processes using geomedia.

4.2.1 Courseware and tools

In order to prepare useful and valuable workshop courseware and to select adequate tools multiple conditions had to be met: It was born in mind that accessibility barriers (might) hamper and discourage participants from the start. As outlined by Neuschmid et al. (2012) and Hennig et al. (2012) – in context with the AccessibleMap" project – this refers to complex computer programs, poorly documented (workflow) instructions, missing additional information (help, user support, glossary etc.), and the use of English language as well as of ICT-specific and planning-specific terms.

Thus, courseware and selected tools not only had to face the situation of varying ICT and computer use background, but also had to consider the need for highly detailed and well-documented training material and description of application use. This allows course participants to (independently) re-pass through learning content and exercises (self-experience). Additional information (access to further information using e.g. links) and exercises support self-directed learning. In doing so, a substantial introduction was given for those characterized by low or no ICT background; those providing advanced background were challenged as they were asked to serve as peer-tutors for ICT-beginners.

Applications belonging to the Google product family were selected to be used in the course. This decision is well-founded: the according tools are easily accessible and usable for everyone (open source, cloud-based storage service); they provide help, tutorials, and user support; and they are available in German language. Further on, they permit to experience a number of different activities related to geomedia handling (see Table 2):

- Google Maps allows users (here: workshop participants) to (cooperatively) create and exchange data and maps. Data can be imported and exported. Multimedia elements and links can be inserted. Several methods exist to share maps with others (send via email, embed in other applications etc.).

- Google Blogger allows users (here: workshop participants) to easily discuss and exchange as well as to publish maps enriching them by verbal information including multimedia and links.

- Google+ allows community building and networking (here: focusing on the workshop participants).

- Google Drive allows sharing of all kinds of documents (doc, xls, ppt etc.) and multimedia elements among a specified community (here: workshop participants). Thus, all materials produced for or during the workshop were made available on Google Drive by both, the educators and the participants.

4.2.2 Workshop structure

The workshop consisted of several units (see Table 4). All course units consist of phases of personal attendance (face-to-face contact) alternating with those relying on self-study and self-experience (self-doing). They combine lectures (imparting necessary theory) with exercises (allowing for practical experience). Time for reflection and recapitulation of the learning content was scheduled in all units. Particularly important was to tie geomedia education with every-day life topics and activities as it is the underpinned for general adult education activities (European Union 2012). Following requirements stressed by BMASK (2010), personal experience, knowledge, and interest were integrated, and benefits were drawn from it. Participants were always encouraged to explore existing possibilities of the used applications and to elaborate individual solutions (e.g. project work).

	Units	Content	Purpose
Personal and group/ team support (f2f teaching, group discussions, email, blog, consultation hour)	Introduction	Collecting participants' perspectives Giving theoretical background Gaining some first own practical experience	Gain insight in participants state of geomedia capabilities and abilities
	Sweetener	Visit of GIS day event hold at University of Salzburg	Provide an overview on the wide range of GI/ geomedia Raise interest and awareness on topics in the context with GI and geomedia
	Handling data and maps	Theoretical Background Practical experience	Provide basic functions of geomedia
	Critical reflection on maps and data	Theoretical Background Practical experience	Provide a critical view on geomedia regarding (political) power etc.
	Project work (team work)	Do a project working (related to an everyday situation) based on learning transfer (prepare a digital map visualizing a self-chosen topic incl. data gathering and management, and deciding on the map layout)	Reflection, recapitulation self-experience
	Presentation	Presentation and discussion of the projects	Reflect on the work done

Table. 4: Introduction of the workshop structure

In the course of the workshop a relevant aspect was to consider the motivational set of the adults: While pupils and in part professionals necessarily have to deal with modern ICT including geomedia, since it is integrated in school education or part of their work, the general public misses such external drivers. Apart from needs triggered by e.g. civic responsibilities and duties, theses users must be seen as self-motivation group. This means that on a first look, no obvious sweeteners exist to encourage this target group to deal with modern ICT and geomedia. Accordingly, it is a pivotal aspect to get these people involved: Adults must be aware of the benefits of acquiring geomedia skills. This asks for inspiration and drive to get them to start activities and further to keep on track.

In addition, courseware and tools must strengthen not only skills on tool use or map design, but also personal attitudes relevant for geomedia use. This covers a wide range of topics: trust in yourself – don't be afraid of

using the computer or the Internet; be curious; transfer of learning concerning the use of other tools (e.g. other web mapping tools); and unfurling the changed way of information and communication etc.

5 CONCLUSION

This paper presented some first practical experience collected in the context of building up geomedia skills on the part of adults. Users providing a certain level of specific competencies are a pre-requisite to allow public participation in urban planning processes benefiting from modern ICT and geomedia. This facilitates to take advantage of important resources for today's' urban planning problems. Education initiatives can therefore draw upon existing approaches on adult education and learning and GI-education

However, it became obvious, that to enable adults to competently use geomedia still a lot needs to be done. Besides, discussions on adults' spatial enablement are closely linked to a number of recently emerging concepts: spatially enabled society (see e.g. Enemark & Rajabifard 2011), societies' digital divide (see e.g. URL 9), and e-Inclusion (see e.g. URL 10). This clearly and further underlines the need for spatial prepared citizens.

Gestione delle risorse ambientali e pianificazione del territorio: le linee guida per la Valutazione ambientale strategica come strumento sistemico nei processi di pianificazione e programmazione

Federica Isola, Cheti Pira

(Research Doctor Federica Isola, University of Cagliari, Via Marengo, 2 – 09123 Cagliari, federica.isola@unica.it)
(Research Doctor Cheti Pira, University of Cagliari, Via Marengo, 2 – 09123 Cagliari, chetipira@unica.it)

1 INTRODUZIONE

L'attenzione per l'ambiente e la necessità di migliorare la gestione delle risorse naturali sono argomenti di costante attualità. La crisi ambientale ha imposto ai governi internazionali delle scelte difficili in campo pianificatorio e programmatorio, ed è andata rafforzandosi l'esigenza, ma anche la difficoltà, di arrivare a breve termine a una svolta nello sviluppo economico e sociale e a una rapida maturazione di una diffusa consapevolezza sulla nuova realtà, per fare fronte velocemente alle minacce esistenti. E' da questa necessità ha preso forza il concetto di "sviluppo sostenibile", introdotto per la prima volta nel Rapporto Brundtland nel 1987, e poi divenuto costante richiamo nei documenti nazionali e internazionali, in esso la concezione della sostenibilità, nel governo del territorio, va oltre la semplice tutela dell'ambiente in quanto oltre la dimensione ambientale include quella economica e sociale. La questione ambientale, si offre oggi, come arena privilegiata per la sperimentazione di nuove forme di discussione pubblica ed elaborazione di nuovi strumenti decisionali, da ciò ne deriva che è necessario gestire le risorse ambientali tramite una pianificazione partecipata, e più in generale che per integrare la dimensione ambientale nei processi decisionali è necessario attivare forme attive di partecipazione. In tale senso le politiche ambientali vanno ad influenzare sempre di più i processi di governance territoriale, intesa come il processo che comprende la formazione delle decisioni che riguardano un territorio.

Riflettere sull'integrazione dei paradigmi della sostenibilità nei processi di pianificazione e di governance territoriale significa pensare che, ai diversi livelli di governo, sia necessario un gradiente d'innovazione capace di affermare nuove logiche e soprattutto una radicata convinzione che la sostenibilità non sia solo un termine "plastico" e stereotipato Le pratiche valutative si prestano come un valido supporto fin dalle fasi preliminari, tramite un approccio integrato e multisciplinare ai problemi ambientali sociali ed economici.

Un importante strumento di governance, utile nell'orientare le scelte di piano al paradigma dello sviluppo sostenibile, è la Valutazione ambientale strategica (VAS). Rispetto al suo rapporto con la governance, si potrebbe definire la VAS come un insieme di regole, principi, tecniche e strumenti con la funzione di supportare, continuamente, il processo decisionale con lo scopo di generare consenso attorno alle azioni da compiere e, soprattutto, di far sì che tale consenso duri nel tempo e si trasformi in una rete di relazioni stabili in grado di garantire continuità e coerenza al processo di pianificazione.

La VAS nella pratica non viene ancora applicata come un attivo supporto ai processi decisionali, causa forse una scarsa "cultura valutativa", nonostante ci siano a livello comunitario e a livello nazionale e regionale delle linee guida che sistematizzano tale processo con il tentativo di definire uno schema procedurale che assicuri la definizione di scelte partecipate e inclusive della considerazione degli aspetti ambientali.

Considerando la necessità di usare meglio le risorse territoriali anche tramite politiche e linee guida, il paper analizza, partendo da un'introduzione teorica sul concetto della VAS, la strutturazione metodologico procedurale, di una serie di strumenti guida, creati con l'intento fornire ai differenti soggetti coinvolti nella predisposizione e nella attuazione di piani e programmi (pianificatori, valutatori, autorità responsabili, pubblico in generale, ecc.) indicazioni metodologiche di integrazione ambientale utili ed efficaci per l'impostazione delle loro iniziative strategiche, sia che si tratti di piani o di programmi. L'ultima parte del paper analizza in maniera critica le linee guida per la VAS, proposte dalla Regione Sardegna, nell'adeguamento dei piani urbanistici comunali al Piano paesaggistico regionale.

2 CONCETTI CHIAVE DELLA VAS

La Direttiva 2001/42/CE ha introdotto un cambiamento di prospettiva nell'approccio alla pianificazione territoriale, che vede nella VAS uno strumento flessibile, trasparente, partecipato e sistemico nella costruzione della conoscenza. Le parole chiave per una buona VAS, secondo quanto indicato dalla Direttiva e presenti in letteratura sono: strategicità, processo, sostenibilità, partecipazione e alternative. Queste sono evidenziate già nel 1992 da Thérivel che definisce in maniera esaustiva la VAS come un "formale,

sistematico e comprensivo processo di valutazione degli impatti ambientali di una politica, di un piano o programma e delle sue alternative, che include la preparazione di un report scritto, i cui risultati devono essere resi pubblici e integrati nel processo decisionale" (Thérivel et al., 1992).

Rispetto a questi concetti, in letteratura è rinvenibile un interesse crescente verso questi temi. Parlando di strategicità già nel 1989 Bartlett e Baber affermano che ciò che determina il successo di una valutazione di impatto non è tanto la metodologia ma la sua efficacia in particolari circostanze di politica implicita (Bartlett e Baber, 1989). Questa riflessione pone l'accento sulla relazione tra strategia e sulle circostanze in cui la VAS è attuata.

La VAS, per essere efficace, deve andare oltre la semplice analisi degli effetti ambientali di una decisione (Brown e Thérivel, 2000; Kørnøv e Thissen, 2000) incentrandosi maggiormente sul processo decisionale e sulla sua dimensione strategica. Essa, inquadrandosi a un livello cruciale delle scelte può integrare, nel rispetto dei principi della sostenibilità, le scelte di carattere tecnico con quelle di carattere politico avendo come riferimento sistemi di valori articolati e complessi, inseriti in realtà conflittuali e mutevoli (Fusco Girard et al., 2005, 2006, 2008). Questa visione della VAS rispecchia quella di Fischer che la definisce come un modello politico (Fisher, 2002).

La VAS mira a definire un insieme molto più ampio di prospettive, obiettivi e vincoli di quelli inizialmente individuati dal proponente (Harvey, 1992; Brown, 1998) di un piano o di un programma e in questo, l'aspetto partecipativo non è meno importante della fase di individuazione degli impatti (Eggenberger e Partidário, 2000).

E' possibile ottenere un insieme più ampio di prospettive solo se il processo di VAS è un processo condiviso e partecipato, con momenti in cui le comunità si esprimono con fasi di sistematizzazione ed interpretazione delle istanze espresse, integrate esplicitamente nelle decisioni sulle politiche di piano (Zoppi, 2009).

L'individuazione di limiti, opportunità, alternative e la definizione di criteri e opzioni possibili di trasformazione territoriale assumono un efficacia diversa se la VAS viene usata come strumento interattivo (Brunetta, 2002).

Nonostante siano passati ormai tredici anni dall'entrata in vigore della Direttiva comunitaria sussistono notevoli difficoltà nel applicare la VAS secondo le sue parole chiave. Una ragione può essere una scarsa consapevolezza delle potenzialità dello strumento valutativo, dovuta anche al grande ritardo del recepimento della Direttiva 2001/42/CE in alcuni ordinamenti nazionali come quello italiano.[1] Gli stessi proponenti i piani in generale sono poco convinti del fatto che la VAS possa rappresentare per i processi decisionali un valore aggiunto (Brown e Thérivel, 2000). Collegata a questo aspetto è l'eccessiva attenzione alla procedura piuttosto che al processo a scapito del raggiungimento di benefici ambientali più sostanziali (Jay et al., 2007), prestando dunque poca attenzione allo sviluppo concettuale della VAS (Cashmore et al, 2004;. Thissen, 2000).

La VAS nella pratica è usata come una Valutazione d'impatto ambientale applicata ai piani, prestando quindi maggiore importanza all'aspetto della tutela ambientale piuttosto che alla contemporanea considerazione degli aspetti ambientali, economici e sociali, che dovrebbero fare della VAS uno strumento di governance della sostenibilità (Sadler, 1999).

L'endoprocedimentalità della VAS nella formazione di un piano, è un requisito necessario affinchè ci sia l'attributo "strategico" nella valutazione. Essa è anche il presupposto fondamentale affinchè ci sia un coordinamento delle varie politiche settoriali con la pianificazione territoriale, ed è anche una delle maggiori sfide affinchè si possa arrivare ad una vera integrazione tra gli aspetti ambientali, le questioni sociali ed economiche. In quest'ottica l'integrazione è un mezzo privilegiato per aumentare l'efficacia della valutazione ambientale e la valutazione sociale ed economica ne processo decisionale (Kirkpatrick e Lee, 1999).

---

[1] In Italia la Direttiva 2001/42/CE è stata recepita con la Parte Seconda del Decreto Legislativo del 3 aprile 2006, n. 152 "Norme in materia ambientale", modificata e integrata dal Decreto Legislativo del 16 gennaio 2008, n. 4 "Ulteriori disposizioni correttive ed integrative del D.lgs. 3 aprile 2006, n. 152, recante norme in materia ambientale," entrato in vigore il 13 marzo 2008 (di seguito D.lgs. 152/2006 ss.mm.ii.), in notevole ritardo rispetto ai tempi prescritti dall'Unione Europea, ragione del procedimento europeo di infrazione che ha portato successivamente ad una condanna della Corte di Giustizia Europea, per la "mancata trasposizione della Direttiva nell'ordinamento nazionale entro il termine prescritto."

3 LE LINEE GUIDA PER LA VAS COME STRUMENTO SISTEMICO NELL'ANALISI DEI PROCESSI DI PIANIFICAZIONE E PROGRAMMAZIONE

La necessità e l'urgenza di controllare l'uso delle risorse naturali nei processi di trasformazione territoriale, ha reso l'utilizzo di linee guida requisito fondamentale, in particolare nella valutazione delle politiche orientate alla pianificazione territoriale; La definizione di strutturazioni metodologiche procedurali può rappresentare un elemento utile ed efficace per la definizione e l'attuazione delle stesse.

In questa sezione si descrivono alcuni esempi di utilizzo di linee guida, analizzate da un punto di vista metodologico, usando come chiave di lettura i temi della VAS, secondo quanto indicato dalla Direttiva 2001/42/CE: la partecipazione, la sostenibilità e l'aspetto strategico.

Le linee guida esaminate sono state create con l'intento di fornire, ai differenti soggetti coinvolti nella predisposizione e nella attuazione di piani e programmi, indicazioni metodologiche utili ed efficaci per l'impostazione delle loro iniziative strategiche, facilitando le applicazioni di un nuovo modello di pianificazione sostenibile, anche attraverso la proposizione di sperimentazioni, esperienze significative e strumenti operativi.

In esse è stato definito un modello tecnico razionale in cui la VAS cerca di influenzare un piano o un programma nel definire un certo set di obiettivi, identificare criticità, definire alternative.

I casi presi in esame sono il Manuale per la valutazione ambientale dei Piani di sviluppo regionale e dei Programmi dei Fondi strutturali 2000 -2006 dell'Unione europea (da qui in avanti Manuale),[2] le Linee guida create per la VAS dei Fondi strutturali 2000-2006[3] e quelle relative alla sperimentazione del progetto Enplan.[4]

Nel Manuale e nelle Linee guida per la VAS dei Fondi Strutturali 2000-2006, il tema della partecipazione è affrontato come elemento chiave della fase decisionale, in particolare, si riconosce nella partecipazione delle comunità locali alla definizione, gestione ed attuazione dei processi della pianificazione territoriale quale presupposto fondamentale per la loro efficacia. E' esaltato il ruolo delle Autorità ambientali[5] nel processo di preparazione dei piani e della valutazione delle loro implicazioni, e si afferma che esse sono chiamate a svolgere un ruolo di grande rilievo, non considerando al contrario, l'importante ruolo svolto dalle comunità locali. In entrambi i documenti non è chiara la metodologia attraverso la quale la partecipazione delle comunità locali possa attuarsi, e considerando che la predisposizioni dei piani (PSR, PSM) e programmi (PO e DocUP) è compito della pubblica amministrazione, ma che la predisposizione dei progetti per i PO. e per i DocUP, è di competenza dei singoli cittadini, imprese, ecc, (Zoppi e Garano, 2003) è chiaro che parlare di partecipazione limitandosi all'ambito relativo alle Autorità ambientali e settoriali, risulti non esaustivo.

---

[2] Nell'ambito della regolamentazione dei fondi strutturali 2000-2006, particolare rilevanza fu attribuita alla valutazione ambientale dei piani e dei programmi da presentare ai finanziamenti comunitari. Relativamente alla necessità di migliorare la comprensione e di fornire orientamenti generali, il Directorate General (DG) XI "Ambiente, sicurezza nucleare e protezione civile", della Commissione europea, pubblicò nel 1998, un Manuale per la valutazione ambientale dei Piani di sviluppo regionale e dei Programmi dei Fondi strutturali dell'Unione, in cui si definiscono dal punto di vista operativo, i diversi passi e fasi per la definizione della VAS di questi piani e programmi.
Il manuale definisce i vari stadi del ciclo di programmazione dei Fondi strutturali relativo all'elaborazione dei Piani di Sviluppo Regionale (PSR), dei Quadri Comunitari di Sostegno (QCS) e dei Programmi Operativi (PO), in particolare definisce le componenti principali della VAS nel contesto della procedura di programmazione dei Fondi strutturali, lasciando liberi gli Stati membri e le regioni di integrare ciascuna fase nel rispettivo processo di pianificazione. (Manuale, pag. 22).
[3] Nel 1999, in Italia, il Ministero dell'Ambiente con il Ministero dei Beni e delle attività culturali e Agenzia nazionale per la protezione dell'ambiente (ANPA) ha elaborato le Linee guida per la valutazione ambientale strategica dei Fondi strutturali 2000-2006, che ricalcano le disposizioni del Manuale, definendone modalità pratiche per l'integrazione, offrendo un immediato supporto alle Autorità ambientali e, più in generale, nella loro partecipazione al processo di programmazione, fornendo alle Regioni elementi metodologici essenziali per attivare programmi sostenibili anche nel lungo termine, individuando processi di collaborazione e confronto fra le autorità coinvolte.
[4] Le Linee guida Enplan per la Valutazione Ambientale dei piani e programmi, sono il risultato di un intenso lavoro da parte di 10 Regioni italiane e spagnole, coordinate dalla Regione Lombardia, durato quasi due anni nell'ambito del Progetto Enplan (approvato nel dicembre 2002 e concluso nell'ottobre 2004), sono state predisposte con l'intento di facilitare l'applicazione della Direttiva 2001/42/CE e di un nuovo modello di pianificazione sostenibile.
[5] Secondo il Manuale i principali responsabili dell'elaborazione di piani e programmi e dei relativi processi di valutazione sono le "autorità dello sviluppo" e le "autorità competenti in campo ambientale". Con il termine generico "autorità dello sviluppo" si intendono tutti i ministeri, le agenzie ed altri organismi pubblici

---

Contrariamente, nelle Linee guida Enplan, si afferma come il processo di elaborazione dei piani e programmi richieda il coinvolgimento "mirato" di soggetti diversi dall'amministrazione responsabile della elaborazione degli stessi. Tali soggetti comprendono amministrazioni esterne e il pubblico nelle sue diverse articolazioni. Si afferma chiaramente che: "Ciascun soggetto apporta al processo complessivo un contributo di conoscenza e di identificazione dei problemi e delle potenzialità" (Linee guida Enplan, pag.79).

Il tema della sostenibilità è per il Manuale, elemento essenziale, in esso si afferma come sia necessario garantire che nel corso dell'intero processo di programmazione si tenga conto dei potenziali impatti ambientali individuati in fase di elaborazione del piano medesimo. (Manuale, pag.25)

Nella VAS le questioni ambientali e quelle legate allo sviluppo sostenibile devono essere prese in considerazione dal primo stadio della programmazione dei Fondi strutturali (ossia durante l'elaborazione del piano di sviluppo regionale (PSR)), per garantire che i risultati e le informazioni ottenuti vadano a vantaggio dei livelli di pianificazione successivi riducendo gli eventuali conflitti tra obiettivi economici e ambientali (Manuale, pag.25). Affinchè vi sia una reale integrazione, tra la componente ambientale e sviluppo, la procedura dei Fondi strutturali e la VAS debbono garantire che gli obiettivi dei PSR siano essenzialmente sostenibili.(Manuale, pag.24) Questo implica che gli obiettivi non devono limitarsi all'attuazione delle direttive comunitarie o delle legislazioni nazionali, ma concentrarsi sulle opportunità e sui vantaggi derivanti dall'integrazione della dimensione ambientale nei piani di sviluppo .(Manuale, pag.39).

Nelle Linee guida Enplan, si afferma che la sostenibilità rappresenta il filo conduttore per rendere effettivi l'integrazione e il coordinamento tra tutti i settori e le scale di pianificazione e programmazione, di conseguenza lo sviluppo sostenibile non deve intendersi come meta da raggiungere, ma piuttosto come un insieme di condizioni che devono essere rispettate nel governo delle trasformazioni.

Nell'ambito delle Linee guida per la VAS dei Fondi Strutturali 2000-2006 e del Manuale, l'aspetto concernente la strategicità della VAS nelle fasi di pianificazione, consiste nella verifica della rispondenza dei Piani di sviluppo e dei programmi operativi con gli obiettivi dello sviluppo sostenibile,[6] verificandone il complessivo impatto ambientale, ovvero la diretta incidenza sulla qualità dell'ambiente.

La definizione degli obiettivi è il risultato dell'analisi ambientale,[7] ossia lo studio delle pressioni più rilevanti sul territorio, delle emergenze e delle criticità riferite ad esso e attraverso tale analisi è possibile comprendere quali siano le priorità di sviluppo per le Regioni.

Le Linee guida Enplan, dal punto di vista strategico, individuano invece, una fase preliminare di orientamento e impostazione del piano o programma, per il quale si rende necessaria un'analisi di sostenibilità degli orientamenti dello stesso; Orientamenti ai quali fanno parte gli indirizzi politici

---

[6] La definizione degli obiettivi deve soddisfare le condizioni di sostenibilità all'accesso alle risorse ambientali. Tali condizioni sono comunemente fatte risalire ai seguenti principi
- il tasso di utilizzazione delle risorse rinnovabili non sia superiore al loro tasso di rigenerazione;
- l'immissione di sostanze inquinanti e di scorie nell'ambiente non superi la capacità di carico dell'ambiente stesso;
- lo stock di risorse non rinnovabili resti costante nel tempo. (Linee guida per la VAS dei Fondi Strutturali 2000-2006 pag. 6).
Nel rispetto di tali principi il Manuale della Comunità europea. individua dieci criteri di sostenibilità per la definizione degli obiettivi del programm. I criteri sono: 1. ridurre al minimo l'impegno delle risorse energetiche non rinnovabili; 2. impiego delle risorse rinnovabili nei limiti della capacità di rigenerazione; 3. uso e gestione corretta, dal punto di vista ambientale, delle sostanze e dei rifiuti pericolosi/inquinanti; 4. conservare e migliorare lo stato della fauna e della flora selvatiche, degli habitat e dei paesaggi; 5. conservare e migliorare la qualità dei suoli e delle risorse idriche; 6. conservare e migliorare la qualità delle risorse storiche e culturali; 7. conservare e migliorare la qualità dell'ambiente locale; 8. protezione dell'atmosfera; 9. sensibilizzare alle problematiche ambientali, sviluppare l'istruzione e la formazione in campoambientale; 10. promuovere la partecipazione del pubblico alle decisioni che comportano uno sviluppo sostenibile.

[7] Nell'ambito di tali Linee guida si fa riferimento a vari tipi di indicatori utili per l'analisi ambientale, e descritti nell'Allegato 1 della guida, dedicato alla presentazione del modello DPSIR (Driving Forces-Pressures-State-Impacts-Responses). Dall'elaborazione dei dati relativi al predetto modello, è possibile ottenere un quadro di riferimento per la definizione degli obiettivi di sviluppo sostenibile, che risultano essere quindi la risposta alle criticità evidenziate dalla descrizione della situazione ambientale e le sue evoluzioni, che offre quindi il sostegno informativo necessario alla esplicitazione delle priorità, all'individuazione di indicatori per valutare in un sistema coordinato l'impatto prevedibile dei piani e consentirne il monitoraggio.

dell'amministrazione responsabile, gli interessi settoriali o territoriali presenti e la pressione sociale su aspetti specifici (Linee guida Enplan, pag. 68).

L'analisi risulta cruciale nella definizione degli obiettivi, poichè essi costituiscono la dichiarazione di ciò che il piano o programma intende raggiungere mediante l'insieme delle sue previsioni. L'integrazione tra obiettivi di carattere ambientale e obiettivi di carattere socio-economico rappresenta uno dei momenti cruciali del processo di pianificazione. Dal punto di vista metodologico le Linee guida Enplan indicano la necessità per un piano o programma orientato alla sostenibilità, di procedere ad una valutazione che non si limiti all'analisi degli aspetti ambientali, ma estesa a comprendere gli aspetti sociali ed economici, considerati componenti intrinseche del concetto di sostenibilità (Linee guida Enplan, pag. 83).

Considerando la situazione odierna, è possibile affermare come i documenti citati nel presente paragrafo, risultino essere comunque attuali, alla luce di una più matura consapevolezza dell'importanza degli aspetti valutativi nei processi di pianificazione. La VAS ha assunto oggi un importante ruolo nel panorama pianificatorio economico e territoriale, con il pieno recepimento nelle legislazioni nazionali della Comunità europea, nonostante le grandi differenze fra i contesti culturali e socio economici di applicazione della Direttiva 2001/42/CE abbiano portato allo sviluppo di molteplici sue interpretazioni conducendo alla composizione di un quadro molto variegato di approcci, strumenti e metodi di applicazione.

4 LE LINEE GUIDA DELLA REGIONE SARDEGNA PER LA VAS DELL'ADEGUAMENTO DEI PIANI URBANISTICI COMUNALI AL PIANO PAESAGGISTICO REGIONALE

Con l'intenzione di fornire un supporto alle amministrazioni comunali e ai professionisti nell'adeguamento degli strumenti urbanistici al Piano paesaggistico regionale,[8] le Linee guida per la VAS dei Piani urbanistici comunali (PUC), definite dalla Regione Sardegna,[9] hanno cercato di integrare il processo di piano stabilito dalla Legge Regionale del 22 Dicembre 1989, n. 45, "Norme per l'uso e la tutela del territorio", con la procedura di VAS disposta dalla parte seconda del D.lgs. n. 152/2006 e ss.mm.ii.

Il tentativo della Regione Sardegna è stato di fare in modo che il processo di integrazione si realizzasse attraverso la completa unione tra il processo di VAS e quello di piano, nonostante si trattasse di due processi disciplinati da normative e tempistiche differenti (Regione Sardegna,2010, p. 11). Tale integrazione non è rinvenibile nelle linee guida predisposte in altre Regioni dove si descrive o solo la procedura di VAS, oppure la procedura di VAS separata totalmente dalla procedura di piano.[10]

Le Linee guida sarde rappresentano per le amministrazioni comunali un valido riferimento non solo dal punto di vista procedurale ma anche metodologico. Sulla redazione del documento di scoping e del rapporto ambientale non si limitano a elencare i contenuti indicati nell'Allegato Sesto del D.lgs. n. 152/2006 e ss.mm.ii., ma forniscono degli indirizzi ulteriori, anche in riferimento ai territori comunali interessati dalla perimetrazione di aree classificate come Siti di Interesse Comunitario e/o Zone di Protezione Speciale e, pertanto, sottoposte oltre che al processo di VAS anche a quello di Valutazione di incidenza ai sensi dell'art. 5 del D.P.R. 357/1997. Il processo di VAS in questo caso è integrato con il processo di Valutazione di incidenza, non soltanto dal punto di vista procedurale (Regione Sardegna,2010, Allegato D).

Le principali criticità rilevabili nelle Linee guida, sono riconducibili a un mancato approfondimento dei temi della partecipazione delle comunità locali al processo di pianificazione, dello sviluppo sostenibile e del processo di costruzione degli obiettivi di piano.

---

[8] La Giunta Regionale ha approvato, con Delibera n. 36/7 del 05/09/2006, il Piano paesaggistico regionale – Primo Ambito Omogeneo. La normativa disciplina ventisette Ambiti di Paesaggio che costituiscono il Primo Ambito Omogeneo, corrispondente al territorio costiero. Comuni, province e gli enti gestori delle aree protette hanno l'obbligo di adeguare i rispettivi strumenti di pianificazione e programmazione alle previsioni del piano. In questa fase di adeguamento la VAS, secondo le indicazioni del D.lgs. 152/2006 ss.mm.ii.), è una procedura obbligatoria.

[9] Assessorato della Difesa dell'Ambiente di concerto con Assessorato Enti Locali, Finanze e Urbanistica. La prima versione del 2007 è stata più volte modificata e integrata fino all'ultima versione, approvata con Delibera assessoriale n. 44/51 del 14.12.2010.

[10] Si possono vedere a titolo di esempio i modelli metodologici – procedurali, definiti dalla Regione Lombardia dove si individua uno schema procedurale generale e uno specifico per i vari piani generali e settoriali di livello comunale, provinciale e regionale. La deliberazione della Giunta Regionale della Lombardia di riferimento è la n. 9/761 del 10 Novembre 2010.

Il D.lgs. 152/2006 ss.mm.ii. stabilisce che la fase preliminare deve essere attivata dal proponente in contraddittorio con l'autorità competente,[11] puntualizzando che le consultazioni tra autorità procedente,[12] autorità preposta alla valutazione e autorità competenti in materia ambientale,[13] devono avvenire sin dai momenti preparatori dell'attività di elaborazione di piani e programmi, sulla base di un rapporto preliminare sui possibili impatti ambientali significativi dell'attuazione del piano o programma.

Secondo le Linee guida regionali la fase di scoping deve prevedere un processo partecipativo che coinvolga i soggetti competenti in materia ambientale potenzialmente interessati dalla redazione del piano urbanistico comunale, affinché condividano il livello di dettaglio e la portata delle informazioni da produrre e da elaborare, nonché le metodologie per la conduzione dell'analisi ambientale e della valutazione degli effetti ambientali (Regione Sardegna 2010, p. 22). Durante gli incontri di scoping devono essere illustrati (Regione Sardegna, 2010, p. 23): modalità con cui condurre il processo di VAS; metodologia per l'analisi ambientale (componenti interessate dall'attuazione del piano, indicatori da utilizzare, possibilità di popolarli, metodo di analisi, ecc.); modalità per la conduzione del processo di partecipazione e approvazione dell'elenco dei soggetti coinvolti nel processo (soggetti competenti in materia ambientale, pubblico[14] e pubblico interessato[15]); contenuti del rapporto ambientale.

Nelle Linee guida il pubblico e il pubblico interessato è individuato ma non coinvolto in questa fase. Eppure si afferma nelle stesse che al fine di pervenire alla costruzione di un piano il più possibile condiviso, il processo partecipativo dovrebbe essere avviato sin dalle prime fasi di elaborazione del piano (Regione Sardegna, 2010, p. 45); le stesse Linee guida suggeriscono inoltre, nonostante il D.lgs. 152/2006 e ss.mm.ii, limiti la partecipazione del pubblico ad una fase successiva all'adozione del piano, di prevedere ulteriori momenti di partecipazione, volti a coinvolgere sia i soggetti competenti in materia ambientale sia il pubblico interessato, anche nelle fasi precedenti all'adozione dello stesso, ovvero durante la sua costruzione (Regione Sardegna, 2010, p. 45). Sembrerebbe che, rispetto a questa affermazione e al non coinvolgimento del pubblico e del pubblico interessato in questa fase, lo scoping non faccia parte del processo di costruzione del piano.

In riferimento alla metodologia da usare per il coinvolgimento dei soggetti competenti in materia ambientale durante gli incontri, si suggerisce la metodologia tradizionale basata sulla presentazione del documento di scoping, seguita da una discussione aperta e dalla verbalizzazione delle osservazioni presentate (Regione Sardegna, 2010, p. 46). Le Linee guida propongono anche un questionario da somministrare agli stessi soggetti, attraverso il quale porre loro specifici quesiti in merito alle modalità con cui si intende condurre il processo di VAS e sulle informazioni che si intende inserire nel rapporto ambientale (Regione Sardegna, 2010, pp. 25-28).

Un'altra criticità che si riscontra nelle Linee guida è che le fasi, dal punto della VAS, sembrano far parte di un processo separato da quelle di formazione del piano, nonostante l'integrazione posta in premessa alle stesse (Regione Sardegna, 2010, p. 11). Tale integrazione infatti si riferisce più ad una integrazione temporale delle fasi, ma non ad una integrazione sostanziale tra i due processi nella definizione di obiettivi e azioni.

---

[11] La pubblica amministrazione cui compete l'adozione del provvedimento di verifica di assoggettabilità, l'elaborazione del parere motivato, nel caso di valutazione di piani e programmi (art. 5, comma 1, lettera p del D.lgs. 152/2006 ss.mm.ii.).

[12] La pubblica amministrazione che elabora il piano, programma, ovvero nel caso in cui il soggetto che predispone il piano, programma sia un diverso soggetto pubblico o privato, la pubblica amministrazione che recepisce, adotta o approva il piano, programma (art. 5, comma 1, lettera q del D.lgs. 152/2006 ss.mm.ii.).

[13] Le pubbliche amministrazioni e gli enti pubblici che, per le loro specifiche competenze o responsabilità in campo ambientale, possono essere interessate agli impatti sull'ambiente dovuti all'attuazione dei piani, programmi (art. 5, comma 1, lettera s del D.lgs. 152/2006 ss.mm.ii.).

[14] Una o più persone fisiche o giuridiche nonché, ai sensi della legislazione vigente, le associazioni, le organizzazioni o i gruppi di tali persone (art. 5, comma 1, lettera u del D.lgs. 152/2006 ss.mm.ii.).

[15] Il pubblico che subisce o può subire gli effetti delle procedure decisionali in materia ambientale o che ha un interesse in tali procedure; ai fini della presente definizione le organizzazioni non governative che promuovono la protezione dell'ambiente e che soddisfano i requisiti previsti dalla normativa statale vigente, nonché le organizzazioni sindacali maggiormente rappresentative, sono considerate come aventi interesse(art. 5, comma 1, lettera v del D.lgs. 152/2006 ss.mm.ii.).

Si evidenzia, inoltre, la mancanza di una spiegazione del concetto di obiettivo generale e obiettivo specifico di piano e di una metodologia per la loro definizione. Gli obiettivi generali, secondo le Linee guida, devono essere definiti già dalla fase di preparazione, prima ancora della fase di orientamento, se ne deduce quindi, al di fuori della procedura di VAS (Regione Sardegna, 2010, p. 12). "Il processo di VAS, contestuale a quello di elaborazione del piano è avviato dall'amministrazione comunale, in qualità di Autorità procedente, mediante pubblicazione di apposito avviso, sull'Albo comunale e sul sito Internet, contenente la prima definizione degli obiettivi del piano (Regione Sardegna, 2010, p. 15)."

Rispetto all'individuazione degli obiettivi/criteri di sostenibilità, nelle Linee guida, oltre ai principi di cui al c. 2, art. 3 delle N.T.A. del PPR,[16] si indica che si può far riferimento ai dieci criteri proposti dal Manuale[17] L'argomento della sostenibilità è dunque ridotto al segnalare l'opportunità, nella predisposizione del piano, della considerazione dei dieci criteri valutando attraverso quali scelte strategiche e attraverso quali azioni specifiche essi possano essere concretamente perseguiti (Regione Sardegna, 2010, p.16).

Infine, non è rimarcato nelle Linee guida che la valutazione della sostenibilità del piano dovrebbe essere cruciale nella fase di orientamento e che gli obiettivi della tutela ambientale devono essere considerati nel momento in cui le decisioni vengono prese: tale considerazione deve avvenire su una posizione di parità con le altre variabili (economiche, sociali) che costituiscono oggetto della decisione (Caratti e Tarquini, 2002). Inoltre non si fa cenno al fatto che gli obiettivi specifici del piano devono essere relazionati ai suddetti criteri, con la finalità di definizione, per il territorio in esame, di una serie di obiettivi (propri) locali di sostenibilità (Mondini e Norberti, 2008). Solo la contestualizzazione dei criteri ne garantisce una funzione efficace a migliorare la qualità della programmazione e della pianificazione (Zoppi, 2010).

5   CONCLUSIONI

L'analisi delle linee guida in riferimento ai concetti chiave per una buona VAS, permette di evidenziare alcune prospettive di ricerca per migliorare le stesse e renderle maggiormente efficaci.

Partendo dal presupposto che l'endoprocedimentalità della VAS nella formazione di un piano o un programma, è un requisito necessario affinchè vi sia l'attributo "strategico" nella valutazione, si ritiene opportuno continuare a lavorare al miglioramento delle linee guida, affinchè vi sia maggiore integrazione nelle forme prospettate da Eggenberger e Partidário (Eggenberger e Partidário, 2000). In particolare tramite esse, si può agire maggiormente nelle sue forma sostanziale, metodologica e procedurale mentre per una reale integrazione istituzionale e politica è necessaria una maggiore sensibilizzazione e consapevolezza, sia a livello di chi propone il piano ma anche al livello di chi definisce le norme, della doppia valenza della VAS, ossia di controllo esterno del processo e di programmazione interna del processo stesso (Bagnod, 2006). A livello normativo (D.lgs. 152/2006 e ss.mm.ii.) attualmente, si è perso del tutto lo spirito strategico della VAS, la cui importanza si riduce all'oggetto della decisione non più al processo che porta ad essa. Applicare la VAS diventa dunque adottare sostanzialmente, una procedura amministrativa, all'interno della quale, la tutela ambientale e un coinvolgimento minimo dei soggetti interessati sembrano dunque i risultati ottenibili nella migliore delle ipotesi.

In questa prospettiva, considerando che il processo decisionale non segue lo stesso andamento tecnico razionale, teorizzato invece dalle linee guida analizzate nel presente paper, ma che il processo dovrebbe essere influenzato dalle risultanze degli atti di negoziazione e da compromessi (Thissen, 2007), sarebbe opportuno considerare maggiormente nella predisposizione delle stesse linee guida questi aspetti. Questa affermazione è supportata da chi ritiene che, nella VAS, la dicotomia tra aspetti tecnici e aspetti politici possa essere superata dalla coinciliazione di una metodologia valutativa strutturata con la determinazione del consenso (Fischer, 2005) tramite i processi partecipativi.

---

[16] Tali principi sono: controllo dell'espansione della città; gestione dell'ecosistema urbano secondo il principio di precauzione; la conservazione e sviluppo del patrimonio naturale e culturale; l'alleggerimento dell'eccessiva pressione urbanistica, in particolare delle zone costiere; le politiche settoriali nel rispetto della conservazione della diversità biologica; le strategie territoriali integrate per le zone ecologicamente sensibili; la protezione del suolo con la riduzione di erosioni, la conservazione e il recupero delle grandi zone umide; la gestione e il recupero degli ecosistemi marini; la conservazione e gestione di paesaggi di interesse culturale, storico, estetico ed ecologico; una più adeguata compatibilità delle misure di sviluppo che incidono sul paesaggio; il recupero dei paesaggi degradati da attività umane.

[17] Cfr nota 6

È quindi auspicabile, a garanzia dell'oggettività e della trasparenza del processo integrato di pianificazione e valutazione che un'ampia partecipazione del pubblico non si risolva in procedure puramente consultative ma in vero dibattito e confronto delle scelte e in seguito, sull'esito della valutazione e sulla definizione delle priorità e degli obiettivi specifici. Decisioni più vantaggiose per tutti gli attori coinvolti presuppongono che gli interessi forti e i conflitti di interesse siano da subito messi in gioco, piuttosto che espressi dietro le quinte.

Graffiti in Graz. Spatiotemporale Ansätze zur Analyse eines sozio-kulturellen Phänomens

Josef Gspurning

(Mag.Dr. Josef Gspurning, Instut für Geographie und Raumforschunge Universität Graz, Heinrichstrasse 36/I/219 A-8010 Graz, josef.gspurning@uni-graz.at)

1 ABSTRACT

Kaum ein augenfälliges Merkmal der städtischen Umwelt und der darin lebenden Gesellschaft wird bereits so lange und so kontrovers diskutiert wie die Phänomene Street Art und Graffiti. Seit den Anfängen dieser Bewegung wurde sie vielfach lediglich als eine mögliche Ausdrucksform für eine vornehmlich jugendliche Kultur in bestimmten städtischen Lebensräumen interpretiert, wobei in diesem Zusammenhang besonders bemerkenswert scheint, dass diese Form der Artikulation trotz der Konkurrenz von neuen Medien und schnell wachsenden sozialen Netzwerken kaum an Bedeutung verloren hat, sondern – ganz im Gegensatz zu mancherorts geäußerten Vermutungen – diese Spielart der Straßenkunst nun vielmehr ihre angestammten Domänen verlassen hat und verstärkt auf bisher kaum betroffene Gebiete (z.B. viel kleinere, ländlich strukturierte Gemeinden) übergreift. Wie bereits angedeutet, ist die Einschätzung und Bewertung von Graffiti recht widersprüchlich. Für die Anhänger der Street Art-Bewegung handelt es sich einfach um eine zusätzliche und heutzutage weithin akzeptierte oder zumindest hingenommene Möglichkeit zur Schaffung und Ausgestaltung künstlerischer Freiräume, während ihre Gegner Graffiti auf einer Ebene mit Vandalismus, Verletzung von Eigentumsrechten und Beschädigung von Eigentum angesiedelt sehen. Darüber hinaus neigen viele (bezeichnenderweise meist betagtere) Bürger dazu, das Vorhandensein/die Platzierung von Graffiti als Kennzeichnung eines gesetzesfreien Raums zu interpretieren, in dem es das Stadtregiment respektive die Exekutive versäumt hat, den „Gesetzesbrechern" entgegenzutreten und die Bürger und ihr Eigentum zu schützen. Die unkorrigierte Prolongation dieser Missentwicklung kann zu sinkenden Mieterträgen oder Handelsumsätzen und schließlich sogar zum Rückgang der Immobilienwerte selbst führen. Mehr oder weniger deutlich erkennbare Blight-Phänomene fördern zusätzlich den Eindruck von Bandenaktivitäten.

Unter Berücksichtigung all dieser Aspekte liegt das Ziel der in der vorliegenden Arbeit dargelegten Forschungen einerseits auf der Erfassung und Dokumentation des status quo bzw. der ihn bestimmenden Faktoren, andererseits aber auch auf der Analyse und Visualisierung der Graffiti und ihrer Verteilungsmuster sowie der Interaktionen/Abhängigkeiten/Korrelationen zwischen den entscheidenden Faktoren. Es ist wichtig zu erwähnen, dass wegen der großflächigen Verbreitung dieses Phänomens die meisten Untersuchungen entweder auf einzelne Arten von Graffiti und/oder auf relativ kleinräumige Areale konzentriert durchgeführt wurden. Im Gegensatz dazu ist es das Ziel des vom Autor entwickelten Ansatzes, flächendeckend möglichst viele bis zu einem bstimmten Zeitpunkt innerhalb der Grenzen von Graz auftretenden Graffiti zu berücksichtigen. Aus methodischer Sicht besteht der Workflow dafür aus drei Arbeitsschritten, der Phase der Datenerfassung und -beschreibung, jenem der Modellbildung und schließlich die Analyse und Visualisierung der Resultate: Der erste Schritt wird mit der Durchführung von Vorstudien gesetzt, deren Ergebnisse den lokalen Kontext für das Wissen über die Eigenschaften der Street Art und/oder Graffiti bereitstellen; daraus werden wichtige Erkenntnisse für Design und Implementierung eines GIS-Datenbankkerns (Stufe 2) abgeleitet, der in weiterer Folge alle Projekt-relevanten raumbezogenen Daten (herkömmliche Attribute, Bilder etc.) aufnimmt, die im dritten Schritt durch die Werkzeuge des Prozessmodells (ebenfalls im Abschnitt 2 entworfen) analysiert werden. Der gesamte Prozess stellt dabei ein iteratives Verfahren dar, in dem schon ab dem ersten Durchlauf der aus zwei Stufen (Vorerhebung und Haupterhebung) stammende Inhalt der Datenbank Einfluß auf die Ergebnisse nehmen kann. Zusätzlich verengen Strategien zur Pattern Analysis und zur Abgrenzung von Hot Spots den räumlichen Fokus (und damit den Aufwand) für zukünftige Datenerfassungs-Kampagnen und ermöglichen daher eine gezieltere Beobachtung und damit indirekt bei gleichem Aufwand auch die Konstruktion von längeren Beobachtungs-Trajektorien. Obwohl damit das Potential der Methode gegenwärtig noch nicht völlig ausgelotet wird, ist das System schon jetzt in der Lage, eine breite Palette von Graffiti-relevanten Einblicken zu gewähren. Lokale Muster der verschiedenen Arten von Graffiti, Untergründe, Stile, etc. der graphischen Daten (d.h. der Zeichen) können miteinander verglichen und mit unterschiedlichsten sozio-ökonomischen Daten überlagert werden und so Hot Spots oder Ganggebiete identifiziert werden. Last but not least kann die Entwicklung des Phänomens Graffiti und seine räumlichen Verteilungsmuster auf dem Bildschirm und durch Hardcopy visualisiert werden.

2 RAHMENBEDINGUNGEN UND MOTIVATION

Wie bereits in der Einleitung dargelegt, handelt es sich beim Themenbereich „Graffiti" noch immer um eines der am widersprüchlichsten aufgenommenen und wohl auch kontroversiell verstandenen Phänomene des menschlichen Kulturbewusstseins. Akzeptiert man die Ergebnisse einschlägiger Studien als annähernd ubiquitär gültig, so kann man davon ausgehen, dass es sich dabei um eine Ausdrucksform von etwa zwischen 10 und 40 Jahre alten Menschen handelt, wobei andere Merkmale zur Person (Geschlecht, Familien-verhältnisse,…) bzw. zum Umfeld (Beruf, Beschäftigtenstand, Schulbildung,…) kaum eine signifikante Rolle zu spielen scheinen; komplettiert wird diese Gruppe von einschlägig Aktiven noch von Studierenden bzw. Künstlern und politischen Aktivisten (HALSEY & YOUNG 2002); vergleichbare Studien wie die der neuseeländischen Stadt Manakau engen den Kreis der in Frage kommenden Personen bei 5 % Irrtumswahrscheinlichkeit sogar noch weiter ein, nämlich auf die 12 bis 17 jährigen (MANAKAU CITY COUNCIL 2006). Während aber hinsichtlich der Charakterisierung der Aktionisten weiter reichende Übereinstimmung besteht bleiben andere Bereiche des betroffenen Umfeldes nahezu unbestimmt. So zeigt eine annähernd repräsentative Untersuchung der Graffiti-bezogenen Beiträge in den Online-Ausgaben der auflagenstärksten steirischen Tageszeitungen bzw. in den wichtigsten Grazer Online-Magazinen seit Januar 2012 – gemessen an seiner gesellschaftlichen Relevanz – eine durchgängig relativ starke mediale Präsenz des Themas. So äußerte sich „Der Standard" 25 Mal, „Die Presse" 7 Mal, „Heute" 14 Mal, die „Kleine Zeitung" 26 Mal, die „Kronen Zeitung" 36 Mal, der „Kurier" 17 Mal und „Mein Bezirk"/„Meine Woche" in 26 Reportagen zum Thema.

Fig. 1: Eine Auswahl von Schlagzeilen aus dem Online-Archiv der Kleinen Zeitung für den Zeitraum Jänner 2012 bis März 2013

Obwohl die in Fig. 1 zusammengestellten Schlagzeilen auf Grund der Ausrichtung des Mediums gesell-schaftspolitisch betrachtet nur einen Teil des tatsächlichen Spektrums widerspiegeln, erlauben sie doch eine über das bisher festgestellte hinausgehende Charakterisierung der „Szene". Dabei bleibt unbestreitbar, dass aus den Aktivitäten zum Teil recht beträchtlicher Sachschaden an privatem und öffentlichem Eigentum entsteht, dessen Begleichung von den Verursachern in den seltensten Fällen eingefordert werden kann. Man kann also davon ausgehen, dass der Tenor der Art wie Graffiti in der Öffentlichkeit verstanden wird eher negativ als neutral besetzt ist. Anders ausgedrückt: Graffiti wird weit weniger oft als Kunstform verstanden denn als Sachbeschädigung, ein Urteil das im übrigen auch mit der Botschaft der gewählten Schlagzeilen korreliert: Positiv besetzten Graffiti-Meldungen wie etwa die Schaffung zusätzlicher legaler „Arbeits-flächen" durch Stadt und Gönner aus der Wirtschaft wird – ebenso wie der Berichterstattung über Graffiti-Workshops – relativ wenig Platz eingeräumt. Desweiteren zeigt die Auswahl, dass es sich dabei längst nicht mehr um ein rein städtisches Phänomen handelt, sondern dass sich die Schadensmeldungen aus den ländlicheren Regionen des Bundeslandes häufen, die „Sprayer-Kultur" aber auch nicht an den Stadtgrenzen Halt gemacht hat und auf diese Art offenbar so etwas wie ein „Graffiti-Tourismus" entstanden ist. Bemerkenswert scheint in diesem Zusammenhang auch, dass trotz des mitunter beträchtlichen Aufwandes der Ordnungshüter (Zivilstreife, verdeckte Ermittler, Bildung von Sonderkommissionen) die Zeitspanne

zwischen Beginn der Aktivität und Ausforschung in den meisten Fällen relativ lange währt; dies bedeutet aus der Sicht der betroffenen Eigentümer eine Erhöhung des Schadenspotentials verbunden mit Frustration und sinkendem Vertrauen in die Möglichkeiten der Exekutive. Und das obwohl sich letztere redlich bemüht, ihre diesbezüglich vorhandenen Erfolge auch ins rechte Licht zu rücken. Was bleibt ist das in der jeweiligen Umgebung vielfach als störend empfundene Artefakt und ein auch objektiv fassbarer Eindruck von Verwahrlosung und Niedergang in einem Gebiet, das als Weltkulturerbe an einem im Sinne des Tourismus positiven Erscheinungsbild interessiert sein muss.

3 GRUNDLAGEN UND EINGESETZTE METHODIK

Im Gegensatz zur bisher in diesem Zusammenhang meist geübten Untersuchungspraxis versucht der dargestellte Ansatz schon wegen seiner umfassenden Ausrichtung das Phänomen möglichst ganzheitlich zu erfassen. Das würde in Richtung einer flächendeckenden Totalerhebung weisen, deren Fehlen von der Forschergemeinschaft zwar beklagt wird, die aber im Vergleich mit ähnlich gelagerten Arbeiten der Street Art Forschung sowohl thematisch als auch räumlich eher die Ausnahme als die Regel darstellt (SIEGL 1993, SCHAEFER-WIERY & SIEGL 2001, BAUER 2002, SIEGL & SCHRAGE 2008, STAHL 2009 und PHILIPPS 2011). Ähnliche Ergebnisse auf der internationalen Ebene wie etwa in Arbeiten über London und New York (MACDONALD 2001) legen zudem die Vermutung nahe, dass die Implementierung umfangreicherer auch konzeptionell untermauerter Datenbanken trotz bemerkenswerter Vorläufer wohl erst mit der zunehmenden Digitalisierung der Gesellschaft in großem Stil angedacht wurden. Bedauerlicher Weise sind aber gerade diese Entwicklungen wie etwa das Auckland City's Graffiti Tracker Database (LOCAL GOVERNMENT NEW ZEALAND 2006) bzw. eine nicht näher spezifizierte Graffiti-Datenbank der „kesicherheit.de" (DIE GRAZER VOLKSPARTEI GEMEINDERATS-KLUB 2011) ausschließlich in sicherheitspolitischem Kontext zu sehen was auch erklärt, warum Hintergrundinformationen darüber nicht zugänglich sind und deshalb auch für wissenschaftliche Arbeiten nicht zur Verfügung stehen.

Für die vorliegende Studie stellte sich hinsichtlich des projektierten Zielgebietes zunächst die Frage nach einer akzeptablen Außengrenze, wobei sich nicht zuletzt wegen der später angestrebten Verknüpfbarkeit der Entitäten mit z.B. sozioökonomischen Daten eine auf Verwaltungsgrenzen (Zählsprengeln) basierende Grenzziehung anbot (die Ergebnisse der später durchgeführten Vorerhebungen haben diese Annahme übrigens insoferne gestützt als sich – mit Ausnahme der an die Ausfallsstraßen angrenzenden Gebiete – stadtauswärts ein deutlicher Rückgang der Graffiti-Häufigkeiten beobachten ließ). Der Aufwand für die Aufnahme möglichst vieler der auf den daraus resultierenden, etwas über 120 km² des Grazer Stadtgebietes vorkommenden „Einträge" konnte dadurch weiter reduziert werden, dass als wenig relevant eingeschätzte Bereiche identifiziert und – je nach dem Befund einer stichprobenartig durchgeführten Überprüfung endgültig ausgeschieden oder – in selteren Fällen – im Unersuchungsgebiet belassen wurden. Nach diesem Schritt zeigte sich im Rahmen von Geländebegehungen, dass sich das Auftreten von Graffiti auf bestimmte Areale entlang der Strassenzüge konzentrierte sowie deutliche „Expositionsunterschiede", wohl infolge der Absicht der Writer, ihre Werke nach Möglichkeit für die Allgemeinheit sichtbar zu machen) zu erkennen waren. Letzteres bringt insoferne sogar erhebungstechnische Vorteile mit sich, als die Zahl der durch Unbegehbarkeit bestimmter Flächen nicht erhebbaren Graffiti (in zeitweilig abgeschlossenen Innenhöfen sowie anderen nicht öffentlich zugänglichen bzw. einsehbaren Bereichen des Grazer Stadtgebietes) sowohl zahlenmäßig gering als auch abschätzbar bleibt. So haben in ausggewählten Gebieten durchgeführte Tests ergeben, dass mit einer Dunkelziffer von etwa 3 % zu rechnet ist. Angesichts dieser Überlegungen versteht sich von selbst, dass der ursprünglich wenigstens implizit erhobene Totalitätsanspruch schon aus statistischen Gründen nur mehr symbolisch erfüllt werden kann: Immerhin ergibt sich aus der schrittweisen Fokussierung ein letztlich zu berücksichtigendes Untersuchungsgebiet von etwa 17,5 km² mit etwa 27 km Strassenlänge (Fig. 2); damit kann sichergestellt werden, dass das ganze Gebiet mit vertretbarem Aufwand auch in sinnvollen Intervallen untersucht werden kann um auf diese Weise auch zeitliche Längsschnitte mit brauchbarer Aussagekraft ableiten zu können.

Die erste Vollerhebung wurde unter diesen geänderten Rahmenbedingungen im Sommer 2011 durchgeführt und beschäftigte sich im Wesentlichen mit der partiellen Umsetzung des in Strategiepapieren für die Vermeidung von illegalen Graffiti niedergelegten Handlungskonzeptes (MINISTRY OF JUSTICE). Dieses sogenannte SARA-Framework besteht in seinem Grundmuster aus einem 4 Stufen-Plan (Scanning-Analysis-Response und Assessment) und definiert dadurch die stragetische Vorgangsweise. Durch das Scanning

sollen einerseits Basisdaten akquiriert und kartographische Grundlagen geschaffen werden; gleichzeitig sollen aber auch mögliche Probleme erkannt und durch geeignete Parameter beschrieben werden, sodass bereits auf dieser Ebene die analytische Herausarbeitung von Hot Spots möglich gemacht wird. Wichtig scheint in diesem Zusammenhang besonders, dass durch wiederholtes Scanning einerseits zufällige Erscheinungsformen und -muster weitestgehend ausgeschlossen werden können, darüber hinaus aber auch die zeitliche Dimension des Problems ausreichend genau beschrieben werden kann.

Die anschließende Analyse wird in Art und Umfang naturgemäß hochgradig von den an SARA geknüpften Erwartungshaltungen bzw. von den nachgeordneten Paketen „Response" (umfasst die aus der Analyse abgeleiteten Gegenmassnahmen gleich welcher Art) und „Assessment" (Überprüfung inwieweit die eingeleiteten Gegenmaßnahmen den erhofften Erfolg gebracht haben) bestimmt. Da sich die Intentionen des vorliegenden Projektes gravierend von jenen des Vorläufers unterscheiden und die in Graz gesammelten Daten ausschließlich zur Beschreibung des aktuellen Zustandes und zur tiefer gehenden Erforschung des Umfeldes einer urban-kulturellen Ausdrucksform verwendet werden sollen, weicht das in diesem Beitrag vorgestellte Konzept bereits in der in der zweiten Phase vom Vorbild ab; so wird auch völlig auf die Einbeziehung der persönlichen Aspekte von (aktiven wie auch passiven) Beteiligten verzichtet; desweiteren bleiben auch allfällige Gegenmaßnahmen unberücksichtigt. Stattdessen wird versucht, das Problem auf rein deskriptive Weise bzw. durch die Auswertung kombinierter Datenebenen zu unterschiedlichen Themen-bereichen zu beleuchten.

Fig. 2: Übersicht über Lage und Ausdehnung des untersuchten Gebietes (rot schraffiert)

4 DAS DATENMODELL

Das aus den Ergebnissen der Vorerhebungen zusammengestellte und durch die dort und während der ersten Haupterhebung (unterstützt von Studierenden des Instituts für Geographie und Raumforschung der Universität Graz) gewonnenen Erkenntnisse modifizierte Datenmodell orientiert sich an den Elementen des Wiener Modells der Graffiti-Forschung (SIEGL 2002), das die Erfassung von 23 Charakteristika vorsieht, auf deren Basis eine mulitvariate Klassifikation ermöglicht werden soll (Tabelle 1).

Merkmal	Ausprägung (exemplarisch) bzw. Erläuterung
Entstehungszeitraum	Datum
Erhebungszeitraum	Datum
Herkunftsregion	Erhebungszone
Produzentengeschlecht	m, w
Altersgruppe	Kinder, Jugendliche, Erwachsene
(Sub-)Gruppe	Skinheads, Punks,…
Gesellschaftsschicht des Aktivisten	keine Angabe (k.A.)
Standort/Fundort	k.A.
Grundfläche/Trägermaterial	k.A.
Technische Ausführung	3 mögliche Varianten
Haltbarkeit	k.A.
Farbe	monochrom/multicolor
formal	flächig, graphisch
Größe	k.A.
inhaltlich/thematisch	k.A.
Absicht	bewusst, neben anderer Tätigkeit entstanden
?	Legalität Illegalität Tradition
Spontanität	spontan, geplante Aktivität
interaktiv mit vorgegebenen Strukturen	k.A.
?	Basisgraffito, Kunstgraffito
Anonymität	k.A.
?	Initialgraffito, Reaktives Graffito (S-R-Modell)
Originalität	k.A.

Tabelle 1: Die Merkmale des Wiener Modells der Graffiti-Forschung

Der für die vorliegende Studie zum Einsatz gebrachte Kriterienkatalog stimmt nur teilweise mit dem Wiener Grundmodell überein, ein Fakt das auf unterschiedliche Gründe zurückzuführen ist. Hauptverantwortlich dafür ist der vom Autor gewählte Ansatz, der vornehmlich auf der Beschreibung des Phänomens durch objektiv erfass- und dokumentierbare Kriterien beruht und Subjektiva (z.B.: Originalität) genauso wie nur durch Befragung direkt oder indirekt beteiligter Personen zu erhaltende Informationen (z.B.: bewusst oder neben anderer Tätigkeit entstanden) ausblendet. Leitidee war stattdessen der Versuch, eine – im Rahmen der Möglichkeiten – universelle Datenbasis zu schaffen, die hochgradig skalierbar, noch genügend Spielraum für spätere Erweiterungen bietet. Als Ausgangspunkt für die Entwicklung des Konzeptes dienten die fünf Fragen: Wo? (Positionsbeschreibung), Wer? (Grobcharakterisierung des Betroffenen/der betroffenen Organisation), Wie? (Beschreibung der Entität hinsichtlich ihrer Umgebung), Was? (Beschreibung der Entität) und Wann? (Zeitpunkt der Erstaufnahme).

Gerade dem „Wo?" kommt dabei in doppelter Hinsicht besonderes Augenmerk zu: Der für die Erhebung vorgesehene Workflow beruht hardwareseitig hauptsächlich auf der Verwendung von GPS-fähigen Kameras, deren hoch auflösende Bilder (18 oder mehr Megapixel) vom Objekt und seiner Umgebung sowohl einen Eindruck von der Szenerie selbst als auch von graphischen Details bereit stellen. Sozusagen on-the-fly protokollieren diese Kameras außerdem noch die Beobachter-Koordinaten (bezogen auf ein frei wählbares Referenzsystem) sowie die Blickrichtung und weitere photographisch relevante Daten. Bei Verwendung des speicherschonenden JPEG-Bildformates können diese Informationen für die spätere Auswertung im EXIF-Header abgelegt werden, sodass sich eine allenfalls notwendige visuelle Nachjustierung von Standortkoordinaten oder Blickwinkel auch im Labor ohne größeren Zeitaufwand genauso durchführen lässt wie etwa die Zuordnung der Photos zu Standpunkten. Nebenbei wurden – sozusagen durch den technischen Fortschritt – auch aus der Sicht des Wiener Modells „neue" Daten gesammelt. Besonders die automatische Verortung des Materials liefert ein zentrales Element in der weiteren Verarbeitung; ihre funktionale Bedeutung für die späteren Analysen und die Visualisierung der Ergebnisse (Kartenherstellung) machte

jedoch auch von vorne herein klar, dass für das Management der anfallenden Datenmengen nur ein Speichermodell in Frage kam, welches dieser Eigenart auch Rechnung tragen konnte. Jede Lösung ohne die Verwendung geo-rationaler Datenbanksysteme hätte den freiwilligen Verzicht auf den Mehrwert aus allen GIS-basierten Analyse-werkzeugen bedeutet und wäre damit einer beinahe vollständigen Entwertung des Systems in seiner vorgeschlagenen Form gleichgekommen.

Schlussendlich haben die geänderten Rahmenbedingungen auch Möglichkeiten für eine Modifikation des zugrunde liegenden Modells geschaffen, um es den Grazer Gegebenheiten besser anpassen und auch in diesem Sinne weiter entwickeln zu können. Fig. 3a-h zeigen Beispiele fürdie in Graz erhobenen Attribute (in Klammer die möglichen Merkmalsausprägungen). Die übrigen Attribute ohne Bildbeispiele finden sich in Tabelle 2. In allen Fällen wird der Ortsbezug dabei über Lagepunkte hergestellt.

5 ANALYSEN UND ERGEBNISSE

Bis zur gegenwärtigen Ausbaustufe lag das Hauptaugenmerk in erster Linie auf der Konzeption eines flexiblken Datenmodells bzw. auf der Akquise und Bereitstellung des Datenmaterials. Deshalb wurden bis dato grundsätzlich zwei verschiedene Auswertungstypen realisiert, die sich grob mit „Abfragen" und „Overlay Operationen" umschreiben lassen. Erstgenannte Variante ist zwar methodisch trivial, ermöglicht aber wegen der Einzigartigkeit der Untersuchung doch auch interessante Quantifizierungen, die an dieser Stelle trotz des knappen Platzes nicht ganz verschwiegen werden können. So konnten seit Beginn der Arbeiten etwa 14 km² des projektierten Untersuchungsgebietes (das entspricht etwa 20 Straßenkilometern) zum Teil mehrfach untersucht werden. Im Zuge dieser Kampagnen wurden ca. 8800 Entitäten lokalisiert und dokumentarisch aufgearbeitet woraus sich – abgesehen von der räumlichen Verteilung – folgende Charakteristika ableiten lassen: Der weitaus größte Anteil der Graffiti wurden an Wänden (68 %) bzw. an Infrastruktureinrichtungen (23 %) und meist in Reichweite von Halbwüchsigen (95 %) platziert. Es handelt sich ferner um kleine bis mittelgroße (insgesamt etwa 96 %) mittels Spraydosen (55 %) oder Stiften (41 %) hergestellte Tags auf Feinputz oder Metallflächen. Abgesehen von extrem ausgeleuchteten oder überwachten Arealen scheinen sich die Akteure eher selten von für sie günstigen Lichtverhältnissen oder von bestimmten Expositionen leiten zu lassen. Besonders auffällig ist weiters der angesichts der absoluten Zahl an Einträgen verschwindend geringe Teil von Graffiti mit politischen bzw. gesellschaftskritischen Botschaften. Hier

lassen sich nur einige wenige einschlägige Zonen ausmachen, was Rückschlüsse auf das Alter bzw. den sozialen/gesellschaftlichen Background der Akteure nahelegt. Als weiterer interessanter Aspekt kann die Existenz von Crossings gewertet werden. Trotz der für Graz relativ zahlreichen Aktivitätszonen finden sich diese Übermalungen die als Ausdruck konkurrierender territorialer Ansprüche gewertet werden können nur in etwa 4 oder 5 „Überlappungsbereichen" was darauf hindeutet, dass die einschlägige Szene in Graz arm an diesbezüglichen Rivalitäten sein dürfte.

Neben diesen basalen Analysen wurde das verfügbare Datenmaterial noch einer Reihen von weiteren Tests unterzogen, wobei ausgehend von a priori durch Experten als interessierend festgelegte Problemfelder mittels Merkmalskombinationen untersucht werden sollten. Aus den zur Verfügung stehenden 11 Analyseszenarien (Tabelle 3) wurde für diese Arbeit der Themenkomplex „Sport/Ultras" herausgegriffen, um damit die Möglichkeiten des Systems näher zu beschreiben.

Schwerpunkt	Zugeordnete Forschungsfragen
Miet-/Kaufpreis	Zusammenhang und Korrelationsmuster zwischen Graffiti und Miet-/Kaufpreis
Politik	Politisch motivierte Graffiti im Umfeld von Einrichtungen politischer Gruppen
Sport/Ultras	Muster und Verbreitung sportlich motivierter Graffiti
Schulen/Ausbildungsstätten	Gibt es eine „typisch schulische" Graffiti-Szene?
Ausländer	Verteilung von Ausländer-/ausländerfeindlichen Graffiti
Öffentlicher Personennahverkehr	Typisierung der Graffiti im der Umgebung von Haltestellen bestimmter Linien
Industrie- und Gewerbegebiete	Wie unterscheidet sich die Graffiti-Kultur im Bereich von I&G-Flächen?
Polizeistationen/Überwachungskameras	Verbreitung und Typisierung von Graffiti in „sicheren Räumen"
Szenelokale/In-Treffs	Gibt es einen Zusammenhang zwischen Nachtschwärmern und Graffiti?
Sehenswürdigkeiten	Werden auch touristische Präferrenzräume zur Vermittlung von Botschaften genutzt?
Beleuchtung	Ist gute Ausleuchtung ein Schutz vor Graffiti-Aktivisten?

Tabelle 3: Übersicht über aktuelle Analyseszenarien und die zugeordneten Forschungsfragen

Das Thema bot sich besonders deswegen zur Analyse an, als die Sportstadt Graz neben 2 rivalisierenden Fußballklubs auch noch über einen Eishockeyklub in der obersten Spielklasse und zahlreiche weitere kleinere Sportvereine mit ausgeprägter Fan-Kultur verfügt. Hinzu kommt noch, dass sich sportbezogene Graffiti/Ultras leicht als solche erkennen und daher auch unmissverständlich zuordnen lassen. Für die vorliegende Studie wurden folgende Forschungsfragen formuliert: Ist eine räumliche Konzentration sportlich motivierter Graffiti im Stadtgebiet bzw. im Umfeld von Sportstätten nachweisbar? Gibt es eher Unterschiede oder eher Gemeinsamkeiten in den Signaturen der sportbezogenen Graffiti-Kultur? Welche Sportarten sind besonders Thema von Graffiti? Zur Klärung dieser Fragen wurde mit „Sportstätten" ein zusätzlicher Datenlayer eingeführt, der die Informationen zu relevanten Grazer Sportstätten verortet. Dabei wurden – entsprechend ihrer unterschiedlichen Publikumswirksamkeit – auch unterschiedliche Einflußräume angenommen. Während der Analyse zeigte sich ein strukturelles Problem dieser Thematik, nämlich die potentielle Verfälschung der Ergebnisse durch den Fakt, dass gerade die raumintensiven Sportanlagen eher an der Peripherie liegen, wohingegen der Graffiti-Gesamtbestand eine deutliche Konzentration im inneren Stadtbereich zeigt. Weiters war – abgesehen von einer deutlichen Erhöhung im Umfeld der bedeutungsmäßig klar dominierenden UPC-Arena keinerlei auffälliger Zusammenhang zwischen Sportstätten und Ultras nachweisbar. Im Umfeld dieses großen Fußballstadions dominierten die rivalisierenden Anhänger-organisationen der beiden Stadtklubs und liefern sich (besonders schön durch die Photo-Zeitreihen zu dokumenieren) intensive Verdrängungswettkämpfe. Auch außerhalb dieses Bereiches dominiert der Fußball, jedoch nur selten in auffälliger Konzentration; so im Weichbild der Universität und bestimmter Schulen, was Rückschlüsse auf den persönlichen Hintergrund der Klientel nahelegt; andere Konzentrationen sind aufgrund des Stils bzw. des Musters eher besonders rührigen Individualisten zuzuordnen als organisierten Gruppierungen. Unter Berücksichtigung anderer Kriterien lässt sich zusammenfassend folgendes feststellen: Hauptziel der mehrheitlich einfarbigen Graffiti-Verziehrungen sind Fronten bzw. Wände von

Infrastruktureinrichtungen der öffentlichen Hand (75 %) gefolgt vom Privatbesitz (23 %). Auffälligkeiten zeigt auch die Anbringungshöhe der Werke: In Sportstättennähe wurden mehr als 36 % unterhalb der „Arbeitshöhe" eines Halbwüchsigen angebracht, dies entspricht etwa dem doppelten des städtischen Durchschnitts. Die Größenverteilung wiederum spiegelt zu einem guten Teil die Verfügbarkeit von Freiflächen wider: 75 % mittlere und große gegenüber nur 20 % kleinen Graffiti; im inneren Stadtbereich kehren sich diese Verhältnisse annähernd um.

6 ZUSAMMENFASSUNG UND AUSBLICK

Obwohl das Informationssystem in seiner gegenwärtigen Ausbaustufe durchaus in der Lage ist, die oben beschriebenen Interessenten – Abfragen bzw. Verschneidungen mit zusätzlichen Datenebenen zufriedenstellend durchzuführen hat doch gerade der vor kurzem parallel zum fortgesetzten Update angelaufene intensivere Testbetrieb gezeigt in welche Richtungen die Entwicklung vorangetrieben werden könnte. Abgesehen von der Einbindung bisher noch unberücksichtigt gebliebener Informationsebenen und der Ausweitung (HAWORTH et. al. 2013) bzw. Automatisierung der bereits implementierten analytischen Fähigkeiten könnte besonders eine verbesserte Visualisierung (perspektivisches, lagerichtiges Draping der erfassten Entitäten) und ein beschleunigtes Handling bei der Datenakquise (etwa Datenübermittlung und Datenbank-Einspielung über web-basierte Crowd Mapping Apps) zur Nutzwertsteigerung beitragen. Schlußendlich könnten auch bisher ausgelagerte untergeordnete Funktionen wie etwa der Test von ähnlichen Graffiti auf Übereinstimmung in den Systemkern aufgenommen werden und so die Kompaktheit des Paketes steigern.

Historical Buildings Integration Into a Modern Industrial Urban Environment of Perm

Anastasia Kuznetsova, Yuliya Bushmakova

(Anastasia Kuznetsova, Master Degree, Perm National Research Polytechnic University, 29 Komsomolsky Av., Perm, Russia, nastyakyz@mail.ru)
(Yuliya Bushmakova, Master Degree, Perm National Research Polytechnic University, 29 Komsomolsky Av., Perm, Russia, bushmakova@yandex.ru)

1 ABSTRACT

Perm is a 300 years old modern industrial city. Architectural heritage was formed by several "architectural layers", each of them has its own period and place in the history of the city. As a whole, architectural styles of Perm have similarities with such styles in Ekaterinburg, Chelyabinsk and other Ural cities. Influence of activity of architects of 18th and 19th centuries and Soviet principles of planning of territories and designing of houses is traced in historical parts of the city.

For preservation of historical heritage of Perm, protection zones are defined in the rules of land usage and in the general plan of Perm. Despite this the shape of all of historical buildings is changing because of expansion of the city, new economic and political conditions, new needs and requirements.

In our research following morphotypes are being observed: houses of 19th century (two floors: 1st – brick materials, 2nd – wood materials), merchant houses (two floors, brick materials), Perm socialistic town, buildings of 1980s and 1990s and new constructions.

To define negative factors influencing historical heritage and to set protection measures for each of morphotypes it's necessary to analyze its existing position from the point of view of primary ideas of the projects. The analyses are in several scales: from large scale describing status of historical buildings in the city or in the district, to smaller scale defining condition of a certain building and its external changing. Moreover, processes are being analyzed which are occurring on the territory around these historical buildings (inside and outside the blocks).

The result of this architectural research is setting directives for the development of regulating documents dealing with certain historical buildings and morphotypes for preservation of unities of ensembles and interrelation with surrounding buildings. The practical application of this research is an establishment of new parameters for each type of historical buildings in urban codes.

2 HISTORICAL AND ARCHITECTURAL HERITAGE OF PERM

Perm is a city on the border between of Europe and Asia with one million inhabitants. In the past it was an industrial city but now Perm is developing as a cultural and scientific center of the Perm Krai and Western Urals.

The master plan of the city was accepted in 2010. Besides, there is a strategic master plan of Perm describing the main directions of the city development elaborated in 2011.

In connection with increasing of new construction and new strategy of the city consolidation of central parts of the city there is an urgent question about preservation of historical parts of the city and preservation of integrity of architectural and planning ensembles which form historical heritage of the city.

Urban environment cannot be absolutely identical and homogeneous. The city is concentration of different styles and times. You can often see variety of buildings "for any taste". Therefore urban planners face a question: "How is it possible to combine this diversity and uniqueness of different morphotypes of the city to get one city fabric preserving identity? Should we understand each building or each group forming city fabric?" Only the main architectural dominants usually are preserved, but ordinary buildings are disappearing. It is important because the majority ordinary buildings are forming shape of the city and "sense of the place".

3 PRINCIPLES OF THE ANALYSIS

Establishing of a strategy of historical heritage preservation is an important issue for the city. Because the heritage is its uniqueness and identity, in the long run it is the history of the city.

The protection zones are set up in the rules of land use of Perm. City-planning activity mode and measures of preservation are defined for each of these zones. But the particular factors which are worsening the life of architectural heritage are not revealed and not described in urban codes.

The work for establishing of the strategy of historical heritage preservation was made by developing strategic master-plan of Perm. In the part "Heritage Strategy" the main ensembles of the central parts of the city are revealed. The results of this work are the main directions within the limits of which the researches and works for preservation of historical heritage will be made (strategic master plan of Perm).

"Within borders of this work there were selected six key ensembles which are possessing an obvious historical value for Perm. The key ensembles are supplemented with individual zones: here we can see groups of buildings estimated as important for architectural and town-planning activity of Perm."

If we talk about preservation of historical buildings we should pay attention to big meaning have such factors as aesthetic parameters and the safety of original appearance. Not only buildings form the ensemble, but it is formed also by the environment around these buildings and buildings situated nearly. All visible facades of the street make its shape, but high, length and decor of buildings make the rhythm of the street. The reflection of ideas of one building to the another and vice versa is "rhyme" of the street creating its integrity.

Our research work is connected with revealing the links between historical buildings and new buildings; the list of the problems connected with integration new buildings into historical center's environment; preservation integrity of historically important buildings within dynamic city environment.

For researching the most widespread morphotypes of Perm are defined: houses of 19th century (two floors: 1st – bricks materials, 2nd – wood materials), merchant houses (two floor, brick materials), Perm socialistic town, buildings of 1980s and 1990s and new constructions.

The plans of each typology are compiled for defining of morphotypes placement. The research aimed at historical parts of Perm. The prevailing buildings which are forming ensembles and the shape of the street are selected for each part. The typical blocks of each typology are described from the point of view of the following parameters:

(1) analysis of their placement in the district/city;

(2) analysis of their planning structure and placement in the quarter;

(3) analysis of the architectural integrity, facades, physical wear;

(4) analysis of the environment around the block.

The analysis has several stages for getting the most general and complete idea of these buildings. The first stage is to identify a common list of problems. The next stage is a detailed reviewing of each of the historic buildings and establishing relationships with the surrounding buildings and environment.

4 THE FIRST STAGE OF THE ANALYSIS. EXISTING SITUATION AND PROBLEMS OF CENTRAL PART OF PERM

The blocks of historical center of Perm are formed by buildings of XIX century in style of classicism and a modernist style with the features caused by character of applied materials and local traditions. Usually it is brick or wood buildings which have two or three floors. For this moment in the city's fabric there are pieces of such historical buildings, but they are replaced by new buildings which are appearing suddenly without a functional design and planning.

One of the main features of this type of buildings is a lot of decorative elements on the facades. The main colours of facades are yellow, green or white. The facades have a certain rhytm which composes a certain rhytm of the whole street. (Fig.1)

Fig.1 Roofs elements. The mercant houses (XIX century).

The quarters with such buildings are closed blocks. Administrative offices and commercial activity are situated on the street-side, but the accesses for people living in these buildings are inside of the quarter.
Fig.2 Fragments of facades of historical part of Perm

The main feature of central streets is using of the first floors for commercial activities. The different shops and service enterprises on the first floors help to enliven the streets.

One of principles of new urbanism is natural surveillance. It means that spaces with social activities are more comfortable. But for historical blocks such activites was usually not provided. Therefore we shoud observe shops and cafes appeared on the first floors not only as functional features but also as components forming an aestetic view of the streets. Moreover, we should think wheather each certain building can receive additional load (additional functions) or not. Probably, these buildings are needed to exempt from unnecessary functions and unusual arcitectural detales.

Sibirskaya and Kirov streets are the main streets of Perm. The visual analysis of facades of these streets revealed that additional functions seem to be a great disadvantage and harm for historical buildings.
Fig.3 Façade of building, Sibirskay street.

In particular, bad solutions of entrances groups, ladders and accesses to buildings broke the red line of the street. Moreover, it is bad for appearance of facades, it makes too strong differences of color palettes (different with original colours). (Fig.3,4)

Fig.4 Façade of building, Kirov street.

In the survey of blocks of buildings of the XIX century one more problem of historical part of Perm was defined.
Fig.5 The revealing of blocks of historical buildings. The central part of Perm (2Gis map).

Blocks formed by historical buildings are situated on the borders of quarters. But inside parts of these blocks are filled by new buildings (usually in other styles), which are higher than historical buildings on the borders. New constructions interrupt complete perception of facades of achitectural heritage.

Nowadays most of blocks of historical buildings have only corner buildings. The new constructions, which are the similar historical buildings, are built in blocks for restoration and reconstruction of historical appearance of the street. It helps to save integrity of composition or ensemble, but in most cases architects design new projects without links to environment of historical blocks, therefore urban environment is disjunct.
Fig.6 Break of the lines of facades by buildings inside block.

Obviously there is a necessity to develop the list of valued elements of historical environment, which are typical for certain morphotypes, and we need to find new tools for preservation of the shape of historical blocks. Moreover, we should pay attention to value of physical wear, the materials of constructions and possibilities for functional adaptation.

5 CONCLUSIONS

For this moment in the Russian Federation there are instruments for preservation of architectural heritage. For example, architects design sweep of the streets for understanding of general shape of the street or block; maps of typologies and conditions of buildings for understanding value of heritage and necessity of restoration. But laws which regulate fulfillment of such analyses cannot work effectively because they doesn't have specific indications, limitations, and tools which could be free and useful for all who are interested in them.

The local normative documents need in rethinking about functional load of historical parts of the city. It needs to more distinctly define the list of types of value elements of historical environment and fix this typology with the help of photomaterials and detailed descriptions.

Sociological polls can help to determine restrictions for usage of historical heritage. It can give understanding of what is really important for citizens: which places are important and significant and what they want to preserve.

Thus, the existing register of historical buildings of Perm needs to be supplemented to be improved. It needs to add descriptions not only of main buildings and architectural dominants, those of ordinary buildings and blocks of historical parts of the city as well. It has to be an open register because it can be an important resourse with information about historical quarters for all who are interested in it.

1 ABSTRACT

In zahlreichen Studien gibt es bereits Hinweise darauf, dass in Zukunft eine kontinuierliche Zunahme der Hitzetage (mindestens 30°C) und -perioden (drei aufeinanderfolgende Tage mit über 30°C) für den städtischen Raum zu erwarten ist (Formayer et al., 2008). Schon heute weist Wien durchschnittlich ca. 11-13 Hitzetage pro Jahr auf – eine Anzahl, die sich bis Mitte des Jahrhunderts sogar mehr als verdoppeln könnte (Moshammer et al., 2007). Dichte Bebauung sowie ein geringer Anteil an Grünräumen verstärken Hitzeeffekte in urbanen Gebieten und es kommt zur Ausbildung von Wärmeinseln. Nicht nur die Bevölkerung, sondern auch Touristinnen und Touristen, die Wien vorwiegend in den Sommermonaten besuchen (Magistratsabteilung 5, 2010), sind von der Hitze negativ betroffen. Um Strategien zu identifizieren, die den Aufenthalt von Städtetouristinnen und Städtetouristen in Zukunft trotz Hitze erträglich gestalten können, wurde das Projekt „Hot town, summer in the city – Die Auswirkungen von Hitzetagen auf das Freizeit- und Erholungsverhalten sowie das Besichtigungsprogramm von Städtetouristinnen und Städtetouristen" ins Leben gerufen.

Ziele des Projektes waren sowohl die Identifikation räumlicher und zeitlicher Adaptionsstrategien der Städtetouristinnen und Städtetouristen an Hitzetagen als auch die Identifikation von Schlüsselfaktoren für Strategien seitens der Tourismuswirtschaft, Stadtverwaltung und -planung, um Anpassungen an die Folgen des erwarteten verstärkten Wärmeinseleffekts vorzunehmen.

2 METHODE

Ein wesentlicher Teil des Projektes stellte eine standardisierte mündliche Befragung dar, in der das Verhalten bzw. die Verhaltensänderungen von Touristinnen und Touristen an Hitzetagen erhoben wurden. Mit Hilfe der Befragung wurde u. a. herausgefunden, wie störend die Temperaturen bei Sehenswürdigkeiten, Einkaufsstraßen, Gaststätten sowie in der Unterkunft empfunden werden und ob das Besichtigungsprogramm an die hohen Temperaturen angepasst wird. Weiters wurde eruiert, welche Maßnahmen sich die Touristinnen und Touristen wünschen, um den Aufenthalt in der Stadt bei hohen Temperaturen angenehmer zu gestalten. Die Touristinnen und Touristen wurden außerdem gebeten, ihr thermisches Wärmeempfinden in einer Skala und die Lufttemperatur in Form einer Maximaltemperatur einzuschätzen. Die Befragungen fanden an drei Tagen (23.07.2010, 10.07.2011 und 14.07.2011) jeweils unmittelbar nach einem Hitzetag statt und wurden in der Umgebung ausgewählter Wiener Touristenattraktionen (Stephansplatz, Burggarten, zwischen dem Kunst- und Naturhistorischen Museum, Prater, Schloss Schönbrunn sowie Grinzing bzw. Kahlenberg) unter Verwendung eines strukturierten Fragebogens sowohl in deutscher als auch englischer Sprache durchgeführt.

Im Zuge der Literaturrecherche wurden sowohl Fachbeiträge als auch aktuelle wissenschaftliche Publikationen im Hinblick auf die Übertragbarkeit der Maßnahmen auf den Tourismus in Wien und Österreich analysiert. Allerdings konnten nur wenige Anpassungsstrategien bezüglich Klimawandel und Städtetourismus im Speziellen gefunden werden, weshalb die Suche auf generelle Maßnahmen, die die Hitze für die Bevölkerung urbaner Agglomerationsräume erträglicher gestalten, ausgedehnt wurde.

Aufbauend auf der Literaturrecherche wurde ein World Café veranstaltet, an dem 34 Personen aus den unterschiedlichen Fachbereichen (Tourismus, Meteorologie, Stadt- und Raumplanung, Architektur, Medizin etc.) teilnahmen, um Anpassungsstrategien und ihre Umsetzbarkeit im Bereich der Tourismuswirtschaft zu diskutieren.

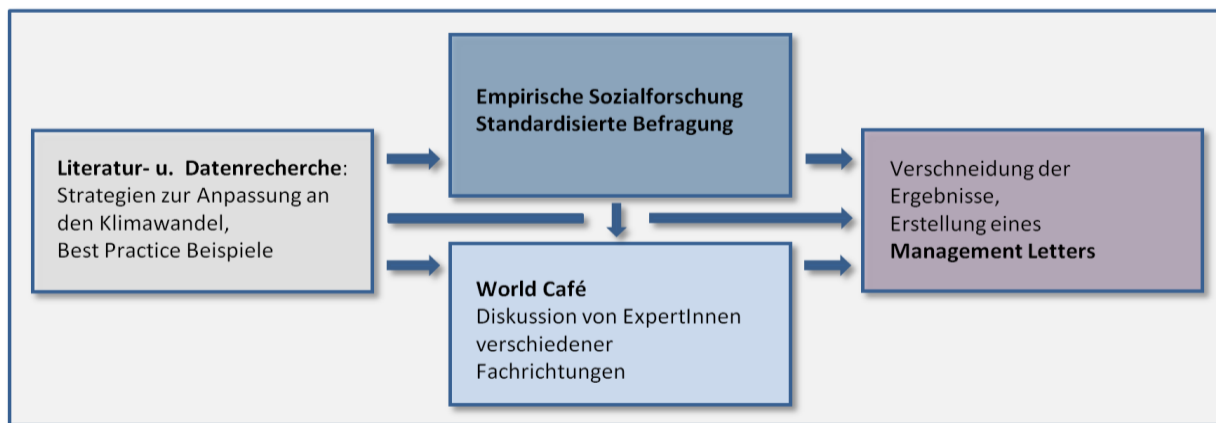
Im Anschluss daran wurden in Form eines Management Letters und aufbauend auf den Ergebnissen der Befragung, der Literaturrecherche sowie des World Cafés Handlungsempfehlungen zur Anpassung an hohe Temperaturen für die Tourismuswirtschaft erarbeitet.


Abb. 1: Projektablauf
Abb. 2: Befragungsergebnisse: „Temperaturempfinden der Befragten bei/in Sehenswürdigkeiten, Einkaufsstraßen/Shoppingcentern und Lokalen/Restaurants"

3 ERGEBNISSE

3.1 Ergebnisse der Befragung

In Summe wurden 365 Interviews mit Touristinnen und Touristen aus 57 verschiedenen Ländern durchgeführt. Der Großteil der befragten Personen stammte aus Deutschland (33,2 %); aber auch die USA (6,6 %), die Niederlande (5,2 %), die Schweiz (4,9 %) sowie Österreich (3,8 %) waren häufig vertreten. Mehr als die Hälfte der Befragten besuchte Wien zum ersten Mal im Rahmen eines Urlaubes, die durchschnittliche Aufenthaltsdauer der Touristinnen und Touristen betrug sechs Nächte.

Ein Drittel der Probandinnen und Probanden gab an, von der Hitze in Wien überrascht worden zu sein und nicht mit derart hohen Temperaturen gerechnet zu haben. Beinahe ein Viertel der Touristinnen und Touristen hat nicht vor, Wien nochmals im Sommer zu besuchen.

Mit welchen Maßnahmen lassen sich die Temperaturen in Wien angenehmer gestalten

Legend:
- 1=sehr wichtig
- 2
- 3
- 4
- 5
- 6
- 7
- 8
- 9=unwichtig

Categories (top to bottom):
- Mehr Wasserspender/Trinkbrunnen
- Mehr beschattete Sitzgelegenheiten in öffentlichen Freiräumen
- Mehr klimatisierte öffentliche Verkehrsmittel
- Mehr beschattete Bereiche bei den Sehenswürdigkeiten
- Mehr beschattete Fußgängerzonen/Gehsteige
- Mit Sprühnebel gekühlte Gastgärten
- Auskunftsservice in der Unterkunft über "Zufluchtsorte"/alternatives Programm
- Längere Öffnungszeiten von Geschäften
- Mehr klimatisierte Museen /Theater
- Längere Öffnungszeiten von Museen/Ausstellungen
- Längere Öffnungszeiten von Gastgärten
- Mehr klimatisierte Geschäfte
- Mehr Open-Air-Lokale der anderen Art (z.B. Strandbar)
- Mehr Angebote an leichterer Kost/kleineren Portionen in Hotels/Restaurants etc.
- Mehr Sitzgelegenheiten in Geschäften
- Mehr Grünflächen

Abb. 3: Befragungsergebnisse: „Maßnahmen, die einen Wien-Aufenthalt bei hohen Temperaturen angenehmer gestalten"

Zwei Drittel der Befragten hatten trotz der Hitze am Vortag ihr Tagesprogramm nicht an die hohen Temperaturen angepasst, wobei jene Personen, die nur ein paar Tage in Wien blieben, dieses weniger stark anpassten als Touristinnen und Touristen mit längerer Aufenthaltsdauer. Die Änderungen des Programms betrafen u.a. das Einplanen längerer Pausen oder das bewusste Aufsuchen von kühleren Orten (z.B. Parks/Erholungsgebiete). Zu einem großen Teil gemieden wurden vor allem (Pracht-)Bauten.

Auf die Frage, welche Sehenswürdigkeiten, Einkaufsstraßen und Gaststätten sie am vorangegangenen Hitzetag besucht haben und ob sie die Temperaturen dort als störend wahrnahmen, gab der Großteil der Probandinnen und Probanden (70 %) an, die Temperaturen in Lokalen/Restaurants als angenehm bzw. sehr

angenehm empfunden zu haben. Mehr als die Hälfte der Touristinnen und Touristen war mit den Temperaturen bei den Sehenswürdigkeiten zufrieden, während hingegen die hohen Temperaturen in Einkaufsstraßen/Shoppingcentern am störendsten empfunden wurden. Die Maßnahmen, die sich die Befragten in allen drei Kategorien am häufigsten gegen hohe Temperaturen wünschten, waren „Klimaanlagen" und „Beschattung".

Als wichtigste Maßnahme gegen hohe Temperaturen in Wien bewerteten die Touristinnen und Touristen „mehr Wasserspender/Trinkbrunnen" (78 %). Daher wurden im Management Letter (siehe Kapitel 4) Maßnahmen zur Verbesserung der Trinkwasserversorgung der Touristinnen und Touristen prioritär vorgeschlagen. Ein weiterer Wunsch, der von einem Großteil der Befragten geäußert wurde, war jener nach mehr Beschattung. So wünschten sich 73 Prozent mehr beschattete Sitzgelegenheiten im öffentlichen Freiraum, 61 Prozent mehr beschattete Bereiche bei den Sehenswürdigkeiten und 60 Prozent mehr beschattete Fußgängerzonen/Gehsteige. Maßnahmen zur Verbesserung der Aufenthaltsqualität der Touristinnen und Touristen im Freien (Pflanzung schattenspendender Bäume, Schaffung „kurzer Wege", Erstellung eines „Hitze-Stadtplans" etc.) haben somit gleichfalls eine hohe Wichtigkeit. Weitere empfohlene Maßnahmen betreffen die Anpassung des Besichtigungsprogramms und die Weitergabe hitzerelevanter Informationen an die Touristinnen und Touristen (z.B. „Cool Tours" bzw. Alternativangebote in der Unterkunft), was eine adäquate Schulung von Mitarbeiterinnen und Mitarbeiter im Tourismusbereich voraussetzt. Da mehr klimatisierte öffentliche Verkehrsmittel (67 %) und mit Sprühnebel gekühlte Gastgärten (59 %) bei der Befragung ebenso als wichtige Möglichkeiten zur Attraktivierung des Wien-Aufenthaltes bei hohen Temperaturen eingestuft wurden, wurden Maßnahmen zur Forcierung der energieeffizienten Kühlung in von Touristinnen und Touristen genutzten Einrichtungen (z.B. Passivkühlung, Dach- und Fassadenbegrünung) auch bei den Handlungsempfehlungen vorrangig berücksichtigt.

3.2 Ergebnisse der Literaturrecherche sowie des World Cafés

Im Rahmen der Literaturrecherche wurden vier übergeordnete Kategorien identifiziert und die jeweiligen – auch im World Café erarbeiteten – Maßnahmen diesen zugeordnet.

Maßnahmen im Bereich der Tourismus-Architektur

Zur Reduktion der sommerlichen Überhitzung von Gebäuden können Maßnahmen der passiven Kühlung (z.B. Nachtlüftung, Hauswandverschattung, Reduktion von Wärmequellen, helle Baumaterialen) sowie „aktive" Kühltechnologien (z.B. geothermische Kühltechnologien, Fernkälte oder solare Kühlung) beitragen. Wasserflächen bzw. Sprühnebel auf Dächern sowie die Dach- und Fassadenbegrünung können ebenso die Temperaturen im Gebäude senken, wobei letztere Maßnahme auch als potenzielles touristisches Ziel beworben werden kann (z.B. Vertical Gardens von Patrick Blanc auf Museen, Ausstellungsgebäuden und Hotels). Allerdings muss bezüglich Umsetzung berücksichtigt werden, dass einige der angeführten Maßnahmen bisher nur in Gebieten mit warmen Wintern erprobt wurden.

Maßnahmen in der Stadt-, Raum- und Landschaftsplanung

Maßnahmen zur Reduktion des Wärmeinseleffekts, die bereits bei der Bebauungs- und Flächenwidmungsplanung sowie der Bauordnung berücksichtigt werden sollten, beinhalten die Entsiegelung sowie die Begrünung von z.B. Straßenzügen und Gleisanlagen, die Errichtung von Parks (z.B. Pocket Parks) oder auch die Freihaltung von innerstädtischen Grünzügen und Frischluftschneisen. Ebenso tragen Verschattungselemente (z.B. Arkaden in stark besonnten Einkaufsstraßen) und – aufgrund der Verdunstungskühlung – bewegtes Wasser (z.B. Springbrunnen, Wasserzerstäuber, in offenen Rinnen abgeleitetes Regenwasser) zu angenehmeren Temperaturen in der Stadt bei.

Infrastrukturelle Maßnahmen

Die Überlagerung der touristischen Hauptrouten mit Wärmebildern (Wärmeinselkataster) kann dazu beitragen, bei den stark durch Hitze belasteten und stark frequentierten Orten (Hot Spots) gezielt Gegenmaßnahmen zu setzen. Diese beinhalten die Errichtung von beschatteten Sitzgelegenheiten (z.B. durch Sonnensegel), Abkühlungsräumen oder Trinkbrunnen (Hochquellwasser als „Unique Selling Proposition") sowie den Einsatz von Sprühnebel in Freibereichen (Gastgärten, Haltestellen, Passagen etc.). Durch die Nutzung von Gewässern als Verkehrsweg könnte der Aufenthalt in der Stadt bei Hitze ebenfalls angenehmer gestaltet werden.

Organisatorische Maßnahmen

Zur Verringerung der gesundheitlichen Risiken von Hitzewellen eignen sich Hitzewarnsysteme und ein auf Hitzebelastungen zugeschnittenes Informationsmanagement. Maßnahmen der Stadtverwaltung bei Erreichen einer bestimmten kritischen Temperatur beinhalten u.a. das Öffnen von „Abkühlungsorten" (z.B. klimatisierte Verwaltungsgebäude), Gratis-Eintritt in Schwimmbäder, verlängerte Öffnungszeiten von z.B. Schwimmbädern, Kirchen oder Einkaufszentren sowie die Verteilung von Wasser. Stadtpläne, die kühle Orte, Trinkbrunnen oder kurze Wege anzeigen, sowie hitzerelevante Informationen, die in der Unterkunft oder im Internet erhältlich sind, erleichtern das Besichtigungsprogramm der Touristinnen und Touristen an heißen Tagen. Die Förderung von kühlen Fortbewegungsmitteln in der Stadt, die Einbeziehung von Naherholungsgebieten in touristische Programme sowie das Vermeiden der heißen Mittags- und Nachmittagsstunden durch die Anpassung von Tagesprogrammen (z.B. durch Unterhaltungsangebote in Quartieren, Führungen in den „Untergrund") sind weitere Maßnahmen, die den Aufenthalt in der Stadt bei Hitze erträglicher gestalten. Bei einigen der organisatorischen Maßnahmen (z.B. angepasstes Lüften) ist allerdings eine adäquate Einschulung der Touristikerinnen und Touristiker empfehlenswert.

Maßnahme	Beschreibung
Maßnahmen zur Verbesserung der Trinkwasser-versorgung der Touristinnen und Touristen	Erhöhung der Anzahl an Trinkbrunnen bei Sehenswürdigkeiten, in Einkaufsstraßen und entlang touristischer Routen (z.B. durch Trinkaufsatz auf Feuerhydranten) – eventuell in Kooperation mit Geschäften/touristischen Einrichtungen in Form von Sponsoring/Patenschaften.
	Vermarktung des Österreichisches Wassers mit hoher Trinkwasser-Qualität als Alleinstellungsmerkmal („Unique Selling Proposition").
	Aufstellung von Wasserspendern in touristisch stark frequentierten Gebäuden.
	Gastgewerbebetriebe und Geschäfte können Touristinnen und Touristen mit eigenen Piktogrammen und/oder Informationen in mehreren Sprachen auf die kostenlose Ausgabe von Leitungswasser hinweisen.
Maßnahmen zur Verbesserung der Aufenthalts-qualität der Touristinnen und Touristen im Freien	Die klimatische Optimierung von touristischen Routen, Einkaufsstraßen und Bereichen vor den Sehenswürdigkeiten sowie bei Wartebereichen sollte erfolgen durch: Begrünung, v.a. schattenspendende Bäume (dort wo diese Maßnahme nicht möglich bzw. sinnvoll ist – bspw. barocke Schlossgärten –, sollten temporäre Sonnensegel zum Einsatz kommen), Errichtung von Sitzgelegenheiten in beschatteten Bereichen, Schaffung „kurzer Wege" (bspw. Öffnung von Durchgängen – ev. Übernahme der Wegehalterpflichten durch die öffentliche Hand bzw. touristische Einrichtungen, die im Umfeld angesiedelt sind).
	Ein „Hitze-Stadtplan" sollte als Print-Version (Verteilung von kostenlosen Plänen sowie Aufnahme in Reiseführer) und als Internet-Applikation für Smartphones erstellt werden, in dem alle Trinkbrunnen, „kühle Routen", Abkühlungsorte (z.B. Kirchen, Arkaden, geöffnete öffentliche Gebäude, kühle öffentliche Verkehrsmittel etc.) eingezeichnet sind.
Maßnahmen zur Anpassung des Besichtigungs-programms und Weitergabe hitzerelevanter Informationen an die Touristinnen und Touristen	Mehrsprachige Informationen über speziell für Zielgruppen zugeschnittene Alternativprogramme an Hitzetagen durch das Personal an der Rezeption in der Unterkunft, auf einer Online-Plattform, in Form von Internet-Applikationen oder über SMS-Dienste.
	Anbieten von attraktiven Angeboten in der Unterkunft während Hitzestunden (z.B. Dokumentarfilme über die Stadt).
	Hitzewarnungen in Unterkünften an Touristinnen und Touristen weitergeben (z.B. durch Aushang an der Rezeption, aktuelle Informationsfolder).
	Angebot eines hitzeangepassten Besichtigungsprogramms durch Stadtführerinnen und Stadtführer („Cool Tours").
	Für die Umsetzung der oben genannten Maßnahmen sind Schulungen von Personal in Unterkünften und von Stadtführerinnen und Stadtführern sowie Adaptierung von Aus- und Weiterbildungslehrplänen erforderlich.
Maßnahmen zur Forcierung der energieeffizienten Kühlung1 in von Touristinnen und Touristen genutzten Einrichtungen	Forcierung von energieeffizienten Kühlungsmethoden wie bspw. Passivkühlung (z.B. Betonkernaktivierung2[, Dämmung), solare Kühlung3 und Verdunstungskühlung (z.B. Sprühregen am Dach) sowie Dach-/Fassadenbegrünung (vermarktbar auch als Touristenenattraktion) für Unterkünfte und touristisch interessante Gebäude.
	Forcierung von energieeffizienten Kühlungsmethoden für öffentliche Verkehrsmittel (Garnituren, Haltestellen) durch Kooperation mit dem Tourismus bzw. Sponsoring durch Betriebe.
	Touristinnen und Touristen sollten darüber aufgeklärt werden, welche Art von Kühlung bzw. warum keine Kühlung (z.B. aus Denkmalschutzgründen) in der jeweiligen Einrichtung angewendet wird.
	Schaffung einer Beratungsstelle („Klima-Coach") speziell für die Tourismusbranche, die über Umsetzung von energieeffizienten Kühlungsmethoden, Fördermöglichkeiten, Denkmalschutz, Vermarktungsmöglichkeiten, Information von Touristinnen und Touristen etc. berät.
	Schulung der Touristiker (Personal in Unterkünften, touristisch interessanten Gebäuden etc.) bezüglich hitzeadäquatem Verhalten wie bspw. richtiges Lüften und Weitergabe dieser Informationen an die Touristinnen und Touristen.
	Betriebe des Gastgewerbes, die zu wenig an Hitze angepasst sind, sollten – z.B. über Förderungen – dazu motiviert werden, adäquate Maßnahmen (Beschattung, Sprühnebel etc.) durchzuführen.

Abb. 4: Auszug aus dem Management Letter: zur Umsetzung empfohlene Maßnahmen (Allex et. al, 2011)

4 SCHLUSSFOLGERUNG UND HANDLUNGSEMPFEHLUNGEN

Da viele der erarbeiteten Adaptionsstrategien nicht nur Touristinnen und Touristen, sondern auch die Bevölkerung betreffen, sind positive Auswirkungen über den Städtetourismus hinaus zu erwarten. Durch die Umsetzung der Anpassungsmaßnahmen und die Hervorhebung der Stärken österreichischer Städte (z.B.

---

[1] Obwohl sich die befragten Touristinnen und Touristen zum Großteil Klimaanlagen wünschten, wurde bei den Maßnahmen auf das Ziel des Klimaschutzes (d.h. eine hohe Energieeffizienz bei möglichst geringem CO_2-Output) geachtet.
[2] Frei zugängliche Betonteile dienen als Kühlelemente.
[3] Betrieb von Kältemaschinen durch thermische Solaranlagen.

Wasserversorgung) kann das Bild einer kühlen Stadt in einem heißen Sommer vermittelt und als Alleinstellungsmerkmal („Unique Selling Proposition") vermarktet werden.

Jene Maßnahmen, die basierend auf den Ergebnissen der Befragung, der Literaturrecherche sowie des World Cafés erarbeitet und zur Umsetzung in österreichischen Tourismus-Städten empfohlen wurden, wurden in Form eines Management Letters zusammengefasst:

Housing Quality and Lost (Public) Space in Croatia

Anđelina Svirčić Gotovac, Jelena Zlatar

(PhD Anđelina Svirčić Gotovac, Institute for Social Research, Amruševa 8/III, 10 000 Zagreb, Croatia, angelinasg@gmail.com)
(PhD Jelena Zlatar, Institute for Social Research, Amruševa 8/III, 10 000 Zagreb, Croatia, zlatar.jel@gmail.com)

1 ABSTRACT

In the post-socialist period and within the current social transition context, urban and rural Croatia has, just like other transition countries, experienced many changes in the social structure and space. One example is the housing quality which is a replica of the situation in the Croatian society and has also undergone some major changes. Socially oriented housing construction co-financed by the state and the cities is in an unfavourable position compared to private housing construction. In the last twenty years the amount of the social housing construction has been only a minor part of the total contruction work in the country. For instance, out of nine newly planned residential housing developments in Zagreb, the capital city, only three have been completed and the work on the rest of them has stopped and is unlikely to continue. Private construction work prevails especially on the edge of the city and is characterised by high density housing. This type of housing construction doesn't benefit the majority of citizens in search of accommodation (price per square meter is too high, low-quality building). There is also a big problem of the community facilities (primary and secondary infrastructure, schools, kindergartens, playgrounds, green areas, sidewalks, public transport etc.). The existing globalisation-transition circumstances of the Croatian society corroborate the fact which experts of various profiles often point out: ignoring the process of (urban) planning will irreparably damage the space. The city transformation shows the absence of comprehensive urban planning which results in an ever increasing number of random buildings which do not fit in the surroundings. This leads up to yet another important issue – the shrinking and, in some cases, disappearance of public space which becomes the "lost space". In recent years there has been a lot of building in the city core and on the edge which does not quite fit in the existing urban structure, image or the skyline of the city. The current situation in the process of planning can be characterized as a conflict and imbalance between the powerful actors (mostly political and economic) and less powerful actors (mostly professional and civil). The actors who have the political power and influence and the ones who possess the capital are forming an "alliance" between two important layers of the social structure. The lack of civil and professional actors, "lost spatial actors", and therefore of civic aggregation is also present and that is also the cause of public space "disappearance" and undermined process of public participation.

2 INTRODUCTION

Croatia and its space are characterised by the post-socialist context in which new and remarkable social, political and economic changes have occurred since the 1990s. The champions of these changes are new social actors, primarily economic actors (for example, investors) and political actors (for example, town mayors). In the past, in socialism, their influence was not big. The state was the most powerful. "In Croatia the existing social context (transition and post-socialism) makes the social actors increasingly important. New social changes affect the activities and behaviour of new and old actors. Their importance and operations can not be separated from the process of restructuring of modern society today, globalization or transition. Both urban and rural space of Croatia has undergone significant physical transformation in the transition period but even more social changes"(Svirčić Gotovac, 2012:13-14).

These changes are mostly visible in spatial and urban planning. In socialism urban planning was based on well-defined, long-term strategies. Post-socialism is determined by a completely different attitude to space: no strategic, long-term planning, no careful consideration for space development. The consequences are evident. "Socialism is believed to be one of the most constructive periods in the urban development of Zagreb. Not only regarding the quantity of housing development but also its quality and the quality of life of Zagreb's citizens" (Jukić, Mlinar, Smokvina, 2011). The new capitalist system and its market laws prefer to make a quick profit on investment. So most investment is private and responsible for urban planning. Politicians often side with investors and not with other segments of the society (for example, professional or civil actors).The consequence are numerous thoughtless and inadequate interventions in space, on the periphery and in the centre of towns. This is visible in both residential and commercial construction. "Consequently, land-use planning at the municipial level has been characterized by the prevalence of ad hoc

political decisions and not long-term strategic visions. Also, the development control was weak, and there was a 'laissez-faire' approach to the city development" (Hamilton, Dimitrovska Andrews, Pichler-Milanović, 2005:475).

In the Croatian society today along with the systematic neglect of spatial development there is also insufficient participation of people in public and political life. It is important to point out that people do not take an active part in problems regarding their immediate living environment."The Law on Spatial Planning and Construction does not precisely define the role of citizens and their participation. The problem is also that the existing regulations are not interpreted to the benefit of citizens and the insistence on their real, transparent participation. They merely satisfy the minimum of legal procedure" (Toš and students, 2012). In Croatia today there is only a public presentation and a public debate which normally last for two weeks after the plans are made. After that, there is no response to the reaction of the public which suggests that people do not have any real influence on the matter. Public debate is not a sufficiently effective method and other steps should precede it, such as information about the stages of the project and some professional opinions about the project (its advantages and drawbacks). For the public this would mean a longer period of involvement leading to more democratic decision-making processes. Greater participation can affect people's living conditions at the local level which correlates with their total quality of living. The quality of living can be measured at different levels, from the quality of immediate neighbourhood to the quality of living in a particular country and they are dependent on each other.

In the existing globalization and transitional circumstances, spatial transformations are happening in Croatia with almost no participation of its inhabitants and citizens. Public interest is often neglected and private interest is promoted (investors' and partial interests). Such relations between different social actors in the process of spatial planning can be characterised as the conflict and imbalance between the powerful (usually political and economic) actors and the less powerful (mostly professional and civil) actors. "Urban phenomenon comprises a complex set of actors and each type of society and each type of urban society means a power hierarchy of actors. A different power structure for a different system"(Bassand, 2001). It is precisely the power of a specific actor which defines how much difference their activities will eventually make to space. In many post-socialist countries the neo-liberal thinking is characterized by a low political priority given by central governments to physical planning, regional development and housing policy. There is an absence of comprehensive national spatial development strategy and coherent regional policies, together with local and regional government reforms and disputes regarding the basis of new planning legislation (Sykora, 1994; Dimitrovska Andrews and Ploštajner, 2000; Pichler-Milanović, 2001).

3 TRANSFORMATION OF URBAN SPACE IN ZAGREB

Zagreb region, the capital city, the largest (macroregional) center and its county has only a little more than one million inhabitants (1,107,623) (Croatian Bureau of Statistics, 2011), and is, according to the world urban population statistics, a relatively small metropolitain area. In comparison with other Croatian towns, however, it is the biggest centre and with its metropolitan area the only one with over a million inhabitants. If compared with big European towns, for example with "ten towns similar in size and the number of people (such as Amsterdam, Athens and Stockholm, smaller than Zagreb, such as Zurich and Dublin or bigger than Zagreb, such as Barcelona, Vienna, Budapest, Prague and Warsaw), Zagreb has the biggest average number of people per household (2.8) and Amsterdam the smallest (1.8)" (ZagrebPlan, 2013:129).

The second-largest Croatian town Split and its county have less than half a million inhabitants (454,798) (Croatian Bureau of Statistics, 2011). These data show that most problems of urbanization, high density housing or moving to towns are connected with Zagreb. With its modernization and transformation characteristics Zagreb greatly differs from the rest of the country. Also various research indicators of the quality of life and especially the quality of housing in Zagreb considerably differ from the rest of the country.[1]

---

[1] The quality of life in the majority of settlements in the Croatian settlements network is defined by the quality of their equipment (infrastructure and institutions), as shown in the 2004 research. It is difficult to compare the biggest towns, such as Zagreb and Split, especially with numerous rural settlements where the quality of life is often reduced to basic existence, whereas higher levels are hard to attain for most people. Urban agglomerations, that is, macroregional centers in Croatia are well ahead of most urban or rural settlements regarding life quality although they also have a lot of

In most countries of the world since the 1990s the role of private investors has become increasingly important and they have made some big financial investments. It also means they have made some major decisions about what cities will look like in the future. Processes related to the construction work in city centres, such as urban renewal and gentrification, have also grown stronger in Zagreb since the 1990s. "Earlier the process of gentrification was generally associated with the real estate market of developed countries and their leading cities (the so-called command-center cities). Today, however, it is becoming a global process and an urban strategy going beyond liberal urban policy or sporadic and local occurrence" (Smith, 2002:427). Attractive real estate in the very city center has made gentrification possible and revived construction work there, with uneven involvement of spatial actors, especially experts and politicians. A large number of shopping centres and underground garages has been built near the centre. By letting the traffic in the city centre rather than reducing the number of cars, Zagreb is not following trends in developed European cities. Experts and residents take part in these city changes only marginally while some actors, namely investors, make a maximum profit. In the process of urban renewal the role of the state has weakened and individuals or private actors play a prominent role. Because of inadequate involvement of the state and city authorities in the process of renewal and revitalization of the city centre, these new actors have become extremely powerful in urban space and responsible for its future look without having sufficient respect for the historical and urban identity of the city. Even some protected parts of the old city core have been radically altered and expanded, the changes usually accompanied by discordant opinions of experts and politicians.[2] Still, the most remarkable transformations of urban space have happened on the edge of the city because of numerous open possibilities there.

4 RESEARCH RESULTS

The paper gives an overview of long-time research carried out by the sociology of space group at the Institute for Social Research in Zagreb[3] regarding the quality of life of residents of Zagreb and the relations among the social actors (economic, political, professional and civil actors). Mixed-type methodology has been used, qualitative (semi-structured interviews) and quantitative (surveys). In order to get an insight into the changes of the last two decades (the transition period) brought about by the new social system and new rules among the actors, the most interesting research results obtained from 2004 to 2009 are presented. The results of the 2004 survey representative sample contribute to the criticism of living conditions in new housing estates and high density housing areas in Zagreb. They show that their level of equipment (infrastructure and facilities) is rather unsatisfactory especially on the edge of the city. Interviews conducted in 2007, 2008 and 2009 with target actors and their representatives point to obvious inequality among actors in the City of Zagreb and the rest of Croatia. This problem becomes bigger when power is frequently abused for selfish interests which is often the case with political and economic actors.

Public space with its facilities is available to everyone and is managed by the city for the benefit of its citizens (Low, 1992). One of the main characteristics of public space is that various organized and spontaneous activities take place there. Also public space is multidimensional: social, cultural, political and economic. Increasing privatization of public space leads to its discrimination and loss.

All attributes of public space which are not connected with the market and economy disappear. Permanent accessibility, openness, safety, constant liveliness – everything is seriously disrupted.

All research done by the above mentioned group aims to contribute to the protection of space, especially public space (squares, streets, parks, playgrounds, all facilities useful in everyday life), in the city centre as well as in various housing estates. Public space is evidently threatened and becoming scarce. It is deliberately eliminated from the planning process as such and converted into private or semi-public space (for example, a new shopping mall, residential or office building). Thus it is becoming lost space.

---

downsides due to their size. Generally speaking, towns still achieve better results. This is why towns permanently attract and receive new residents, especially the City of Zagreb, the biggest urban centre.

[2] Flower Square is a Lower Town protected architectural unity in the heart of the city where a modern shopping centre and an underground garage have been built in spite of strong protests coming from experts and citizens.

[3] The sociology of space group at the Institute for Social Research in Zagreb has been researching urban and rural issues (including the quality of life in urban and rural areas of Croatia) for almost 50 years. The authors of this paper are part of the group.

In the sequence of this paper the mentioned results will be shortly introduced on the examples of spatial transformations in Zagreb, primarily transformations of residential and business construction.

4.1 Residential construction

High density housing in residential areas has paradoxically led to a reduced quality of life in broader city areas. The reason is that the housing construction has not always been matched by the housing quality. The life quality of residents in some new housing estates in Zagreb has therefore fallen (Pictures 1 and 2). Private investment has taken little care of either technical or social (institutional) infrastructure of the new settlements. The city authorities, on the other hand, have not demanded the investors' help with the infrastructure necessary for everyday life of citizens when giving them municipal land plots (schools, kinder gartens, shops, health and culture centres, playgrounds, parks, green areas). And the city itself often lacks finance for the complete infrastructure so the present one does not meet the citizens' real needs and requirements.

Picture 1 New housing construction and high density housing in Zagreb

Picture 2 High density housing in a new estate in Zagreb

The housing quality has undergone a lot of both positive and negative changes in the period of transition. The most obvious change is a large number of new flats and housing estates initiated by private investors,

much less by the state (city). Socially oriented housing construction subsidized by the state (city) is currently stagnating although in the last few years new projects have been considered offering flats to citizens at a favourable price (new housing estates). Fewer than planned have been built and then the construction has stopped. And so it has remained in the shadow of the private sector.

The quality of living in such housing estates is often low and the private-public partnership model[4] is a complete failure. The city authorities frequently refer to this particular model, well recognized and successful in Europe. It is used for various projects where investors make a profit but also offer useful services and additional attractions to citizens. In Croatia, because of the crisis in the town planning process, investors are given locations which are not necessarily economically advantageous to the city and the whole profit fills their pockets making them the sole beneficiaries of the partnership. The city authorities fail to realize that the model has been unsuccessfully applied. Building flats for citizens has not benefited them, the citizens of Zagreb, only specific individuals, the so-called new actors (investors, developers etc.).

Picture 3 High density housing in a business district

Picture 4 Business tower near the centre of the city

The above mentioned is supported by the fact that "40,000 new flats were built in Zagreb from 2001 to 2008. There are about 20,000 unsold new flats on the real estate market now, plus some old flats on sale. A lot of people live in parts of the town with no essential services, no local employment, low-quality public spaces, no green areas, sport and recreation facilities" (ZagrebPlan, 2013:127). At the same time, paradoxically, the

---

[4] The term refers to the cooperation between big private investors (often corporations) and the local authorities. The partnership has become quite common recently (Carmon, 1999).

new flats are unaffordable to most citizens because of their exorbitant prices per square meter. It is therefore clear that the principal goal is not being achieved: citizens are not provided with the satisfactory housing quality. European Charter on Housing states that "controlling the expansion of suburban and urban zones should become an important goal for the Community if sustainable development is to be maintained (Article 5, Section 2, European Housing Charter). Suburban zones of Zagreb are hardly good examples of sustainable development.

4.2 Commercial construction

Beside residential construction in broader city areas, urban transformations are visible in other types of construction: shopping centers, new business zones and high-rise office blocks. In the twenty years of transition we have witnessed in both residential and commercial construction (Pictures 3 and 4). In socialism business high towers grew on vacant land areas expanding horizontally. Today they are placed in already occupied zones. This results in the shrinking of public space and the infrastructure of the chosen locations is insufficient for new high-rises. They are yet another example of urban transformations dictated by private investment.

Zagreb has become crowded with shopping centers, in the city center and on the periphery, as well as with underground parking garages, mostly in the centre. Shopping centres usually buy cheap land and the infrastructure is already there. After some time they close down (there are too many) and become brownfields available for re-use. Underground garages are seemingly solutions for the traffic but are in actual fact just additional profit for investors.

These examples in Zagreb (high rises, shopping centers and underground parking garages) do not stand for urban renewal but random, incomplete and chaotic urban transformations. And so does residential housing construction. "In town planning for many years now there has been a string of illogical decisions. They have allocated the best municipal land to shopping centers and businesses and moved residential projects to less convenient locations" (Jukić; Mlinar; Smokvina, 2011:43).

5   DISCUSSION

Looking at high density housing in Zagreb, another aspect of the problem that comes to mind is used and irretrievably lost space, especially public space. When public spaces are generally shrinking and being destroyed, this building surplus is a paradox (lost space). It is not useful for the public. What is useful (schools, kinder gartens, sport centers, parks) is not being built and the old, existing institutions are put under additional pressure. Such inadequate use of space speaks at the same time of unnecessarily wasted space and the absence of strategies and policies for managing the city better, both its residential and business needs.

It is apparent that there is a serious imbalance between social actors in Croatia. The imbalance is visible between very powerful (economic and political) actors and less powerful (civil and professional) actors who are even completely powerless in some circumstances (lost spatial actors). A situation like this is not problematic as such because it is a normal part of social reality; when, however, it puts public interest and public space in danger, everything changes. Participation of the public in spatial planning and decision-making processes regarding their immediate environment has not been satisfactory for a while now. Non-government organizations (NGOs), a new type of actors, have come in conflict with economic actors. They are critical of the present situation and try to introduce some changes in the decision-making and increase participation of the public. They are therefore "regulators" of democracy. Zagreb's authorities manage the town development weakly and non-transparently favouring private investors. Some professional actors also side with investors forgetting the rules of their profession and contributing to "dotted", random housing construction. Decision-making procedures are non-transparent and frequent alterations of the Master Plan are noticeable, too. This should not be the case because of the Plan's importance for the city urban planning.

Bearing in mind everything mentioned so far, it is essential to correct the mistakes of the transition period and give a more prominent role in the management of town affairs to professional and civil actors. Today's random and chaotic construction at locations lacking the necessary facilities, will not help. Interdisciplinary urban planning does not exist either, one can talk about the so-called "death of urbanism" in the transition period. Spatial planning should be given greater care and appreciation than has been the case in these last years. This comprises transparent participation of the public (experts and civil actors) in practical and legal matters.

Today when the concept of sustainable development has been globally accepted and the majority of countries are planning their spatial development accordingly, it is impossible to behave otherwise. Everybody's commitment should be to preserve our space for the future and yet its irrevocable waste or neglect contradict the concept. The 2009 strategy for sustainable development[5] "brings together various development policies trying to find suitable solutions for all three sustainable development components: economic, social and environmental... and will be guided by the following general principles..."; here we wish to stress "the creation of an open and democratic society and the participation of citizens"(Narodne novine, the Official Gazette of the Republic of Croatia, 2009:2-3). Since strategically important documents exist, they are to be applied which has not always been the case so far. It is vital to raise the awareness that space is an important resource for the future development. Only then can space be saved and its loss minimized.

1 ABSTRACT

With the advancement of digital and sensor technologies, architecture as well as planning domains are continuously endeavoring to reach new horizons. Various kinds of sensor networks are producing data, which can be relevant for urban environments. This data can concern a variety of fields such as infrastructure, mobility, or climate. Primarily, data should be gathered to supply people with information about their environment. With the help of this data and information, surrounding impacts, which influence peoples' perception, can be identified. The main problem is the lack of comprehensive methods for measuring how people feel in their cities, and how they react on certain urban impacts. The main interest of urban planning should not be limited to infrastructures, buildings, and spaces, but rather concentrate on the people who use those buildings and spaces. It is therefore necessary to develop new methods for measuring "people's feelings" in the city with specific indicators and parameters. The presented joint German Egyptian project between the University of Kaiserslautern and Alexandria University aims at exchanging experiences and knowledge in the field of Human Sensory Assessment and its potential use for urban planning. Technologies and methodologies for data collection, analysis, and visualization are part of the research. Within the project, emotional data has been gathered and analyzed for a walk of locals and foreigners on one of the main promenades of Alexandria. The goal is to study if and how different cultural backgrounds might affect the perception of the participants in different urban spaces.

2 INTRODUCTION

Improving the living conditions in our cities should be the main goal of every planner, developer, politician, and citizen. This research makes use of emerging technologies of geo- and mobile-data processing within the field of urban planning to efficiently collect and visualize qualitative data rather than only quantitative data. An example from the field of emission control explains the circumstances: A sound impact can be clearly classified in decibel labels with the help of sensors, but it is not quite clear to what extent sound is felt as personal burden. There are other parameters in a city like green areas or fountains that can positively influence the feelings in an urban environment. This project focuses on collecting information about cities with up-to-date applications and methods. It is also discussed if and how residents and foreigners respond differently to the same urban settings and situations. In this collaborative project of German and Egyptian University partners, the exchange of experiences and knowledge between both groups within the fields of urban planning and computer science was another important aim. Therefore, different state-of-art applications for data collection through geo- and mobile-data processing methods were developed and tested. Within the project, data has been gathered, analyzed, and compared for several urban spots in Egypt and Germany. The aim of the project was not only to test the data processing methods, but also to compare measured emotional stress in the given case studies. They enable to figure out the existence of indications, which can define to what extent different cultural environments can influence the perception of the surrounding situations.

3 STATE OF RESEARCH

Background research on using human sensory assessment methods in urban planning to identify "points of (negative) emotions" was already conducted by several research groups, starting with the "Mental Maps" by Kevin Lynch in his "Image of the city" (Lynch, 1960), where participants sketched a map out of their mind of the investigated city. Yet critics claim this technique needed drawing skills to produce the map. Results of

tracking people with the help of GPS technology were delivered by Phillips et al. (2001) and by Elgethum et al. (2003). The approach to digitally map feelings like fear in a city was introduced by Sorin Matei. In his "Mental Maps Concept", he visualized for the first time feelings on a digital map and created a three-dimensional model for a better understanding of the environment in the city of Los Angeles (Matei et al., 2001). Unfortunately, he gave his approach the technical term "mental map" similar to Lynch. The difference is that Lynch created maps "out of the mind" and Matei made "emotional maps".

As a result of the developments in recent years, from "ubiquitous computing" towards "pervasive sensing", small, connected, flexible sensors (like smartphones) build the basis for pervasive sensing approaches of urban areas (Martino et al., 2010). Goodchild refers to this phenomenon as "Citizens as Sensors" (Goodchild, 2007). Other authors use the term "People-Centric Urban Sensing" (Lane et al., 2006, Campbell et al. 2006) or simply "urban sensing" (Cuff et al. 2008). Citizens that want to be involved in a planning process, can now produce and deliver data, and thus are more in the focus of planning considerations. They act as active sensors for the urban environment. Based on the development of mobile communication techniques, Mark Weisers vision of "ubiquitous computing" comes true (Weiser 1991). This contextual shift, described as "urban sensing", can be a trigger for a "fundamental transition from science and engineering into the realms of politics, aesthetics, interpretation, and motivation" (Cuff et al. 2008, p.1).

The first one who combined emotional data with the help of physiological parameters (skin resistance level) and GPS data was Christian Nold in his art project Biomapping (Nold, 2008 and 2009). Other examples for collecting "human sensor data" in cities were provided by the MIT Senseable City Lab (Martino et al., 2010 and Resch et al., 2011). Characteristical features and peculiarities of the Geoweb are "the development and changing nature of map-based data mash-ups" and the explanation of "the basic concepts behind map mash-ups, how geospatial data gathering and analysis has changed and how new technologies and standards are impacting on this" (Batty et al. 2010, p. 1089).

4 METHODOLOGY AND TECHNICAL SPECIFICATION

With the help of the psycho physiological monitoring, a practicable method was created to identify geo-referenced stress reactions in a city (Zeile et al. 2009, Bergner 2010, Zeile et al. 2011, and Exner et al. 2012). The experimental research consistently shows that emotional reactions are associated with changes in specific physiological parameters, like skin conductivity and skin temperature, resulting from the activity of the autonomic nervous system (Kreibig, 2010). In several projects, the method, the analysis, and the workflow were tested in pre-studies (Taha et al 2012a and Taha et al 2012b), or tailored to a specific target group (Bergner & Zeile 2012). However, the analysis is still to a large part carried out manually, which consumes a large amount of time. One task was to speed up the workflow by implementing some automated analyses, with the aim to improve quantitative and qualitative test methods concerning human sensory assessment. Furthermore, another research task was to figure out the possibilities for identifying a difference of participants' measured emotions, especially based on their country of origin and cultural background. The main focus is to find efficient ways to analyze the difference between participants from different cultural backgrounds, both in local and foreign environments. In order to do this, the study took place at the Eastern Harbour/Cornice in Alexandria.

4.1 Scientific Approach

Human sensory assessment is based on the usage of body sensors for measuring human physiological data (in this case skin conductivity and skin temperature) in real-time. Besides the physical activity, reasons for changes in physiological data are found in psychological processes (Kreibig, 2010). Trigger is a humans' emotion in context of their current environments. In the research project at hand, the sensor wristband "BMS Smartband" (Bodymonitor Systeme, 2013) was utilised. The wristband records physiological data in a TXT-file, which can be analyzed in a further step to find emotion patterns. The synchronization of the resulting emotion data with geo positions gathered by means of mobile GPS trackers is obligatory. The participants were also equipped with cameras for linking the collected emotion data with the perceived surrounding environment.

In previous studies, the transformation of raw physiological data to resulting emotion data (linked with geo position) was a time intensive and not fully automated process. Combining different processing steps in a defined workflow, and especially the reduction of complexity regarding the exchange of data between

different software components, was an elementary success of the project. Furthermore, whole data sets can directly be linked with individual video data of the participants to separate identified emotion sequences. A qualitative analysis of the trigger for specific emotions can thus conveniently be conducted afterwards for every study participant. Finally, the resulting data can automatically be formatted to allow the generation of heat maps that visualize identified stress hot spots in urban spaces.

For an identification of the original triggers of stress in these urban areas, a closer look to the individual runs is essential. Therefore, it was necessary to create a new workflow of analyzing the corresponding movie files, in which all the tracks in the line of sight of the respective participant were recorded. In earlier projects, the analysis of the movies was manually carried out by comparing the timestamps of the movie, the GPS tracker and the timestamp of the Smartband which delivers the data of the individual stress level of each participant. For the visual comparison of the results, all datasets were integrated in a movie timeline (Figure 1). As a result, it is possible to synchronize heart rate, skin conductance, and stress responses with GPS and the video signal. In addition, the visual detection of individual impacts on stress – like bad road conditions, orientation problems etc. – is possible (compare Exner et al. 2012).
Fig. 1: Retrospective individual video analyses of a test run during a hiking tour of one proband (Exner et al. 2012)

4.2 Technical Specification

One of the main tasks was to develop tools that facilitate the carried out tasks: (1) Automatically synchronizing the datasets of GPS-Tracker, camera, and Smartband, and (2) Identification of the stress phases of the track, and automatic extraction of movie snippets of the corresponding time periods. Based on this, the identified stress points have to be stored in a geo-database and then visualized. This task was done to aggregate all the individual stress points in a so called "stress hotspot heatmap", in which all the individual stress spots were combined by a point density analysis (similar to RADAR Sensing, compare Zeile et al. 2012). Some of these tasks can be realized using the RADAR platform (Memmel & Groß 2011), which is based on the ALOE framework (Memmel & Schirru 2007).

The data processing was mainly realized using Perl scripts that can be applied on any common operating system to provide the flexibility to also allow a web-based processing of data in the future. Perl is a general-purpose, interpreted programming language that offers powerful means to analyze and manipulate data, especially by means of regular expressions. Using this as basis, the tools could quickly be developed, and required adaptation request could instantly be considered in situ. To merge all the different data sources, the data has to be synchronized on a common frequency. In our studies, a one-second span was used. In case there are unwanted time gaps in the data provided by the GPS tracker, a further preprocessing step can be conducted by applying the "GPS Interpolation" script. Using the generated CSV as an input, this script

automatically interpolates missing data by taking into account the last and next known position and timestamp of an identified gap.

Once the data is correctly aggregated, a software called "StressPhaseIdentifier" can be applied to identify stress phases based on a previously conducted analysis on changes of humans' physiological data. The script provides an enhanced CSV file with information about the stress phases, a short overview of all identified stress phases, and statistical information such as the average length of a phase. In addition, the script can also automatically extract corresponding video snippets when the user provides a respective file. In this case, an offset has to be specified to match the timestamps of GPS and video data. The extraction of snippets was realized using the "ffmpeg library" that is available on any common UNIX-based system. Finally, the file with identified stress phases can be used as input for the "GenerateHeatmapInput" component that will automatically generate a JSON representation usable as input for the generation of heatmaps within the RADAR system (Figure 2).

Figure 2: An exampe for a heat map of aggregated stress reactions in the market and old town area, Alexandria – Egypt

5 CASE STUDY: EMOTIONAL MAPPING IN ALEXANDRIA

This study is a continuation of a previous test carried out in 2011 (Taha, Raslan, & Bergner, 2012b). Both tests took place on the promenade along the Eastern Harbor in Alexandria. The Eastern Harbor Promenade, or as called "El Cornice" by Alexandrians, is an average of a 4.0 km stretch along the water front (3.87 km on the sea side and 4.30 km on the inner side), from the Citadel on its west end to the Bibliotheca Alexandrina on the east (Figure 3). It is a path heavily used by pedestrians and vehicles alike, as well as for locals and city visitors. Characteristics for the inner side of the path are that it is almost completely planted with palms or trees, and that there exists almost 40 intersections without crossing aids along the path. The outer (waterfront) side is only partially planted with palm trees in its first half, and again towards the end of the path, across the Bibliotheca Alexandrina. There exists only two minor intersections along this side of the walk by the recreational zone is section four. The carried out study aims at drawing two comparisons: The first is between both sides of the promenade, and how they differently affect pedestrians, while the second comparison is drawn between locals and foreigners, to study if and how background, culture, or previous acquaintance with the place might influence the emotions of pedestrians.

For this general comparison of the test runs and the collected emotion data of the study participants, the analysis was carried out with the statistical indicators "average time span between stress reactions" and "average duration of stress reactions". With the help of these indicators, the differences between the test groups was figured out in a statistical approach.

Figure 3: The Study Area with Street Sections along the Path

5.1 Pre-study

A similar study was carried out one year prior to this study with only two Egyptian female participants. The previous study took place on Thursday, November 3rd 2011, around 8:30 am. The exemplary results of last year's study can be found in (Taha, et al., 2012b) and are recapitulated as hypothesis for future research as follows: Passing cars don't affect the participants. Shady areas as well as sunny parts of the course have no influence on people's wellbeing in November weather conditions. The area with high volume of traffic area around the monument of unknown soldier was expected as a stress hot spot, but in this experiment, there was no change in skin response of the participant. The wider perception of the waterfront participant involves more spatial impressions, more stress signals are measured here.

5.2 Study Eastern Harbour

The experiment took place on Sunday, November 18th 2012 around 8:30 am. Both studies were executed on normal working days. It started at the west side of the Eastern Harbor (green node) and ended almost 45 minutes later at Bibliotheca Alexandrina at the east side of the Harbor (blue node). The weather conditions were pleasant that day, with a clear sky and moderate temperature. A group of seven persons participated in this test: Three Egyptian females and four German males. Each participant was equipped with one video camera, one GPS tracker, as well as one SMART-Band. Three participants took the outer side of the path (the one closer to the waterfront), while four participants took the inner path (the one adjacent to the buildings). Each group included locals as well as foreigners. Besides the testing of the above mentioned new workflow and techniques, another task in this set-up was to re-examine the hypotheses of the above mentioned study. Especially the points if there are more impacts on the waterfront side and how people feel in the high dense traffic areas should be proofed, because these results from the former study were unexpected at that time. Another interesting task was, if there is a speed reduction of the urban flaneurs, if the have to cross small intersections and are there differences between locals and foreigners.

5.3 Findings and Analysis

5.3.1 Speed, Stress Reaction durations and Intervals

When comparing both sides of the promenade, it is noticeable that participants taking the outer and longer side of the walk had more uniform speed and were relatively faster than those taking the inner side (4.65 km/h and 4.14 km/h), who had bigger variations in their speed (Table 1, Figures 4 & 5). The average speed of both groups was around 4.5km/h, which is, accordingly to literature, a normal average speed for pedestrians (Knoblauch, Pietrucha, Nitzburg, 2007). Stress reactions on the outer side were less in number (127.75 vs. 146.75), longer in duration (5.6 vs. 4.9 sec) and with bigger time span intervals (16.99 vs. 13.58 sec) than those on the inner side of the promenade (Table 1).

	Average Duration of Stress Reaction (sec)	Average Time Span between Stress Reactions (sec)	Average Speed (km/h)	Number of Reactions
Outer Path	5.60	16.99	4.65	127.75
Inner Path	4.90	13.58	4.14	146.75
Foreigners	5.12	13.80	4.24	150.75
Locals	5.38	16.77	4.45	123.75

Table 1: Average stress analysis indicators based on walked path and nationality

When comparing the readings of foreigners and locals, it is noticed that the speed discrepancy might be negligible, where it varied between 4.24 km/h for foreigners, and 4.45 km/h for locals. As for stress reactions, foreigners demonstrated a bigger number (150.75 vs. 123.75), slightly shorter duration (5.12 vs. 5.38 sec), and smaller time span intervals (13.8 vs. 16.77 sec) between stress reactions than locals.
Figure 4: Speed and stress response by time for two participants on the outer side of the promenade
Figure 5: Speed and stress response by time for two participants on the inner side of the promenade
Figure 6: Heat maps for outer path vs. inner path along the waterfront

5.3.2 Stress Reactions Locations

As evident from charts, heat maps, and tables (Figures 4, 5, and 6 and Table 1), stress reactions were present all through the path on both sides- although not uniform. Coinciding with our expectations, however contradicting with a previous study carried out on the same path (Taha, et al., 2012b). More stress reactions were sensed on the inner side of the path than on the outer side. Along the outer side of the path, intense

stress reactions were sensed when participants had to cross the street by the recreational zone at point four, and by crossing the major Cornice Avenue by Bibliotheca Alexandria towards the end of the walk. Another high intensity stress zone can be found through the middle part of the path between the French Gardens and Saad Zaghloul Square (Figures 6 & 7).

Figure 7: Locations of intense stress reactions along the outer path. (Left) Recreational area, (middle) between French Gardens and Saad Zaghoul Square and (right) crossing El Cornice to reach endpoint at Biblioteca Alexandrina on "inner path"

As for the inner side of the path, intense stress reactions are higher in number and cover a larger part of the path. Again, they occur at street intersections (Figures 6 & 8), which significantly occur more often on this side of the path, as well as at sections with bad or missing pavements, where the study participants had to walk side by side with passing-by vehicles.
Figure 8: Locations of intense stress reactions along the inners path. (Left) Citadel area, (middle) between Court House area and Saad Zaghloul Square, (right) Bibliotheca Alexandrina

Through the middle part of the path, more vehicles were passing by, and more public trasportation micro-busses were stopping to let passengers in and out of the cars. This caused a higher level of noise and crowdiness than on both end of the path, and caused higher number in stress reactions during this part and on both the inner and the outer sides of the path.

One of the questions this project is trying to answer is if and how locals and foreigners respond differently to the same urban settings and situations. From the preliminary results of this carried out test, it is evident that foreigners faced a higher number of stress reactions than locals (Table 1). These were distributed along the whole path, although in higher intensities in locations of major street crossings, high densities of pedestrians and vehicles and in noisy zones. On the other hand, locals faced a less number in stress reactions, and were concentrated in the middle part of the path, where high levels of noise and dense numbers of vehicles and pedestrians were present (Figure 9).

5.4 Results

The results of this study, although to a certain limit, contradict with those of the year before (Taha, et al., 2012b), but nevertheless they are more reasonable and cope with the initial expectations made for stressful situations within urban environments. Major intersections, like the intersections at the Unknown-Soldier Monument represent two of the major streets with a high traffic density, where the traffic situation gets often quite chaotic, even for locals. The first intersection – walking direction from the right side of the image) to the left side of image) – is a hub for all sorts of public transportation: taxis, mini-buses and larger buses. While crossing this intersections, the study participants had to take care of mini-buses parked at the intersection, loading and unloading passengers, as well as other vehicles coming from the main street, taking a right-turn (coming from the blind spot) into the side-street. On the second intersection, participants had to dodge vehicles, since there are no means to slow vehicles down by traffic signals or speed tables. Both intersections caused stress situations for both foreigners as well as locals (Figure 10).

Figure 9: Heat maps for foreigners vs. locals along both sides of the path

Figure 10: Equal Stress responses at the crossings of the Unknown Soldier Monument for locals (red & orange) and foreigners (green & yellow)
Figure 11: Increased number of stress responses for foreigners (green, yellow & blue) than for locals (red, orange & dark red) at minor crossings, as well as at the Cornice Avenue crossing

Other situations were pretty different between foreigners and locals. Crossing minor intersections on the inner side of the path presented almost no stress reactions for locals, while they presented stressful situations for foreigners. Another evident situation was the crossing of the Cornice Avenue across Bibliotheca Alexandrina. For a foreigner participant, the crossing of the avenue was an extremely stressful situation, where more than 20 stress reactions were measured during the process of deciding and actually crossing the avenue. On the other hand, for the local participant, only three stress reactions were measured (Figure 11).

At intersections, where it was hard to anticipate from which direction vehicles are coming, or when they are coming from a blind spot of the study participants, both foreigners and locals faced almost the same level of stess. While at other intersections, where locals might be accustomed to crossing streets where no street signals are present, foreigners show a higher level of stress than locals.

Unlike previous measurements (Taha et al., 2012b), there were more stress responses on the sidewalk of the inner path than on the sidewalk near the waterfront in this study. This concurs with our initial assumptions that having to cross street intersections, and passing by sections where the sidewalk is blocked by cars or has bad or missing pavements, would cause more stress situations. Hence in this study, stress reactions were recorded all through the path on the inner side, while they were mainly recorded in outer side only when noise was caused through the middle part of the path. This doesn't refute the hypothesis that a wider perception angle might cause higher stress reactions (compare Taha et al., 2012b). Finally, the authors are aware of the fact that there is a need for further studies with more participants with different local circumstances for further validation of the given hypothesis.

6 CONCLUSION

The presented method of human sensory assessment in urban planning shows a high potential for a better understanding of urban space and the perception of its users. In the case studies, it was researched if different cultural backgrounds influence the perception of space. Besides the mentioned restraints relating the resilience of the gathered data, the results indicate that being in one's native environment or in an estranged one, does not influence how Egyptians or Germans experience their surroundings. In general, German participants have shorter stress reactions than the Egyptian participants, but the frequency of stress reactions of the German participants is higher. Individual stress reactions can now be identified in an efficient way in the optimized workflow. To achieve more quantitative results for statements about urban environment, a higher number of participants is needed. The next step in research will be the combination of the fields "Human Sensory Assessment" and "CAVE-Technologies" (Cave Automatic Virtual Environment – Technologies) for an objective verification of the gathered data and for an exclusion of impacts, which do not belong to the "real" built and architectural environment. This can be applied to interior spaces as well as open urban spaces. Users can navigate through spaces in real-time to simulate a virtual tour. With this setting, it might be possible for the first time to create an urban environment in which the user only reacts on the (virtual) built environment. This means, a laboratory situation, free of external influences will be created.

As a conclusion, the presented method repertoire has a high chance to become an important component for urban planning and sociological analysis in perception of space. It can give planners tools for a more comprehensive view of interdependencies between people and their urban environment.

Incremental Planning – Cooperative Scenario and/or Masterplan? Long- and Short-Term Planning Horizon of Urban Design Projects within the Existing Urban Fabric. Analysis of Projects in Vienna and Switzerland with Regard to the Factors Triggering Varying Planning Times

Silja Tillner

(Mag. arch. Silja Tillner, Architekten Tillner & Willinger, silja.tillner@tw-arch.at)

1 ABSTRACT – INCREMENTAL PLANNING – COOPERATIVE SCENARIO AND/OR MASTERPLAN?
Fig. 1: Vienna River Valley Masterplan by Tillner & Willinger / Auböck & Karasz – interactive information and communication

Incremental planning means to break down the long-term planning horizon into smaller entities, i.e. to develop an overall plan with intermediate stages which are complete projects by themselves. These "plans within the plan" can be implemented independantly at different points in time. They work combined or parallel but add up to a whole like pieces of a puzzle.

2 INCREMENTAL PLANNING – CASE STUDIES IN DELFT, VIENNA AND ZUERICH

Currently, in the City of Vienna, as in many other European cities after Stuttgart 21 and after the financial crisis 2008, urban planners and architects can no longer conceive a comprehensive masterplan for an urban area and then hope to see it implemented as planned. The era of long-term master-planning has long gone. It is replaced by a more open system that adresses flexibility for future changes of developments.Participatory processes of all kind that are mainly structured to be inclusive for all stake-holders, community members, politicians have become . In these processes the planners retreat into the back-ground, they are invited to develop creative ideas in discussion groups and interdisciplinary working-groups. The advantage of this process is clearly the inclusion of all parties, the amicable and open atmosphere in which all issues are discussed before the planning process starts. The potential disadvantage of this type of process is, that with the disappearance of an "author" also vanishes a sense of responsibility. Several recent planning projects that were organized as a "cooperative workshop" ended with no clear result. In this paper this new trend is illustrated with two projects in Vienna: the Gürtel URBION and the Vienna terraces in the Vienna River Valley. A different type of cooperative process and masterplan is illustrated with a long-term planning project in Switzerland, the european country with the longest tradition of particpatory planning due to its

direct democracy. Swiss citizens are used to vote on a multitude of subjects – the addition to the modern art museum in Zuerich or the bonus payment of Swiss executive managers of private companies. Before the actual vote, they are supplied with in-depth information on the subject at-hand. Nevertheless, the creative process of design and the responsibility of decision-making are not transferred to the public. Finally, the Guertel project is an early and exceptional example of incremental planning; it was conceived in the late 1990s at a time when traditional master-planning was still the norm. The most recent and dramatic european example for a change in planning approaches is to be found in the dutch city of Delft: Spoorzone Delft (2009-2012), a   municipal project of exceptional magnitude. Spoorzone Delft consists of a new railway tunnel below the city centre and the subsequent area development of the current above-ground railway tracks and station area into a mixed use area (housing, office space, retail, services, etc.)1)

An existing railway is moved underground, the large tunnel project is covered with public green spaces, adjacent to the park large sites for new development are created. The land value was calculated based on the potential sq.mt. of housing created and one developer was selected by the city of Delft who should invest and contribute with the land purchase to the municipal tunnel expenses. The original concept was conceived by the spanish planner Busquets before the crisis in 2008 and represents a classic master-plan, 95 % of the planned uses were residential apartment-buildings arranged in classic block structures.

Fig. 2: Spoorzone Delft, original Masterplan by Joan Busquets with linear park and residential blocks

The crisis in 2008 brought the project to a sudden halt, the developer was no longer capable of financing the project. By 2012, the city of Delft found a viable solution in reducing the developers responsibility to one third of the project and inviting other developers to participate. The masterplan was rethought and a new participatory process started with three new planning teams. Some components of the old plan were fixed, i.e. the park by Busquets above the tunnel. The new plan was created in an open atmosphere by including various parties and the public, it features built-in flexibility, the percentage of housing was reduced to approximately 78 %. The plan is now conceived in phases and temporary uses are included, so various cultural groups and initiatives will be selected to activate the area while the construction of the tunnel continues.

3   PUBLIC PARTICIPATION OVER A LONGER TIME PERIOD – HOW TO KEEP THE INTEREST ALIVE WITH PHASED IMPLEMENTATION AND SMALLER PROJECTS

Planning and Urban Design projects that are focused on the public realm and are not immediately linked to building projects quite often face a long time frame until implementation actually starts. The absence of private property development and related stake-holders make these projects "purely public" and therefore dependent on public financing. The lengthy processes to secure financing are usually accompanied by political change. Therefore, strategies have to be developed to secure support for these projects over a long time-frame. Public awareness is high when projects begin with public meetings, participation processes, ect. But when the process lasts too long with no signs of pending implementation, dwindling public interest is the consequence. Once formerly active community members have retreated from the process, it is difficult to rekindle their enthusiasm. Therefore, it is advisable to design smaller projects into the overall plan that can be implemented quickly and without problems. The planners have to actively search for these situations on the site in order to successfully organize their separate implementation.

3.1 Strategies to start with small-scale short-term projects to actively engage the community

One strategy that can help to start implementation immediately, is to plan on several levels and for parallel processes. Short-term measurements that can be realized quickly and with small budgets are conceived, as well as an overall planning concept for the mid- and long-term.

This strategy has the advantage, that first steps can be approved and financed more easily than large-scale projects where the public debate and the political agenda can delay the implemenation ad infinitum. These exemplary projects have not only a high quality of their own but also act as a "scout" and represent the overall planning concept.

The public, the client and the planners can readjust the concept following the first experiences. Since community participation has become quite common in order to accommodate different needs in a changing society and to increase identification with the neighborhoods, the test case can actually reinforce and deepen the community involvement.

3.2 International Examples of long-term and short-term planning projects with high levels of public support

Internationally, several famous planning projects have become extremely successful, once they were finally implemented. An aspect that is often forgotten though is the long process and the enduring public engagement before these projects were finally realized. One of the most popular public space projects of all time is the New York Highline. Today, it is hard to imagine that for decades, James Corner,(Field Operations), the landscape architect, the architects Diller + Scofidio and local community groups fought for the creation of this public space on an abandoned rail line against severe public resistance. The Boston Dig or the Seattle Freeway Bridge, the L.A. River or the Glendale Freeway Park are other examples that spanned decades. In Barcelona the extension of the Avenida Diagonal and in Madrid the Rio project are examples where with intense political backing projects of that magnitude were implemented faster. The absence of public participation processes in Spain is one reason why in the past, these projects could be realized in comparatively short time spans. Today, as a consequence of the financial crisis and many scandals in connection to land development, also Spain has experienced an awakened and alert public, where projects can no longer be implemented without information and public discussions and will readjust towards a more participatory planning approach. Smaller public budgets will also inspire innovative low-budget projects.

3.3 Local Examples of incremental planning in phases – Opfikon, CH

The "incremental planning process" and the public involvement will be investigated by exploring three practical examples in Zuerich and Vienna over the course of 20 years.

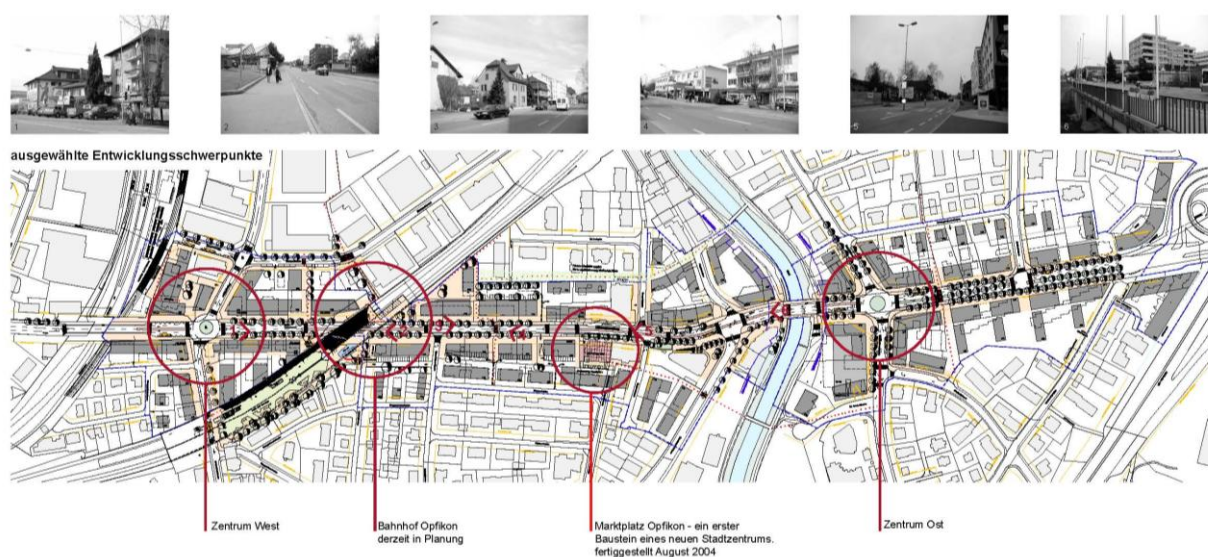
To combat the bland suburban sprawl of metropolitan Zürich, Swiss authorities desire the creation of new small urban centers to root the expansion. The creation of the Opfikon Master Plan is part of this initiative and the Market Place is its first intervention.


Fig. 2: Opfikon Masterplan by Tillner & Willinger with four areas selected for implementation

One is the "planning of a center" for the community of Opfikon, a suburb of Zürich, located only 5 minutes from the airport Kloten. The lack of a center was apparent to the city authorities and a motion to reduce through-traffic and increase pedestrian movements led to the planning initiative of a new master-plan by Tillner & Willinger in cooperation with swissplanners Planpartner and the innovative traffic planners METRON from Bern. In 2000 this new plan started and also adressed the topic of incremental planning – therefore it included immediate action: a public square „ market-place" as a gathering spot for the community that was designed already after the 1st year of planning and built in 2006. This was possible thanks to an unbureaucratic linkage to a private construction project. The 2nd intervention, the redesign of a traffic intersection, was to follow in 2011.

The Master Plan defined four urban centers along the main traffic axis, Schaffhauserstrasse. One of the new centers, the Market Place transformed the square into a multifunctional plaza that provides a place with a sense of identity to anchor the disparately developed area. The ground surface, made of red prefab concrete panels, and the red-housed access ramp of the underground garage are the strikingly new defining elements of the square.

Fig. 3 : Opfikon Market Place, the 1st intervention of the masterplan by Tillner & Willinger

Fig. 4 : Opfikon Market Place

Reacting to the inconsistency of the surroundings, the square is organized into three different areas of activity. Parallel to Schaffhauserstrasse, there is a footpath separated from the busy road by a strip of green and clearly delineated from the center of the square by a layer of black asphalt. On the opposite side, the southern edge serves as a buffer zone to the adjacent residential area. An elevated wooden area with benches, sheltered by a greening pergola, invites passers-by to stop and rest. The various materials used for the surfaces accentuate the different qualities of the three zones. The inclusion of a quaint café with an outdoor area breathes new life into the square.

The whole process was accompanied by public meetings with the property-owners and stake-holders. Their recommendations and responses were adressed in a professional manner while still adhering to the desired high level of quality. The Swiss model of an open public debate with citizens and property owners is a result

of a long tradition of direct democracy. This allows for in-depth discussions of the planning agenda with a non-professional audience and consequently, a successful implementation of the plan by private developers.

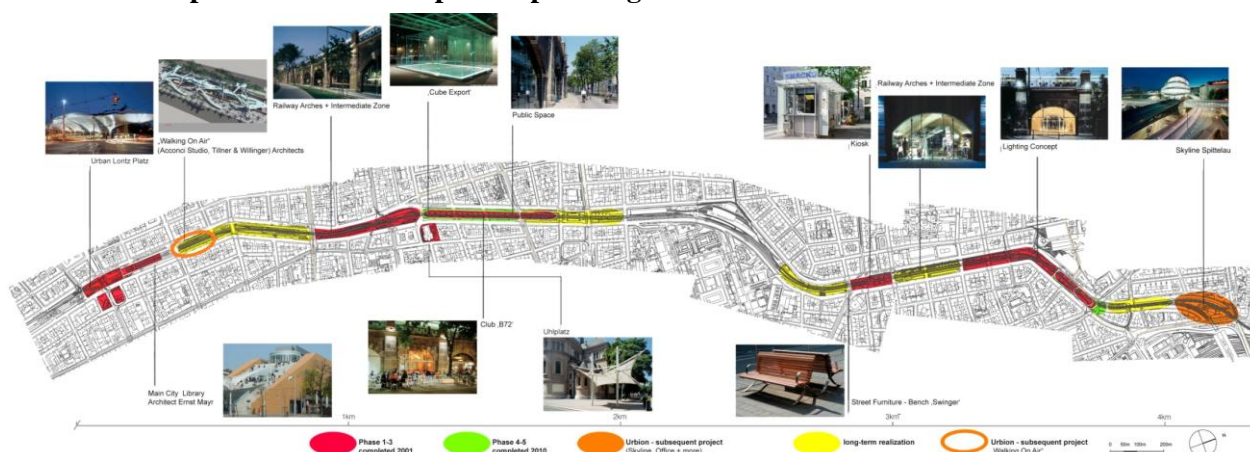
3.4 Local Examples of incremental phased planning – Vienna URBION


Fig. 5 : Vienna Gürtel map of phased intervention with various interventions of the masterplan by Tillner & Willinger

The second example is the re-programming of the center of the Vienna Westgürtel 1994-2000, a highway separating the inner from the outer city districts since the 1960s which was the target of numerous planning initiatives until the mid 1990s. 1995 a successful EU co–funded project started: "URBION". City-wide revitalization of the Vienna Gürtel, implementing new urbanistic uses to transform the image of a previously derelict zone. URBION was one of the five key projects of the EU URBAN program.

The Vienna Gürtel is the transportation backbone of the city with ten municipal districts bordering its busy lanes. The historic railway "Stadtbahn" project by Otto Wagner (today the Vienna Underground), which runs along the highway, is the primary means of access to the entire URBAN zone. At the core of the Gürtel concept was the preservation of the architectural heritage of Otto Wagner and how to address the conflicting demands of public space versus high traffic volumes. By designing transparent and connective architecture for the Gürtel median, the area re-emerged as a pivotal space of interaction that once again links the outer and inner districts.

URBION developed a comprehensive set of measures for a new, low-cost design of the median strip that would respect existing structures and could be implemented in consecutive phases.

Key to the success was the immediate implementation of certain measures, i.e. lighting the arches or installing new uses, while the overall plan was developed further. The open space was transformed to accommodate newly designed bike paths, pedestrian areas with generous landscaping, squares and parks. The arches were filled with new activity thanks to the life-music-clubs. Image transformation was the key to the success of URBION

Fig. 6 : Vienna Gürtel: electronic music event with DJ in the RHIZ

Fundamental to the "image transposition" strategy was the general improvement of the Gürtel with green landscaping, pedestrian and bicycle zones, and populating the "Stadtbahn" brick arches with cultural and

entertainment facilities, restaurants and music clubs. Thus, the lively Gürtel provides daytime recreation as well as a progressive nightlife destination.

At first, immediately implementable measures were instrumental for the success of the project. The public awareness of the project was extremely high – therefore it was important to proof that this was not yet another theoretical plan but finally a realistic chance for improvement of this forgotten and neglected part of the city. Therefore, the strategy to start with implementable and modest improvements of the public spaces proved successful. The first step taken was to illuminate the dark areas of the Gürtel median. Formerly unattractive and inhospitable public spaces were transformed into inviting public promenades. But even before any design measures were taken, a use concept was developed in order to secure long-term social acceptance and liveliness of an area that had a negative reputation and as a consequence was derelict and unattended at night. This use concept was based on an analysis of the adjacent neighborhoods and a series of interviews with their inhabitants. Young families, singles and students had moved to this area that was traditionally populated by immigrants from Turkey and eastern european countries, thus creating a lively ethnic mix with an attractive open-air market, „Brunnenmarkt“ and some original stores and interesting affordable restaurants. This was a good starting-point for the idea of a „life-music-mile“, a series of pubs and bars with live-music entertainment. The idea was first tested by inviting a reknown music-club, the Chelsea, to move to the Gürtel. After the opening it then became an immediate success and established the Gürtel median as „the spot for avant-garde life-music“. The RHIZ was the second club to follow and quickly became the hot-spot for avant-garde electronic music in Vienna. Today, the scene has established itself and celebrates annually in August the „Gürtel night-walk“ with open-air concerts along the median.

A lighting concept was also developed, on one hand to illuminate the historic structure, on the other hand to create an inviting atmosphere and increase public safety on the promenades.

Fig. 7 : Vienna Gürtel illuminated public spaces in the median as one of the first immediate interventions of the masterplan

4   FAÇADE CONCEPT

Decades of newglect had left many of the Stadtbahn arches below the elevated train line either bricked-over or shuttered with billboards, thereby concealing the original viaduct structureThe aspect of securing and reviving the historic heritage of Otto Wagner (who thought long-term) became an important chapter of the revitalization project.

Fig. 8 : Vienna Gürtel – historical image of the historic Otto Wagner facades

A flexible modular system was created to accommodate the varying arches, in addition to a discrete lighting solution for the viaduct and overpasses. A minimal steel structure and a uniform, spot-fixed glazing system achieves a high level of transparency, promoting public safety and cultural preservation. The structural elements respect the design principles of Otto Wagner's original façade.

Fig. 9 : Vienna Gürtel – the transparent facade respects the proportions of the historic Otto Wagner facades

4.1 Local Examples of incremental phased planning – The Vienna Valley

Within the boundaries of Vienna the River Wien runs along a length of 14 kilometres, from the retention basins in the west of the city to the point where it flows into the Danube Canal. Along its length the urban context of the Wiental (River Vienna Valley) shows a number of very different characteristics, from the scattered development, commercial areas and extensive green spaces in the west followed by a gradual, but at places very abrupt, development to the densely developed inner city areas.

In the course of history the Wiental has developed from a natural river into a regulated urban watercourse and from the mid-20th century onwards, thanks to the intensive development of road and rail connections, it became the most important traffic artery leading into the city from the west.

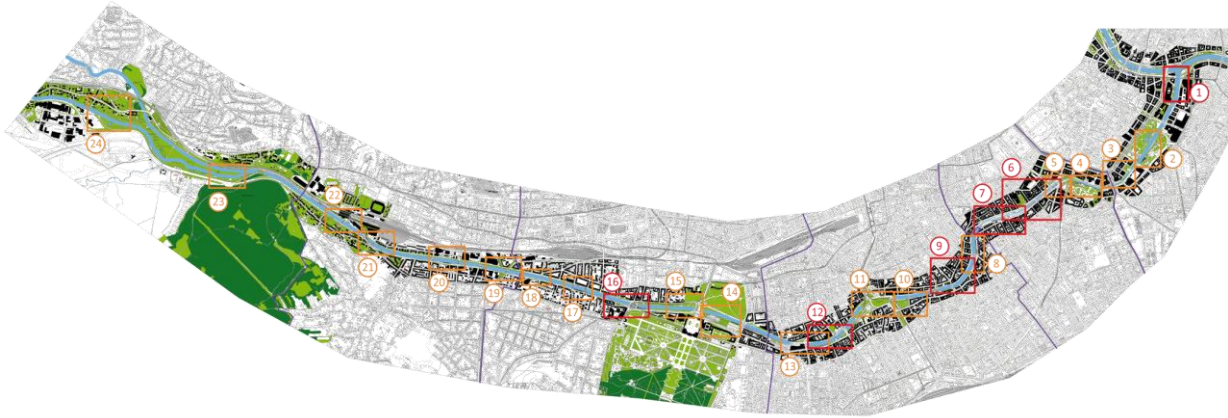
The Vienna Valley also was the target for numerous planning initiatives, most of them were abandoned due to incompatibility with the historic heritage of the river walls, a protected monument. The previous projects relied on major public investments along the entire length of the river and would have caused enormous costs, which also led to their cancellation. 2008 a new plan took a different, more local and sensitive approach and identified locations where existing public amenities can be maintained and immediate improvement of the public realm for the citizens could be realized.


Fig. 10: Vienna Valley – selected areas of intervention

4.2 The Wiental – a study on five levels

The considerable length and linear nature of the Wiental as a space means that it presents urban planning with a very special kind of challenge.

To deal adequately with the scale and complexity of this planning area in the framework of the study, the latter is divided up into five spatial or content layers that allow the preparation of a detailed yet overall view, an analysis and a design concept. The study proceeds in steps from the large to the small scale, in this way not losing sight of the overall context.

4.2.1   Level 1

In the 1st level an examination is made of the overall regional context of the Wiental, and the historical, hydrological and cultural background of this planning area is explained.

4.2.2   Level 2

On the basis of level 1 an understanding of the nature of the Wiental within the Vienna metropolitan area boundaries can be acquired. The second level deals with the important overall characteristics of the Wiental within Vienna itself.

4.2.3   Level 3

In Level 3, the next step, the Wiental is divided into six sections, each of which is characterised by a relatively homogeneous urban appearance and therefore offers the next, more precise framework for an urban analysis.

4.2.4   Level 4

On Level 4 local urban areas are identified within these six sections that make focused, strategic and detailed planning and design possible. These sections are described in the report as "intervention areas".

4.2.5   Level 5

Finally, on Level 5 individual typological measures for the respective intervention areas are suggested and are then summarised in an overall catalogue. By using these typologies along the entire length of the Wiental a continuous linear design language is developed. The goal is to enable the development of a "Wiental identity" and to anchor the river in the public consciousness.

4.2.6   Level 1: The Wiental in Vienna and Lower Austria

Level 1 outlines the historical background, the hydrological conditions as well as the cultural context within the regional setting.

4.2.7   History

In historical terms the transformation from a natural river to a regulated watercourse, or the planning of a monumental boulevard from Karlsplatz to Schönbrunn, which Otto Wagner carried out in part by culverting

the River Wien in the area of the Naschmarkt, represent important measures that have had a lasting impact on the appearance of the city of Vienna. These are the current basis for planning.

4.2.8   The Wiental as a culture axis

Here the issue is the cultural identity of the River Wien.

It is not just the river itself that is a constant within the urban diversity. The many cultural monuments arranged like a chain of pearls along it also form a constant and a culture axis that contributes to the linear identity of the Wiental.

This on the one hand gives the current experience of the Wiental a special quality, while on the other these cultural attractions form important lynchpins, also for future urban planning, where local measures can be employed to further develop the current experience of the linear River Wien.

Other examples of important planning strategies for the Wiental include improving urban connections between important cultural features such as the Urania and Karlsplatz, or making it possible for people to experience the River Wien, for example in the Naschmarkt area where the river was culverted and an open space made over it.

4.2.9   Level 4: Intervention areas (fig.10)

Within the study 24 intervention areas were identified which are distributed across the six sections, starting from where the River Wien flows into the Danube Canal to the retention basins in the west of the city.

These areas were chosen because in them the necessity for individual urban design measures condenses to such an extent that, on account of their complexity, their spatial dimensions or due to the way in which they overlap, the measures necessary can only be planned within an overall context.

Each intervention area is examined in three respects:

(1) Current situation: urban characteristics

In a first diagram the current situation is sketched, here attention is paid to urban design qualities and categories such as existing high urban quality and attractors, open spaces with potential for upgrading, barriers or visual axes.
Fig. 11: Vienna Valley – selected areas of intervention – 4 terraces above the subway connect to the river

 (2) Goal: improved connectivity

A second diagram depicts the targeted improvements to connectivity. Here the special focus is on important routes, the connections of pedestrian and bike paths including those that need to be optimized, as well as the shortage of crossings over the River Wien.

(3) Goal: urban cohesion, the creation of identity

A third diagram shows a series of measures aimed at upgrading the urban mesh. Important measures proposed include improving the amount of open space available by means of parks, green areas or public squares, reduction in traffic volume, urban furniture, improved street crossings with traffic lights, individual tree planting as well as so-called info or aqua points and crossings over the River Wien.

The proposed measures were organized into those that can be implemented in the short-term, medium term or long term, as well as an approximate classification of the measures in terms of the financial expenditure they involve.

The project also proposes the conversion of traffic areas into pedestrian zones, novel connections between the districts and the river embankments, and introduces green landscaping. Thanks to the „small implementable" projects, a public space and river terraces will be realized in 2014, following and representing the overall plan.

Fig. 12: Vienna Valley – selected areas of intervention – Terrace 1, wooden deck above the subway connects to the river

Nevillebrücke/Underground station Pilgramgasse (Intervention area 9)

This intervention area is in an urban area with a high population density that is characterised by the footpath and bike path running along the River Wien. However this important traffic connection is unclear, too narrow and not adequately connected to the neighbouring urban districts.

The low amount of traffic travelling across the Nevillebrücke means that it could be closed to motorised vehicles and used as public green space. Here a proposal for a new design will be presented.

5 CONCLUSION

In order to not only conceive but also implement long-term planning projects that improve the public realm within the built-up city fabric, it has obviously become necessary to actively engage the community. But furthermore the "incremental planning" process helps to keep the public interested and heighten their enthusiasm while being able to test the ideas and readjust the plan if necessary.

The applicability of this strategy of incremental planning to similar challenges lies at hand. In times of dwindling city budgets and rising media attention authorities and planners have no longer the time to develop elaborate plans.

Information Around Us: Questions Connected to Information and Data Heterogeneities in Planning Activities

Otakar Cerba

1 ABSTRACT

Information, data and knowledge represent the most interesting and desired resources and commodities in the world. It relates also to spatial planning and urban planning activities as well as to development of cities. These processes are strongly connected to spatial plans but also to another types of supporting information and data such as Volunteered Geographic Information, social media, data provided by local authorities or by business subjects and last but not least information, knowledge and experience of particular users).

We (as a data experts) suppose that there is enough various information and data resources to satisfy all needs and requirements of participants of above-mentioned activities (planners, decision-makers, researchers, visitors, business subjects and citizens). In contrast to our opinion they feel a lack of information and data. Why can we see totally different views?

There are several reasons. Data sets are provided as self-standing products without a chance to interconnect independent data from various resources. All involved subjects want and need to have data and information, but they are not able to find them, because they are provided in very complicated and unintelligible form. For example the metadata and data catalogues based on metadata are mainly focused on experts or computers and not on common users. Similarly the conditions of using (licences, digital rights management) are also connected to expert terminology and usage. Users are confused by a quality and reliability of data and information (e.g. the latest problems related to a quality of some map products in mobile navigation systems).

Current research in the field of processing and distribution of data and information is focused on technological aspects (e.g. implementation of standards or data models). But typical users do not need sophisticated and complicated solutions, but intelligible and understandable products. For example they do not use the large possibilities of connection of web services and support of standards. They need to have connected useful and reliable data and they are not interesting in processes and technologies running in the background.

The low attractiveness is the latest factor of "inaccessibility" of information and data connected to spatial planning and urban development. Except above-mentioned orientation to technical solution it means ways of presentation and publication. Information and data producers prefer raw data (tables, database queries) instead of processed data and information (maps, graphs, infographics) connected with approaches of data journalism.

Goals of this paper are not only to show general questions related to information and data exploitation in the contemporary cities (that are indicated in previous paragraphs). We would like to present simple case study indicating some solutions. The case study covers a proposal of list of necessary harmonization and integration steps and examples of data integration and presentation to provide local information for citizens.

2 INTRODUCTION

Information, data and knowledge with spatial component represent the most interesting and desired resources and commodities in all levels of spatial planning and urban planning activities as well as in development processes of regions, cities and municipalities. These processes are strongly connected to spatial plans but also to another types of supporting information and data, including Volunteered Geographic Information (VGI), crowdsourcing activities and data provided as results of international of global activities.

We (as a spatial data experts) suppose that there is enough various information and data resources to satisfy all needs and requirements of participants of above-mentioned activities (planners, decision-makers, researchers, visitors, business subjects and citizens). In contrast to our opinion they feel a lack of information and data.

The heterogeneity of data is one and very important reason. The research in projects such as Humboldt, Plan4all, Habitats or Plan4business have been focused on technological aspects of processing and

distribution of data and information (e.g. implementation of standards, formats conversion, INSPIRE complience or data models). The main goals of this paper are not only to show general questions related to information and data exploitation in the contemporary cities and regions (they are mentioned for instance in Cerba et al., 2012a and Cerba et al., 2012b). We would like to present simple case study based on interconnection of three data sets indicating some solutions. The case study covers data description, a proposal of list of necessary harmonization and integration steps and examples of data integration and presentation to provide local information for citizens.

This paper is composed of four parts. The first (Introduction) is focused on presentation of different view of amount of accessible spatial data. In the second section (Data Sets) the three data sets mentioned in next part are introduced, including their properties important from the view of data harmonization. The third section ()Harmonization describes selected case study of harmonization of spatial data of themes "land use" and "land cover". The last part (Conclusion) summarizes results of harmonization and proposes new steps that can improve the harmonization effect and usability of data.

3 DATA SETS

Our case study developed in the Plan4business[1] and Habitats[2] projects has worked with three main data sets. All these data are free accessible and could be used for collecting information about "land use" and "land cover". Therefore they are important from the view of planning activities above all in regional level or in cross-border areas without any other consistent data set.

	CLC (version 2006)	UA	OSM
Coverage	EU states + European Free Trade Association (EFTA) + states Turkey,	EU Large Urban Zones with more than 100.000 inhabitants	Global
Theme	Land use / land cover	Land use / land cover	All spatial features
Provider	European Environment Agency	European Environment Agency	OpenStreetMap Foundation
Geometry	Areas (in vector version)	Areas	Points (nodes), lines (ways), areas(or polygons as closed ways)
Nomenclature	CLC nomenclature; three-levels hierarchy containing code numbers and explanations	CLC nomenclature; four-levels hierarchy containing code numbers and explanations	Tag containing key (type of element) and value (detail specification of key)
Original format	GeoTIFF	ESRI shapefile	.osm (XML based format)
Granularity	100 m resolution	100 times higher than CORINE land cover	Depend on each contributor
Updating / Last version	Temporal coverge: 2006; Last upload 7 May 2012	Temporal coverge: 2005-2007; Last upload 28 May 2010	Every day (but not systematic, it depends on an activity of particular contributors)
Download	http://www.eea.europa.eu/data-and-maps; including seamless vector versions in ESRI shapefile format	http://www.eea.europa.eu/data-and-maps; ZIP archives containing ESRI shapefile data	http://wiki.openstreetmap.org/wiki/Download; including links to external sources containing ESRI shapefile data
Licence	EEA standard re-use policy: unless otherwise indicated, re-use of content on the EEA website for commercial or non-commercial purposes is permitted free of charge	EEA standard re-use policy: unless otherwise indicated, re-use of content on the EEA website for commercial or non-commercial purposes is permitted free of charge	Open Data Commons Open Database License (data); Creative Commons CC-BY-SA (maps)
Level of Open Data (5 star deployment scheme for Open Data)	**	**	***

Table 1: Comparison of the main attributes of CLC, UA and OSM.

CORINE Land Cover (CLC; CORINE land cover, 1995) is probably the most known "land cover" (as well as "land use") data set and classification system in Europe. The project CORINE (Coordination of Information on the Environment) was realized in Europe in years 1985-1990. It was focused on collecting, coordination and ensuring of high-quality information on environment and natural resources. The regular updated database is managed by EEA (European Environmental Agency). The CLC nomenclature is composed of 44 classes that are divided into three levels. The CLC system was extended in many another

---

[1] http://www.plan4business.eu

[2] http://www.inspiredhabitats.eu

projects – in the paper (Feranec & Oťahel, 2004) is described the 4th level of CLC and the document (Kopecká, 2006) mentions the 5th level at that.

Urban Atlas (UA) data set provides reliable, inter-comparable, high-resolution land use maps for 305 Large Urban Zones and their surroundings (more than 100.000 inhabitants) for the reference year 2006. It is published by EEA. Urban Atlas uses the classification that is very similar to CLC, but in some categories (e.g. natural landscapes) is simplified, while categories describing artificial surfaces are more detailed. (the paragraph is based on Meirich, 2008 and Urban Atlas web page)

OpenStreetMap (OSM; http://www.openstreetmap.org) represents one of the most typical example of neogegraphy and Volunteered geographic information. The data are not focused on "land use" and "land cover" in the first place. But OSM contains many elements related to both above-mentioned themes (e.g. forest, waters). More information about OSM and another project based on OSM are found in the web page of the project or in the paper Hackly & Weber, 2008.

The table 1 summarizes main attributes (coverage, type of geometry, formats or links to download) of above-mentioned data sets. The last row contains the classification of data sets according five star deployment scheme for Open Data suggested by Tim Barners-Lee. Two stars means using of open licence (we consider the EEA rules as "open") and providing structured-data. The third star label using of non-proprietary format.

4   HARMONIZATION (UA A CLC A OSM)

The harmonization of spatial data of CLC, UA and OSM data sets is based on general principles of spatial data harmonization (see Cerba et al., 2012a, Cerba et al., 2012b). They come out of the statement that data represents just a limited model of real world and therefore the efficient spatial data harmonization has to be composed of particular harmonization steps that process particular properties of data such as spatial reference systems, portrayal rules or data models (an overview possible harmonization steps in figure Data harmonization components in D2.5, 2007).

All harmonization steps follow the first main and the most important task – why do we need harmonize? There are several reasons for the case study presented in this paper. CLC is complete (it covers most of Europe). But it is not very detailed and frequently updated. UA is more detailed but it provides isolated data (not complete coverage of interest area, but only densely populated regions). Similarly to CLC the UA is quite old. OSM is regularly updated, but this data set has with different quality (including low granularity and missing elements). Exploitation of benefits of all three data sets represents the real reason for harmonization. Users should be able to find the best information about "land use" and "land cover" themes without regard to original data.

In the next paragraphs we follow selected harmonization steps that are important from the point of view of harmonization of CLC, UA and OSM (above all information about "land use" and "land cover" as a reference data of spatial planning). Harmonization of conditions of usage arise from licences (see Table 1). The CLC and UA data sets are based on EEA standard re-use policy, that enables re-use of content on the EEA website for commercial or non-commercial purposes is permitted free of charge unless otherwise indicated. OSM is licensed by two different ways – maps by Creative Commons CC-BY-SA (it means users are free to copy, distribute and transmit the work, to adapt the work and to make commercial use of the work; they must attribute the work in the manner specified by the author or licensor and distribute the resulting work only under the same or similar license). The OSM data uses the Open Data Commons Open Database License. It has similar approach – to keep an attribution and share-alike.

All three data sets are connected to European space, but except OSM they do not cover complete Europe. CLC and UA include countries cooperating with EEA, moreover UA does not represent continuous coverage. Therefore the following course of advance of harmonization has been suggested:

(1) To take CLC as fundamental data set.

(2) To add UA objects that are not a part of CLC data.

(3) To replace these CLC objects with UA objects that cover or overlap original CLC data.

(4) To decide if OSM data in particular areas are suitable to an accuracy improvement of combination of CLC a UA data.

(5) To add OSM objects in the same way as UA data (see points 2 and 3). There is established the wiki project transforming CLC data set to OpenStreetMap[3], including nomenclature.[4]

(5) Because the CLC nomenclature is the most detailed, the UA and OSM classification should be transformed to CLC classes.

The process of harmonization will be consisted in following steps:

(1) Development of common data model – a minimal variant has to contain geometry, an id and a nomenclature code (CLC), extended model can include for example original code or another attributes.

(2) Transformation of OSM elements (ways and closed ways) to polygons to have one geometry. This step will be realized by a GIS (Geographic Information System) tool.

(3) Harmonization of classification codes – this activity could be implemented by a matching table. There is also an advanced solution based on ontology (describing particular nomenclatures, their components, properties and relations) and an ETL (Extract-Transform-Load) tool, that enable to transform source data to common data model, including changing classifications. The rules of classification transformation will be derived from ontology (more information about this approach in Cerba, 2011).

Another technical solution of proposed harmonization process could be based on application of spatial databases. This approach is very fitting for large data set, that could be processed very effectively. Databases enable to implement the majority of above-mentioned harmonization steps (e.g. transformation of nomenclatures or changing of data models). More about spatial data harmonization based on databases as well as another approaches to harmonization are published in Cerba et al., 2012a.

5 CONCLUSION

This paper shows the essential principles of spatial data harmonization in the case of integration three data sets (CLC, UA and OSM) that contain information of themes "land use" and "land cover". These types of information are important for many human activities including spatial planning or regional development. These data sets are also illustrative of example of sufficient amount of data that could be felt as apparent shortage because of difficult way of possibilities of data integration and combination.

The real harmonization (presented in this article) represents a sequence of simple harmonization steps depending of spatial data aspects that have to be harmonized. Just a design of the whole harmonization process (including particular sub-steps and their parameters) means the key (and usually underestimated) part of the spatial data harmonization and integration. It is connected to essential question – What is the target and meaning of concrete harmonization?

In the introduction there is mentioned a feeling a lack of information and data by real users and providers of spatial planning activities. The spatial data harmonization (as the main topic of this research) does not represent a final solution of this problem. There are another reasons lack of information and data. (1) Data sets are provided as self-standing products without a chance to interconnect independent data from various resources. (2) All involved subjects want and need to have data and information, but they are not able to find them, because they are provided in very complicated and unintelligible form. For example the metadata and data catalogues based on metadata are mainly focused on experts or computers and not on common users. (3) Similarly the conditions of using (licences, digital rights management) are also connected to expert terminology and usage. These reasons do not represent the scope or this paper, but a subject of following research. (4) Spatial data problems can include also a transformation to KML (Keyhole Markup Language) format instead of using of very complicated GML (Geography Markup Language) format for spatial data storage or (5) links to semantic tools such as controlled vocabularies, gazetteers or thesauruses. The next research in the field of making spatial data more accessible to common users can be focused on an (6) improvement of the low attractiveness which is the last (but not least) factor of "inaccessibility" of information and data connected to spatial planning and urban development. Except above-mentioned orientation to technical solution it means various ways of presentation and publication. Information and data producers prefer raw data (tables, database queries) instead of processed data and information (maps, graphs, infographics) connected with approaches of computer graphics (including 3D objects) and data journalism.

1 ABSTRACT

Energy and communication networks are in today's urban environment ubiquitous and are highly dynamic infrastructures. It is important for these networks to quickly respond to changes and adapt the parameters in order to be able to strive for the best possible utilization and also to satisfy the needs of the user. The aim of this paper is to show the influence of intelligent networks on users, and the integration of information via smart platforms in everyday life is examined. Smart power grids and control systems for Electric Mobility will be used as examples. Since conflicts between the optimum utilization of networks, human needs, and economic aspects, occur regularly, their interdependencies will be shown in a conflict triangle. The core function of smart networks, in addition to collecting and interpreting the information and the control of the endpoints , is to generate an optimal solution of the conflict. Hence, the features of smart grids will be worked out with special emphasis on renewable energy and electric mobile transport systems. Particular attention is paid to the information flows, which are caused by a high demand of the data source and the control of the systems at the endpoints. As a result, an assessment with regard to privacy aspects will be presented. Then the most widespread and most innovative smart grids used platforms are shown and analyzed. Criteria for the assessment of usability, transparency and efficiency of the platform will be defined and subsequently included in a utility analysis. In focus are mobile applications because of their ubiquitority. Finally, a concept of a meta-platform for centralized and simplified control of various smart networks is designed and presented.

2 INTRODUCTION

The dream of an inexhaustible source of light, heat, energy, and agility seems to be in reach in face of new technologies and developments. Renewable energy sources have the potential to provide an inexhaustible supply of energy. These sources include geothermal energy, renewable resources, hydropower, wind power, and solar radiation. The statement about the inexhaustibility of these resources is limited to the human perspective. It must be assumed that even the sun and our planet have a limited lifespan. In politics, sustainable energy and an energy revolution, is often an issue. The global initiative, "Sustainable Energy for All," attempts to connect three aims and to implement them by 2030. These aims are a universal access to modern energy services, doubling the share of renewable energy in the global energy mix, and doubling the global rate of improvement of energy efficiency [cf. SUSTAINABLE ENERGY FOR ALL OF US, 2012]. In Germany, objectives or strategies and long-term scenarios for sustainable energy policies have been developed as well. The main aspects of these scenarios are the substantial development of renewable energy (RE), the significantly increased use efficiency in all sectors, and the increased conversion efficiency. The increase of the conversion efficiency is to be realized in mutual structural and temporal interaction in all sectors of the energy industry, by further extension of combined heat and power, and the replacement of obsolete power plants (nuclear power plants) through more efficient ones [cf. BMU, 2009].

On a national level, the federal government attempts, through the Climate Change Initiative of the German Federal Ministry for the Environment, to reduce greenhouse gas emissions by 40 % by 2020 (compared to 1990) [cf. BMU, 2007:1FF]. Additionally, on an international level, the federal government attempts, through the International Climate Initiative, to support Countries with funded projects. The projects should especially help developing countries, emerging countries, and the transition countries in protecting the climate. Furthermore, hope is set in the computer and artificial intelligence (AI) and network to solve current global problems. These techniques may offer some help with the protection of the climate, climate monitoring, and in the energy industries. Just networking and knowledge by linking such networks are an important part to solve many problems of humanity. Due to the high penetration rate of networks in the population, mobile information systems can help us to connect knowledge. Mobile information systems

provide access to information resources and information services through "end-user terminals," which are mobile and whose operation is possible in almost any environment or location [cf. PERNICI, 2006:4]. Examples of these are mobile phones, netbooks, notebooks, PDAs, etc. The devices differ from each other especially in size, weight, performance, power consumption, built-in sensor technology, and usability. Increasingly, computers surround us. Often they are imperceptible or we use them unconsciously, for instance a brake assist supports driving a car or, in the household, we get help of intelligent waste disposal units. In the future, we will not adapt to the computer, but the Computer will adapt to us. These small computer systems that are incorporated into other articles, are referred to as "embedded computers," and they are highly interconnected. Literature also often speaks of "ubiquitous computing" or "pervasive computing [cf. MOSEMANN, 2009: XII]." Now, it is time to integrate these tools in the protection of the climate and in the energy industry.

3 ELECTRICITY PRODUCTION AND POWER GRIDS

The power grid consists of different parts, which are differentiated by their voltages: The transmission and distribution grid. The passage of current generates costs, which are fees for grid use and are part of the electricity price. The transmission and distribution grid operator`s range of tasks changed through the integration of renewable energy (RE): From the pure transmission and distribution "on demand" towards more balance and flexibility. In addition, the grid gains a more and more important storage function. In particular, through the feed-in of wind power there are grid shut-downs, because the existing network capacity is not sufficient to accommodate the amount of electricity produced. The wind turbines must be switched off in order to prevent damage to the grid.

Integration as such is heterogeneous: It must be distinguished between grid-related problems (smart grid) and market issues (smart market) even if the concatenation is narrow. This distinction is analogous to the categorization of the Federal Grid Agency (FNA) [cf. BUNDESNETZAGENTUR, 2011:4FF]. Due to subadditivity, the power grid has all the characteristics of a natural monopoly. After the liberalization of the electricity market, which was associated with an unbundling of vertically integrated energy producers and suppliers, various instruments of incentive regulation for grid fees were introduced by law (AregV) since 2009. Currently (2013), the revenue cap regulatory tool is applied in Germany. As part of the unbundling, the energy producers were forced to outsource their grids to legally independent companies. Since the opening of the internal market in 1998, the energy producers are forced to lead through the current from other providers, in order that the end user has the possibility to choose between different suppliers. The aim of the incentive regulation instruments is to encourage the efficiency of the grid operator, which should lead to lower grid fees. It is important to secure the availability of supply and reliability.

For this reason, there is always a quality component integrated into the various regulatory instruments, which ensures that efficiency gains, in form of cost savings, do not lead to a higher failure rate. Prior to the introduction of the renewable energy law (REL), electricity was generated on demand, which was estimated from the aggregated consumption curves of the end users. The priority purchase and transmission obligation of RE, which is derived from §4 of the REL, leads to an extension of the grid function. Additional to the pure transport function from the generation source to the customer and a guarantee to deliver the desired amount of energy at any time, great flexibility and storage function is required of the power grid because of the additional feed-in of RE. The ideal grid is able to absorb, store, and deploy any amount of electricity generated at any time. Such a grid would have to be capacitatively oversized by a multiple. This cause significant higher fees for grid expansion and, therefore, higher fees for the grid use, which would ultimately lead to higher electricity prices. At this bottleneck, the idea of the Smart Grid applies: The available grid capacity and electricity is supplied to the end user, who is able to directly control it, by purchasing energy and capacity.

Definition of a Smart Grid: "The conventional electricity grid is a smart grid when it is upgraded through communication, measurement, control and automation systems, and IT components. As a result, "smart" means that grid conditions can be recorded in "real time" and opportunities for control and regulation of the grid are integrated, so that the existing grid capacity can be fully used."

Definition of a Smart Market: "Smart Market is the area of the grid in which quantities of energy or derived services, based on the available grid capacity, are traded between various market partners [cf. BUNDESNETZAGENTUR, 2011:11]."

The challenges for the Smart Grid and Smart Market are: More coordination, more flexibility, and more innovation. Just by feeding-in fluctuant RE, the demand for grid capacity increases significantly. Greater fluctuation and the need for storage are the causes for this. In addition to grid-related means, in the form of smart grid components, it is necessary to influence production and consumption according to market signals, in order to guarantee stable grid operation. The resulting price-sensitive behavior of grid users, leads to an integration of electricity from RE into the market. Nevertheless, a wide grid extension is still necessary, but to a much lesser extent than without smart grid and smart market. Through the integration of information and communication technology into the grid, consumers have the possibility to participate in the energy markets itself. Thus, new marketplaces will emerge that differ significantly from the traditional ones.

Changes of the energy consumption could be monetarily valued and traded in order to increase grid stability. In the development of a safe, economical energy supply, which is mostly based on RE, a smart grid is not an end in itself, but rather plays a subservient role. Out of this reason, it has to be the aim to bring as many parts as possible of the grid services to the market. The allocation of competitive functions to the grid operators is not possible due to the unbundling regulations. Economically, a scenario with vertical integrated energy providers would not be desirable because of the risk of cross-subsidization of competitive areas, to the detriment of the regulated areas. This leads to distortions of competition. Occurring grid problems should mainly be solved by the market, regulatory intervention should be kept to a minimum. A good solution in the conflict between economic efficiency, consumer needs, and grid utilization has to be found. Due to the importance of energy supply and the market characteristics, a regulatory instance cannot be completely eliminated.

To generate the data, which is needed to control the power grid and the consumption, smart meters are used. These form the basis for the introduction of flexible rates and energy efficient behavior, being essentially used for the market, not for the grid. While the transmission grids in Germany are already lead intelligently, there is still space for improvement in the distribution grids. However, since there are 850 electricity network operators with completely different characteristics, it is impossible to introduce a standard. The legal provisions of ARegV require the selection of the most efficient path, taking into account the necessary grid expansion. The expansion towards smart grids is done as capital-effective as possible by means of intelligent restructuring. The technical requirements, such as the laying of fiber optic cables for the customers, are not prerequisites for the installation of smart meters. Indeed, depending on market conditions and stakeholder needs, the form of the communication infrastructure will be decided individually. The additional amount of information is not considered separately from the rest of the infrastructure, but can be integrated into the planning, because neither a special optimization for smart grids nor a particular bandwidth is necessary. It can be assumed that a low-sized broadband internet access to transport the information flows is currently sufficient. To achieve the aim of the grid capacity management in the form of the most efficient power grid usage, the market involvement for the users should be facilitated, to avoid, or respectively to reduce inhibitions. This requires constantly available instruments, which allow the users` participation in the market in a simple, understandable way. This may be ensured by programs, or mobile applications (Apps).

4 ELECTRIC MOBILITY

The expansion of electric mobility in combination with RE is considered to be strategically important by the federal government of Germany. The reduction in carbon dioxide (CO_2) emissions and the dependence on fossil fuels are the crucial reasons. Additionally, the German supremacy in the automobile sector should be maintained and strengthened. Electric mobility was identified as an essential element on the way to a sustainable energy supply and the introduction of electric vehicles will take place in several phases, which are designed by the political framework and the interaction of global and local operating participants [cf. DIE BUNDESREGIERUNG, 2009:4FF].

By incorporating batteries into the power grid, the grid stability can be increased in the long term. This is becoming more and more important. Smart charging systems contribute to the load management besides the additional energy demand. A constant load curve can be generated by an increased absorption in production peaks. In medium term, there will be the option of providing control energy.[1] With the ability to store the

---

[1] Control energy serves to compensate unforeseen fluctuations in current demand. The batteries of smart vehicles are able to provide control energy.

absorbed energy and release it again into the grid, electric mobility affects the whole concept of RE in a positive way. In the future, the forms of mobility, especially in conurbations, will change. They will adapt to the needs of the residents of metropolitan areas. However, these changes must offer economic advantages and an increase in the perceived quality of life. Thus, the ownership of a vehicle is emotionally important for many people [cf. DIE BUNDESREGIERUNG, 2009:9].

In the first phase of the grid integration, the charging of electric vehicles will still be vehicle sided. Capacity bottlenecks are avoided due to the vehicle's intelligent control of the charging process, which takes place during off-peak times. In the second phase of the grid integration, the vehicle's battery can also function as a grid storage component with the possibility of back-feeding energy. In this stage, additional power capacity is needed due to the increased number of vehicles. The use of smart grids is necessary for the equalization of load curves, since they help to avoid inefficient utilization of power stations and grid utilization, and the reduction of the power station`s control and reserve capacity. Since 2008, the research program "E-Energy: ICT-based energy system of the future" of the federal government of Germany, whose aim is to test new concepts for digital energy grid systems and market relations, is being tested in six regions [cf. DIE BUNDESREGIERUNG, 2009:21FF].

Information and communication techniques are used for the accounting of the loading and unloading of electric cars, which communicate the data generated by smart meters through networks. These mechanisms serve both, the individual needs of users and the grid-sided coordination. Not all interests can be satisfied to the same extent at all times. Appropriate priority-based conflict resolution mechanisms need to be established where the grid stability and security of supply must be guaranteed. Mobile applications are ubiquitous helpers for the users to acquaint themselves with costs and amounts and control over the flexible pricing of their own consumption within their individual preference.

5 CONFLICT TRIANGLE

The conflicts between the needs of users, the optimal grid utilization, and economic aspects of electricity generation can be represented in a conflict triangle (Fig. 2). The user needs to get any amount of energy at a reasonable price at any time, especially during times of high demand. Through the aggregation of numerous private and commercial consumer demands, one can observe an equalization of load peaks, but they are nevertheless significant. Demand peaks are mainly in the morning from 7am to 8am, around noon, and from 6pm to 8pm. Minima are usually between 2am and 4am in the morning. To guarantee security of supply, large over capacities need to be kept ready on generation and supply side. Additionally to the needs of an affordable energy supply and security of supply, environmental awareness has been added in the last years. This includes interest in the origin and generation of electricity, an awareness of energy conservation, as well as an increasing price consciousness. These, partially new emerged, customer needs are supplemented by the claim for more comfort. Smart grids bear, on the one hand, the new user needs; on the other hand, they reduce overcapacities in supply and generation and facilitate the integration of RE.

An appropriate solution for the control of smart grids is offered by software solutions with user-friendly graphical interfaces, which are ubiquitously usable in the form of mobile applications. They offer the user a permanent overview of consumption and prices as well as a way to control their feed-in of current. Looking at the power supply of a fictitious operator, which consists of various types of power plants, the marginal costs of production per kilowatt hour (kWh) emerge in the following ascending order: nuclear power plant, lignite power plant, hard coal power plant, gas and steam power plant, gas turbine power plant, oil-fired power station. According to the merit order effect, the power plants are activated in ascending order of their marginal costs and according to their physical and operational characteristics, when demand increases. Thus, gas turbine and oil power plants have extremely short reaction times and can respond to needs very fast and flexible, but weeks and months are needed to regulate nuclear power plants. The last activated, and regarding the marginal cost most expensive power plant, determines the price of electricity for the entire quantity sold. In consequence, for power plant operators it is of major economic interest to sell their electricity during peak load times. Since the introduction of the REL, there is an obligation for priority supply of renewable energy. Therefore, RE will be fed-in regardless of their marginal costs. On average, the use of the most expensive types of power plants becomes increasingly rare, so the producer surplus is consequently reduced as a consequence of the law [cf. SENSFUSS, 2011:3]. This situation is not marked-based, because RE are fed-in with priority, not in order of their marginal production costs. Only through the integration of the external

effects of the conventional current production, RE are competitive. This observation refers to the average marginal cost per kWh of renewable electricity. In individual cases (hydroelectric and wind power) RE are competitive with cheap conventional alternatives. Externalities such as air pollution or the long term consequences of nuclear power plants can hardly be measured monetarily. Thus, the internalization of externalities is just vague and speculative. The capacity and infrastructure of transmission and distribution grid must be designed so that the needs of the customers are covered at all times. Ideally, the power supply can also take up the energy generated at any time. If the share of RE increases, this is more and more difficult, for instance due to the high volatility of fluctuating energies like wind. To protect the grid from overloading under certain weather conditions, the plants must be taken off the grid. The tasks of the power grid are increasingly in transition: From a transmission medium, purely driven by demand, into an intelligent infrastructure, which determines market prices for the existing grid capacity and to adapt the demand to the offer. Without this coordination function significant power overcapacities would be feed into the grid, which would cause higher electricity prices for the costumers. A smart grid leads to a reduction of overcapacities and a better integration of RE. The core functions of stability and availability with minimal downtime, must remain unaffected by this paradigm shift.

6 PRIVACY ASPECTS

In the context of smart metering, detailed and finely granular data of the energy use of customers is gained. The data will be used to equalize peak loads and to optimize the utilization of grids and producer capacities, and therefore the costs. Due to the broad and highly detailed data base an accurate profile of individual households and persons, which contains personal and sensitive private data, can be created. In this context, data privacy considerations have to be done. By law, all Member States of the European Union are obliged to introduce smart grids and smart meters [cf. EUROPÄISCHE UNION, 2009].

Germany started with these measures in 2011 as part of the amendment of the Energy Act. The resulting data are worthy of protection, because of their high sensitivity. For this reason, the European Commission published appropriate recommendations to protect privacy in March 2012 [cf. EUROPEAN COMMISSION, 2012].

The constitutional inclusion of the right to informational self-determination results from Article 2 paragraph 1 of the German Constitution (GG), in conjunction with Article 1 paragraph 1 GG. The principles are purpose limitation, data prevention, transparency, data sovereignty of the individual, data security, and "privacy by design." Smart meters only collect the data which is necessary for purposes of §21.1 German Energy Act (EnWG). Data processing systems shall be designed in a way that as little as possible personal data will be gathered and the reading intervals should be large. The data has to be aggregated and made anonymous, as far as it does not circumvents the original purpose. The data generation is expected to be at the end-user side and not at an external processing point so the number of data access points is minimal. The end-user should be informed of the nature and use of the smart meter data and he or she has enforceable claims for cancellation, change, and contradiction at all times. In order to comply with the requirements of the right to informational self-determination, the collected person-specific data may be solely processed under the control of the person concerned. Specific technical mechanisms have to be implemented, allowing the end-user to control all available data. Technical and organizational measures should be taken to prevent the misuse of the data. Standards must be established that provide the necessary protection and control options to the consumer [cf. KONFERENZ DER DATENSCHUTZBEAUFTRAGTEN DES BUNDES UND DER LÄNDER UND DÜSSELDORFER KREIS, 2012:5FF].

Depending on the granularity and time intervals, it was measured by current studies that 15-minute-intervals are sufficient to determine when people stay at home, and whether they eat or sleep [cf. MOLINA, 2010]. Investigations, in which a smart meter of the company Discovery GmbH has been tested (results were obtained in August and September 2011, the measured distances were two seconds) confirmed that. It was possible to extract the activities of refrigerator, water heater, geyser, kitchen appliances, washing machine, TV, lamp, and stove from the consumption profiles. Especially, by the power consumption of the TV, the TV, the exact determination of light and dark sequences can be identified, and, by this, even the watched film.

To read-out of the pattern of the total consumption profile was possible without great technical effort. This leads to the conclusion that from a large data set the recognition of a predefined audio-visual content is

possible. The users' power consumption data could also be used for finding copyright protected material. The comparison of the pattern of consumption profiles with a corresponding database data could identify law violations [cf. DAPRIM, 2011:1F]. This example shows the scope of collection and analysis of consumption data. To avoid a development towards the "transparent consumer," appropriate technical measures must be implemented. For this, the profiles need to be made technically fuzzy, or aggregated and made anonymous to a certain level.

7 MOBILE APPLICATIONS FOR SMART GRID DEVICES

Various mobile applications for smart home and smart mobiles are examined on the criteria of functionality, usability, transparency and efficiency. They were weighted and supported by sub-criteria, which were evaluated (Fig. 1, Tab. 1).

© Allbach, Germann 2012
Fig. 1: Use Mobile apps to control smart devices and vehicles (Extract!).

valuation	School note	meaning
++	1	The component or function meets all the requirements in their entirety or beyond

o	3	The component or feature satisfies the key requirements to a satisfactory extent
-	4	The component or feature has significant deficiencies
--	5	The component or function does not meet the requirements

Table 1: Valuation scheme.

It was noticeable that none of the programs which were analyzed had the opportunity to control all intelligent devices, including electric vehicles. Instead, there were some standard functions, such as counter and overview of costs, which worked out well in general. As a result, the use of multiple applications is required in order and to control the whole, with smart technology equipped home and the electric vehicles. The lack of coordination among the components makes the use difficult and can discourage potential users. Another common feature was the fact that many of the apps were downloaded for free, but the access to the service has to be paid. There is also a lack of transparency. The pricing is confusing and complex in itself. An extensive test was complicated since a contract had to be completed with the electricity supplier to obtain access and to test the application. Under data protection aspects, the installation of apps is disputable. Therefore, some programs require full access to Internet, phone book, and the cell phone's memory card.

Mobile devices already have useful features and a rudimentary ability to conduct a kind of "Urban Sensing." Unfortunately, this is only available for the purchaser's own internal use of the mobile telecommunication companies. By CDRs (Call Detail Records), which are gathered of each SMS (Short Message Service) or of

every call, additional data is gained. It is possible to determine the position of every CDR with an inaccuracy of one kilometer. From the recorded data conclusions about the distance traveled were gained. It was further found that, for example, residents of Manhattan had covered only 2.5 miles per day, as opposed to the residents of Los Angeles, which moved five miles per day. The data is not 100 % accurate, but it shows clearly how much this information could bring to city and energy planners. [cf. SIMONITE, 2010]. This data can be also used to optimize the schedules of carsharing-concepts and to control the devices in the smart houses. Mobile device applications act as coordinator between the supply and demand for network capacity, transport infrastructure and energy consumption (Fig. 2). A future use of Near Field Communication (NFC), Smartphones, and a meta-app could, besides paying and buying tickets, serve to steer users currents. Examples are users (e.g. at a bus stop) who want to travel by public transportation, carsharing, or ridesharing. The app would allow them to group together and use the available transport possibilities. Social, economic, and environmental benefits can be gained by connecting the interfaces to various social media platforms.
Fig. 2: Conflict triangle with smart phone and meta-app as coordinator.

A meta-app for smart grid devices has to meet various technical and content requirements:

- Stability
- Security
- Provide interfaces
- Standardization
- Always online
- Semantic analysis
- Usability
- Modularity
- Scalability
- Storage capacity
- Simplicity
- Expendability
- All-in-one solution

The meta-application has to be easy to use for all user groups-even old people with only little technical knowledge should be able to use it. Usability is a key criterion for a successful market introduction of such a project. Only if it is easy to understand, to configure and to use, people can explore the benefits of the program. These benefits consist of cost savings, more comfort, and social aspects like a good environmental consciousness. It is also important to offer the user the possibility to share his opinion und data via the Social Media platforms. It can also be considered to integrate an own Social Media platform into the app. A standard for an interface has to be definedin order to guarantee a smooth exchange of the different data types. It has to be ensured by the the meta-app that the sensitive private data cannot be abused. This can be done by a secure transmission with encoding and an integrated firewall. The app should consist of different modules, which can be chosen by the user to adapt to his or her individual needs. A semantic analysis can be used to interpret the user`s behavior and to recommend and inform the user about new offers, developments and laws. Despite an analysis tool, persistent storage must be provided for this function. To keep the storage scalable and always available, the data can be stored in online clouds which are independent of devices or locations.

The most important function of the meta-app is the unique selling proposition: The all-in-one-solution. It has to be extendable and flexible to react to new developments in energy market, technology, and society. This seems to be the only possibility that users will accept such an application as omnipotent control tool for their smart homes, devices, and vehicles.

8   CONCLUSION

Through the energy revolution and integration of RE, society faces significant challenges. Awareness of energy saving, environmental protection, and generational responsibility must be strengthened. These changes must be as economically efficient and as convenient as possible to overcome resistance. Without tangible benefit, monetarily, social and legal incentives, it will fail to perform a complete change in the responsible use of resources and capacities. Goods, such as current and grid capacity according to their timing and quantity of availability, will receive a market price and will thus be tradable. Smart power grids, the intelligent control device, and electric cars are essential to master a successful energy revolution. Modern ICT collects data, transmits it via the Internet, evaluates them, and serves for coordination and allocation. The Internet owes its success to the principle "keep it simple and smart." It offers information and communication possibilities to almost everyone. Nobody is excluded per se. This must also be the basic idea for smart grids, smart devices, and cars. A system that is to be successfully established in the market must, in all its complexity, be easily accessible and invite to participate. The implementation of the system implies an immense need for coordination, for which the current infrastructure is sufficient. However, the use for consumers must be as easy and comfortable as possible. This can be realized through mobile apps, respectively a meta-app, which handles all the tasks and the control and coordination of intelligent structures.

The ideal meta-app is modular, scalable, compatible and adaptive to individual needs, drives all smart devices of a user, is safe and intuitive to use, and produces a noticeable benefit (e.g. economically or climate change). It is a critical fact that smart devices and apps still have significant gaps in data protection. This has to be corrected by far-reaching legislative requirements to prevent a possible refusal of the users. The technological gap between developing countries and the modern ICT society becomes increasingly larger. The countries with lower economic standards have no access to smart technologies. It is essential to integrate these regions to reach global climate change aims. This must be institutionalized through agreements between governments. On the production side, cost reductions and compatibility can be realized through mass production and standardization. Under the given market conditions and with focus on the needs of the users, apps could serve to adjust the energy consumption by a significant degree of the production and to relieve the grids, as well as to avoid over capacity and bottlenecks in grid and current production. Ultimately, mobile apps to control smart components accelerate this development. They make sure to shape the energy revolution faster, more economical, more efficient, and comfortable, thus, they make a contribution for saving energy and an economic, secure, and sustainable power supply.

1 ABSTRACT

The private and public sectors try to expand the scope of decision-making In return for a reduction of uncertainly concerning the decision- making environment. In many cases, neither planners nor citizens have sufficient information about how the various alternatives will play out over the long term and This represents a gap in informed decision making. Sophisticated urban simulation models can support such analyses by predicting the long-term effects of alternative policies. Again a simulation approach may be used to help professional as well as participant planners in learning about the problems they are facing and the available methods for dealing with them, and In providing relevant information about the external environment. But data is not the only element of effective democratic decision making. In a democratic society, public deliberation by citizens and their elected representatives must precede such major decisions. While urban simulation systems have been investigated for many years, do not simulate detailed interactive aspects. Instead, they use regular grids as spatial data structure. To better support the use of urban simulation systems in public deliberation, it is intended to design tools to support urban planners, citizens, and other stakeholders in their interaction with today urban indicators. The development of these tools is guided by Value Sensitive Design, theoretically grounded approach to technology design that accounts for human values throughout the design process. It is intended to introduce a simulation system for 4D cities that can simulate interactive three-dimensional urban environments over time. The main novelty of this research is that it does not rely on land-use simulation on a regular grid, but instead present a complete and inherently interactive simulation that includes visualizing alternative futures of urban environments as change over time. To meet these goals, technical documentation designed, indicator perspectives and household indicators are refined to help a variety of stakeholders, planners, modelers and citizens.

2 INTRODUCTION

Regional officials, urban planners, and citizens must grapple with issues such as traffic jams, resource consumption, and urban sprawl. Decisions about new freeways, transit service expansion, or land-use regulations are often controversial and expensive, with long-term consequences. Simulation is a technique for representing the workings of a complex system such as the governmental activities of a large city or the total economy of a multi-county region. Planning applications of simulation models will vary with the style of planning. Simulation models provide scenarios and projections of what is likely to happen. In policy planning limiting factors in local and regional change are identified and alternative approaches for moving away from an unsatisfactory social or economic situation are devised and tested.

Decision-makers must attempt to understand how different alternatives might affect land use, transportation, and environmental impacts over the next several decades. Without carefully considering longterm effects, the chosen alternative might lead to the exact opposite of the original goal. Because these decisions will affect the entire region for many years, it makes sense to inform decision making with long-term analyses that are as accurate as possible. Sophisticated urban simulation models can support such analyses by predicting the long-term effects of alternative policies. But, in regarding to the effective democratic decision making in a democratic society, in addition to providing accurate information, a design goal for an urban simulation system should also be able to facilitate public understanding and citizen engagement.

Participant planning refers to community forms of decision making which can involve neighborhoods, cooperatives or voluntary organizations. Spatial contiguity of individuals in the participant style of planning is an important, though not necessarily essential, requirement. Again a simulation approach may be used to help professional as well as participant planners in learning about the problems they are facing and the available methods for dealing with them, and in providing relevant information about the external environment. Value Sensitive Design is a theoretically grounded approach to technology design that

accounts for human values, such as privacy, fairness, and democracy, throughout the design process. The method has three key features: an interactional perspective, attention to indirect as well as direct stakeholders, and a tripartite methodology. An interactional perspective views values as stemming from a symbiosis of technology and social forces: People and social systems influence technological development, while technologies shape individual behavior and social systems.

To better support the use of urban simulation systems in public deliberation, tools are designed to support urban planners, citizens, and other stakeholders in their interaction with Urban Simulation indicators. The development of these tools is guided by Value Sensitive Design. To meet these goals, three tools are refined to help a variety of stakeholders planners, modelers, citizens: technical documentation designed to make information about indicators readily accessible; indicator perspectives that provide a platform for organizations to advocate for the use of particular indicators in decision making; and household indicators that let citizens look at simulation results from the viewpoint of their own household within the region.

A simulation system is presented that can simulate a three-dimensional urban model over time, which does not rely on land-use simulation on a regular grid, but instead builds a complete and inherently interactive simulation that includes variety of democratic society aspects. While urban simulation has been investigated for many years, even micro-simulation systems such as UrbanSim (Waddell.p,2002-2003) do not simulate detailed social aspects. Instead, they use regular grids as spatial data structure. Each grid cell represents a collection of households and businesses, but no social features is simulated. Including detailed urban community in an urban simulation is aimed. This will allow to create 4D cities i.e. interactive three-dimensional urban environments that change over time.

3   CHALLENGE OF URBAN SIMULATION INDICATORS

One of the most famous urban simulation system which is widely used,UrbanSim, is a complex software system that models a region's urban processes over the next several decades. The system takes hours to run, resulting in a massive database that contains detailed information about the region's households, jobs, travel routes, and real estate in each simulated future year. Our indicator tools aim to help stakeholders extract useful information from this very large database. UrbanSim currently supports 55 indicators for extracting information from simulation results, and one of our goals in the indicator tools is to support urban planners in developing new indicators for their particular region. Presenting simulation results with a consistent set of indicators for all the candidate policy alternatives can greatly enhance scenario assessment and comparison.

Most UrbanSim models are discrete-choice models, in which the probability that a given agent will make a particular choice is a function of a set of variables that measure the relative attractiveness of that choice. For example, in a residential location, the probability that a particular household will choose to locate to a residential unit within a particular area depends on household attributes, such as income and number of children, as well as attributes of the potential dwelling, such as cost and location. An external travel model simulates trips between the locations of various households and jobs. The resulting patterns of transportation use and congestion then give rise to accessibility measures for different locations, which in turn influence the desirability of these locations for housing or jobs.

So, User-centered design methodologies focus their attention on direct stakeholders, those who actually use the system.Value Sensitive Design emphasizes consideration of indirect stakeholders as well, those who do not use the system but are affected by its use. For UrbanSim, direct stakeholders are urban planners and modelers; indirect stakeholders include the residents of the region being modeled. Part of the UrbanSim vision is to empower indirect stakeholders to become direct stakeholders to let citizens interact directly with UrbanSim's output, and ultimately to run different simulations themselves. Finally, the tripartite methodology consists of conceptual, empirical, and technical investigations.The application of these investigations is both interactive and integrative; results from new investigations build on and integrate earlier ones. As part of supporting a democratic society, it is decided that the system should not a priori favor or rule out any given set of stakeholder values, but should allow various stakeholders to articulate the values most important to them and to evaluate alternatives in light of these values (Davis.j et al,2006).

4   VALUES IN DEMOCRATIC PLANNING

Commitment to three core values helps Urban Simulation achieve the goal of supporting democratic urban planning: democratic engagement, freedom from bias, and political legitimacy.

4.1 Democratic engagement

Democratic urban planning requires that citizens be engaged in decision making. While acknowledging that engaged citizenship is not simple to characterize. A democratically engaged citizen is one who participates in civic and political life, and who has the values, attitudes, opinions, skills, and resources to do so effectively (Carpini.M.X,2004). To foster engaged attitudes, consistent opinions, and enthusiastic participation, a planning system must provide information about the issues that form the substance of political life. Urban simulation helps fulfill that requirement by providing information about the potential impacts of land-use and transportation alternatives a major political issue. But providing information is not enough. Citizens must want to use it. Through urban simulation, it is intended to seek to foster such democratic engagement, not only to help citizens make more informed decisions, but also to encourage an attitude that can lead to participation in public decision making. Information systems, such as online discussion forums or tools for citizens to propose new policy and investment packages, for example, could provide new opportunities for citizen participation in urban planning. Of course, systems such as UrbanSim supplement not replace informal discussions, town meetings, and voting.

4.2 Freedom from bias

It is refered to bias in computer systems as computer systems that systematically and unfairly discriminate against certain individuals in favor of others (Friedman.B and Nissenbaum.H,1996). A system discriminates unfairly if it denies an opportunity or a good or if it assigns an undesirable outcome to an individual or a group of individuals on grounds that are unreasonable or inappropriate. To warrant the term biased, then, discrimination must be both systematic and unfair. Freedom from bias was first identified as an explicitly supported value, on that it was intended to support the simulation, because it is a moral good in itself. However, there are other reasons to support this value: Freedom from bias is instrumental in providing an equal opportunity to participate in a democratic society; stakeholders whose concerns are represented in the system could have a privileged place in deliberation relative to those whose concerns are not represented.

4.3 Political legitimacy

UrbanSim's legitimacy is crucial for its effective use in urban planning. Unresolved disagreements about its legitimacy might disenchant some stakeholders or cause the agency to stop using the system. The conceptual investigation of political legitimacy draws primarily on the work of Jürgen Habermas. The use of modeling software is just one part of the planning process, and even the best-designed system could be used in a process lacking in legitimacy. Because most factors are beyond control, it is focused on the modeling system's "legitimation potential" rather than the legitimacy of the entire decision-making process (Habermas.J,1979). Communicative action plays a key role in legitimation potential. Habermas defines communicative action as speech in which all parties aim for mutual understanding without manipulative or strategic designs. In communicative action, each utterance raises four validity claims, which they have been mapped to testable design goals. Achieving these goals helps establish urban simulation's legitimacy.

- Comprehensibility: Can a wide range of stakeholders understand the information provided?

- Accuracy and transparency: Are the models and data a reasonable representation of reality? Are the inner workings and design of urban simulation transparent to stakeholders so they can assess its accuracy?

- Clarity of intent: Is the intent behind the information, to advocate for a particular position, or to provide relatively neutral, factual information, clear to the users?

- Appropriateness with respect to values and norms: Is the information relevant to the stakeholders' values in the decision-making context? Although comprehensibility, accuracy, transparency, freedom from bias, and relevance to decision making are not new goals for operational models,(Fleischmann.K.R and Wallace.W.A,2005) trying these goals to the potential for achieving legitimacy helps us understand their significance for models that must support democratic decision making.

5   INTERACTIVE DESIGN OF URBAN SIMULATION INDICATORS

Part of our work described in this article is intended primarily to create an interaction design around urban simulation indicators through technical documentation, indicator perspectives, and household indicators.

5.1 Technical documentation

Technical documentation in being set to provide comprehensible, useful, factual information about the indicators to urban planners and other stakeholders, with an eye toward minimizing both actual and perceived bias (Winograd.T and Flores.F,1986). Feedback from urban planners, modelers, and policy experts has led to standardize the technical documentation for each indicator to consist of eleven sections, including (among others) its name, an informal definition, a more formal specification, known limitations, and advice for interpreting results. The technical documentation also includes the Structured Query Language (SQL) code used to compute the indicator from databases of simulation results, as well as input and expected output for a unit test to check the code's correctness (Borning.A et al,2005). Through interviews in which the planners interacted with this system, it has been obtained that they required much less time to complete each of four tasks using the technical documentation as compared with their current work practices. This result is evidence that the information fragmentation problem in terms of both consolidating information and making it readily accessible has been solved at least partially. This in turn would improve task performance by increasing comprehension and making indicator evaluation more meaningful. The results also supported our hypothesis that including live SQL code, unit test information, and limitations increases indicator transparency and comprehensibility.

5.2 Room for advocacy

In formative evaluations of design for technical documentation, much of the strongest feedback was about neutrality. Earlier documentation versions included a section describing the desired direction of change for the indicator. Given the goal of democratic urban planning, having stakeholders advocate values and put forth opinions is an essential and integral part of the overall process, not an inconvenient blemish on an otherwise clean technical exercise. In order to enable stakeholders to use indicators to represent and express their views, yet maintain the informative role of technical documentation, one solution is to construct indicator perspectives, which stakeholders can use to tell a story and advocate particular values and criteria for evaluating outcomes. In keeping with emphasis on fair representation, it is needed to choose partners that cover a range of views. Thus, it is logical to provide opportunities for broader involvement, actively soliciting partners as needed to ensure that the perspectives cover a wide range of political views and economic interests. Preliminary results of examining this hypothesis confirm that the indicator perspectives framework is indeed useful in advocating for specific views and values and will be a valuable source of information about urban simulation indicators.

5.3 Personal touch

While indicators such as population density and total vehicle miles traveled are familiar to urban planners who monitor or model regional trends, such aggregate measures are probably less compelling to citizens not well versed in urban planning. To reach these citizens, household indicators are created that show how policy alternatives could affect their own households (Davis.J,2006). Through such indicators, It is considered to encourage citizens to become involved in evaluating the impact of transportation and land-use choices. On the basis of this information, the application answers questions the users might pose: Where could I afford to live in the region? How long would it take to get to work? How long would I have to travel to get out of the city? Initial user study results support the hypothesis that citizens can more readily understand household indicators because they can compare such indicators directly to living, working, and getting around. Household indicators also aim to engage citizens by showing them how policy decisions could affect their lives in the long term. Earlier work on the technical documentation aimed to provide comprehensible, accurate, transparent, useful and relatively neutral technical information to urban planners. Household indicators, in contrast, focus on providing information that is comprehensible to citizens and clearly relevant to their own lives. However, commitments to accuracy, transparency and freedom from bias remain. In meeting accuracy commitment, it is intended not to oversimplify to enhance comprehensibility. The commitment to transparency presents the challenges of conveying uncertainty in simulation results and having results explanations at hand when questions arise.

6 INTERACTIVE SIMULAION RESULTS

Virtual worlds can be achieved by simulating time-depended phenomena such as urban growth, transitions in land use, changes in building density, changes in the wealth and cleanliness of urban neighborhoods, and changes due to transportation policies or infrastructure. Urban simulation can be made more comprehensible by visualizing alternative futures of urban environments. One of the approaches to tackle the problem is to make the simulation inherently interactive. In order to show how to use urban simulation as an efficient modeling tool for nowadays democratic communities, it is necessary to answer that how to model the three-dimensional geometry of urban environments as it changes over time due to the democratic society and human values. Evaluating that how urban planning applications can benefit from more detailed simulation can be as a concept of future works. The main contributions of this research is to extend previous procedural urban modeling methods by entering human value features appropriate for changing cities over time. Instead of creating a single static city, a sequence of urban configurations can be created at interactive speed that can be edited during simulation. The results of interactive simulation will be expessed here in three categories of making 4D image for future, achievement of democratic view in planning and coordination between planning and design.

6.1 Making 4D image for future

System of interacting urban simulations are applied due to the complexity of urban environments, while previous work in simulation uses drastic geometric simplifications and aggregation. For example, UrbanSim uses grid cells with a side length of 150m. While this is considered a micro-simulation it produces a gridded output and is still at a scale that does not capture any interesting visual geometric details for threedimensional urban visualization considering human values. The major challenge of this design is to integrate various components into a coherent framework and to make sure that all necessary quantities are simulated. Comparison to computer graphics simulations, While there is some initial work in urban simulation, the existing attempts are not developed far enough to be competitive. The main difficulty of such a large simulation system is to find a useful set of parameters to produce simulations of high quality by regarding to social values. Two series of simulations are shown in the columns in Fig.1. The left series shows the transition from low density to high density by considering physical elements. The right column shows a simulation for a transition of a city based on social values and sustainable development features such as sufficient green areas.
Fig. 1: The left series shows the transition from low density to high density by considering physical elements. The right column shows a transition of a city based on social values and sustainable development features (Weber.B et al,2009).

6.2 Achievement of democratic view in planning

Optimistic theorists have commonly argued that increased participation in democratic deliberation will produce better decisions, a more legitimate system, and a more sympathetic and public-spirited citizenry.

However, researchers have found little evidence to support this wishful thinking; indeed, the evidence indicates that participation in problematic processes will as easily produce cynicism, distrust, and a widespread desire to avoid being required to participate in political decision making processes at all. People are most interested in a process of governance that is usually invisible, with opportunities for imposing accountability when citizens feel the need. What people really want is for participation to seem unnecessary.

If citizens are to learn to engage in an effective democratic process of debate and compromise, they need to recognize that experts can disagree over goals and strategies in areas where there are value-driven choices to be made. They also need to be convinced that "details matter" when considering alternative approaches to important issues, and that details can matter for reasons that transcend particular interests. In other words, the process of deliberation and decision making, with its detailed considerations, needs to be explicitly oriented to substantive concerns.

This is precisely one of the ways that a design-centered process can make a difference, at least in so far as the design process is a careful study of the ways that details can matter, and to the extent that the public can be engaged in this process. Discussions of the importance of design have tended to get caught up in the issue of whether design can cause changes in social behavior. This is a misleading question, however, because design is already social action. Places are not just containers for social life, but themselves social accomplishments, things we do together, with more or less coherence, purpose and self-consciousness.

Design matters first and foremost because it is a practice of organizing our intentions in a series of explicit decisions concerning those qualities of the world we choose to recognize as significant. Urban design may matter most to the extent that its "logic of action" is shifted from a practice of creating visual and social effects by manipulating urban form to a practice of engaging others in the cooperative game of place making. Conceived in this way, urban design can link the sustained collaboration that gives coherent and meaningful form to diverse, complex places to a capacity for democratic self-government and the inclusive, vital, and open-ended quality of democratic culture.

The neighborhood provides a concrete image of a combination of uses into a "balanced mix" relevant to the practical geography of everyday life. The neighborhood unit is not just a nostalgic image, but a paradigmatic representation of the core value of urbanism as a particular normative condition: the extent to which each house, each project built in a community, contributes to the completion of a street, neighborhood or town; to the achievement of emergent possibilities; to a history that gives the place depth and meaning; and to the richness, variety, amenity, functionality, and pleasure of a shared world. Ideally, this is to be achieved not by the hand of a single designer emulating historic cities or working scenographic effects, but as the cumulative effect of individual projects of diverse architectural type and stylistic expression as an open conversation and not simply a scripted dialogue. Even as the mix of uses in a place changes, even as unpredictable social changes take place, the distinctiveness and quality of the place can be maintained.

In order to emphasize on the importance of moving from the scale of the lot and block to the scale of the region, the idea of a rural-urban transect offers a way to think analytically and systematically about neighborhoods, cities and regions as ecologies of diverse places in a way that makes explicit connections between issues of form, scale, geography, and social experience. The transect organizes empirical description of real places as built, experienced and lived, using a typological analysis that moves from the finest level of detail to the regional interlacing of human settlement and natural ecosystems. The gradient from rural to urban encompasses variations in the relationship between human settlement and natural conditions; in the articulations of public and private life; and in spatial morphology and building typologies associated with interconnected variation in managing relations of humans with each other and with nature.

As a transect-based analysis thus highlights ways that form matters at every level of scale, urban design acquires a clear purpose as a practice aimed at realizing the formative aspirations of a community. One of the key components in the production of urbanism is time and the expectation that no planner or designer completes the process, only provides conditions for a collaboration that includes not only current stakeholders but future cohorts. Emphasis on form-based coding is one way to create a framework for the collaborative capacity necessary to sustain certain qualities of place over time, elevating common practice to a consistent level while not constraining either excellence or individualizing impulses. Any design intervention can be regarded as contributing to the history of the place, and as participating in an open-ended but still coherent, goal-oriented process. Urban design becomes a medium in which civic connection can be

manifested in tangible form. At the same time, this also implies that a community has the political capacity to sustain the realization of a coherent urbanism, and come to terms with real divisions and conflicts in the community as it articulates a shared vision (Brain.D,2006).

The idea of a transect thus enables urban designers to build a place-making toolkit out of precise community analysis. A transect-oriented planning process can frame the issues in terms of an articulated range of interconnected differences, establishing the ability to debate each decision in terms of principles operationalized at different scales. To put it simply, it allows us to understand each building, development project, or design decision as tied not just to individual utility but to a process for sustaining place value.

In the context of design-centered public process, such analysis can become the scaffold for effective public discourse, enabling citizens to learn what is at stake if a particular decision were to be codified. Citizens can make clear and principled decisions about what goes appropriately where, avoiding absolute prohibitions in favor of the question of where something might actually contribute to the emergent quality of a place. The combination of analytical clarity and the flexibility of a system of transformation rules enables a continually improvised urban order, reflecting not just the vagaries of the market or the randomly aggregated aspirations of individuals, but a civic sensibility that infuses each individual project with a sense of responsibility for a positive collective outcome.

6.3 Coordination between planning and design

In spite of the expansion of participatory opportunities over the last couple of decades, ultimately the form and character of urban development is determined by developers' ability to work through a highly politicized and unpredictable regulatory process with their bottom line intact. The conventional planning process often produces documents that are little more than summaries of vaguely defined goals, transcriptions of public comment, and broad policy recommendations generally leaving implementation to the vagaries of negotiation between marketoriented entrepreneurs and bureaucratic regulators. Meanwhile, the low-density, automobile-dominated patterns built into current zoning ordinances, subdivision regulations, and conventional traffic design standards become the path of least resistance through the regulatory gauntlet. In a sense, the more "democratic" the public process seems to be, the less genuinely democratic the process of shaping the future of our communities has actually become. The conventional development regime has the effect of literally dis-placing politics, both in the sense that politics are removed from whole arenas of technical decision making, and in the sense that the politics of land use come to be increasingly about technical issues, rather than about the qualities of place.

Emphasis on a design-centered process has been reflected in the practice of allowing the public to engage the specific decisions about urban and architectural form in the context of a charrette, and broad efforts to establish a clear and collaboratively produced vision. This is not to say that simply proposing an urban ideal will bring about a revival of civic life, much less resolve all the challenging issues of social justice and democratization. There has not been explicit recognition of the ways that might more systematically engage the broader movement of civic innovation oriented to democratization, social justice, and environmental responsibility. Nor have the advocates of social capital and civic engagement generally recognized the potential importance of urban design.

Designers and planners generally need to work with a more sophisticated understanding of the conditions and possibilities of democratic politics. We need to get past the naïve notion of democracy that makes us think that a process becomes more democratic simply by including more people in the meetings. In practical terms, communities need to build civic capacity around an understanding of the complex forms of human settlement, not simply as the reflex of market activity or the unintended consequence of regulatory policy, but as a clear and purposeful reflection of a democratically constructed vision. Designers and planners need to face up to the political challenge implied in such a goal (Brain.D,2006).

The shaping of the urban environment needs innovative solutions like those that have emerged over the last

decade in connection to issues like watershed restoration and environmental justice. A design-centered and transectbased approach offers the possibility of a planning process capable of enabling effective engagement and constructing a sense of collective responsibility across even deep social and political divisions. At the same time, civic groups need to understand that cities might be made better on purpose, but that to accomplish this we need to get past the reduction of urbanism to social and economic functions apparently

beyond our control and understand the ways that design can matter as a medium in which to recognize, articulate and realize civic aspirations.

7 CONCLUSION

The following research aimed to inform public deliberation and decision making about major effects of entering human values in the process of urban simulation for a democratic society in order to support citizen discussion and comment. All these efforts are part of an overall agenda: to better support informed public deliberation and democratic engagement in the urban planning process. Our application of this method has led to five interaction design goals:

- Improve the system's functionality by developing new tools for stakeholders to learn about, select, and visualize indicators to use in decision making.

- Support citizens and other stakeholders in evaluating alternatives with respect to their own values.

- Enhance the system's transparency with respect to its design, assumptions, and limitations, so it is not a black box.

- Contribute to the system's legitimacy by providing information that is credible and appropriate to the use context.

- Foster citizen engagement in the decision process by providing tailored information and opportunities for involvement.

As a result it was demonstrated that the output of the interactive simulation can be drastically improved compared to previous work opening the door to new applications of urban planning.

1 ABSTRACT

A research process lasting from 2009 to 2012 has conceptualized, designed and implemented multiple tools and strategies to experiment novel forms of technologically-supported urban interaction. The goal of this process has been to understand the rituals which have started to shape contemporary citizens' perception and performance of urban public and private spaces. An ethnographic approach has been used to gather insights about these emergent rituals, affecting the ways in which people have transformed the ways in which they work, learn, relate, consume, travel and entertain themselves in the city.

With the active collaboration of public administrations, organizations, citizen groups, tourist operators and research teams these practices have been enacted in the cities of Rome, Turin, Trieste, Cosenza, London, Berlin and Hong Kong for variable amounts of time. Engagement and results have been formally gathered, observed, processed and measured, allowing the research team to both explore the current scenario and envision new ones.

Real-time content harvesting from social networks, natural language analysis, geo-referencing/geo-coding/geo-parsing technologies, expert systems and ubiquitous technologies such as smartphones, custom electronic devices and conceptual consumer products have been employed to explore the ways in which people are and will be able to: perceive and understand their urban surroundings; access services and information; co-produce knowledge and distributed intelligence; collaborate in the creation of shared projects and city-governance practices; create and maintain peer-to-peer infrastructures for connectivity, commerce, services and culture.

This paper will present the initial analysis – including previous research taken into account in the fields of urban sensing, citizen science, urban planning, urban infrastructure management, urban environment perception and more –; the methodologies, both shared and project-specific, used to conceive, design, implement the prototypes and to measure their effects; the reports about each project in the aforementioned cities, including their usage on-the-field as well as elements of urban and digital ethnographic observation and user experience analysis; a description of a scenario for further research and for the production of service and product concepts, some of which are already in-progress, in the areas of the arts, culture, tourism and city administration.

What emerges is the opportunity to create multi-layered interactive landscapes in urban contexts which allow city dwellers to communicate, collaborate, govern their city, exchange knowledge and information, consume, entertain themselves, produce and distribute services.

2 INTRODUCTION

2.1 What is a map?

In current times we are often exposed to the opportunity of looking at satellite images or to global views of our planet.

With no earthly frontiers left to discover, it is possible and appropriate to step back to assess a few of the fundamental questions which form the foundation of the ways in we see and experience space.

What is a map?

Maps are metaphors: abstract, scaled models of space that, in some of the many possible ways, relate to "real" space according to one or more approaches.

A map is an abstracted model of space to aid in understanding spatial relationships and better decision making (MacEachren, 1994; Kraak & Ormeling, 1996).

Furthermore, the Humanities focus on a more critical point of view, stressing context. For example in the structuralist approach exemplified by Norman J. W. Thrower, in 1972, in which he states that "the map is a sensitive indicator of the changing thought of man".

Both definitions, as well as the many others which are available, stress the fact that no map is ever neutral in the representation of a space. They, are, in fact, an abstraction of space produced by its interpretation in terms of a set of goals set forth a-priori by the subject making the map, to support decision making processes, to highlight a certain set of features of the territories being represented, or to share specific knowledge an information about them.

This idea is related to the one which sees a map emerging as a result of a specific mental model according to which we represent a territory.

For example Kevin Lynch suggests the possibility of creating a map as the result of "both of immediate sensation and of the memory of past experienced [that] is used to interpret information and to guide action". This concept of map allows for both a sense of emotional security and a deeper human experience: knowing where one is in space makes one feel secure, happy and situated.

In "The Image of the City" Lynch's focus emphasized the connection of this state of well-being with concept of "knowing the place", going beyond the to idea of the utility of way-finding and point-of-interest services, and highlighting, instead, the opportunities for individual and cultural growth brought on by this condition of knowledge and perception.

For Lynch it was not of primary importance to know the exact whereabouts of a certain place or location, but, rather, to have a distinct sensation of a specific place, a story to tell, a memory or information to share. He saw the city as an incredibly complex time-based media, as a potentially dis-harmonic symphony of prodigious proportions in which millions of people collaborated in playing their score, their own vision and perception of space, both influencing and being influenced by others by acts of diffused micro storytelling (e.g.: giving a direction; narrating a memory...). Including the suggestive and radical possibilities exposed by authors such as Debord and de Certeau, in which perception of space became performance of space, to suggest its critical usage and reinterpretation.

This is, basically, what a map is: a way to express what we perceive of a territory, coming from memory, narrative, cognition, sensation, possibility, opportunity, or availability of information, statistics, services.

A way to experience, perceive and perform the territory.

2.2 Interweaving the digital and analog lives of cities

It is from this idea that we can imagine analyzing the ways in which contemporary's wide, accessible and ubiquitous access to all sorts of digital media have radically transformed the ways in which human beings relate, learn, work, consume, entertain themselves and collaborate.

Among the most influential factors which contribute to this transformation is the availability of digital tools, devices and frameworks which have direct impacts on our perception of space at individual, social, collective and cultural levels.

The "Curious Rituals"[1] project is aimed at identifying "gestures, postures and digital rituals that typically emerged with the use of digital technologies". The project's approach is remarkable in understanding these "rituals" as "the results of a co-construction between technical/physical constraints, contextual variables, designers intents and people's understanding". They are seen as a possibility to "envision the future of material culture", as a way to be able to observe those practices which constitute the present of the ways in which we are influenced by the digital objects around us, and to infer those ones which will constitute its (near) future.

In is possible to imagine extending the "ritual" approach to go beyond the areas of industrial and application design, to include all the domains in which the digital and analog parts of our lives interweave with each other.

---

[1] Found ad http://curiousrituals.wordpress.com/about/

It is possible, thus, imagine to prepare a methodology which allows us to observe and research the practices (the rituals) by which human beings in a diverse set of contexts have learned to use certain kinds of technologies to substantially transform their experience of public and private spaces.

In doing so, we must show how these digital technologies act at the level of transcoding (Manovich, 2001), by being able to communicate through interfaces establishing crucial boundaries among our reality and the digital. There is a definite decay in this perceived boundary, a turn towards a more permeable membrane, through which digital information flows out and human information flows in, respectively enhancing our lived experience and structuring and organizing data around biological, evolutionary and cultural patterns.

The concept of variability is, according to Manovich, just as fundamental, as it implies both the possibility for this information and its flows to be recombined, enriched and reassembled in multiple ways.

This is one of the main connections that link historical changes in media technologies to social change.

The possibility to construct systems in which a multiplicity of points of view can be freely expressed by allowing people to produce digital content that can be, in turn, recombined and reassembled (curated) to contribute to other people's view on the world perfectly fits the logic of post-industrial society (Zook & Graham, 2007).

These two features, transcoding and variability, together with the wide availability and accessibility of digital tools and devices (such as smartphones) which allow users to ubiquitously produce information in real-time, merge to describe a scenario in which many of the rituals of our daily lives can be seen to revolve around the possibility to experiencing our urban lives through the contributions of the expression of a multiplicity of points of view.

We can, thus, imagine multiple types of digital tools and devices which are conceived to allow people to generate information about their urban surroundings in a multiplicity of ways – both intended and to be created by city dwellers themselves through the availability of accessible tools – that can be harvested – in real-time or offline – to create a novel form of spatial infrastructure: a multi-author, emergent, non-linear, ubiquitous, polyphonic, multi-layered narrative of the city which can be used by multiple types of stakeholders to explore the visions, imaginaries, desires and emotions of people to gain better, more informed insights which can help shape urban policies and architectural practices.

2.3 Ethical and methodological issues

The frameworks that we're dealing with assume the possibility of being able to disseminate – with the population and around the city – a number of devices, sensors and visualization tools which are able, on one side, to harvest user generated data and, on the other side, to make it available for further elaboration to those services – created by administrations, organizations, companies and autonomously by citizens and other types of city dwellers – that allow people to conceive novel ways to perceive their urban environment: to collaborate; to become more aware and active in using energy and natural resources; to learn and exchange knowledge; to promote well-being.

A number of ethical and methodological issues open up with this kinds of practices. Here we wish to briefly address them.

2.3.1 Privacy and control

The scenario in which a system of some type is able to capture masses of data related to the behavior of its users can become dangerous in terms of the possible breaches in people's security an privacy.

The information regarding the fact that User X is at a certain location and stuck in a traffic jam can conveniently be used to promote alternative paths or the usage of public transportation. But it can also be used to harvest information about the user's habits, the paths he/she follows every day to go to work, the places he/she goes to to have fun, where he/she goes shopping, etc.

This is something that already happens with credit cards, store carts and with the CCTV cameras disseminated along our public spaces, and awareness about these mechanisms, on both their positive and negative uses, has been promoted all along the research.

In the research presented in this contribution, specific care has been given to this kind of problem, using multiple tools and approaches: the possibility for anonymity; clear, transparent interfaces and procedures that

allow users to understand the exact ways in which their data is used, and to conveniently block usages which they don't agree on; opt-in strategies, more than opt-out ones; full transparency and disclosure; and more.

2.3.2 The risks of semplification, the loss of complexity

Statistics are not „real life".

The fact that 48 % of the population of the city i live in has used, in the past 24 hours, the word „sad" in one or more of the content they published on social networks doesn't necessarily mean that 48 % of its citizens are „sad".

This kind of problem is typical of the algorithmic systems that aim at being able to interpret user behavior in some way, to extract information about emotions, behavioral patterns, sentiment, relational structures etc.

In is due to a number of causes: the extreme difficulty for these kinds of systems to interpret things such as irony, sarcasm, poetics, etc; the lack of further contextual information; and more.

Furthermore, statistics can be built according to different strategies to obtain different results, and they can be performed to varying levels of detail, aggregation and granularity, in ways according to which specific phenomena may become less evident, of disappear altogether.

To address this issue we have focused on a number of different strategies.

First of all, the complete transparency and availability of data and information.

All collected data and information has been publicly released, in real-time, using open licensing strategies and by providing users (institutional, administrative, corporate as well as citizens) those tools which can be conveniently used to gain access to them: dashboards, APIs (Application Programming Interfaces, openly available software programming libraries which allow users to develop their own applications and elaborations the data), extraction tools, etcetera.

Secondarily, but not less important, by working on the territories (by performing workshops, lectures and entire projects, anywhere from communities to full enterprises or organizations) to suggest possible usage scenarios for this kind of data and supporting the autonomous development of the tools which they perceive as being more useful and effective: to collaborate, work together, learn and exchange knowledge, to support novel forms of welfare and well-being and, in general, to truly become active, more informed and aware, agents in the governance of their city and in the promotion of the well-being of their communities.

Third, by providing mechanisms for wide accessibility and usability of this information, allowing even non-experts to be able to interpret, if not use, the available knowledge through easy to use customizable visualizations and interactive systems.

In this way, whenever we have been able to, we have supported the creation of entire urban ecosystems, more than the emergence of single initiatives, in which hierarchical and a- hierarchical strategies combine and co-exist a the level of p2p (peer-to-peer), by allowing for the existence and free, accessible, manifestation of a multiplicity of – even dissonant – voices and points of view.

Our approach, thus, is that of going beyond the service-based approach: to use urban sensing as an anthropological opportunity instead of a series of packaged services and bureaucratic/administrative tools.

2.3.3 The industrialization of human experience and narratives

Strongly connected to the previous issue, is the one that sees the emergence of a tendency to industrialize the availability of Open Data and, as an extension to that, the products of human experience and narratives.

Starting from the latter, it is not a mystery that, whenever we use the web to subscribe to social media services, such as Facebook or Twitter, we are not adhering to a „free" service but merely joining one which we pay for with the possibility, for the service providers, to use our personal data to support their business models. In this way, businesses are able to use the things we say every day, the information about the places we have visited and the media (video, images, audio) we have produced to sell anything from marketing data, user behavioral patterns up to, in the more serious cases, to information about the political alignment of users.

On the other side, the wide spread of the Open Data movement – that global tendency which is seeing more an more organizations changing their approaches towards the ownership of the data they produce or collect

through their institutional or business activities – is experiencing the rise of a trend which sees the emergence of these new practices of transparency and disclosure as a mere opportunity for the development of business, administrative and bureaucratic processes.

The two issues meet at the point where it is becoming progressively clearer that the focus on most organizations dealing with social media and Open Data is really more on the possibility to develop new business models than on the promotion of the wider opportunities which become globally available through these practices, both at cultural, anthropological levels, and at the level of developing a true, global process that is able to support people in becoming active, aware agents of their times.

Everything points in this direction: from the lack of a true cultural, diffused approach to people's education on the matters regarding their participation to social networks, allowing for the de-facto privatization of the digital ecosystem of people's relationships and information; up to the reduction of the processes of Open Data to a mere sequence of transactions at business, administrative and bureaucratic levels, without addressing the cultural and anthropological dimensions of these types of operations.

In our approach we tried to assess these two issues by doing the exact opposite.

We have focused on the educational, cultural and anthropological dimensions of these processes, using technologies as an opportunity to develop the imaginaries and visions of people (students, citizens, activists...) to try to promote their own possibility to envision ways in which they will be able to collaborate to become active, aware agents of their times.

In the specifics: we have focused in using engaging, exciting tools to suggest the possibility to build emergent, polyphonic, ubiquitous, non-linear narratives of the urban environment, to be used to construct community driven tools dedicated to the promotion of well-being, welfare, wise and effective usage of energy and of natural resources, collaboration, knowledge sharing and, more in general, to promote new tools which are able to suggest novel forms of perception in the urban environment and of diffused, p2p city-governance.

3 METHODOLOGY

A formal methodology has bees developed and refined over time and across the various iterations of the projects dealing with Urban Sensing.

The first phase of each project begins from a context analysis, from an anthropological point of view, and on its desired impacts on the urban ecosystem. The contextual analysis can assume many forms, from scenarios involving surveys, to more advanced techniques involving user observation and co-participation.

The result of this phase, the scenario, is intended to be merged to the project's objectives to try and determine the which forms of new urban rituals could embody the urban practices which are the object of the project: could it be an application? An interaction with an urban screen? A typical transmedial user journey?

At this point the concept is developed, in respect of the ethical issues.

The concept is created across several iterations, and can (and usually is) refined multiple times throughout the project's life.

The means and methods through which it will be possible to measure and evaluate the quantitative ad qualitative usage of the designs is also formalized at this stage, together with the concept.

To support the project's technical/technological requirements software, devices and infrastructural platforms are developed at this point, and refined/integrated throughout the project's lifecycle.

During this phase special care is put on providing the tools and documentation to enable the educational and cultural strategies which are a fundamental component of our approach, and that will be used across workshops and as freely available development platforms.

At this time the project is deployed. The systems and practices are introduced to territories and population, by promote practical experimentation in real-life scenarios. Feedback processes are also suggested and promoted, to imagine redesign iterations or suggestion for next designs.

Measurements and evaluations are performed on the usage of the systems and frameworks (both qualitative and quantitative). Documentation is produced. Best practices and design guidelines are extracted.

In the different scenarios explored in the following sections, multiple approaches and strategies have been chosen to engage both the local population and different types of city dwellers (tourists, people coming to an event...), and to provide them with short and long term benefits. In the Atlas of Rome, for example, participants were easily recruited among the visitors of the exhibit, and a very detailed scenario about the possibility to research and establish participative practices for urban governance was provided as a possibilitisic benefit that many of them were ready to explore.

More difficult situations took place as well, such as in the case of the VivaCosenza example below, which featured a very low level of spontaneous citizen engagement which we were able to raise only by performing a capillary set of workshops together with citizen associations, local arts collectives, schools and with the support of already trusted communities which we have been able to identify after a thorough ethnographic observation on the field.

Also, the expected outcomes of the single projects vary depending on the cases. While each of the described examples has its roots in scientific research and academic practice, the different techniques and solutions found in each case have easily opened up to multiple usage scenarios. From the more artistically oriented, such as in the VersuS example below, to all the ones which have had a tangible business impact, such as the ConnectiCity and Trieste examples.

4 CASES

4.1 The Atlas of Rome

After an initial test produced for the Franz Mayer museum in Mexico City, we designed a 35 meter long architectural projection and sound environment for Rome's "Festa dell'Architettura" in 2010, organized by the City Administration together with the Italian Order of the Architects.

The Atlas of Rome's purpose was to portray in real-time the evolution of the visions, desires and actions created by architects, institutions, operators and citizens onto the city of Rome: 16 information domains had been classified to describe the overall wellness of the city.

Information was captured from multiple sources and processed using Natural Language Analysis (Hanks, 2005; Tuulos, 2004), and then was geo-referenced either through GPS enabled devices or by using a large database of Named Entities, including the names of streets, malls, cinemas, museums, landmarks, neighborhoods, common alternative names of places, pubs, bars, shops, stores, gyms, and other dozens of types of locations.

Content was also directly provided by citizens using web and mobile interfaces.

Illustration 1: The Atlas of Rome

Collected information was shown on the 35 meter wide surface using a Processing application. Different information visualizations were designed to aggregate information according to themes, time-frames and types of activities.[2]

Passer-by's possibility to interact in real-time with the installation produced radically positive effects: the fact that a large-scale architectural surface was actually responding in real-time to their interactions powerfully combined with the tangible effect of having own information published onto the projection. The combined effect of being able to both contribute and interact had a distinct empowering effect on people, who spontaneously started to discuss possible uses for this kind of system in areas such as participatory urban planning, policy making and decision-making at city level.

A neighborhood version of the Atlas was also produced, to experiment on the possibility to visualize the trending topics of the digital conversations taking place in neighborhoods in which a smaller, urban-screen based, version of the visualizations was placed.

4.2 Riots in Rome

The possibility to harvest information in real-time from cities using user generated content on social networks was used in occasion of the first instantiation of the VersuS project.[3]

The first prototype was created in occasion of the protest which took place in the city of Rome on October 15th 2011, in occasion of the event organized worldwide by the "Occupy" movement, and which quickly degenerated into violent uprisings all over the city's centre.

VersuS was created to collect all social network activity during the protest.

Different social networks were observed using different techniques, including Twitter, Flickr and Foursquare APIs and Facebook's Graph API to first identify relevant sources (user profiles and pages focused on the city and on the themes of the protest) and then harvested for information (about 16000 profiles and their connections were harvested).
Riots VS Rome

Natural Language Analysis and GeoParsing/GeoReferencing procedures were applied to identify content which was actually relevant to the protest allowing us to select more than 92000 information elements in the time-frame of the protest.

A series of visualizations were designed to investigate on the results of the process.

A geo-referenced parametric surface showed the real-time geographical intensity of communication and allowed to clearly follow the protest, documenting how a large number of individuals actively used social media to communicate and collaborate during the riots.

[3] http://www.artisopensource.net/category/projects/versus-projects/

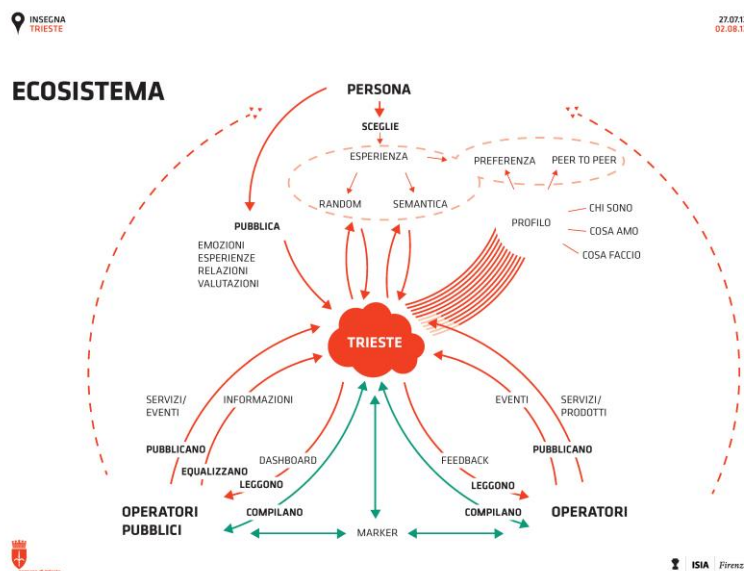
Qualitative analysis was then visualized to display usage scenarios for this information, from the points of view of administrations, police and security and citizens. In this occasion we were able to observe how tens of thousands of valuable information elements emerged in real-time for each of these application scenarios.

4.3 Love versus Turin

A similar technique was used in the city of Turin to harvest information about the emotions of citizens and tourists.
Love VS Turin

This time the content collected from social media sites and, then, geo-referenced was processed to explicitly extract information related to the emotions expressed by users. "Love" was used, specifically.

The experiment was able to express multiple interesting elements about the ways in which citizens experience and perceive the city in emotional terms, including: the emergent definitions of landmarks; the distribution of specific emotions through different neighborhoods; the time-based sequences according to which different emotions manifest themselves in various locations of the city (for example their emergence across traffic jams and various situations of urban distress).

The project served as a useful foundation for its next instances.


Insegna Trieste

4.4 Urban communication in Trieste

Organized by the City Administration of the City of Trieste and by ISIA Design Florence, and with the collaboration of the Regional Administration of Friuli Venezia Giulia, the Faculty of Architecture of the University of Trieste, ISIA Urbino, IUAV University and the University of Nova Gorica a workshop has

gathered students to explore the city of Trieste from a new point of view, and trying to answer the question: "What is the information architecture of the city, as interpreted from a variety of cultures and points of view? How is it possible to define strategies and methodologies to design a system of signs, technologies and methodologies to represent it in meaningful ways? What is the future of urban signage?"[4]

Urban signage is the street-interface for the city's Information Architecture.

Starting from the existing scenario we have imagined to extend the set of techniques, methodologies and technologies which were classically used to design urban signage, and to include a wider, holistic, set of considerations into the discourse.

Ubiquitous technologies, tagging, augmented reality, urban screens and other technologies can be used to radically transform our experience of cities, as we navigate through streets, landmarks, businesses and opportunities for socialization, entertainment, culture, information and relation.

To transform the city into a place where no spectators exist: in the Network everyone is a performer.

Choosing, connecting, looking, conversing, recognizing and interacting: everything in the Network becomes construction.

From consumers to cultural producers, disseminated in time and space, and connected by transforming links, multiple and emergent.

The results of the workshop, which engaged the local population as well as the students coming from the universities, have been many and varied, including the draft definition of a possible urban ecosystem, the idea of the "City as a Platform" as an opportunity for free expression and business, a concept for a movable landmark and the definition to setup a "city construction kit", a mix of free hardware and software technologies which can be used to develop the city's digital ecosystem and its connection to its analog life.[5]

4.5 A contemporary arts festival in Cosenza

VivaCosenza Performance Lab is an international event about art and performance that is held in December in the city of Cosenza, an ancient and beautiful site of the south of Italy.[6]
VivaCosenza

We were invited to create the "digital life" of the city during the festival, so we created some tools which could be used by students and citizens to enact the real-time, participatory narratives of the event.

Using a series of open technologies which we had developed for the VersuS family of projects, we have setup a system which is able to capture in real-time all of the social network activity of citizens, students,

[6] http://www.artisopensource.net/2012/12/01/vivacosenza-how-to-transform-a-city-event-into-a-real-time-participatory-performance/

visitors, organizations and institutions of the city of Cosenza and also of the people who have used social networks to communicate about the festival and the city from other locations.

A set of language-based technologies have then been used to classify all this information, in real time.

Furthermore, special projects have been created by high-school and university students, who have been asked to create communication formats for the festival, dealing with arts, food culture and new forms of journalism and storytelling.

All of the emergent communication which has been generated in real-time during the festival has been visualized both online, on smartphone/tablet applications as well as using a projection mapping in a public space in the city, so that all citizens have been able to experience the digital life of the city directly from public space.

The objective of the platform is to understand the ways in which these kinds of technologies can be used to transform the life of the citizens of the city, to imagine, design and enact novel participatory approaches.

In this, we have suggested a new role for institutions, who can become promoters and maintainers of new forms of expression which are available and accessible to everyone.

Just as we used technology to create an infrastructure for expression to be used by students to create their own formats, we imagine a "city as a platform" (for example as we suggested in Trieste), where ubiquitous infrastructure (both cultural and technological) is made accessible and usable through public policies, enabling citizens and city dwellers to basically have the tools to design and build their own digital, cultural, business, communication, storytelling, envisioning ecosystem.

In the project we have started from scratch with students and have setup a basic set of technologies, for them to be used as building blocks for their communication and storytelling formats.

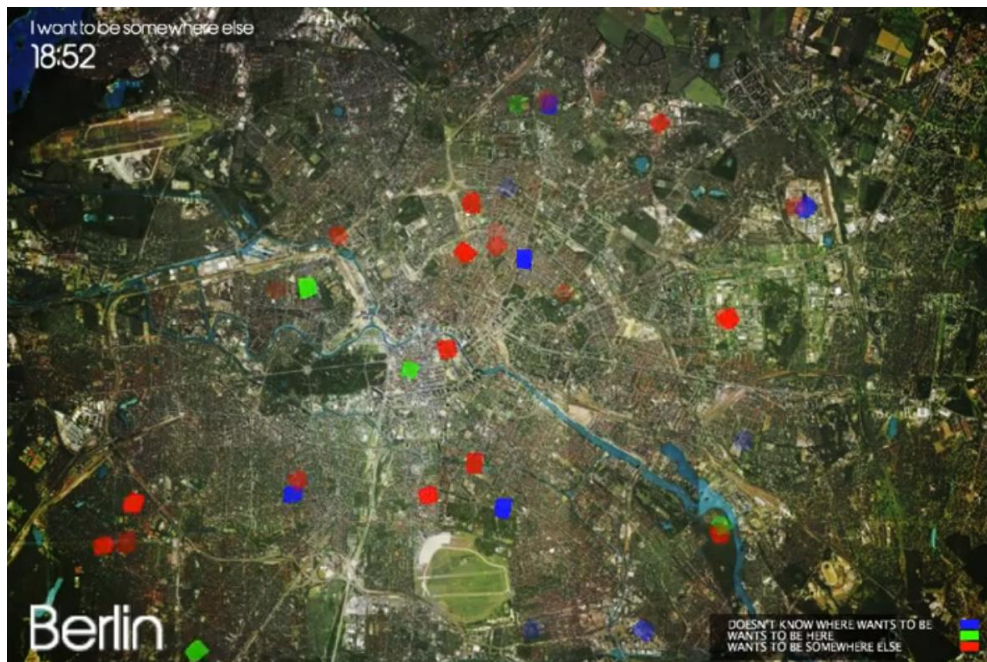
The issues of privacy and control have also been the object of multiple workshops which engaged the wider population in imagining convenient, safe usage scenarios for these technologies.

4.6 Feeling happy to be in London and Berlin

A series of installations were presented at the Ljubljana Design Biennial exploring the possibility to listen in real-time to the emotions, expressions and information generated by users on social network and using ubiquitous technologies, and to publish them onto the cities which they are related to.[7]

Berlin Wants to be here

---

[7] http://www.artisopensource.net/2012/09/20/versus-at-bio23-ljubljana-design-biennial/


A scenario emerged according to which it becomes possible to realize information landscapes which are ubiquitously accessible and which change our experience or urban spaces.

These projects also suggest the possibility to use these methodologies and technologies to promote novel forms of participatory practices in urban spaces, for decision-making, policy-making and urban planning and design.

Among the installations, two dealt with the well-being expressed by social network users in the various locations of the city of Berlin and London.

5 CONCLUSION

The next steps of this series of projects will engage the exploration of the possibilities offered by using novel forms of devices (such as the ones that will be produced in Trieste with the "city construction kit") as well as an even stronger push in the direction of various forms of mobile interaction, as the possibility to disseminate ubiquitous technologies is, in our experience, among the leading drivers to this kind of innovation.

A specific note has to be made in relation to the themes of urban screens. Our experiences have shown how their limitations in terms of ubiquity and on the possibility to show only a limited number of decipherable points of view are matched by the ways in which they provide user-generated interventions high visibility and the distinct perception of participation to city life and governance.

Thus, they can and need to be carefully chosen in the design of such kinds of projects.

As far as we are concerned, and from the point of view of a research that allows us to cross the boundaries of architecture, anthropology, cognitive science, interaction design and many more, this type of projects represents both an opportunity and a frontier, in which the dangers coming from the industrial open data and of human experiences and narratives match the opportunities to promote a sustainable, feasible rise of new, free, accessible "anthropological gestures", and the freedom of expression, self-determination, organization that go with them, situated in the location of what seems to be the place of the destiny of human beings of the near future: the city.

Keeping the Public Sphere Anchored to Social Changes

Cecilia Scoppetta

(Cecilia Scoppetta, PhD, Sapienza University of Rome)

1 ABSTRACT

Despite the theoretical passage from the regulatory approach of (especially Italian) spatial planning to the „soft" and „synaptic" dimension of planning theory, due to the spread of European policies and visions towards a broader perspective that considers physical and social aspects as strictly inter-connected, a „stellar" distance still remains between urban planning and social practices, formal projects and true life, „shadow" and official „production" of urban space, and the continue irreducible re-emerging of what formal planning tends to exclude.

Moving from an analisys of the still existing and deeply rooted resistences – and related „dis-regulations" – against innovative trends in Italian planning practice and research, a possible experimental path (rather than a „best practice") is proposed as a tentative way to re-lead „shadow" experiences and actions within official planning processes without denying their alternative vision, in order to keep a broadened public sphere anchored to social changes.

2 INNOVATIVE TRENDS AND ROOTED RESISTENCES IN THE ITALIAN PLANNING PRACTICE AND RESEARCH.

Despite the theoretical passage from the regulatory approach of (especially Italian) spatial planning, that substantially means land-use regulation, to the „soft" (Faludi, 2010) and „synaptic" (Scoppetta, 2012) dimension of planning theory, due to the spread of European policies and visions towards a broader perspective that considers physical and social aspects as strictly inter-connected, a „stellar" distance still remains between Italian urban planning and social practices, formal projects and true life, „shadow" and official „production" (Lefebvre, 1974) of urban space, and the continue irreducible re-emerging of what formal planning tends to exclude (de Certeau, 1980). Recalling Rimbaud – and also André Breton's Manifest of Surrealism, both quoted in Kundera (1992) – one could say „la vie est ailleurs" („life is elsewhere").

In the case of Italy – a country in which „planning" means „urbanism", and requires a design input so that planning education is strongly connected with architecture and engineering, differently from both French regional-economic approach and the more discretionary comprehensive integrated approach of UK and North-West European countries – the Europeianisation of urban and territorial policies has meant, during the decade of the '90s, the flourishing of innovative tools and practices that, despite their heterogeneity, can be grouped at least in two main „families": on the one hand, programs concerning urban renewal and regeneration; on the other, programs aimed at the economic development. Such integrated and necessarily inter-sectoral experiences, sharing an attitude towards managing rather than planning in traditional „spatial" terms, tend to emphasise the learning dimension as a basis for further implementations as well as the involvement of both local actors and social networks. Such innovative actions could lead to a shift in traditional planning practices, since the old and rigid hierarchies of plans (in which only one solution is allowed from the general to the more detailed level) are subverted, as more contextualized multiple suggestions can usefully come from the local level.

But traditional approaches still remain, and seem to be strongly rooted also in academic research,[1] so that we can find proposals aimed at regenerating urban peripheries based on a 1000 x 1000-meters „rational" grid (with a central place obviously located in the centre: where, otherwise?) that is exactly the same of certain plans of the early '30s – such as, for example, the Albertini's or Greppi's plans for the city of Milan (see: Albertini, 1929) – in which the idea of the territory as an a-historical tabula rasa, traffic (and market)-oriented engineering, juridical technical tools and „methodologies" were utilised for the increasing of the value of soils as well as the role of the planner itself was to be framed within the need of clearly identify (and steadly occupy) its own disciplinary (and professional) field of action outside the architectural sphere (see: Bianchetti & Ernesti, 1987).

---

[1] As an estreme case, see: http://www.urbanisticatre.uniroma3.it/RICERCA/cerasoli_periferie_cittalia.pdf (anyway, a Spanish version also exists, and it is surprisingly labelled as „peer reviewed").

In other words, the three main (often interrelated) research paths explored since the end of the '70s – networking, governance, and rescaling – often seem to remain still ignored in certain pockets of Italian planning theory and practice, and this probably deals with the difficulties in abandoning an (also professional) „mythical" role by making space for further social actors. Not to mention the too often ambiguous relationship between planning practice (and practitioners) and always changing political purposes, which are strictly linked to electoral needs and end up to be „intricately involved in framing and re-framing property markets" (Adams & Tiesdell, 2010) (in other words: to be functional to global/local private interests). In this sense, it is to be added that, in the highly bureaucratic and sectoralised Italian administrative context – too often collusive or, at least, concentrated in preserving its fragment of corporative power – each administrative step can correspond to a „dis-regulation" (Donolo, 2001), that is: a hypertrophic characteristic of formal system that is used by particularist circles to strenghten their power of intermediation as well as the production of non-decisive regulations, whose sense consists of preserving ad infinitum the power of such particularistic circuits by multiplying the opportunities that allow the mediators to mediate.

Such strong persistence of the traditional „rational" and bureaucratic planning frame ends to lead to a substantial distrust towards the „suspicious intentions" (De Carlo, 1980) of the rhetoric on civic engagement in planning processes in all its multifaceted and variegated declinations, since the comforting recipe of standardised and self-referential participatory „best practices" can be seen as corresponding to the first five – „manipulation", „therapy", „informing", „consultation", „placation" – of Arnstein's (1969) „ladders of citizens participation", where the latter is thought as embedded in a „system maintaining" and not in a „system transforming" (Chawla & Heft, 2002) approach. According to this perspective, also the „collaborative rationality" (Innes & Booher, 2010) substantially ends to support the structure of hegemonic power, as it supposes mainly cooperative interactive networks and tends to deny the existence of conflict. In fact, even though a somewhat political dimension of urban planning is recognised, the latter paradoxically ends to be not really explored.

Furthermore, this merely formal approach to civic engagement cannot allow the production of social capital as a pure public good unintentionally resulting from participatory activities and constituting the prior condition to the development of a local society (Coleman, 1988). On the contrary, it rather tends to favour the persistence of the particularistic social capital, i.e.: the result of intentional actions and utilitarian strategies of certain (and often well-known) groups whose scopes are limited and unsustainable in the long run for the society as a whole. As also the academic context tends to be (and too often really is) involved with such particularistic networks and economic interests, the lack of independent academic research – focusing more and more on often unilaterally defined „best practices" as a useful way to avoid considering the existing critical scientific literature produced abroad – obviously does not help in offering insights into the ways in which both contrasting dis-regulations and strenghtening innovative existing trends. It is not a coincidence, however, that illegal planning (and academic) practices and their negative spatial effects are little studied[2] in a country in which illegal interests are strongly rooted due to the historical presence of criminal organisations and activities, and, as many national scandals have shown, corruption largely influences the economic development (and sometimes the academic world).

Last but not least, the described situation does not allow to undestand the shift concerning social needs that contemporary planning is asked answering, namely post-modern social needs emerging from the relevant changes occurred in the still ongoing re-structuring of the contemporary urban space/society.

3   FREE-ZONES INTO URBAN VOIDS, AND THE PARADOX OF CREATIVITY.

3.1 Something happens in residual urban spaces.

Structural changes that have led to the emerging of the so called „new economy" are also the origin of a visible change in urban morphology. Indeed, the European and North American cities that were invested by the processes of industrialization, are dotted with „urban voids" following the process of de-industrialization. The large urban containers, emptied of their previous functions, remain unused for a long time and caught between the complexity of decision-making and speculative expectations dictated by the market. Thus, they end up being both resources diverted from cities and places of insecurity. These abandoned and unused areas

---

[2] Exceptions can be found, for example, in studies carried out in recent years by Marco Cremaschi or Daniela De Leo.

are often gradually repopulated by spontaneous, creative and often temporary actions reflecting the self-organizing capacity of urban communities and their minorities. These „free-zones" are often located where living and working arrangement have momentarily run wild: areas of illegal building, residual spaces and demolition areas, red-light districts, temporary occupations, and so on. They are characterized by permanent elusiveness, guerrilla tactics, fundamental uncontrollability and relative isolation, and they also often deal with the ever-shifting relationship between what is legal and illegal, legitimate and illegitimate, authorized and unauthorized.

Free-zones are strictly connected with the practice of squatting: these are urban actors, with specific needs, that are generally excluded or undervaluated by the traditional planning practices and urban policies, and they have neither the political power to see their interests prevail in the ordinary property market and through traditional planning practices. But their presence may enhance the general cultural diversity of an urban area since they often introduce there those uses, such as open spaces, social, cultural and commercial amenities as well as new kinds of informal accessible spaces where people can act, perform and interact (Franck & Stevens, 2007; Haydn & Temel, 2006), that the existing urban form, property values, institutional regulations had previously precluded, so that one could say that these uses compensate for deficiencies in publicy-founded action (Urban Catalyst, 2001).

3.2 Free-zones and creativity.

As Jacobs (1961) had noted by underlining lower rents of disinvested building as a reason enabling creative and risky experimental tenancies for their location, architecture, and former uses, post-industrial „free zones" of cities often host and inspire those „creative" activities that are seen by the well-known Richard Florida's theory (2002) as a driver of attractiveness of the city, since it is believed that economic growth and competitiveness do not just depend on the presence of high-value production, services or flows of goods and investments, but also rely on the city's innovativeness and creative environment, which in turn will attract further creative people and innovative knowledge. Such approach has emerged as part of the broader debate on social economic regeneration as a consequence of the transition to a post-Fordist economy, within which urban cultural policies – in both consumption-oriented and production-oriented version – have assumed a relevant role. Their nature has substantially changed compared to that they originally played from the post-war period onwards, since their function shifted towards fighting the economic decline through flagship projects, city marketing, and the „construction" of decisive mutations in the social behaviours and lifestyle of the urban population (Zukin, 1995), affirming a new post-industrial identity (Cochrane, 2007). All these factors have led to a „culturalisation of entrepreneurialism" (Ribera-Fumaz, 2009) as part of the new „cognitive capitalism" (Moulier-Boutang, 2007), based on the „convergence of economic and culture" (Garcia, 2004) aimed at producing „goods and services whose consumer appeal is derived pre-eminently from the fact that they transmit non-utilitarian aesthetic and semiotic signals" (Scott, 2007). Thus, the cultural dimension has lost its meaning of empowerment (in the sense used by Friedman, 1987) as it has become nothing but an „instrumental" goal.

Thus, on the one hand, creative milieus tend to appear in those areas (and related to those themes) which are deliberately left unplanned, revealing a sort of „shadow planning" involving niches and disadvantaged or neglected zones: contested and „waiting" spaces located in-between different options regarding uses, different life trajectories, different projects and city ideas. On the other hand, instead, creative use of derelict urban sites can also be interpreted as a case of post-fordist production aimed at exploiting the niche of amortised investments – and creative enterprises are typically small, low-capital, and flexible about the spaces they occupy – that are able (and especially in time of reduced public spending!) to accelerate their re-commodification and to optimise their economic potential by cultivating new consumer groups. These ambiguous aspects are documented in the case of Berlin (SenStadt, 2007), where both creative actors and the unused spaces they transform are seen as „the few remaining pools of untapped resources" (Colomb, 2012a), since such new goldfields of symbolic capital fit well to neoliberal demands. It is not a coincidence, therefore, that many scholars (Colomb, 2012a; 2012b; Hamnett, 2003; Pratt, 2009) have found significant parallels between creative re-appropriation and earlier waves of gentrification of post-industrial cities such as New York and London, since they can be seen as „an attractive 'first step' for numerous start-up ventures in the creative economy" (SenStadt, 2007). Thus, those urban actors generally excluded or underevaluated by the traditional planning practices and urban policies can also end being seen as „entrepreneurial self-starters"

or „role models for a neo-liberal society" (Lange, 2007) as well as the activities they informally introduce can be framed within the neo-liberal shift from stable government-led urban service provision and regulation to flexible governance and increasing reliance on entrepreneurial private investments.

3.3 Free-zones and current (preoccupying) trends in urban policies.

At the same time, especially in recent times, tolerance – whose crucial significance for the city's creative and innovative capacity seems to be obvious – is often at odds with another challenge facing metropolises, i.e: how to guarantee sufficient basic quality in areas such as safety, restricting anti-social behaviour, preventing street garbage and so on.

A (preoccupying) example in this sense is given by the British case, where a „zero tolerance" program (Hubbard, 2004a; Belina & Helms, 2003) was promoted since 1997 by the Tony Blair's New Labour party as well as a „Crime and Disorder Act" (1998), an „Anti-Social Behaviour Act" (2003), a „Respect Action Plan" (2006) (see: Johnston, 2004; Lees, 1998), all focusing on the enforcing on control especially over the youth (Rogers & Coaffee, 2005) through „Anti-Social Behaviour Orders", „Child Curfews", „Parenting Orders". Together with the spread of surveillance and control techniques, such as Closed Control Television systems (Coaffee, 2005; Fyfe, 2004; Fyfe & Bannister, 1998; Norris, 1998), such legislative tools, mirroring the Major Giuliani's policies in New York (Schneider & Kitchen, 2002), include not only crimes, but also a wider spectrum of incivilities and anti-social behaviours (Charman & Savage, 2002; Flint, 2006; Flint & Nixon, 2006), which tend to blur the distinction between disruptive and criminal behaviour (Charman & Savage, 2002) and to highlight the emerging of a „politics of behaviour" (Field, 2003) aimed at removing forms of „intimidation" and „tyranny" (Bannister et al., 2006) in public spaces and based on a concept of „majority" that seem to correspond to a specific target group, i.e: the „respectable" (Bannister et al., 2006) consuming urban dwellers (Coleman et al., 2005; Amin et al., 2000; Flusty, 2001). In this sense, many scholars (MacLeod, 2002; MacLeod & Ward, 2002; Atkinson, 2003; Raco, 2003b; Hubbard, 2004b; Bannister et al., 2006; Cameron & Coaffee, 2006; Johnstone & MacLeod, 2006) underline that elements of „revanchist urbanism", as defined by Smith (1996), have characterised New Labour's urban policies. They also highlight the fact that such forms of control of public spaces against certain specific categories of people or activities considered „suspicious" (Coleman & Sim, 2000; Coleman, 2003; 2004) go hand in hand (Morton & Kitchen, 2005) with the emphasys on the concept of „quality" of public spaces given by a extremely detailed design, i.e.: „interdictory architectures" (MacLeod, 2002) of regenerated urban spaces, associated with expectations of specific behaviours (Atkinson, 2003) in spaces where non-consumption can be seen as a form of deviance, according to the deterministic assumption of „a relationship between urban forms and urban behaviours" (Raco, 2003a; as an antecedent, see: Newman, 1972; 1997).[3]

Therefore, a paradox is to be highlighted here. On the one hand, the acceptance of a multiplicity of compatible or conflicting outlooks, lifestyles, codes of behaviour and urban expressions is assumed as a prerequisite for innovation. On the other hand, the strict rules on city use and zero tolerance for wild-side activities tend to snuff out inspiring innovations and lead to the migration of creative potential. But, beyond the absence of commercial attention to derelict urban spaces, cheap rents, and flexible spaces, it is precisely the freedom from constraints that allows new creative actors, who are not purely motivated by profit, to inhabit and operate there.

Furthermore, it is to be underlined that, although free-zones activities may take shape in specific locations, since its informal nature the so-called „creative class" is not so much organised around places as around

---

[3] With reference to the Italian case as described in the previous chapter also in its academic and cultural (but also political) dimension, it is to be noted that, despite the existing vast and harshly critical literature on the London case and the wide public debate involving academics and opinionists, with criticism also coming from Richard Rogers himself (i.e: the main New Labour's planner), in Italy Blair's urban polices are presented, instead, as a „best practice" by generically emphasising the concept of „quality of design" as well as the „zero-cost" dimension especially concerning social aspects (who quality is for?). As a significant example, see the issue n. 231 of the Italian journal „Urbanistica Informazioni" (which claims being a peer-reviewed journal) and , particularly, the Lucia Nucci's article (p. 14), without bibliography with the exception of a few official documents. In this sense, the title of the journal allows some irony, since „informazioni" means „informations", so that one could say „dis-informations": in fact, the violent riots occurred in London in August 2011 (with the regenerated and gentrified Southwark literally fenced by police testifying the substantial failure of such approach in achieving its explicit social goals) as well as the related intense debate are not mentioned.

autonomous networks of like-minded participants. The condensation of free-zones activities is not particularly determined by physical conditions, but rather by societal and informal forces in local and global networks of innovators. This means that the creative milieus cannot simply be pinned down in a defined zoning perimeter or in bureaucratic regulations. Finally, as creative activities and uses are intrinsically „bottom-up", they are difficult to create „top-down", and being them short-term, unavoidably contrasting with planning's general focus on fixed long-term visions. Thus, as creative milieus simply happen, and basically cannot be planned, how can urban planning – which is too often primarily oriented towards imposing and regulating – possibly be expected to come up with an effective, appropriate response to something like the fostering of creative milieus? How should policies respond to bottom-up movements and how should the free-zones be facilitated in a way which preserves their own dynamics and characteristics?

4 FREE ZONES AS „RE-ACTIVATION DEVICES".

4.1 Unpacking free-zones.

The establishing of free-zones derives from temporary actions that may have different lifetimes, visibility, opening and closing effects, may result in improving or deteriorating the physical conditions of the area, may produce involvement or mimesis, cohabitation or conflict among actors. Anyway, opening and cleaning, designing and changing, imagining and adapting residual spaces can be intended as a creative activity that requires actors' organisational and relational skills and may be defined as „re-activation devices".

By analysing such re-appropriation of urban spaces as a process, it is possible to clearly distinguish different phases corresponding to specific behaviours, tactics and roles of actors. The first phase may be termed as „colonization", for which well fits the geological metaphor of the earthquake, flooding space with new activities and communication codes, upsetting established local balances and activating energies and competencies that are able to re-organize the area but also to arouse strong oppositions and turmoil. It may take the form of an „event", which can be a planned action and have different durations: the rave parties are the extreme version of this tendency to such rhapsodic constructing of temporary and mobile places that leaves a trace only in the local imaginary. Vice versa, the event can become a pioneer tactic when some temporary uses redefining the abandoned site are able to settle and become permanent. Ephemeral actions can then trigger new uses and practices permanently subverting the semantic codes of that space by staying as symbols of a project and, finally, becoming a rooting place. In this case, seems appropriate the botanic metaphor of the „graft", understood as a practice with different transformation stages: sowing, flowering, and harvesting.

In fact, the beginning of temporary activities results in a start-up phase disseminating new uses and populations; then a waiting time to flowering, in which practices may die or germinate to root and, finally, to be collected and cared for by a „community of practices" (Wenger, 1998). Such communities are spontaneous groups of individuals whose identity is defined from a common interest or a shared activity and who interact in an informal and not hierarchical way through a process of socialization of forms of knowledge that are not easily transferable or formalizable through traditional learning procedures. Therefore, the gradualness of such a process of creative re-appropriation allows time to root activities, and this rooting is a premise in constant care, which is not simply public and civic maintenance of spaces – even necessary – but a guarantee that the re-activation process will continue over time.

When a temporary action stops a permanent use or an already established practice (e.g.: by occupying spaces as a political action), this addresses the need for networking with other organizations and/or finding the support of media. Otherwise, it will be a practice of short lifetime, which, anyway, will show how that space could host other activities. It also may be the case of coexistence (or clashing), in the same abandoned spaces, of different actors and temporary uses, which can be understood in two ways: the first concerns the possibility that the same space is contested by groups with different goals. There will then give rise to conflict or to negotiation and possible co-habitation. A form of co-existence is the persistence of temporary uses even after the settling of new permanent activities, as in the case of an abandoned area that „officially" becomes a parking, but continues to host an informal market on certain days of the week. Anyway, the consolidation of re-appropriation practices can occur after a long period of negotiation with the institutions, but especially by building consensus around temporary activities through the establishing of the new informal uses within the collective imaginary and, then, by formalizing them. In this sense, information and

communication are active devices in witnessing the existence of activities and actors in the residual spaces: both short neighborhood and longer networks may accompany the transformation. At this stage, the artistic expression and experience can play a relevant role.

4.2 Extending networks and coalitions.

In fact, moving from the link connecting art and society (Dewey, 1989), the metaphorical „natural" language historically allowed over time a constant creative reinterpretation of spaces, in which the artistic experience played a crucial role in self-representation of communities: think of religious or popular celebrations and events that defined urban hierarchies and structured public spaces. In this sense, artistic experience can be seen as strictly (re)linked to social practices.

This leads to focus on the articulated field of the contemporary urban art, especially on those artistic experiences based on an overcoming of the concept of form, as dadaist, surrealist and situationist approach. These kind of artistic expressions are based on an interpretation of space as inter-relation and on practices, which are intended as „la partie la plus vivante qui se joue sur l'échiquier de l'art" (Borriaud, 2001). Therefore, it is possible to intend contemporary aesthetic approaches as a contested field of perceptions, experiences, lifestyles and values which articulate cultural practices, research of meaning, processes of individual or collective identification. It means that the artistic experience constitutes a sort of potential multiplier of sensitive experiences, also by those who are not definable as belonging to underground urban movements. In this sense, examples in establishing larger coalitions are given by experiences in which squatting costituted a tactical tool used in the preservation of a cityscape or landscape (for example: against the construction of roads or office blocks) by occupying those places where original inhabitants and users have already been displaced. In neighbourhoods that are under threat of function change, opportunities exist for coalitions between squatters and „legal", traditional inhabitants that share the same interest in protecting their dwellings. Furthermore, coalitions can be extended to cover the issue of quality of life in the neighbourhood. Wider coalitions, across neighbourhoods and across social groups, are possible as well. In Amsterdam, squatting played a role in most of the major protests in the '70s that substantially thwarted the planners' program to modernize the old city. The 1979-1981 squatting wave in Berlin started as conservational squatting. In 1979 in Kreuzberg, the community action group „SO 36" occupied an empty fire station to prevent demolition. The activists proceeded to occupy houses that were slated for razing, because they wanted to preserve both useable housing stock and the structure of the neighbourhood. Historically, squatters have also played an important role as initiators of community groups, as in the case of the neighbourhood committee in Amsterdam's Bethaniën district, the first neighbourhood group to resist city development. Also, protesters against the destruction of a cityscape or landscape deliberately occupied houses that were in the way of a planned subway line (Amsterdam, Nieuwmarkt, 1972-1975), a motorway (UK, the No M11 Link Road campaign in the 1990s) or railway (Betuwelijn, Netherlands. 1998-99). In the case of Rome, occupations of publicly-owned (sometimes historical) office or industrial building that are going to be sold at a very low price in the name of the economic crisis mean highlighting a relevant national issue, and claim social uses rather than 5-stars-hotels or luxury residences, as well as occupations for housing needs show that a low-cost housing problem exists and needs to be urgently tackled, exactly in the same way in which occupations of public schools and universities demand public investments in public (and not private) education.

Finally, such low-impact and reversible „re-appropriations", which act on the urban fabric as an „acupuncture" (Oswalt, 2000), seem able to create micro-economies, as witnessed by experiences such as „Bricolage Plantage" in Bremen, „No Longer Empty" or „Mutual Housing Association" in New York, „Micronomics" and „Micromarchè" in Bruxelles, and many others.

5 CREATIVELY MANAGING URBAN TEMPORARITY.

5.1 A more sensitive approach for re-connecting „shadow" to official planning.

Moving from the evidence of the relevance of free-zones – „micro-utopias under construction" (Paba, 2004), „spaces of insurgent citizenship" (Sandercock, 2003), „places of possibilities" (Lefebvre, 1968) – also in the achievement of an international status, the challenge is to involve within planning theory and practices such interstitial, molecular and often invisible micro-movements without erasing their distinctive features.

Such challenge is to be framed within the emerging deliberative planning theories focusing on the need to elaborate new forms of interaction and innovative not codified answers and solutions to urban (social) problems. This research field focuses on an interpretation in which city is not only intended in a physical (material) sense, but also as a complex plot of inter-subjective emotional inter-relations which involves places. The attention is oriented towards the effects of social representations and actions on urban spaces in order to allow the construction of a local (not global) „actionable knowledge" (Argyris, 1996) enlarging the objectives of planning to the production of social capital. Sensitivity thus needs to be developed in urban and planning policies regarding the conditions under which spontaneous bottom-up initiatives arise. The formal, regulatory, ossifying, territorial-based aspect of urban policy needs to be at least complemented with a greater attention to informal, self-managed, pioneering, elusive, network-based free-zones issues. The reference to Landry's concept (2000) of „cultural literacy", although not appropriate at all, perhaps may be helpful to recall the fracture historically determined between languages – between the objective, scientific („modern") language of planning and the subjective, metaphorical and symbolic („pre-modern") language of „natural" (Alexander, 1975) historical cities – used in the construction of public spaces. In this sense, Landry's „cultural literacy" may be intended as close to the Sandercock's „new literacies" (Sandercock, 2003) through which planners should plan „by negotiating desires and fears, mediating memories and hopes, facilitating change and transformation".

Re-connecting „shadow" to official planning, inter-acting with the always changing free-zones, understanding the role of creative temporary activities within urban regeneration strategies delineate a subtle and contaminative path, which is difficult to lead within a model since shadow planning, free-zones, ephemeral creative activities can assume diverse forms and intensities. Furthermore, because the terrain of some particular artistic experiences is that of a playful dimension, it is implicit that rules are in turn determined by the players. In addition, the difficult to lead them within a model lies in their strong relationship with the specificity of places and problems. But, surely, such an approach may constitute an interstitial experimental space, open to free expression, and also to errors. It need time to be spent, an inter(trans)-disciplinary and contaminative attitude, investment on social capital and also a sort of renewal of planning imaginary. In this sense, the co-evolution of both actors and spaces directly involves the public administrations and their capacity in overcoming traditional and codified procedures and practices: this needs a „visionary leadership" (Sandercock, 2003), which is able to decide to assume and manage all the (inevitable) risks in terms of political consensus, also related to the time factor, strictly linked to this particular kind of experiences. This also implies a shift from an only „material" renewal of spaces towards a broader meaning of regeneration intended as empowerment, which also includes the „immaterial" dimension. Last but not least, problems and risks related to the ambiguities connected to „processes of construction of images" (Scoppetta, 2006; 2009) – as observed in many cases of gentrification – are not to be excluded.

A common feature of such tentative experiences may be that they generally start from spontaneous phenomena of appropriation and often illegal occupation in order to develop self-interested actions that – once proved effective with respect to a wider circle of people – end up to attract the attention of institutions. The latter comes into play later, by making themselves available to negotiation paths that may result in agreements and partnerships not initially considered and sometimes defined through incremental and even conflicting processes. Very often the contrast between the regeneration purposes expressed by the local institutions – inspired by traditional models and oriented to the demolition or renovation of spaces in order to set up traditional functions and/or conventional services – and the aspirations of the informally settled groups (also carrying out their own informal experimentations) can generate an inter-active space that may become an opportunity for collaboration and creative planning, developing new frames within which mobilising additional skills and expertise (architectural, technical, commercial, management, and so on). Obviously, ideas for project cannot derive from pre-established patterns, but they rather may be the innovative outcome of both the area and the long rooting process of new activities. Even the identification of possible managing models, moreover, can only derives from the practical organization and functioning of spaces, by involving multifaceted and different expertise, knowledge, experiences and interests.

5.2 Shifting in planning practices by introducing the concept of temporary „re-use".

Anyway, what is sure is the loss of meaning of certain traditional categories, such as that of „destination of use", which is well adapted to a no longer feasible model of government alluding to an unidirectional and pre-structured assignment of functions. On the contrary, the category of re-use can be more easily traced back to an idea of planning as an articulated and incremental process resulting of the intersection and overlapping of multiple forms of rationality and dynamics among the actors. Such an approach also allows to tackle in an integrated way physical and social aspects that – despite the evolution of planning discipline from the rationalist and functionalist spatial planning, now finally passed – continue to be pointlessly considered as opposite spheres. It shows, on the contrary, that one can be functional to the other: physical aspects, in fact, may be an opportunity in new ways to tackle social aspects, while the latter may be in turn a diriment criterion for rethinking the first ones.

The way in which the temporal dimension is tackled and perceived by the actors becomes crucial since it concerns the possibility of sedimentation and rooting of actors, knowledge, interactions, images and imaginary, mutual learning processes, policies and projects. In this sense, difficulties lie in the fact that public institutions and social groups generally have different routines, needs and time horizons: while the former are stable organizations that base their ability to act and their legitimacy on standardised procedures responding to internal logic (too often allowing dis-regulations), the latter usually act according to different times and priorities, which are related to the achievement of specific goals. Therefore, two different needs are to be reconciled: on the one hand, to construct inter-active spaces that will enable the institutions to move according to their specific abilities; on the other hand, to allow social groups to develop their potential by following appropriate times.

All this implies, of course, a radical shift in urban planning (in fact, already occurred, at least in part) and forces to rethink the role of planner: although – as Faludi (2000) suggests – many planners still like to see themselves at the centre of the action, controlling or reining in other actors, in the globalization age, they can no longer play the „mythical" technical role of the origin of a discipline founded to address the problems due to the industrial revolution by clearly separating functions and designing „modern" orthogonal grids as if there had been neither the crisis of the so-called „normal science" nor the assumption of the paradigm of complexity (Prigogine & Stengers, 1979). Time (and post-colonial studies) raised, moreover, the veils that concealed the essentially political nature of „technical" solutions. And, on the other hand, European policies have definitively sanctioned the shift from government to governance, i.e: from a model centred on the exclusive role of the public actor to another based on collaboration among different and multifaceted subjects.

6   KEEPING THE PUBLIC SPHERE ANCHORED TO SOCIAL CHANGES (A CONCLUSION).

It is evident, therefore, that re-connecting „shadow" to official planning also implies a radical shift in public administration in terms of a greater inter-sectoral and integrated approach, by re-organizing the internal structures. Neither the involvement of creative resources of the society can be intended (as it commonly happens) as a strategy of conflict anticipating/mediating or as an action aimed at building consensus in advance on institutional initiatives. And, in practices of „participatory planning", in spite of significant investments in listening and consultation processes, ideas and proposals are too often trivial and obvious (more green, more security, a playground, a parking ...). It rather means moving on to consider citizens not only as passive recipients of services but as active agents, with knowledge, experiences, skills and abilities that are no longer exclusively concentrated within the institutions. This rather requires the experimentation of innovative configurations of the relationship between institutions and society by exploiting the specific resources that both are able to offer in different situations: for every actor involved, this means to be ready to play different, sometimes multiple and not pre-defined roles, with the institutional as a potential point of reference.

More generally, it is to be understood – by both public administrators and planners – that re-connecting „shadow" to official planning does not deal with the need of subtracting urban spaces to irregular, anti-social and dangerous activities according to a pervasive (presumed) „safety" demand (too often hiding not explicit interests of specific groups). It rather deals with the possibility to enlarge and re-conceptualize the public sphere by intercepting the new and not always easily decipherable social needs (Amin & Thrift, 2005) that have added to the well-known traditional ones, which are (were) normally faced by conventional services. In

this sense, considering free-zones as a not irrelevant factor in the production of urban space means to keep the public sphere anchored to social changes by abandoning the traditional (but no longer useful) logic based on the old concept of „needs" (which requires direct strategies) and rather privileging the opportunities for action, which refers to indirect strategies through which the new emerging needs may be intercepted.

As delineated, the proposed experimental and contaminative path aims to offer insights into alternative ideas of „creativity" – into what creativity could be – by shifting from a neo-liberal vision in which it is intended as a tool for attracting global investments towards, instead, a more comprehensive concept of creativity as „capacity" (Sen, 1999), positive freedom and awareness.

1 ABSTRACT

Die Bundesrepublik Deutschland will bis zum Jahr 2020 den Ausstoß von Treibhausgasen[1] um 40 % im Vergleich zum Jahr 1990 verringern. Langfristig wird sogar eine Reduzierung von mindestens 80 % angestrebt. Im Vergleich zum Basis-Niveau 1990 sind die sind die Treibhausgasemissionen – trotz eines leichtes Anstiegs in Höhe von 2,7 % im Jahr 2010 gegenüber 2009 – um fast 25 % zurückgegangen. Hauptverursacher der Treibhausgasemissionen ist der Ausstoß von CO_2. Um eine nachhaltige Klimaschutzpolitik umzusetzen und die gesteckten Ziele auch wirklich zu erreichen, sind vielfältige Maßnahmen notwendig; Deutschland ist immer noch einer der größten Emittenten der Industriestaaten (Umweltbundesamt 2012). Die Klimaerwärmung und globale Umweltprobleme sind zu einem wesentlichen Teil auch auf den Verkehrssektor zurückzuführen; ist er doch mit ca. 28 % der größte Energieendverbraucher und für knapp 20 % der CO_2-Emissionen verantwortlich (BMVBS 2011). Während der CO_2-Ausstoß seit dem Jahr 1990 bundesweit insgesamt um ca. 20 % gesunken ist, beträgt der Rückgang im Verkehrssektor aufgrund steigender Verkehrsleistungen jedoch nur knapp 6,5 % (dena 2010).

Zum Anstieg der Verkehrsleistung trägt auch der demografische Wandel in nicht unerheblichem Maße bei: So stieg die Führerscheinquote in Deutschland seit dem Jahr 2000 bei den über 60-Jährigen von gut 63 % Prozent auf ca. 80 % an (BMVBS 2010). Und auch die Autonutzung steigt in der Altersgruppe stetig. Mobilität bedeutet – nicht für ältere Menschen – Selbstständigkeit, Freiheit und ein hohes Maß an Lebensqualität. Aufgrund der aktuellen Führerscheinquote der heute 40-Jährigen von mehr als 95 % können die künftig Älteren potentiell häufiger einen Pkw führen. Dies kann sich auf der einen Seite negativ auf den Klimaschutz auswirken und hat auf der anderen Seite auch Folgen für jeden einzelnen: sich auf komplexe Straßenverkehrssituationen und neue Strecken einzustellen, wird mit zunehmendem Alter nicht leichter. Selbst für viele routinierte Autofahrerinnen und Autofahrer kommt irgendwann der Zeitpunkt, da sie sich hinter dem Steuer nicht mehr sicher fühlen. Auch die Entwicklung der Mobilitätskosten spielt eine zentrale Rolle bei der Sicherung einer eigenständigen Mobilität, hängt doch die Pkw-Ausstattung eines Haushaltes direkt mit der Höhe des Haushaltseinkommens zusammen. Je größer der Haushalt und je höher das Haushaltseinkommen ist, desto höher ist i.d.R. auch die Anzahl der Pkw im Haushalt. Alternative Mobilitätsangebote tragen nicht nur zu einer Teilhabe bei, sie können insbesondere bei älterern Menschen Fitness und Selbstvertrauen stärken und die Selbstständigkeit sichern und erhalten.

Das Thema Wohnen und Klimaschutz wird bislang vor allem unter dem Aspekt der energetischen Sanierung behandelt, Mobilität findet in diesem Zusammenhang bislang hingegen kaum Berücksichtigung. Das ist auf den ersten Blick auch nicht verwunderlich, werden doch ca. 35 % der Endenergie zur Beheizung, Warmwasserversorgung und Beleuchtung von Gebäuden benötigt. Andererseits starten oder enden aber mehr als 80 % aller täglichen Wege an der Wohnung; der Wohnstandort ist damit der zentrale Ausgangs- und Endpunkt fast aller Alltagsaktivitäten (BMVBS 2010). Hier werden jeden Tag aufs Neue Entscheidungen zur Verkehrsmittelwahl zur Bewältigung vielfältiger (Alltags)Wege getroffen. Schon bei der Wahl des Wohnstandortes spielt die Verkehrsanbindung eine entscheidende Rolle. Insbesondere für ältere Menschen, aber auch für Familien mit älteren Kindern und Jugendlichen ist dabei die Anbindung an Öffentliche Verkehrsmittel von besonderer Bedeutung. Der Standort und die verkehrliche Erschließung einer Wohnsiedlung bilden die „harten" Rahmenbedingungen für das Mobilitätsverhalten ihrer Bewohnerinnen und Bewohner. So ist der Verkehr ist ein nicht unerheblicher Belastungsfaktor für ein gesundes und sicheres Wohnumfeld, aber gleichzeitig auch ein Motiv für das „Häuschen im Grünen": eine Spirale der Verkehrserzeugung. Durch eine stärkere Verknüpfung der Themenfelder Wohnen und Mobilität sowohl im Hinblick auf die „Hardware" wie wohnstandortnahe Verkehrsinfrastruktur (und das meint nicht nur eine gute Erschließung für den MIV) als auch auf weiche Maßnahmen wie wohnstandortbezogene

---

[1] Kohlendioxid (CO_2), Methan (CH_4), Fluorchlorkohlenwasserstoffe (FCKW), Distickstoffmomoxid(N_2O) und Schwefelhexafluorid (SF_6)

Mobilitätsdienstleistungen (z. B. ÖPNV-Ticketing, Car-Sharing oder Car-Pooling, Mobilitätsinformation, Verleih von E-Bikes, Reparaturdienste, Zustellservice) kann der Zugang zu verschiedenen Verkehrsmitteln am Wohnstandort verbessert werden. Wohnungsunternehmen, Verkehrsunternehmen und weitere Mobilitätsdienstleister können durch die Bereitstellung verschiedener Mobilitätsangebote, einen Beitrag leisten, die Wahlfreiheit bei der Verkehrsmittelwahl am Wohnstandort zu sichern. Die Förderung einer umweltfreundlicher Mobilität am Wohnstandort bietet neben den positiven Effekten für das Klima auch signifikante Vorteile für alle Bewohnerinnen und Bewohner und insbesondere ältere Menschen und finanzschwache Haushalte.

2   UNTERSCHIEDLICHE VORAUSSETZUNGEN IN STADT UND UMLAND

Dass der Pkw-Besitz und die Siedlungsstruktur eng miteinander verknüpft sind, ist nicht weiter verwunderlich. So ist der Motorisierungsgrad in ländlichen Regionen am höchsten; die Bewohnerinnen und Bewohner sind aber genauso viel (oder wenig) unterwegs wie Menschen in verdichteten Kreisen und den Kernstädten. Sie sind insgesamt weniger lange unterwegs, legen aber weitere Wege zurück. Dass städtische Dichte verbunden mit einem guten Angebot an Öffentlichen Verkehrsmitteln zu einer reduzierten Nutzung des Pkw beiträgt, zeigen auch die Ergebnisse der deutschen Mobilitätserhebung „Mobilität in Deutschland 2008" (MiD).[2] Mit abnehmender Bevölkerungsdichte – verbunden auch mit einem schlechter werdenden Angebot des Öffentlichen Verkehrs – steigt auch die Anzahl der Pkw im Haushalt. Aber auch zwischen Stadt, Stadtrand und direktem Umland zeigen sich deutliche Unterschiede.

Dicht bebaute Gebiete weisen i.d.R. deutlich bessere Bedingungen für die Nutzung Öffentlicher Verkehrsmittel auf; dispers verteilte Einfamilienhausgebiete und am Stadtrand liegende Einzelhandelszentren oder Gewerbegebiete können oftmals nur mit dem MIV effizient erschlossen werden. Das Verkehrssystem hat umgekehrt aber auch einen hohen Einfluss auf die Ausprägung der Raum- und Siedlungsstruktur. (BMVBS 2010)

So zeigen beispielsweise die Kernstädte Frankfurt am Main und Offenbach die Potenziale einer umweltfreundlicheren Mobilität im Vergleich zum Umland deutlich (Endemann 2013): In der Region Rhein Main besitzen insgesamt 19 % der Haushalte keinen Pkw: in den Kernstädten Frankfurt am Main und Offenbach sind es 31 % , im Umland dagegen verfügen nur 12 % der Haushalte nicht über einen Pkw.

Zwei und mehr Pkw im Haushalt besitzen in den Kernstädten nur 17 % der Haushalte, im Umland hingegen sind es mehr als ein Drittel aller Haushalte. Ein Grund dafür ist sicherlich auch, dass in den Kernstädten deutlich mehr 1-Personen-Haushalte zu finden sind. Steht dem Haushalt allerdings ein Pkw zur Verfügung, dann werden Öffentliche Verkehrsmittel deutlich weniger genutzt (BMVBS 2010).

Kein Auto zu zu besitzen, kann aber auch bedeuten, dass man keinen eigenen Pkw haben möchte; so verzichten ca. 20 % der Haushalte ohne Pkw aus Einstellungsgründen oder weil sie „einen Pkw einfach nicht brauchen" auf ein eigenes Auto. Diese Haushalte sind allerdings aus guten Gründen eher in den Kernstädten zu finden und zu einem sehr großen Anteil 1-Personen-Haushalte (BMVBS 2010).

Bei guten Mobilitätsoptionen werden Öffentliche Verkehrsmittel auch häufiger genutzt, dies zeigen die Auswertungen der MiD beispielsweise in der Region Rhein-Main ganz deutlich. So besitzen dort 33 % der Personen (ab 14 Jahre) in den Kernstädten eine Zeitkarte für den ÖPNV; im Umland sind es nur 16 %; allerdings können auch zwei Drittel der befragten Stadtbewohner einen Schienenhaltpunkt im Umkreis von maximal einem Kilometer erreichen; bei den Menschen aus dem Umland sind es nur gut 40 % (Endemann 2013).

Im Hinblick auf die täglichen CO_2-Emissionen pro Person, den sogenannten CO_2-Fußabdruck aus dem Verkehr, lässt sich feststellen, dass dieser in ländlichen Kreisen um fast ein Viertel höher liegt als in den Kernstädten. Dies ist insbesondere auf den deutlich höheren Anteil des motorisierten Individualverkehrs zurückzuführen – weniger auf die etwas längeren Wege.

---

[2] Mobilität in Deutschland (MID) ist die bundesweite Haushaltsbefragung zum Verkehrsverhalten der Bevölkerung. Hierbei werden die außerhäuslichen Aktivitäten und Wege aller im Haushalt lebenden Personen von ausgewählten Stichprobenhaushalten in einem bestimmten Stichtag mittels eines standardisierten Fragebogens erfasst. Im Rahmen der letzten Erhebung im Jahr 2008 erfolgt eine Stichtagserhebung über 12 Monate in ca. 25.000 Haushalten mit mehr als 62.000 Personen.

Insgesamt lässt sich sagen, dass in den weniger dicht besiedelten Gebieten der motorisierte Indivdualverkehr zunimmt, bei einem gleichzeitigen Bedeutungsverlust des ÖPNV.

3 BEDEUTUNG DER ÖV-ANBINDUNG DES WOHNSTANDORTES UND MOBILITÄTSVORAUSSETZUNGEN

Dass die Anbindung an Öffentliche Verkehrsmittel bei der Wohnstandortwahl eine hohe Bedeutung hat, zeigen u.a. die Ergebnisse des Forschungsprojektes „Demographischer Wandel und Wanderungen in der Stadtregion" deutlich. Im Rahmen dieses Vorhabens wurden unter Beteiligung des ILS Zu- bzw. Umzügler zu den Anlässen ihres Umzugs und zur Bedeutung verschiedener Kriterien für die Wahl ihres neuen Wohnstandortes gefragt. Für elf verschiedene Kriterien wurde dabei um eine Bewertung gebeten. Wie nicht anders zu erwarten, haben die Wohnkosten eine besondere Bedeutung und werden von ca. 60 % als „sehr wichtig" eingestuft, für knapp 40 % ist das „Wohnen im Grünen" sehr wichtig und an dritter Stelle steht schon das Kriterium „Anbindung an Busse und Bahnen"; für 33 % der Befragten ist dieser Aspekt sehr wichtig und 40 % von ihnen bewerten die Anbindung an Öffentliche Verkehrsmittel immer noch als wichtig.

Betrachtet man die Gewichtung der verschiedenen Kriterien nach Lebensphasen, so zeigen sich interessante Unterschiede (vgl. Abb. 1). Bei den jungen Haushalten, unabhängig davon, ob Single- oder Paar-Haushalt sind die Wohnkosten von zentraler Bedeutung. Andere Kriterien spielen in dieser Altersgruppe kaum eine Rolle. Dass die Kosten für die Mobilität bei dieser Betrachtung mit einbezogen werden, darf bezweifelt werden, wie auch verschiedene Untersuchungen belegen.

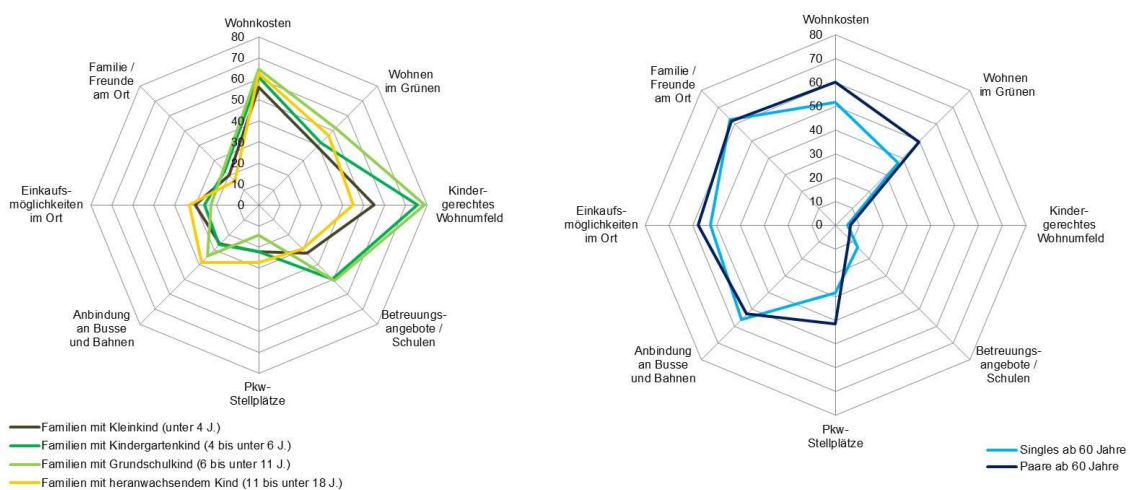
Bei den anderen Haushaltstypen und mit zunehmendem Alter werden die Anforderungen an den Wohnstandort deutlich umfangreicher. Für Familien stehen die Belange der Kinder eindeutig im Vordergrund („kindgerechtes Wohnumfeld", gerne im „Grünen" und „Betreuungsangebote und Schulen"), andere Ansprüche an die Infrastruktur wie etwa „Einkaufsmöglichkeiten im Ort" oder auch die „Anbindung an Busse und Bahnen" werden zurückgestellt. Wahrscheinlich auch deshalb, weil bei einem begrenzten Budget nicht alle Wünsche gleichermaßen zu erfüllen sind. Die Folgen für die alltägliche Mobilität sind absehbar: die Kosten steigen, weite Wege zu Einkaufsmöglichkeiten benötigen einen hohen Zeitaufwand, Kinder werden zur Schule und zu Freizeiteinrichtungen gefahren, bei einem hohen Zeit- und Organisationsaufwand – insbesondere für die Mütter. Ältere Menschen hingegen beziehen deutlich mehr Aspekte in ihre Wohnstandortwahl ein; gleichermaßen bedeutsam sind für sie: kurze Wege zu Versorgungseinrichtungen und Grünanlagen, die Anbindung an Öffentliche Verkehrsmittel zur Gewährleistung ihrer persönlichen Mobilität auch unabhängig vom Pkw, aber auch der Erhalt persönlicher Bindungen („Freunde/Familie am Ort") sowie die Wohnkosten spielen eine Rolle (Dittrich-Wesbuer, Osterhage 2008). In Verbindung mit der absehbaren demographischen Entwicklung bekommen diese Ergebnisse sicherlich noch einmal eine ganz andere Bedeutung.


Abb. 1: Kriterien der Wohnstandortwahl nach Haushaltstypen im Bergischen Land; Quelle: ILS trends 2/2008

Betrachtet man die tatsächliche Verkehrsmittelwahl der Bevölkerung so sind je nach Alter und Lebensphase deutliche Unterschiede zu erkennen. Verglichen mit Alleinerziehenden, Personen aus Familienhaushalten und Alleinlebenden unter 65 Jahren, bewegen sich Ältere Menschen ab 65 Jahren (bislang noch) häufig mit

Verkehrsmitteln des Umweltverbundes (zu Fuß, mit dem Fahrrad und öffentlichen Verkehrsmittel) fort. Während Männer in dieser Altersgruppe immerhin noch auf der Hälfte ihrer Wege den Pkw benutzen, sind es bei älteren Frauen nur 23 % (Abb. 2). Dafür sind diese aber auch überdurchschnittlich häufig als Mitfahrerinnen im Pkw und zu Fuß unterwegs.

Dass der ÖPNV älteren Menschen besonders wichtig ist, spiegelt sich in der Verkehrsmittelnutzung nicht direkt wider; werden doch nur 9 % der Wege mit Bus und Bahn zurückgelegt. Deutlich ist jedoch, dass die Verkehrsmittel des Umweltverbundes insgesamt im Alter an Bedeutung gewinnen, auch wenn der Pkw weiterhin das Verkehrsmittel ist, welches am häufigsten genutzt wird.

Das Geschlecht hat noch immer Einfluss auf das Mobilitätsverhalten – insgesamt legen Frauen deutlich kürzere Distanzen als Männer zurück, wobei ihre tägliche Unterwegszeit nur unwesentlich geringer ist. Dies ist darauf zurückzuführen, dass Frauen in allen Altersgruppen und Lebensphasen häufiger zu Fuß und mit öffentlichen Verkehrsmitteln unterwegs sind. Sie sind auch diejenigen, die eine Vielzahl von Begleit- und Versorgungswegen zurücklegen; sie sind es, die die Kinder zur Schule und zum Sport fahren und sich um die Versorgung ihrer älteren Angehörigen kümmern und dazu einen Großteil der Hausarbeit übernehmen.

Personen aus Familienhaushalten messen dem ÖPNV insgesamt keine große Bedeutung zu. Sie sind diejenige Gruppe, die am häufigsten – zumindest einen Pkw zur Verfügung hat und diesen dann auch entsprechend nutzen.
Abb. 2: Hauptverkehrsmittelnutzung nach Gendergruppen, Quelle: MiD 2008, eigene Berechnungen

Eine zentrale Mobilitätsvoraussetzung ist der Führerscheinbesitz; der Anteil der Personen, die einen Führerschein besitzen ist in den letzten Jahren kontinuierlich angestiegen. Insgesamt verfügen 93 % der Männer und 83 % der Frauen in Deutschland über einen Führerschein (BMVBS 2010). Dass der Führerscheinbesitz nicht automatisch mit der Pkw-Verfügbarkeit und damit auch der Pkw-Nutzung einhergehen muss, zeigt sich insbesondere in der Gruppe der jungen Erwachsenen. Besondere im urbanen Raum sind sie immer häufiger mit Öffentlichen Verkehrsmitteln oder dem Fahrrad unterwegs (ebenda). Ob dies eine Trendwende bedeutet, wird sich den kommenden Jahren zeigen.

Die zukünftig älteren Menschen können zwar potentiell häufiger einen Pkw führen – das verdeutlicht die hohe Führerscheinquote, jedoch bestimmen im hohen Alter auch Faktoren wie gesundheitliche Einschränkungen, Beeinträchtigung des Bewegungsapparates etc., aber auch die finanziellen Ressourcen die Mobilitätsmöglichkeiten, weshalb zu vermuten ist, dass der Umweltverbund von großer Bedeutung bleibt.

Die Pkw-Ausstattung eines Haushaltes hängt auch mit der Höhe des Haushaltseinkommens zusammen. Es zeigt sich, dass mehr als die Hälfte aller Haushalte der unteren Einkommensklassen keinen Pkw besitzt. Je größer der Haushalt und je höher das Haushaltseinkommen ist, desto wahrscheinlicher ist der Pkw-Besitz und auch die Zahl der Pkw im Haushalt. Eine weitere wichtige Rolle spielen Faktoren wie die Raumstruktur oder ob Kinder im Haushalt leben.
Abb. 3: Anzahl der Pkw in Haushalten nach monatlichem Haushaltsnettoeinkommen, Quelle: Eigene Darstellung nach BMVBS 2010

4 MOBILITÄTSSICHERUNG EINE AUFGABE AUCH FÜR WOHNUNGSUNTERNEHMEN

Seit einiger Zeit verfolgen bereits viele Wohnungsunternehmen die Strategie, ihr „Produkt Wohnung" zum „Produkt Wohnen" auszuweiten, um Kundinnen und Kunden zu gewinnen und an ihr Unternehmen zu binden. So bieten sie beispielsweise einen Umzugsservice, Notrufsysteme, aber auch vergünstigte Mitgliedschaften in Fitnessstudios oder Urlaubsreisen an. Angebote, die die Alltagsmobilität der Bewohnerinnen und Bewohner unterstützen finden sich bislang jedoch noch eher selten.

Durch eine stärkere Verknüpfung der beiden Themenfelder Wohnen und Mobilität sowohl in Bezug auf die wohnstandortnahe Verkehrsinfrastruktur als auch auf „weiche" Maßnahmen wie ÖPNV-Ticketing, Car-Sharing, Mobilitätsinformation, Reparaturdienste, Zustellservice etc. kann der Zugang zu allen Verkehrsmitteln am Wohnstandort verbessert und so eine Wahlfreiheit ermöglicht werden.

Unter diesen Voraussetzungen können Bewohnerinnen und Bewohner immer wieder neu entscheiden, welches Verkehrsmittel sie für welchen Weg aktuell nutzen möchten – auch wenn kein eigenes Auto vorhanden ist oder aufgrund von altersbedingten Einschränkungen das Führen eines Pkw nicht (mehr) möglich ist. Dieser Ansatz ist nicht nur im Wohnungsneubau interessant, sondern kann auch im Bestand etabliert werden. Bei der Umsetzung entsprechender Maßnahmen sind neben der Kommune, die in Ausübung ihrer Planungshoheit Voraussetzungen für den Umweltverbund schafft, viele weitere Akteure gefragt.

Wohnstandortbezogene Mobilitätsdienstleistungen können die traditionellen Geschäftsfelder der Wohnungswirtschaft „rund ums Bauen und Wohnen" ergänzen und die Wohnzufriedenheit der Mieterinnen und Mieter steigern. Insbesondere größere Wohnungsunternehmen können ihr Kernprodukt „Wohnung" durch entsprechendes Engagement attraktiver gestalten.

Um den Bewohnerinnen und Bewohnern eine umweltfreundliche Verkehrsmittelwahl am Wohnstandort zu erleichtern, können neben infrastrukturellen Maßnahmen eine Vielzahl bereits erprobter Mobilitätsdienstleistungen – auch oder gerade durch Wohnungsunternehmen – implementiert werden. Denn

schon bei der Wahl des Wohnstandortes (s.o.) spielen die Anbindung an die örtlichen Verkehrssysteme sowie Art und Umfang der Mobilitätsangebote eine entscheidende Rolle.

Für die Verkehrsunternehmen und andere Mobilitätsdienstleister ergeben sich durch neue Kooperationspartner wie Wohnungsunternehmen auch neue Vertriebswege. Über den „Großkunden Wohnungsunternehmen" können neue Absatzmärkte erschlossen werden, Kundinnen und Kunden können über Direktmailing zielgruppengenau angesprochen werden. Zudem besteht durch einen Kooperationsvertrag mit dem solventen Partner „Wohnungsunternehmen als Großkunde" eine gesicherte Finanzierung und hohe Planungssicherheit.

Auch für Kommunen als Aufgabenträger für die Stadt- und Verkehrsplanung sind wohnstandortbezogene Mobilitätsdienstleistungen ein Beitrag zur umweltverträglichen Abwicklung des Verkehrs und damit eine Maßnahme zu einer nachhaltigeren Stadtentwicklung. Die wohnstandortnahe Bereitstellung aller Verkehrsmittel und eine umfassende Information über das Angebot vor Ort, ermöglichen die Erreichbarkeit alltäglicher Ziele unabhängig vom Besitz eines eigenen Pkw. Davon profitieren alle Bewohnerinnen und Bewohner und insbesondere ältere Menschen und finanzschwache Haushalte.

Die Initiierung, Umsetzung und Finanzierung entsprechender Mobilitätsangebote, sollte vor diesem Hintergrund nicht länger nur eine Aufgabe der kommunalen Stadtentwicklung, Verkehrsplanung und der Verkehrsbetriebe sein, sondern in Kooperation mit Wohnungseigentümern und ggf. auch mit anderen Anbietern von Mobilitätsdienstleistungen angepackt werden.

Definition Wohnstandortbezogenes Mobilitätsmanagement

Unter wohnstandortbezogenem Mobilitätsmanagement werden Maßnahmen bzw. Maßnahmenpakete verstanden, die für Bewohnerinnen und Bewohner bestimmter Quartiere oder Mieterinnen und Mieter bestimmter Wohnungsunternehmen in Kooperation von Wohnungsunternehmen und Mobilitätsdienstleistern entwickelt werden und über die herkömmliche Dienstleistung hinaus einen spezifischen Nutzen für die Adressaten beinhalten.[3]

5 BEISPIELE WOHNSTANDORBEZOGENER MOBILITÄTSDIENSTLEISTUNGEN

Zu Hause beginnen und enden die meisten aller Alltagswege(ketten); hier werden jeden Tag aufs Neue Entscheidungen über die Wahl des geeigneten Verkehrsmittels zur Bewältigung dieser Wege getroffen. Dass wir inzwischen deutlich multimodaler unterwegs sind und festgefahrene, autoorientierte Verhaltensmuster – zumindest in Ansätzen (gerade bei der jüngeren Generation) aufgeweicht sind, zeigen inzwischen eine Reihe von Studien (z. B. ifmo 2011). Je nach Anlass und Ziel werden unterschiedliche Verkehrsmittel gewählt oder auch miteinander kombiniert. Damit dies auch funktioniert, muss ein entsprechendes Angebot vorhanden sein – hier gilt es entsprechende Voraussetzungen zu schaffen, nicht zuletzt auch vor dem Hintergrund der demographischen Entwicklung und der Umweltproblematik, die die aktuellen Herausforderungen für die Städte darstellen.

Es gilt also, Handlungsspielräume zu erweitern sowie Mobilitätsalternativen und die dafür notwendige Infrastruktur am Wohnstandort bereitzustellen, um auch wirklich eine Wahlfreiheit zu errreichen. Diese setzt neben Infrastruktur und Verfügbarkeit verschiedener Verkehrsmittel auch den Zugang zu Informationen über die entsprechenden Verkehrsmittel voraus. Hier setzt das wohnstandortbezogene Mobilitätsmanagement an.

Im Folgenden werden verschiedene Servicefelder und einige bereits erprobte Maßnahmen kurz vorgestellt.

5.1 Angebote rund um den öffentlichen Verkehr

Im Fokus dieses Servicefeldes stehen zwei Dienstleistungen: preisreduzierte ÖPNV-Abonnements, so genannte „Mietertickets" und wohnortbezogene Informationen zum öffentlichen Nahverkehr.

Beim Mieterticket garantiert ein Wohnungsunternehmen als Großkunde eine Mindestabnahme an Tickets und erhält so vom lokalen Verkehrsunternehmen einen Preisnachlass, den Großkundenrabatt. Die Wohnungsunternehmen geben diesen Preisnachlass an ihre Mieterinnen und Mieter weiter, die so in den Genuss preisreduzierter ÖPNV-Tickets kommen. Die speziellen Konditionen variieren nach lokalen und

---

[3] Diese Definition wurde im Rahmen des EU-Projekts ADD HOME unter Mitwirkung des ILS entwickelt. http://www.mobilitaetsmanagement.nrw.de/cms1/index.php?option=com_content&view=article&id=88&Itemid=55

regionalen Tarifen und werden zwischen Wohnungsunternehmen und Verkehrsunternehmen ausgehandelt. Erfolgreiche Umsetzungen finden sich in Deutschland beispielsweise in Bielefeld, Bochum oder Kassel.

Ort	Akteure	Merkmale
Bielefeld	moBiel – als lokales Verkehrsunternehmen; Bielefelder Gemeinnützige Wohnungsbaugesellschaft mbH; Baugenossenschaft Freie Scholle e. G.	10 %iger Preisnachlass auf herkömmliche Abotarife bei gleicher Leistung
Bochum	BOGESTRA – Bochum-Gelsenkirchener Straßenbahnen AG; VBW Bauen und Wohnen GmbH	11,5 %iger Preisnachlass auf herkömmliche Abo-Tarife bei nahezu gleicher Leistung (Ticket jedoch nicht übertragbar), gilt für alle Haushaltsmitglieder
Kassel-Unterneustadt	Kasseler Verkehrsgesellschaft und Nordhessischer Verkehrsverbund; WOHNSTADT GmbH, Vereinigte Wohnstätten 1889 eG	für eine Person pro autofreiem Haushalt 75 % Preisnachlass auf herkömmlichen Abo-Tarif im ersten Jahr (durch finanzielle Beteiligung der Wohnungsunternehmen); 10 % in Folgejahren und für weitere Haushaltsmitglieder

Tabelle. 1: Beispiele erfolgreicher Mieterticket-Angebote, Quelle ILS 2011

Die Nutzung von Öffentlichen Verkehrsmitteln setzt Kenntnis über Tarife, Abfahrtszeiten, Liniennetz, Takt usw. voraus. Informationen am „Schwarzen Brett" im Hauseingangsbereich oder elektronische Fahrplan-Terminals, die an zentralen Orten im Wohngebiet aufgestellt werden, können den Zugang zu Informationen erleichtern. Die Bochumer VBW Bauen und Wohnen hält beispielsweise ein Starterpaket für neue Mieterinnen und Mieter bereit, das u.a. Informationen zum ÖPNV, Gutscheine für Tagestickets und Informationen zum Mieterticket enthält.

In Zusammenarbeit mit den örtlichen Verkehrsunternehmen lässt sich oftmals auch die Bedienqualität der Öffentlichen Verkehrsmittel (durch Taktverdichtung, Quartiersbusse etc.), Erreichbarkeit und Ausstattungsqualität der Haltestellen in den Wohngebieten verbessern.

5.1.1   Beispiel: VBW Mieterticket

Bereits seit dem Jahr 2003 bietet die Bochumer Wohnungsbaugesellschaft Vereinigte Bauen und Wohnen GmbH (VBW) als Kooperationspartnerin des örtlichen Verkehrsunternehmens Bochum-Gelsenkirchener Straßenbahnen AG (BOGESTRA) ihren Mieterinnen und Mietern ein vergünstigtes Ticket an. Beim VBW-Mieterticket handelt es sich um ein spezielles Großkundenabonnement des Wohnungsunternehmens; das Wohnungsunternehmen garantiert gegenüber dem Verkehrsunternehmen eine Mindestabnahme. Die Tickets werden (im Jahresabo) mit einem Preisnachlass von ca. 11,5 % angeboten. Dabei können die Mieterinnen und Mieter auf das gesamte Ticketsortiment des Verkehrsverbundes Rhein Ruhr zugreifen. Die Tickets können für alle Haushaltsmitglieder erworben werden, sind jedoch nicht übertragbar.

Die Verträge für die Tickets werden zwischen der BOGESTRA und den Mieterinnen und Mietern abgeschlossen; der Geldeinzug wird von der BOGESTRA übernommen.

Auch wenn der Preisvorteil bereits ein schlagkräftiges Angebot für den Bezug der Tickets ist, muss das Produkt intensiv kommuniziert und beworben werden. Die Produktion von Werbematerialien wird vom Verkehrsunternehmen übernommen und auch die Schulung der Mitarbeiter und Mitarbeiterinnen des Wohnungsunternehmens übernimmt das Verkehrsunternehmen. Alle neuen Mieterinnen und Mieter erhalten mit Abschluss des Mietvertrages entsprechende Informationen zum Mieterticket. Regelmäßig wird auch in der Mieterzeitschrift über das Ticket informiert und über die Homepage der VBW beworben.

Dass sich die Anstrengungen für beide Seiten gelohnt haben, belegen die Zahlen. Derzeit nutzen mehr als 1.250 Mieterinnen und Mieter dieses Angebot, dabei halten sich Neukunden und Stammkunden die Waage. Der größte Anteil der Mietertickets – fast 50 % – aller Tickets entfallen auf die Seniorentickets, die sog. Bärentickets, die von Menschen ab 60 Jahren erworben werden können.

5.1.2   Mieterticket Bielefeld

Bei der Mobilitätsdienstleistung „moBiel-Mieterticket" handelt es sich um ein vergünstigtes Ticketangebot für die Mieterinnen und Mieter der „Bielefelder Gemeinnützige Wohnungsbaugesellschaft" (BGW) und die Mitglieder der Freien Scholle eG. Durch die Garantie einer Mindestabnahme von 100 Tickets treten die Wohnungsunternehmen als Großkunden auf und handeln mit moBiel einen Großkundenrabatt von 10 % aus, der an die Mieterinnen und Mieter weitergegeben wird.

Der 10 % Preisnachlass gilt für das gesamte Ticketangebot im Abonnement und ist für alle Mitglieder des Haushaltes.

Die Verträge werden auch hier zwischen dem Verkehrsunternehmen und den Mieterinnen und Mietern direkt geschlossen, sie gelten zunächst für ein Jahr bei automatischer Verlängerung und sind monatlich kündbar. Die Zahl der verkauften Mietertickets hat sich seit der Einführung im Jahr 2005 um 320 % auf ca. 1.500 Tickets pro Monat gesteigert; die Tendenz ist weiter steigend (Kutziewski 2012).

5.2 Verkehrsmittelübergreifende Informationsdienstleistungen

Neben Informationen, die Verkehrsunternehmen bereitstellen, können verkehrsmittelübergreifende Informationen von den Wohnungsunternehmen selbst weitergegeben werden. Als Informationsmedien sind in erster Linie Kunden- bzw. Mieterzeitungen und Internetauftritte zu nennen.

Informationen speziell für Neukunden können auch über individuell zugeschnittene, persönliche Beratungen oder sog. Starterpakete platziert werden. Diese können beispielsweise Fußgänger- und Fahrradstadtpläne, Stadt-, Stadtteil- und Verbundfahrpläne, Infoflyer zum Car-Sharing, zur Radstation oder zum örtlichen Nahversorgungsangebot beinhalten. Darüber hinaus können den Starterpaketen Schnupper-Tickets für Bus & Bahn oder andere Mobilitätsdienstleistungen beiliegen. Die Entwicklungsgesellschaft Langenhagen hält beispielsweise in Kooperation mit dem GVH – Großraum-Verkehr-Hannover und Stadtmobil Hannover für Hauseigentümer ein Starterpaket bereit; enthalten sind u.a. Radwegekarten, ÖPNV-Fahrpläne, Informationen zum Car-Sharing und einen Gutschein für eine ermäßigte Car-Sharing Mitgliedschaft.

5.3 Wohnstandortbezogene Dienstleistungen rund um die Nahmobilität

Fahrräder brauchen eine diebstahlsichere, witterungsgeschützten und nach Möglichkeit ebenerdige Abstellmöglichkeit; dies gilt verstärkt für E-Bikes und Pedelecs. Was so banal klingt, ist leider immer noch nicht selbstverständlich. Fahrradboxen oder -häuser nahe den Hauseingängen bieten einen solch guten Service zur Fahrradunterbringung. Lassen sich aus Platzgründen – z. B. in Altbauquartieren – auf dem Grundstück keine Fahrradboxen unterbringen, ist dies unter bestimmten Voraussetzungen auch im öffentlichen Straßenraum möglich. Fahrradkeller können mit Hilfe von Rampen und Elektronik ebenfalls barrierefrei zugänglich sein. Fahrradbügel für Kurzzeitparker vor den Hauseingängen vereinfachen den Alltagsgebrauch.

Reparaturmöglichkeiten vor Ort oder gar ein entsprechendes Dienstleistungsangebot sorgen für rasche Instandsetzung und Instandhaltung von Fahrrädern. Weitere Serviceleistungen können beispielsweise Verleihangebote von Kinderanhängern und -trailern, Pedelecs, Lastenfahrrädern oder Tandems sein.

Verbesserungen für den Fußverkehr liegen hauptsächlich im baulich-gestalterischen Bereich des Wohnumfeldes – Begrünung und Bepflanzung, Möblierung und vor allem Fußwegeverbindungen in die Stadtteilzentren. Aber auch Transporthilfen können das Zufußgehen bequemer und einfacher machen. Einkaufstrolleys – durch ein Wohnungsunternehmen als Dankeschön bereitgestellt und mit dem Firmenlogo versehen – können darüber hinaus als Werbeträger eingesetzt werden.

5.4 Wohnstandortbezogene Serviceangebote rund um den Pkw

Hier steht vor allem der Wunsch nach einer hohen Pkw-Verfügbarkeit durch ein entsprechendes Car-Sharing-Angebot im Vordergrund. Meistens wird das Angebot in Kooperation mit einem örtlichen Car-Sharing-Unternehmen realisiert, welches entweder eine neue Car-Sharing-Station wohnortnah einrichtet oder bereits in Wohnortnähe vertreten ist. Die Parkplätze werden i. d. R. von den Wohnungsunternehmen oder Eigentümergemeinschaften zur Verfügung gestellt. Die Fahrzeugbereitstellung sowie die Wartungs-, Buchungs- und Abrechnungsvorgänge übernimmt das Car-Sharing-Unternehmen.

Unterscheiden lassen sich offene und exklusive Angebote. Bei offenen Angeboten stehen die Fahrzeuge den Wohnkunden zu besonderen Konditionen zur Verfügung, sind aber auch offen für alle anderen Kunden des Car-Sharing-Unternehmens und kann so auch zu einer Verbesserung der Auslastung beitragen. Gleichzeitig können die Wohnkunden nicht nur die Fahrzeuge an "ihrer" Station nutzen, sondern sämtliche Fahrzeuge des Car-Sharing-Unternehmens und damit auf eine große Vielfalt an Fahrzeugtypen zugreifen.

Exklusive Angebote können hingegen ausschließlich die Wohnkunden nutzen. Damit ist der Nutzerkreis eher klein, dafür aber persönlich bekannt. Die Fahrzeuge werden vom Wohnungsunternehmen selbst

bereitgestellt. Besonders interessant für Wohnungsunternehmen wird ein Car-Sharing-Angebot, wenn die eigenen Dienstfahrten ebenfalls mit Car-Sharing-Fahrzeugen durchgeführt werden und so die Anzahl der Firmenfahrzeuge reduziert werden kann.

Ort	Akteure	Merkmale
Berlin	GSW Immobilien GmbH; Greenwheels	neue Stationen in unmittelbarer Nähe zu GSW-Wohnungsbeständen; offenes Car-Sharing; günstige Konditionen für Mieterinnen und Mieter (wie für ÖPNV-Abo-Kunden)
Bonn	Bewohner des autoarmen Stadtquartiers Bonn-Amaryllis	nachbarschaftlich organisiertes Car-Sharing
Köln	GAG Immobilien AG, cambio carsharing Köln	neue Stationen in unmittelbarer Nähe zu GAG-Wohnungsbeständen; vergünstigte Teilnahme an offenem Car-Sharing

6 FAZIT

Eine Reihe von Pilotprojekten hat bereits gezeigt, dass mobilitätsbezogene Serviceangebote von Wohnungsunternehmen in Bestandsquartieren mit einkommensschwächeren Haushalten, mit älteren Bewohnerinnen und Bewohnern und mit vergleichsweise geringer Pkw-Quote auf messbare Nachfrage treffen. Gerade für diese Nutzergruppen werden Angebote geschaffen, die ihre Mobilität und damit Teilhabemöglichkeit sicherstellen.

Darüber hinaus tragen die Angebote zumindest bei den Nutzerinnen und Nutzern zum Imagegewinn, zur Kundenzufriedenheit und damit auch zur Kundenbindung sowohl für das Wohnungs- als auch das involvierte Verkehrsunternehmen bei. Das Engagement für die Mobilität der Mieter wird insgesamt positiv wahrgenommen und überwiegend als wichtig erachtet. Im Falle des Mietertickets ist zu vermuten, dass zumindest bei einem Teil der Neukundinnen und Neukunden, die als sogenannte Wahlfreie mehrere Verkehrsmittel zur Auswahl haben, mit dem Abonnement auch Veränderungen des Mobilitätsverhaltens einhergehen. Finanzschwache Haushalte profitieren monetär von dem kostengünstigen Ticket.

Mobilitätsdienstleister können über den Kooperationspartner Wohnungsunternehmen gegebenenfalls neue Absatzmärkte erreichen und ein zielgruppengenaues Marketing entwickeln, da die Zielgruppe i. d. R. bereits gut bekannt ist. Bei der Akquisition neuer Kunden kann der Mobilitätsdienstleister unter Umständen von dem Vertrauensverhältnis profitieren, das das Wohnungsunternehmen als vermittelnder Partner mit seinen Mieterinnen und Mietern pflegt. Wenn das Angebot über den vertrauten Partner kommuniziert wird, genießt dies eine höhere Akzeptanz. Wohnstandortbezogene Mobilitätsdienstleistungen können darüber hinaus die Kundenbindung von Mieterinnen und Mietern, die bereits Kunden des Mobilitätsdienstleisters sind, erhöhen.

Für die öffentliche Hand kann das verstärkte Engagement einer Verknüpfung der Bereiche Wohnen und Mobilität bedeuten, dass der kommunale Modal Split positiv zu Gunsten des Umweltverbundes beeinflusst wird. Es kann dazu beitragen, dass Mobilitätsoptionen für benachteiligte Bevölkerungsgruppen gesichert werden. Vor allem bei der Setzung der infrastrukturellen Rahmenbedingungen kommt der Kommune eine zentrale Bedeutung zu; aber auch in weiteren Handlungsfeldern haben haben Kommunen gute Voraussetzungen, Wohnstandortbezogenes Mobilitätsmanagement zu unerstützen und so, auch in ihrem eigenen Interesse, eine effizientere und umweltverträglichere Mobilität zu fördern.

Insagesamt lässt sich sagen, dass insbesondere sogenannte „weiche Maßnahmen" kostengünstig realisierbar sind und reletiv schnell umgesetzt werden können. Und es besteht in der Regel eine Win-Win-Situation für alle beteiligten Akteure und die Bewohnerinnen und Bewohner.

1 ABSTRACT

In view of uncertain and incomplete knowledge, predictions and forecasts often turn out to be an insufficient base for decision making in urban planning. Moreover, strictly science driven approaches are not sufficient to provide a full problem analysis and evaluation and to develop broadly accepted strategies for future development (Truffer 2007). In this context, participatory scenario planning offers a method for the synthesis of manifold sources of multi-disciplinary expert knowledge and lay knowledge of the local population (e.g., regarding the local problems perceived or the future urban development desired). This paper argues that participatory scenario planning allows the integration of qualitative target-knowledge such as visions on desired development paths with expert knowledge and may contribute to a broader sense of community and cohesion by offering a partnership learning environment. The paper draws on experiences from a case study in the city of Korneuburg, a district capital in Lower Austria with about 12.000 inhabitants, next-door to the metropolis of Vienna. The methodological framework relies on building stones of formalised scenario analysis, a structural and development analysis combined with normative future visions of stakeholders and a participatory process giving special attention to community building. Different forms of direct interaction are complemented by a web-blog, an online mapping tool for the youth and an analogue (B)logbook.

The still ongoing process already showed that the scenario method was very helpful for the integration of expert and lay knowledge into four scenarios for the future development of Korneuburg until 2036. Incidentally, it created a framework for social learning on the question of what constitutes desired urban development and – maybe even more important – it generated sense of community, identity and social capital among those who will have to implement the future strategies by their collective action.

2 EINLEITUNG

Entscheidungsträgerinnen und Entscheidungsträger in der Stadtentwicklung sind herausgefordert, Zukunftsstrategien zu entwerfen, die einem hohen Ausmaß an Komplexität gerecht werden. Dem demographischen oder klimatischen Wandel muss beispielsweise ebenso Rechenschaft getragen werden, wie technologischen Entwicklungen oder der Vielzahl an involvierten Akteurinnen, Akteuren und Interessen. In diesem Kontext oft unvorhersehbarer Veränderungen und Unsicherheiten sollen Entscheidungen in der Gegenwart dennoch vorausschauend reflektiert und zukunftsfähig ausgerichtet werden können (Kosow und Gaßner 2008; McDonald et al. 2009). Angesichts des hohen Grades an unsicherem und unvollständigem Wissen sind Vorhersagen und Prognosen oft eine nicht adäquate Entscheidungsgrundlage.

In diesem Kontext bietet die Szenarioentwicklung eine Methode für die Synthese vielfältiger Quellen multidisziplinären Expertenwissens und des Erfahrungswissens der lokalen Bevölkerung (z.B. Wahrnehmung lokaler Problemstellungen oder Wünsche für zukünftige Entwicklungen) und unterstreicht damit die Stärke der Regionalentwicklung, lokalem Wissen mit hoher Sensibilität zu begegnen (Barnes, 2003). Die Szenariomethode hat sich bereits als vielversprechendes Werkzeug etabliert, mögliche Zukunftsperspektiven als Entscheidungsgrundlage für lokale und regionale Entwicklungsstrategien zu veranschaulichen (Kirchner-Heßler 2004). Der vorliegende Artikel stellt dar, dass Szenarienprozesse darüber hinaus geeignet sind, qualitatives Zielwissen wie Visionen und gewünschte Entwicklungspfade in Planungsinstrumente zu integrieren sowie zur Stärkung von Gemeinschaftssinn und Zusammenhalt beizutragen, indem soziale Lernprozesse initiiert und forciert werden.

Die Argumentation stützt sich auf Erfahrungen aus dem partizipativen Leitbildprozess der Stadt Korneuburg. Die niederösterreichische Bezirkshauptstadt mit rund 12.000 Einwohnerinnen und Einwohnern, unmittelbar vor den Toren Wiens gelegen, startete im April 2012 einen partizipativen Szenarienprozess. Dieser wurde bottom-up initiiert und umfasst Akteurinnen und Akteure aller im Gemeinderat vertretenen Fraktionen, der Verwaltung sowie aus Zivilgesellschaft und Bürgerinnen und Bürger ebenso wie ein Wissenschaftlerteam

mit disziplinären Hintergründen in Geographie, Architektur, Landschaftsplanung und Regionalentwicklung. Ende 2013 sollen ein breit akzeptiertes und politisch verabschiedetes Leitbild mit der Ausrichtung auf das Jahr 2036 (900 Jahre Stadtjubiläum) sowie ein Masterplan mit Handlungsempfehlungen für die nächsten zehn Jahre fertiggestellt sein.

Im Rahmen des Projekts Korneuburg 2036 wurde die Methode der formativen Szenarioentwicklung (Erheben von Trends und Einflussfaktoren sowie der Bandbreite möglicher zukünftiger Ausprägungen und deren Kombination) mit einem normativen Visions-Prozess verknüpft. Verschiedene Wissensebenen – quantitatives und qualitatives Systemwissen, Zielwissen darüber, wie die Zukunft Korneuburgs in den Augen der Bürgerinnen und Bürger aussehen könnte und Handlungs-/Transformationswissen, um den angestrebten Zustand erreichen zu können – werden im diesem Prozess integriert (Truffer 2007). Die Zusammenführung von verschiedenen Akteurinnen und Akteuren und deren Wissensbeständen impliziert auch die Chance, einen gemeinsamen Lernprozess und damit einen Beitrag zum Community Building zu leisten – nicht zuletzt als Beitrag zur Steigerung der Akzeptanz der erarbeiteten Ergebnisse.

Da der Szenarioprozess hinsichtlich seines Potentials für Community Building und Wissensintegration diskutiert werden soll, wird zu diesen Themen im folgenden Abschnitt ein Überblick aus der Literatur gegeben. Danach werden die Fallstudien-Stadt Korneuburg, die beteiligten Stakeholder und die einzelnen Schritte des Szenarioprozesses sowie die Ergebnisse im Detail dargestellt. Schließlich wird diskutiert, ob die Erwartungen hinsichtlich community building, social learning und Wissensintegration tatsächlich erfüllt werden konnten.

2.1 Die Szenariomethodik – eine Einführung

In der Literatur finden sich vielfältige Definitionen von Szenarien, auch die methodischen Verfahrensweisen zu deren Erstellung unterscheiden sich je nach Zielsetzung. Wilms (2006) beschreibt ein Szenario als "plausibel ausformuliertes, hypothetisches Zukunftsbild eines abgegrenzten Problemfeldes, das alternative Entwicklungsmöglichkeiten berücksichtigt und der Entscheidungsvorbereitung dient". Szenarien bieten "eine Einschätzung dessen, was denkbar und plausibel ist" (Groß et al. 2011) und zeichnen damit (im Gegensatz zu Prognosen und Trendfortschreibung) nicht die Zukunft, wie sie (vermutlich) sein wird, sondern wie sie sein könnte (Wiek 2002). Normative Szenarien konstruieren mögliche positive und wünschenswerte Zukunftssituationen "Was wollen wir und wie können wir es erreichen?" (Schulz-Montag 2006). Gleichzeitig kann aufgezeigt werden, worin gegenwärtiges Handeln resultiert und welche Entwicklungsperspektiven sich durch Verhaltensänderungen einstellen. Ein Szenario beschreibt demnach nicht nur einen hypothetischen Zustand in der Zukunft, sondern auch die Entwicklungswege, Handlungsschritte und treibenden Kräfte, aus denen ein bestimmtes Zukunftsbild resultiert und dient u.a. der "Ermittlung von kritischen Entscheidungspunkten und Eröffnung von Handlungsoptionen" (Schulz-Montag 2006).
Abb. 1: Der Szenariotrichter (verändert nach Liening und Mittelstädt, 2009)

Allen Ansätzen gemeinsam ist das Aufspannen möglicher Zukunftsräume in einem weiten Planungshorizont. Ziel ist ein – von gegenwärtigen Bedingungen, Normen und Grenzen losgelöstes – Aufzeigen von

Entwicklungsperspektiven. Die Szenariomethode versucht zunächst, auf Basis struktureller Analysen von Vergangenheit und Gegenwart jene driving forces zu identifizieren, welche die Entwicklung des Systems wesentlich steuern und analysiert darauf aufbauend mehrere Zukunftspfade dieser Entwicklungsfakoren in ihren Wechselwirkungen zueinander, um schließlich konsistente Bilder über mögliche Zustände in der Zukunft darzustellen. Unter Einbezug qualitativer Informationen von lokalen Wissensträgerinnen und Wissensträgern werden verschiedene plausible und mitunter stark divergierende Zukünfte in narrativer Form erarbeitet. Qualitative, narrative Szenarien-Elemente eignen sich vor allem zur Analyse komplexer Situationen mit einem hohen Ausmaß an Unsicherheiten und wenn relevante Informationen nicht gänzlich quantifiziert werden können. Gleichsam kann die Kombination qualitativer und quantitativer Elemente die Konsistenz und Robustheit von Szenarien erhöhen (van Notten et al. 2003).

Ursprünglich im militärischen Kontext entstanden und zunächst vorwiegend im Kontext ökonomischer Fragestellungen weiterentwickelt hat sich die Szenarioerstellung als Methode in der räumlichen Planung etabliert. Auch in Österreich wurden bereits mehrere Szenarienprozesse zur Entwicklug von Regionen und Städten durchgeführt (z.B. ÖROK 2009; Penker und Wytrzens 2005; Muhar und Freyer 2006). Die Stärken der Methodik im Anwendungskontext dieses Papers liegen darin, "die vielschichtigen qualitativen und quantitativen Informationen zu verknüpfen, deren Systemdynamik zu erfassen und in einer vernetzten, ganzheitlichen und interdisziplinären Betrachtung transparente und nachvollziehbare Zukunftsbilder zu entwickeln, aus denen eine zukunftsrobuste Leitstrategie abgeleitet werden kann" (Kirchner-Heßler 2004). Die Ergebnisse des Szenarioprojekts beruhen auf der Integration wissenschaftlicher Studien und quantitativem sowie qualitativem Datenmaterial mit implizitem (Ziel-)Wissen von Expertinnen und Experten aus Zivilgesellschaft, Politik und Verwaltung. Ziel ist der Entwurf von zwei bis fünf visionären Szenarien sowie die anschließende Auswahl (Abstimmung durch Bürgerinnen und Bürger) des gewünschten Zukunftsbildes und dessen Überführung in ein Stadtleitbild, welches in der Folge als Grundlage für zukünftige Entscheidungen dienen kann (Masterplan). Anspruch an die methodische Vorgehensweise war, komplexe Szenarienbilder (im Gegensatz zu sektoralen Szenarien) erarbeiten zu können, die multiple, miteinander in Wechselwirkung stehende und multidisziplinäre Fragestellungen auf verschiedenen räumlichen Ebenen erfassen. Die Szenarien sollten nicht eine Fortschreibung aktueller Entwicklungen abbilden, sondern als backcasting-Szenarien von der Gegenwart losgelöste Zustände in der Zukunft entwerfen sowie die Wege zu deren Erreichung explorieren (dazu auch van Notten et al. 2003).

2.2 Die partizipative Szenarioentwicklung als Lernort für nachhaltige Stadtentwicklung

Die Komplexität räumlicher Entwicklung und ihrer Planbarkeit für die Zukunft erfordert eine neue Form der Wissensproduktion, als "Mode 2 Wissenschaft" (Gibbons et al. 1994; Nowotny et al. 2001) oder "post normale Wissenschaft" (Funtowicz und Ravetz 1993) bezeichnet. Der gemeinsamen Wissensproduktion durch Gesellschaft und Wissenschaft kommt dabei neben Interdisziplinarität, Problemorientierung und Kontextualisierung eine entscheidende Rolle zu. Hirsch-Hadorn et al. (2008) betonen die Bedeutung regionaler Akteurinnen und Akteuren als Trägerinnen und Träger impliziten Wissens zu regionalen Präferenzen und Prioritäten sowie über die "Erfahrung, ob, wo und wie in bestehende Verhaltensmuster interveniert werden kann". Die Szenarioentwicklung bietet hierzu ein geeignetes Instrument, um "gemeinsam mit den Akteuren eine zukunftsrobuste Strategie in einem komplexen Themenfeld zu entwickeln" (Kirchner-Heßler 2004). Sie stützt sich nicht ausschließlich auf wissenschaftliches und quantifizierbares Expertenwissen (im Gegensatz zu Prognosen oder Simulationen), sondern integriert als transdisziplinäres Instrument alltagspraktisches Wissen von Praxisakteurinnen und Praxisakteuren sowie deren Einschätzungen zu regionalen Prioritäten oder regionaler Handlungsfähigkeit (Graf 2004; McDonald et al. 2009), was die Problemlösungskompetenz des Methodeneinsatzes erhöht (Truffer 2007).

Damit Leitbilder nicht allein Papier bleiben, sondern sich in an einem gemeinsamen Ziel ausgerichteten kollektiven Verhalten der relevanten Kräfte einer Stadt niederschlagen, damit sie tatsächlich zu Problemlösungen und Verhaltensänderungen führen, wird soziales Lernen als zentraler Erfolgsfaktor gesehen. Gerade Erfahrungen aus der nachhaltigen Stadtentwicklung, unterstrichen durch neueste Ergebnisse der Umweltpsychologie, zeigen die Relevanz eines kollektiven Lernprozesses, der sich dann in gemeinsamen Handeln für die Stadt ausdrückt.

In der Nachhaltigkeitsforschung herrscht Konsens über die zentrale Rolle von Bildungs- und Lernprozessen für die Umsetzung nachhaltiger Entwicklung (UNCED 1992; Schmidt 2009,). "Sowohl die formale als auch

die nichtformale Bildung ... sind auch von entscheidender Bedeutung fur die Schaffung eines ökologischen und eines ethischen Bewusstseins, von Werten und Einstellungen, Fähigkeiten und Verhaltensweisen, die mit einer nachhaltigen Entwicklung vereinbar sind, sowie fur eine wirksame Beteiligung der Öffentlichkeit an der Entscheidungsfindung.“ Daraus leitet sich die Notwendigkeit, ab "die Öffentlichkeit verstärkt fur Umwelt- und Entwicklungsfragen zu sensibilisieren und ihre Beteiligung an der Lösungsfindung zu steigern sowie ein Bewusstsein fur die eigene Verantwortung fur die Umwelt sowie eine bessere Motivation und ein stärkeres Engagement fur die nachhaltige Entwicklung zu fördern.” (UNCED 1992). Crompton (2010) betont, dass Emotionen und gesellschaftliche, kulturell geprägte Werte einen bedeutenderen Einfluss auf Entscheidungen und Handlungen der Menschen haben, als die Verarbeitung von kognitiven Fakten. Dieses Argument unterstreicht die Unzulänglichkeit rein wissenschaftlich geleiteter Entscheidungsverfahren und die Relevanz der Möglichkeit jedes Einzelnen, an Entscheidungsprozessen beteiligt und in Mitverantwortung gezogen zu werden. Die lokale und regionale Ebene gelten als uberschaubare Systeme gesellschaftlicher Entscheidungen und erfahren dadurch „eine Stärkung im Kontext nachhaltiger sozialer Entwicklung“ (Albert et al. 2001, 15).

3 DAS SZENARIENPROJEKT "ZUKUNFTSVISION KORNEUBURG 2036"

3.1 Korneuburg 2036 – die Stadt und die beteiligten Akteurinnen und Akteure

Die niederösterreichische Bezirkshauptstadt Korneuburg mit rund 12.000 Einwohnerinnen und Einwohnern liegt unmittelbar vor den Toren Wiens, wodurch sich spezifische Herausforderungen für die Gemeinde ergeben. Im April 2012 startete die Stadt, die im Jahr 2036 ihr 900-jähriges Stadtjubiläum feiert, den partizipativen Szenarienprozess "Zukunftsperspektiven Korneuburg 2036", der Ende 2013 abgeschlossen sein soll. Zielsetzung des Projektes ist die partizipative und kommunikative Leitbildentwicklung entlang der Frage "Wie wollen wir im Jahr 2036 gemeinsam wohnen, leben und arbeiten?" sowie die Erarbeitung eines Masterplanes mit Handlungsempfehlungen zu dessen Umsetzung für die nächsten zehn Jahre. Der Prozess wurde vor Beginn der Projektlaufzeit von der Zukunfts Initiative Korneuburg (ZIK) initiiert und an die politisch Verantwortlichen herangetragen, weshalb von einem bottom-up Prozess mit einem hohen Grad an Motivation und Identifikation einzelner Akteurinnen und Akteure gesprochen werden kann. Zur Begleitung des Prozesses wurde ein wissenschaftliches Team mit disziplinären Hintergründen in Geographie, Architektur, Landschaftsplanung, Regionalentwicklung und partizipativen Methoden bestellt.

Die breite Beteiligung der Korneuburger Bürgerinnen und Bürger am Leitbildprozess wurde als ein zentrales Projektziel durch die Initiatoren (ZIK), aber auch durch die politisch Verantwortlichen formuliert und als Auftrag an die wissenschaftliche Projektbegleitung gerichtet. Dem Design des partizipativen Prozesses kam daher besonderes Augenmerk zu. Die Szenarienmethodik erfüllte diesen Anspruch durch ihre Flexibilität und Anpassungsfähigkeit an die Fragestellung, sowie den damit verbundenen kreativen und offenen Arbeitsprozess. Um die Beteiligung der Bevölkerung im Rahmen des Projektes zu gewährleisten, wurde einerseits ein repräsentatives Kernteam (Steuerrad, s.u.) gegründet, dessen Mitglieder die Bereitschaft tragen, das Projekt mit einem hohen Grad an Motivation, persönlichem Zeiteinsatz und Kontinuität voranzutreiben und inhaltlich mitzugestalten. Andererseits wurden gemeinsam mit diesem Kernteam Wege gesucht, einem möglichst großen Anteil der Korneuburgerinnen und Korneuburger die Mitsprache in der Leitbilderstellung zu ermöglichen.

Die Beteiligung unterscheidet sich in der Intensität je nach den Projektphasen und reicht von Information über Konsultation bis hin zur Abstimmung. Besonders während der ersten Projektphase der Szenarioerstellung stehen ein Webblog sowie ein Online-mapping-tool für die Jugendlichen (Youthplaces) zur Verfügung. Um die Erreichbarkeit nicht auf Personen mit Zugang und Affinität zu digitalen Medien zu beschränken, wurde darüber hinaus ein analoges (B)Logbuch zur Verfügung gestellt, das sich auf „Wanderschaft“ in Korneuburgs Lokalen, Geschäften, Einrichtungen,... befindet und an diesen Orten jedermann/frau einlädt, seine/ihre Wünsche und Vorstellungen einzutragen. Die Ergebnisse aus Webblog und (B)Logbuch werden laufend in den Prozess integriert.

Das Steuerrad umfasst 28 Personen (inkl. Vertretungen), die als Kernteam am Projekt arbeiten und stimmberechtigt sind. Vertreten sind neben dem amtierenden Bürgermeister sämtliche politische Fraktionen, die lokale Verwaltung, Zivilgesellschaft und Bürgerinnen und Bürger, die ihre jeweiligen Herkunftssysteme repräsentieren. Zu Beginn des Prozesses wurde gemeinschaftlich eine Geschäftsordnung erarbeitet, die das

Zusammenarbeiten und die damit verbundenen Rechte und Pflichten regelt. In im Schnitt einmal pro Monat stattfindenden Workshops arbeiten Prozessbegleiter und Steuerradsmitglieder zusammen an I) der Entwicklung von 3 – 5 plausiblen, visionären Zukunftsbildern, die einerseits durch quantitative Analysen und Fortschreibungen sowie andererseits durch normative Zukunftsvorstellungen (Visionen, Wunschbilder) der Bevölkerung gestützt sind, II) an einem Design sowie der Durchführung eines breiten partizipativen Rückkoppelungsprozesses (Konsultationswoche), zur Unterstützung der Entscheidungsfindung und der Auswahl eines Wunschszenarios (oder einer Kombination aus mehreren), sowie III) dessen Überführung in ein Leitbild sowie im weiteren die Ausarbeitung konkreter mittelfristiger Handlungsanleitungen zur Erreichung des gewünschten Zustandes (Back-Casting/Masterplan).

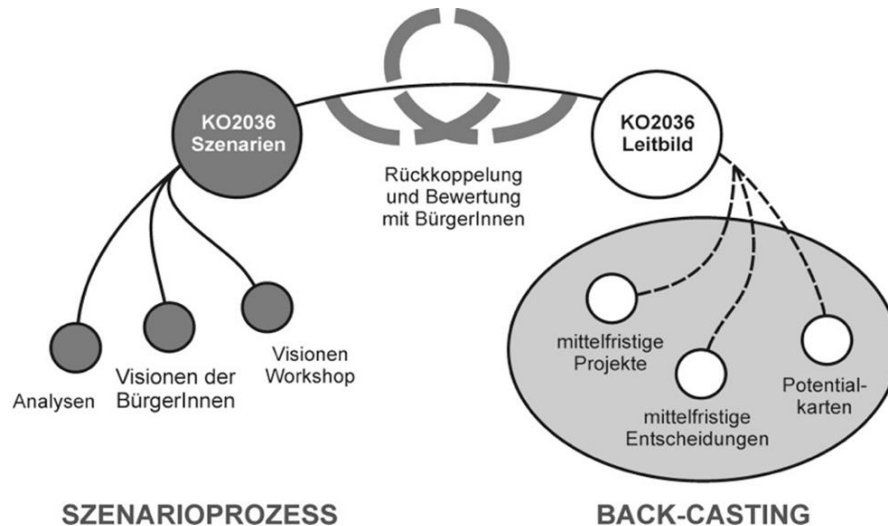
Ende 2013 soll ein breit akzeptiertes und politisch abgesegnetes Leitbild für Korneuburg 2036 sowie der Masterplan für die nächsten zehn Jahre fertig gestellt und der Öffentlichkeit präsentiert sein.


Abb. 2: Prozessdarstellung und Beteiligung im Projekt Korneuburg 2036 (verändert nach Dumreicher 2010)

3.2 Die methodischen Schritte – vom Heute in die Zukunft

Abbildung 3 stellt die Abfolge der methodischen Schritte im Rahmen des Projektes „Korneuburg 2036" chronologisch dar. Die einzelnen Arbeitsschritte werden in den folgenden Kapiteln näher erläutert.

3.2.1 Systemanalyse und Systemabgrenzung – Zusammenschau von externem Expertenblick und Insiderwissen

Die Systemanalyse und -abgrenzung wurde in mehreren Stufen vollzogen. Die Einschätzungen von Wissenschaftlerinnen und Wissenschaftlern sowie lokalen Wissensträgerinnen und Wissensträgern wurden in diesem Prozess erhoben (wissenschaftsgeleitete vs. partizipative Systemanalyse) und die Ergebnisse anschließend synthetisiert.

Zu Projektbeginn stand eine wissenschaftsgeleitete Struktur- und Entwicklungsanalyse (Untersuchung von Vergangenheit, Gegenwart und Zukunftstrends der Stadtgemeinde, quantitatives und qualitatives Systemwissen), deren Ergebnisse mit qualitativen Erfahrungen der lokalen Wissensträgerinnen und Wissensträger (qualitatives Systemwissen) abgeglichen wurden (siehe Workshops). Die Struktur- und Entwicklungsanalyse fokussierte vor allem auf eine Analyse und Bestandsaufnahme der Siedlungsstruktur und Bevölkerungsentwicklung und hatte zum Ziel, die komplexen Zusammenhänge aufzuzeigen, von denen eine weitere Entwicklung abhängen kann und die auf ganz unterschiedlichen Maßstabsebenen wirken. Neben Siedlungs- und Bevölkerungsentwicklung wurden auch die Bereiche „Wirtschaft ", „Verkehr" und „Umwelt" und deren Wechselwirkungen analysiert. Die Ergebnisse geben Antworten auf die Frage „Welche Spiel- und Gestaltungsräume stehen zur Verfügung?", um zukünftige Entwicklungsmöglichkeiten der Stadt hinsichtlich ihrer Machbarkeit zu beleuchten.

In einem nächsten Schritt wurden durch die Kombination der Ergebnisse aus der Strukturanalyse und der Einschätzung der Steuerradmitglieder sieben zentrale Handlungsfelder definiert.

Im Rahmen von Workshops im Steuerrad, zu denen jeweils externe themenbezogene Expertinnen und Experten geladen wurden, wurden die Handlungsfelder gemeinsam diskutiert und die jeweiligen

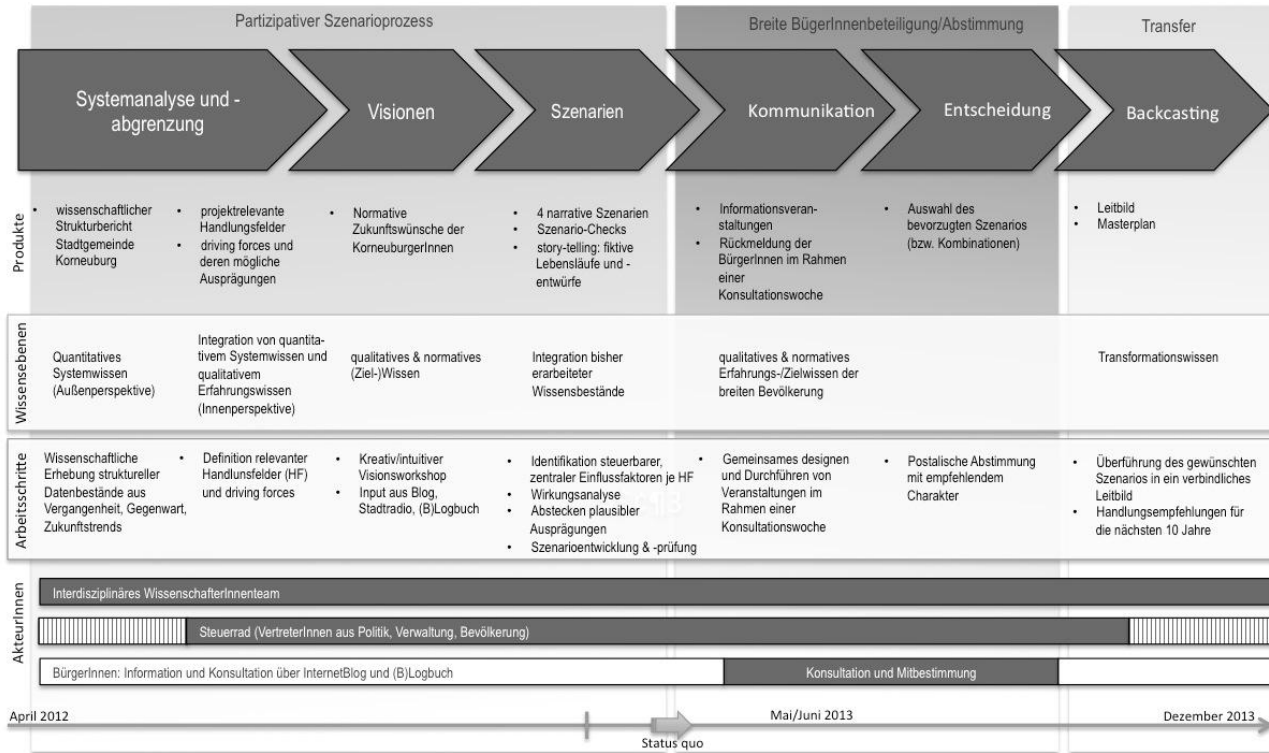
Einflussfaktoren (driving forces) für jedes der Felder abgeleitet (partizipative Systemanalyse). Besonderes Augenmerk wurde auf die Frage gerichtet, welche Faktoren durch Korneuburg (Politik,Wirtschaft, Zivilgesellschaft) selbst steuerbar sind. Im Zuge dieser Workshop fand ein sehr konstruktiver, gemeinsamer Lernprozess statt, der ein individuelles wie auch kollektives Verständnis des Systems Korneuburg entstehen ließ. Die Ergebnisse beruhen auf der Integration wissenschaftlicher Studien und quantitativem sowie qualitativem Datenmaterial mit implizitem Wissen von Expertinnen und Experten aus Zivilgesellschaft, Politik und Verwaltung.


Abb. 3: Prozessschritte im Projekt Korneuburg 2036 – Wissensebenen, Arbeitsschritte, Akteurinnen und Akteure

3.2.2 Die Zukunft hat viele Gesichter – die Integration von visionären Wünschen der Bevölkerung

Um Szenarien entwickeln zu können, die an den Wünschen der lokalen Bevölkerung anknüpfen, wurden in einem nächsten Schritt Zukunftswünsche (Visionen, qualitatives Zielwissen) der Steuerradsmitglieder im Rahmen eines kreativen Visionsworkshops im Steuerrad erhoben. Ergänzt wurden die Ergebnisse durch Einträge im Webblog des Projektes sowie des (B)Logbuchs, welche der breiten Bevölkerung zugänglich sind.

Die Mitglieder des Steuerrades wurden gebeten, in einem lockeren und kreativen Setting Zeitungsartikel zu erarbeiten, die zeigen, wie sich Korneuburg im Jahr 2036 ihren Wünschen nach präsentiert. Daraus entstand eine große Bandbreite an Entwicklungsoptionen, die sich aufgrund der wissenschaftlichen Analyse nicht ergeben hätten, die in weiterer Folge – je nach Realisierbarkeit – in die Szenarien einflossen.

3.2.3 Szenarioentwicklung und Konsistenzanalyse

Die zentrale Vorgehensweise der Integration von Systemwissen und Zielwissen erfolgte über die Szenariomethode, basierend auf Bausteinen der formativen Szenarioanalyse (nach Scholz 1999; 2002). Aus diesem integrierten Wissensbestand wurden für die sieben Handlungsfelder jeweils die relevantesten Einflussfaktoren identifiziert (aus Strukturanalyse und Stakeholder-Workshops). Der Fokus lag dabei auf jenen Faktoren, die durch Korneuburg steuerbar sind.

Die Einflussfaktoren wurden einer Wirkungsanalyse unterzogen, die der Darstellung und Bewertung von Beziehungen zwischen den einzelnen Faktoren dient. Anhand einer Wirkungsmatrix wurden durch das wissenschaftliche Beraterteam die Einflussfaktoren paarweise auf ihre Wechselwirkungen hin untersucht (Skala 0 = keine Wirkung bis 2 = starke Wirkung.). Auf diese Weise lässt sich auch feststellen, wie die

einzelnen Faktoren die Entwicklung des Gesamtsystems beeinflussen (aktive, passive Faktoren, puffernde, kritische Faktoren), siehe Abb. 4.

Cross-Impact-Matrix
Abb. 4: Cross Impact Matrix der Einflussfaktoren

Für jeden dieser steuerbaren driving forces wurden in einem nächsten Schritt basierend auf der Strukturanalyse und Experteneinschätzungen die Bandbreite möglicher zukünftige Ausprägungen abgesteckt.

Aus den Visionen wurden im Anschluss die dahinter stehenden Wertestrukturen abgeleitet (z.B. innovativ, kompetent oder nachhaltig und energieautark). Entlang dieser Wertestrukturen führte das Beraterteam konsistente Kombinationen von möglichen Ausprägungen der Einflussfaktoren zu plausiblen Szenarien zusammen. Diese Szenarien wurden sodann einer paarweisen Konsistenzbewertung unterzogen (vgl. dazu Kirchner-Heßler 2004). Auf diese Weise konnten Inkonsistenzen in den Szenarien identifiziert und durch Adaption ausgemerzt werden. Das Ergebnis sind vier Szenarien, die in der Folge dem Steuerrad vorgestellt wurden.

3.2.4 Robustheitscheck

Um die Szenariogeschichten in Hinblick auf Risiken in der Realisierbarkeit und Umsetzung zu prüfen, wurden diese einem Robustheitscheck unterzogen. Dabei wurde ihre Stabilität in Bezug auf europäische Herausforderungen sowie die Abhängigkeit von nicht beeinflussbaren Faktoren überprüft. Anhand von fünf zentrale Herausforderungen (Europäische Kommission 2011) – Globalisierung, demographischer Wandel, Klimawandel, sichere, nachhaltige und wettbewerbsfähige Energieversorgung und soziale Polarisierung – wurde jedes Szenario hinsichtlich der entstehenden Risiken und Chancen diskutiert. Zwei der Szenarien stellten sich als weitgehend robust gegenüber den Herausforderungen dar, bei zwei weiteren wurde deutlich, dass sich Chancen wie auch Risiken gleichermaßen ergeben. Ob positive oder negative Auswirkungen enstehen, hängt nicht zuletzt von einer bewussten Steuerung ab. In einem nächsten Schritt wurde beurteilt, wie abhängig die Szenarien von nicht beeinflussbaren Rahmenbedingungen, wie z.B. Entscheidungen auf nationalpolitischer Ebene oder Abhängigkeit von öffentlichen Budgets und Förderungen sind.

Beide Analysen zeigten, dass vor allem eines der Szenarien mit einem relativ hohen Risiko behaftet ist, durch äußere Bedingungen in seiner Umsetzung beeinträchtigt zu werden. Im Steuerrad wurde dennoch die Entscheidung gefällt, alle vier Szenarien weiter zu tragen und an die Bürgerinnen und Bürger zu kommunizieren, unter Offenlegung der Risiken und Umsetzungschancen.

3.2.5 Storytelling – vom abstrakten Text zum Leben im Jahr 2036

Um die bislang noch recht abstrakten Szenarien an die Bürgerinnen und Bürger kommunizieren zu können, formulierten die Mitglieder des Steurrads kreative Geschichten und Lebensläufe zu den vier Entwicklungsperspektiven. Sie wurden herausgefordert, allgemeine Eckpunkte auf konkrete Lebenssituationen anzuwenden. Dadurch sollte sich einerseits die Identifikation mit den Szenarien erhöhen und andererseits vom reinen Vorstellen dessen, wie etwas sein könnte, zum individuellen und kollektiven Handeln angeregt werden, das zur Umsetzung nötig ist. Die entworfenen Lebensläufe und Geschichten aus

dem Alltag von Korneuburgerinnen und Korneuburgern im Jahr 2036 dienen als Basis für die weitere Aufbereitung der Szenarien für die Konsultationswoche im Juni 2013 und als Grundlage für eine visuelle Veranschaulichung.

3.2.6   Weitere Projektschritte in der Zukunft

Nächster Meilenstein ist die Präsentation der erarbeiteten Szenarien im Korneuburger Gemeinderat Ende März. Diese dient der Information der politisch Verantwortlichen über den Prozessfortschritt sowie der gemeinsamen Entscheidung darüber, welche Szenarien im Rahmen der Konsultationswoche präsentiert werden und wie die Abstimmung durch die Bürgerinnen und Bürger vonstatten gehen wird.

Ende Mai/Anfang Juni findet die Konsultationswoche statt, im Rahmen derer die Korneuburger Bevölkerung eingeladen ist, sich über die Szenarien zu informieren und Wünsche und Vorschläge einzubringen und zu diskutieren. Eine Kombination aus aufsuchenden Veranstaltungen in einzelnen Stadtteilen und zentralen Präsentationsveranstaltungen soll eine möglichst hohe Beteiligungsquote erzielen. Die Ergebnisse werden im Steuerrad zu konkreten Fragen und Szenarienvarianten verdichtet und schließlich zur postalischen Abstimmung durch die Bürgerinnen und Bürger freigegeben. Das Abstimmungsergebnis wird wiederum im Steuerrad weiterbehandelt und dann als Empfehlung an den Gemeinderat weitergegeben.

4   ERGEBNISSE

Die Wirkungsanalyse der Einflussfaktoren (Prüfen von Aktivität, Passivität und Wechselwirkungen der Faktoren) machte sichtbar, dass im Besonderen die Faktoren „Zahl der Einwohner" und „Schwerpunkt der Siedlungsenwicklung" kritisch für die zukünftige Entwicklung der Stadt und deren Gestaltungsmöglichkeiten sind. Die Frage der Einwohnerzahl war ein von Beginn an sehr kontrovers diskutiertes Thema. Verschiedene Ressentiments und Vorurteile die mit der Vorstellung des Wachstums einhergingen, prägten die Diskussionsrunden. Die Spannbreite der Wünsche reichte vom „Konservieren" der bisherigen Überschaubarkeit, die Korneuburg in den Augen einzelner einen dörflichen Charakter verlieh, bis hin zur Anpassung/Angliederung an das System Wien. In diesem Punkt war die objektive Außensicht besonders hilfreich, um eine realistische Einschätzung kommunizieren zu können. Ein Null- bis Wenigwachstum ist für Korneuburg aufgrund verschiedener Faktoren kaum wirklichkeitsnah.

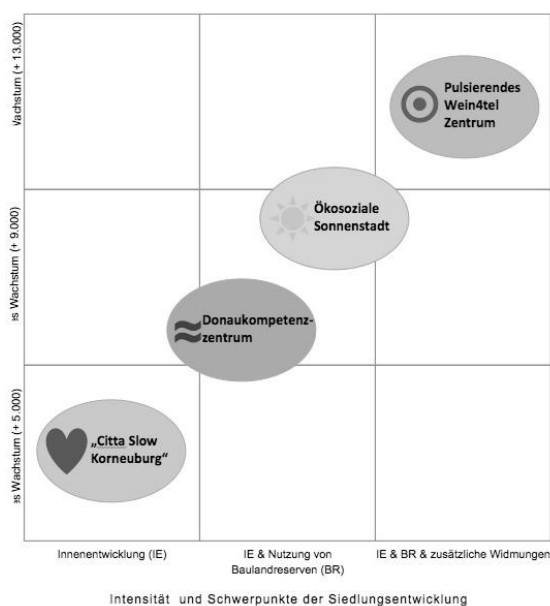
Die vier Szenarienentwürfe unterscheiden sich deutlich bezüglich der zentralen Stellschrauben „Bevölkerungszahl" und „Siedlungsentwicklung" (siehe Abb. 5), die konsequenterweise in starker Beziehung zu einander stehen. Wie sich Korneuburg im Jahr 2036 darstellt, hängt wesentlich davon ab, wie auf den Bevölkerungs- und Siedlungsdruck reagiert wird und welche Strategien dafür entwickelt werden. Doch auch in Bezug auf die anderen Einflussfaktoren sind sehr unterschiedliche Zukunftsoptionen für die Stadt Korneuburg entstanden (Tabelle 1).


Abb 5: Szenariogeschichten in ihren Ausprägungen entlang der zentralen Einflussfaktoren Bevölkerungs- und Siedlungsentwicklung

Szenario 1: Donaukompetenzzentrum Korneuburg	Szenario 2: Ökosoziale Sonnenstadt
Korneuburg hat sich als Zentrum für grüne Zukunftstechnologien etabliert. Technologieunternehmen, Forschungs- und Bildungseinrichtungen und in den Bereichen Wasser- und Umwelttechnologien haben sich am Wissenschaftscampus an der Donaulände angesiedelt und sind über Wirtschaftscluster mit Unternehmen in den umliegenden Regionen verbunden. Der Technologiestandort profitiert auch von seiner Nähe zu Wien und dort ansässigen Firmen, Wissenschaftlern und F&E-Einrichtungen. Die Stadt bietet ein vielfältiges Bildungsangebot an diversen Schulstandorten, aber auch im Bereich der Erwachsenenbildung. Schülerinnen, Schüler, sowie Forscherinnen, Forscher und hochqualifizierte Arbeitnehmerinnen und Arbeitnehmer pendeln aus Wien und der Region nach Korneuburg und beleben das städtische Leben der rund 21.000-Einwohner-Stadt mit urbanem Flair. Bauaktivitäten finden vor allem im innerstädtischen Bereich statt, zusätzlich wird ein junger Stadtteil an der Donaulände/Werft entwickelt. Bei den Neubauten wird auf eine attraktive Grün- und Freiraumgestaltung sowie auf eine funktionierende Nahversorgung und attraktive Sportangebote geachtet, um die Lebensqualität auch in dichteren Gebieten zu steigern. Leistbares Wohnen ist nicht nur im energieautarken, schwimmenden Studierendenheim realisiert, sondern auch durch geförderte Wohnungen in anderen Stadtteilen realisiert. Die Stadt behält ein heterogenes Stadtbild, dichtere Strukturen und lose Verbauung wechseln einander ab. Das neue Donauviertel mit seinem Kongresszentrum ist öffentlich bestens mit dem Zentrum sowie dem Bahnhof verbunden, ein Cityliner mit flexiblem Fahrtendienst verbindet Korneuburg mit Klosterneuburg und Wien auf dem Wasserweg , abgestimmt mit den Fahrplänen der weiteren öffentlichen Verbindungen ins Hinterland. Für jene Personen, die mit dem Pkw einpendelt bietet Korneuburg ein attraktives Parkraum- und Garagenkonzept. Im gesamten Stadtgebiet werden der öffentliche Verkehr mit guter Abstimmung auf Fahrpläne der Regionalbusse sowie Rad- und Fußgängerrouten ausgebaut. Die Energieversorgung ist auf Effizienz und Nachhaltigkeit hin optimiert – Energieautarkie ist ein erklärtes Zukunftsziel.	Korneuburg nimmt als erste energieautarke Stadt Niederösterreichs eine Vorreiterrolle als ökosoziale Stadt ein. Die Energieproduktion übersteigt den Bedarf der Stadt mit rund 22.000 Einwohnern. Korneuburg wurde zum Netto-Exporteur von Energie. Das Stadtbild ist geprägt von dichterer Bebauung, vor allem verdichtetem Flachbau (2-3 geschossig). Die Gebäude sind zum überwiegenden Teil mit Solaranlagen versehen. Der Fokus der Bebauung liegt auf der Innenentwicklung sowie der Erschließung des Zwischenlandes und des Nordrands. Generationen-gemischtes Wohnen hat sich als Erfolgskonzept für Jung und Alt erwiesen. Gleichzeitig weisen Korneuburgs Neubaugebiete einen hohen Grünanteil und hohe Lebensqualität auf, erreicht durch innovative Grünraumgestaltung wie grüne Fassaden, Dachgärten und einer Vielzahl an Flächen für urban gardening und city farming, die das soziale Miteinander beleben und Identität und Zusammenhalt steigern. Vor allem am Donauufer locken attraktive Kultur-, Sport- und Freizeitangebote sowie Erholungszonen. Am autofreien Hauptplatz ist ein mit einem Photovoltaikdach versehener Arkadenbau im Einklang mit der historischen Bausubstanz entstanden. So ist zum einen die Nutzung des Platzes bei jeder Witterung möglich, zum anderen wird so zur Energieversorgung beigetragen. Der modern gestaltete Platz zeichnet sich durch Grünzonen und Aufenthaltsqualität genauso aus wie durch ein qualitativ hochwertiges Einkaufsangebot und einen attraktiven Branchenmix. Der Hauptplatz ist DER soziale Treffpunkt der Stadt. Rege Marktaktivitäten sorgen für die Nahversorgung – u.a. mit Produkten aus der Region – und fördern das Miteinander. Korneuburg bietet eine hohe Quantität wie auch Qualität öko-sozialer Dienstleistungen und hat österreichweit einen hervorragenden Ruf als ökosoziales Innovationszentrum . Klein- und mittelständige Unternehmen profitieren von der kritischen Masse an Solarprojekten und entsprechendem Know-how in der Stadt und haben sich auch international unter den technologieführenden Unternehmen etabliert. Die meisten Wege werden mit e-Autos oder öffentlichen Verkehrsmitteln bzw. auf den gut ausgebauten Rad- oder Fußwegen zurückgelegt. Die Bewohnerinnen und Bewohner übernehmen Eigenverantwortung für ihre Stadt und gestalten das Gemeindeleben aktiv mit.
Szenario 3: Pulsierendes Wein4telZentrum	Szenario 4: Citta Slow Korneuburg
Korneuburg ist DAS Einkaufs- und Dienstleistungszentrum des Weinviertels, das im Handel nicht in Konkurrenzkampf zu naheliegenden Einkaufszentren tritt, sondern sich durch Persönlichkeit, Kundennähe, Flexibilität und Aufenthaltsqualität sowie durch die hohe Qualität regionaler Produkte positioniert. Das Stadtbild ist von urbanem Charakter und von dichter Verbauung geprägt – bei gleichzeitig sorgsamen Bedacht auf den Erhalt der historischen Bausubstanz. Sämtliche Baulandreserven (Stand 2012) wurden bebaut und zusätzliche Widmungen an den Rändern vorgenommen, wo neue Stadtteile entstanden sind (Zwischenland, Nordrand, Donau). Nach den jüngsten Eingemeindungen zählt Korneuburg 30.000 Einwohnerinnen und Einwohner (davon ca. 20.000 im ursprünglichen Stadtgebiet). Das differenzierte Bildungs- und Dienstleistungsangebot, städtischer Lifestyle und der pulsierende Hauptplatz ziehen Menschen aus allen Teilen des Weinviertels an und machen Korneuburg zur sozialen Drehscheibe im Wein4tel. Das städtische Leben ist geprägt von Barrierefreiheit und Offenheit. Die öffentlichen Verkehrsanbindungen in die Region wurden intensiv ausgebaut (z.B. S-Bahntangente Krems-HL-KO-GF-MB) ebenso wie die Verbindungswege für den motorisierten Individualverkehr, z.B. ein durchdachtes Park- und Garagensystem. Korneuburg bietet mit der großen Bandbreite an sozialen Dienstleistungen und einen umfassenden Branchenmix attraktive Arbeitsplätze für die Stadt und die Region. Ein buntes Angebot an kulturellen und touristischen Einrichtungen und Events belebt die gesamte Stadt, vor allem auch das neue Wohn- und Freizeitviertel an der Donau (Strandmeile mit Bars, Kultureinrichtungen, Hotels, Kino), das mit öffentlichen Verkehrsmitteln und weiteren Straßenverbindungen direkt vom Stadtzentrum aus rasch erreichbar ist.	Nähe, soziales Miteinander und Lebensqualität werden in der eigenständigen Kleinstadt Korneuburg groß geschrieben. Das Erscheinungsbild ist geprägt von suburbanem Charakter, kleinen und individuellen Einheiten und einem großen Ausmaß an öffentlichen Plätzen und Grünflächen, die zusammenhängende Grünachsen durch das gesamte Stadtgebiet bilden. Das Angebot in der rund 18.000-Einwohner-Stadt ist vor allem für junge Familien aber auch die älteren Generationen attraktiv. Barrierefreiheit ist im Wohnbau sowie im öffentlichen Raum ein wichtiges Thema. Der städtische Verkehrsraum ist für Fußgängerinnen und Fußgänger optimiert, die Stadt der kurzen Wege ein gelebtes Ideal. Der verkehrsberuhigte Hauptplatz ist ein beliebter Aufenthaltsort, der für alle Generationen attraktive Angebote (Kinderspielplatz, Grünflächen, Cafes etc) bietet. Der entschleunigte Lebensstil erlaubt es, dass der Mensch im Mittelpunkt steht. Das Donaugelände ist ein beliebter Ort der Erholung. Radfahrerinnen und Radfahrer am Donauradweg machen gerne einen Abstecher auf den einladenden Hauptplatz wo spezielle Angebote (Cafés, Restaurants, geführte Stadtspaziergänge, E-Tankstelle, Fahrrad-Reparatur, Kleinkunst etc.) auf sie warten. Korneuburg ist auch ein attraktives Ausflugsziel für Personen aus Wien und dem Umland, die das gemütlich kleinstädtische Flair und das Angebot in puncto Kleinkunst und sanftem Tourismus schätzen. Neue Wohnungen wurden vor allem im zentralen Bereich errichtet (Innenentwicklung), wobei auf kleinteilige Einheiten und flexible – der jeweiligen Lebensphase angepasste – Wohnformen gesetzt wird. Autofreie Plätze, Märkte mit regionalen Produkten, Cafés und kulturelle Angebote beleben den Alltag in der Kleinstadt. Gelebte Nachbarschaft, soziale Dienste, hochwertige Kinderbetreuung und qualitative Altenversorgung sind das Aushängeschild der Stadtgemeinde.

Tabelle 1: Entwicklungsszenarien Korneuburg 2036

5 DISKUSSION UND AUSBLICK

Der noch andauerende Prozess zeigte bereits, dass die Szenariomethode ein hilfreiches Tool zur Integration verschiedener Wissensebenen darstellt. Sie schuf darüber hinaus einen Rahmen für soziales Lernen und ließ aus einem sehr partnerschaftlichen Prozess eine gemeinsame Identität und Zusammenhalt unter den Beteiligten vor Ort entstehen, die in weiterer Konsequenz durch ihr individuelles und kollektives Handeln

zur Realisierung des Stadtleitbildes beitragen müssen. Nicht zuletzt fand ein spannender Lernprozess für beide Seiten – Wissenschaftlerinnen und Wissenschaftlern sowie lokalen Expertinnen und Experten – statt, der neue Eindrücke und Erfahrungen über Erkenntnisgewinn und den Umgang mit Unsicherheiten hervorbrachte.

5.1 Kontinuität und Wertschätzung im Projekt

Obwohl seitens der Steuerradsmitglieder ein vergleichsweise hoher Zeiteinsatz gefordert wird, zeigt sich eine relativ hohe Kontinuität der Beteiligten, was vermutlich auch auf die bottom-up Genese des Projektes, zurück zu führen ist. Einzig für die Vertreterinnen und Vertreter der lokalen Wirtschaft ist es problematisch, konsequent an den Sitzungen teilzunehmen, da die geschäftlichen Verpflichtungen sich mit den Terminen z.T. überschnitten (Weihnachtsgeschäft, Lange Einkaufsnacht etc.), hieraus entsteht Handlungsbedarf für zukünftige Projektvorhaben. Innerhalb des Steuerrads herrscht eine sehr wertschätzende Grundhaltung, die eine konstruktive Diskussion und Zusammenarbeit, auch über politische Fraktionen hinweg, und im Dialog mit den Bürgerinnen und Bürgern ermöglicht.

Die Entscheidung darüber, wie der Beteiligungsprozess (Einbindung der breiten Bevölkerung und Entscheidung über das gewünschte Szenario als Grundlage für ein Leitbild) gestaltet wird und welche Rolle den Bürgerinnen und Bürgern dabei zukommt, wurde dem Steuerrad überlassen. Daraus wird auch das hohe Maß an Vertrauen, das dem Prozess seitens der Stadtregierung entgegengebracht wird, deutlich. Das Steuerrad entschied sich für eine Informations- und Konsultationswoche (s.o.) mit anschließender postalischer Abstimmung und überstieg mit diesem Entschluss letztlich die Erwartungen des Betreuerinnen- und Betreuerteams, da zu Beginn des Prozesses lediglich ein formloses Bewerten der Szenariengeschichten angedacht war.

5.2 Die Szenariomethode als Rahmen zur Wissensintegration

Der methodische Zugang ermöglichte es, quantitatives und qualitatives Systemwissen, Zielwissen und Handlungs-/Transformationswissen zusammenzuführen. Dass die Integration dieser Wissensbestände nicht ein rein summarisches Zusammenfügen von Forschungsergebnissen und Expertinnen- sowie Experteneinschätzungen am Ende eines Projektes sein kann, unterstreicht Truffer (2007): die Frage der Wissensintegration darf nicht als eine rein technisch-organisatorische diskutiert werden, sondern ist vielmehr "als aktiver sozialer Konstruktions- und Aushandlungsprozess zu verstehen". Wissensintegration kann demnach als gemeinsamer Lernprozess verstanden werden, der wiederum neues Wissen generiert. Dieser Lernprozess fand für die wissenschaftlichen Begleitung und die Beteiligten vor Ort gleichermaßen statt. So mussten Kompromisse darüber eingegangen werden, was die „richtigen Annahmen" oder die „Wahrheit" darstellt und es musste ein Verständnis darüber geschaffen werden, dass mit Unsicherheiten auf verschiedene Weisen umgegangen werden kann. So konnte z.B. die Festlegung der relevanten Handlungsfelder nur durch eine gegenseitige Annäherung in einem Aushandlungsprozess vorgenommen werden. Der Robustheitscheck der Szenarien ergab wiederum, dass ein Szenario aus externer Expertinnen- und Expertensicht mit einer zu hohen Unsicherheit verbunden ist und damit nicht zur Umsetzung empfohlen werden kann. Die lokalen Beteiligten entschieden trotz dieses Risikos, dieses Szenario weiter zu bearbeiten. Darin liegt eine wesentliche Herausforderung transdisziplinärer Projekte – zu lernen, dass die wissenschaftliche, objektive Aussensicht oftmals nicht genügt und nicht immer mit subjektiven Erfahrungen vor Ort korreliert.

5.3 Die Szenariomethode als Beitrag zu sozialem Lernen, Sense of Coummunity und Identität

Die klare Untergliederung der Szenariomethode in einzelne, gut abgrenzbare Teilschritte stellt für die Anwendbarkeit in einem partizipativen Lernprozess einen Vorteil dar: Das gemeinsame schrittweise Erarbeiten der Szenarien ermöglicht ein hohes Grad an Identifikation und Motivation durch die Teilnehmerinnen und Teilnehmer (Kirchner-Heßler 2004). Als essentiell stellt sich dabei die kontinuierliche Beteiligung der Akteurinnen und Akteure am Planungsprozess dar, um Brüche im Wissensstand und Planungsablauf zu vermeiden (Kirchner-Heßler 2004).

Gleichzeitig wird ein gemeinsames Lernen der Beteiligten gefördert, die einerseits einen Einblick in das zu untersuchende System und dessen Entwicklungsdynamik erlangen, aber auch für die Verantwortung des individuellen und kollektiven Handelns sensibilisiert werden. Das Verstehen von Systemen (z.B. kommunale Entwicklung) sowie der Dynamik der Einflussfaktoren trägt dazu bei, die Komplexität analytischer zu

begreifen, das eigene Handeln und dessen Konsequenzen zu erkennen und Bedarf in der Änderung von Verhalten zu sehen. Durch die individuelle Betroffenheit und die kollektive Auseinandersetzung mit einer gewünschten Zukunftsgestaltung des gemeinsamen Lebensumfeldes (Gemeinde, Region) ist von einer steigenden Umsetzungswahrscheinlichkeit auszugehen.

Der Einsatz der partizipativen Szenarioplanung in der städtischen Entwicklung ermöglicht demnach einen Erfahrungsraum für kollektives soziales Lernen, in der partnerschaftlichen Auseinandersetzung über die Frage, was erwünschte nachhaltige städtische Entwicklung auszeichnet und welche Handlungs- und Verhaltensweisen in der Gegenwart erforderlich sind um die gesteckten Ziele zu erreichen.

1 ABSTRACT

This research deals with several problems of the contemporary city – problem of administrative boundaries and relationship between the city and its public spaces.[1] Cities are ever increasing, often uncontrolled and rarely planned as a whole, almost always without thinking about city's identity. Furthermore the problem of boundaries in general is evident in the periphery which is undeveloped edge of the city. In Croatia boundaries are an obstacle to urban planning, they make it difficult to overview the entire space of the city because its illogical divisions. What is an urban landscape and how it can contribute to development of the new image of the 21st century city is a current theme of planning (eg. Grand Paris considerations). At the Faculty of Zagreb cities from different regions are being researched through a series of workshops in Landscape Architecture and Urbanism. The aim is to reject administrative boundaries in order to create new area of a city based on the landscape.

We analysed current trends in urban planning with the landscape as a main resource, connecting separated city units and periphery. There are three types dealing with the activation of public spaces: first is about different highlines (Paris, NewYork, Rotterdam), second is about linear parks systems above infrastructure (Milano, Barcelona) and third are waterfronts (along canals, rivers and coastlines). Case study for this article demonstrates how these examples and world trends can be used to connect two cities in a logical way – beyond boundaries. The motto of graduate work was: the future of the city will be created on the periphery as the core is taken by the history. Project result is connection of the ancient city of Salona with the current centre of the city Split – the historic and world heritage Diocletian's Palace. The connection is achieved through linear park.

2 INTRODUCTION

Urban settlements (towns and cities) are never completed duo to continuous changes in spatial treatment and way of life. However the city until the 19th c. had a clear edge with its fortifications of bastions and lawns of glacis. This fortification space frame was in the 19th c. used for new roads, public buildings, parks and walkways creating new urban, representative, social and public places for future city perimeter. Since then cities are growing and old boundaries are being erased, merging the city with suburbs, regions and landscape. Administrative boundaries are a necessity for effective functioning of the city. Today different administrative networks share common role in organizing political, municipal and economical life of the city, region or country. All together, while special boundaries are disappearing, administrative boundaries are being determined. As a consequence urban planning is becoming more challenging discipline which needs to mediate between both administrative directive and special facts in growing urban areas.[2]

3 THEORETICAL BACKGROUND

3.1 City and urban landscape

Since the 18th c. landscape architecture has an important role in shaping of urban space and it affected on public places in various ways. Viennese Ringsstrasse and Zagreb Horseshoe are models for how urban landscape can influence upon the urban surrounding of public buildings and special connection. Landscape architecture can induct cultural, social and urban process of development, like the Central Park in New York, or it can be financial basis in living areas as it is with Regent's Park and squares in London. It is also an element of urban representation – avenues and boulevards of Paris and other cities. Some of these places have different aim: places of city excursions and recreation (Maksimir in Zagreb, Bois de Boulogne forest in

---

Paris, Prater and Augarten in Vienna etc.), or places of daily rest (thematic parks, park squares, pocket gardens etc.).[3]

Fig. 1: Zagreb Horseshoe; Viennese Ringsstrasse; New York Central Park; London Regent's Park; Paris La Villette[4]

In theoretical thinking of the city concepts every time has its characteristic idea, like green belts in the 19th c. Europe replacing city fortifications, or large recreational space in American cities at the same time. In the 20th c. there is the landscape concept of garden city and its counterpoise modern urbanism where quantitative criteria of "empty or green" space are the main element of the void among the city structure. At the end of the 20th and the beginning of the 21st c. there are new rethinking of the cityscape and landscape in general out of which new deconstruvistic parks (La Villette) are created in the context of the transformation of cities. This initiated a global process of affirmation of landscape architecture and also the development of new urban-landscape theory such as New Urbanism, Landscape Urbanism and Ecological Urbanism. While the New Urbanism aims to make contemporary interpretations of historic urban patterns, Landscape Urbanism seeks to comprehensively address to the spatial and social problems of the city by offering a socially active urban space. Ecological Urbanism logically carries on ideas of Landscape Urbanism with strong ecological approach adequate to the contemporary times. Landscape Urbanism as a new paradigm o the 21st c. has had the most influence in Europe practice. Town planning in the spirit of Landscape Urbanism is not based upon territorial city growth but upon reaffirmation and rediscovery of neglected and ignored city space, connecting them into system for the new urban image guided by landscape beyond the boundary division.[5]

3.2 Landscape Architecture Workshop at the Faculty of Architecture in Zagreb

Series of Master Workshops and Master Thesis within topic of Urbanscape Emanation[6] are being held since 2010 at the University of Zagreb on a described theoretical basis. The main goal is rediscovery of space led not by administrative and existing situations but guided by impressions – modification of consciousness. Most important part of the Workshop is research work where by mapping and analysing we search for the meaning of time and structures in the space. Students choose a task and the space they wish to research and design and in this way Croatian cities from different regions are being compared and analysed in the context of contemporary examples of town planning in which landscape architecture is primary medium for more humane-scaled planning and protection of heritage and public space.

4   LANDSCAPE AS A CONNECTION

Cities in current planning are viewed more as dynamic systems and less as a formal and static configurations and constellations. Squares, parks and districts known to us as traditional urban typologies, are fading in their design meaning. Meanwhile contemporary city is shaped by infrastructure (indeterminate by space boundaries) and its network that envelops the whole city and more.[7] Out of this contemporary projects there are three types of urban landscape, described in next segments of text and all of them establish connections of public, multipurpose places.

4.1 Highlines as Airscape

Reshaping and transforming character of space by reaffirming it through landscape architecture often leads to the creation of new pedestrian walkways and bicycle paths which rise above the level which can be achieved also by lowering the existing level of vehicular traffic. Those are contemporary promenades and James Corner's project with Diller Scofidio+Renfro – High Line of New York City[9] – shows how this concept can become a great success for inhabitants and tourist. This is an urban renewal project which has transformed unused elevated freight rail line into a 1.6 km public space and extraordinary touristic attraction on the West Side of Manhattan. The project has its conceptual origins in 4.7 km green belt that follows the old Vincennes railway line in Paris called Promenade plantée designed by landscape architect Jacques Vergely and architect Philippe Mathieux and opened in 1993. High Line has opened its first stage of the project in 2009, second in 2011 and third is under construction. Since than many cities are thinking about the elevated parks and airscape projects of transformations in urban fabric. There are plans for 4.3 km Bloomingdale Trail in Chicago; also for an old Reading Viaduct elevated rail in Philadelphia; old railway arches at the Bishopsgate Goods Yard in London. Location of another old elevated track which is being considered for new park and shops can be found in Rotterdam. This success is a result of attractive mix of today increasingly popular walkspace and walkscape.[10] Humans have always had the need to have a better view, which is probably why we have stood ourselves on two feet through evolution.

Except the highline there are many other new types of airscape in general that can be seen as contemporary landscape architecture projects with interventions of elevating from the ground. They can be lifted structures like the highline itself is (Tiger and Turtle, Magic Mountain 2011; Tezuka Architects, Ring around Tree, 2011) or they can be in close connection with the landscape which they emphasizes (Massimiliano Fuksas, The entry in the cave Niaux, 1993; Reiulf Ramstad Architects, National touristic route Trollstigen, 2010).[11] These projects help the communities and small neighbourhoods to be better connected with healthier urban environment and more profitable touristic public spaces.

4.2 Linear parks above and along the traffic and infrastructure

Similar to the highlines but in much larger scale there are linear parks systems or even networks for the new future image of the cities. La Sagrera linear park,[12] a project for Barcelona diagonal green axis by West 8, 2011, connects Natural environment of the City: sea and the mountains, bringing the City strong ecological mark for this European metropolis. It is counterpoint to today's backbone of the city Diagonal Avenue with shaded way for the pedestrians, bicycles and skaters through neighbourhoods, El Clot Park, historical gardens and installations of fountains. Inspired as a solution for the new railway connections this linear park has underground and ground traffic depending upon the urban situation through 40 ha of urban landscape. After huge city road in Madrid went down below the ground a large linear park along the river Manzanares was built. It is a project that consist of 6 parks, city beach, recreational and cultural space and it is called

[10] Walkspace = space of motion, space where we are moving; walkscape = places that we observe during the motion.

[11] This is a part of the student seminar, author Jakov Fatović, univ.bacc.ing.arch., mentor: Prof. Bojana Bojanić Obad Šćitaroci, PhD, from course: Contemporary Landscape Architecture at the Faculty of Architecture University of Zagreb

[12] http://www.west8.nl/projects/sagrera_linear_park/?s=Sagrera %20Linear %20Park [28.2.2013.]

Madrid Rio.[13] Altogether there is 30 km of bicycle routes, 33 pedestrian bridges and more than 30000 new trees. This project revitalized the town on the other side of the river and made possible future development of the city. Both project give strong landscape concept to the city, more ecologically aware image. In this scale city is planned together with its periphery and further with its surroundings, respecting the historical urban patterns but giving it new idea(s) in dealing with contemporary problems of city growth. Madrid Rio is at the same time part of the subgroup type of waterfront projects.

4.3 Waterfronts

Waterfronts are fortunate to have the natural element of water as attraction and motivator for relaxation and recreation. Its shoreline area can be the edge of the sea, lakes, rivers or canals, all places that are attractive for designing and redesigning in the new spirit to make them more active in the cities life. Research project that deals with this topic is called URBEM[14] (Urban River Basin Enhancement Methods).

One of the most known contemporary project is Irwell City Park[15] in Manchester from 2010, FoRM ass., in which along 8 km of new vision for the river and its corridor cities conurbation is connected. It connects also two parts of the city on the other side of river by creating new and regenerating areas that have become isolated and fragmented. Toronto has developed explicit strategies of different relations of the city user and the shore of the lake Ontario. Grand Paris[16] – Axe Seine is solution for Grand Paris by the author Antoine Grumbach, it follows and creates linear network of extended community of the Seine which goes beyond city boundaries and landscape creating connection from Paris to Le Havre.

Waterfront projects in urban space are attractive but delicate places which have particular surprising and valuable natural feature. Waterfront landscape is logical in its appearance but it is hard to articulate relationship between its elements and the city.

4.4 Comparison of urban landscape concepts

By these three types of urban landscape it is possible to distinguish some of the themes at Landscape Architecture Workshop and Master Thesis in Zagreb. The knowledge gained through the analysed project samples is first interpreted and readjusted to the scale and space and then applied adequately in the solution concepts in both urban or landscape environments or scenarios.

4.4.1 Lungomare Airscape

Intersection of Urban and Natural Scenery of the Brač Island[17] is the name of Master Thesis at one of the south islands of Croatia in Adriatic Sea. Island was recognized in division of its north / urban side (with the large number of settlements), and south / landscape side (with only one bigger settlement – Bol). Due to the topography, this touristic attractive island especially south side can't be connected by lungomare at the coast. That is why in this thesis lungomare is displaced along the top contour of the Island where urban and landscape side of the Island meet (fig. 3). This kind of project where different and many settlement units need to work together in common goal are rare because it is hard to make an agreement from all sides, although the Master plans for islands in Croatia need to be done for the whole islands. The quality of this project is that it uses existing pathways (pedestrian, bicycle or road) to connect interesting viewpoints, historical and new landscape places. It becomes airscape of "elevated lungomare" making it possible to put it into realization almost immediately.

Fig. 3: Elevated Lungomare. Project for island of Brač – author: Nera Nejašmić (footnote 17)

4.4.2   Infrastructural re-use

Two projects can be compared with the examples of highline and linear parks along infrastructure. They are somewhere in between this two types creating the linear landscape along forgotten historical road Napoleon road at the Pelješac peninsula or unused railroad south of Dubrovnik in Konavle.[18]

They are both the results of the Landscape Architecture Workshop projects and the first one is named Napoleon's road of Pelješac – Touristic and Recreational Route and it re-activates 61km of historically strategically important road along the peninsula making accessible 48 of historical localities around the road from prehistory to the 19th century. Second work called Konavle-Reactivation of Railroad aims to, like High line, redefine in War (nineties of the 20th c.) destroyed rout. It is situated in the topographically demanding area, which is why this rail is an engineering achievement and it gives a lot of spectacular views and ambience. Altogether it connects the southernmost parts of the Croatia in the interesting manner making it very important for the whole country.

Fig. 4: Reactivation along Infrastructure. Project for peninsula of Pelješac – author Dijana Pavić, project for region of Konavle – author Marija Milić (footnote 18)

4.4.3   Waterfront connection and comparison

Croatian littoral is characterised by its coast with numerous islands along the eastern side of the Adriatic Sea. To make this attractive and interesting landscape a vivid place during the whole year, it`s necessary to put into network a hinterland, mainland and islands. This theme was a part of research in one Master Thesis of Zadar Archipelago, where analysis was based on historical processions and nowdays migrations and processions in order to explain and direct new future processions as the east-west connection.[19]

Here we want to show how waterfronts are very important topic for Croatia, especially in the Mediterranean part on the coastline, but also in the continental part at the shores of rivers. In Mediterranean coast we can compare two approaches in different cities with the Toronto waterfront.

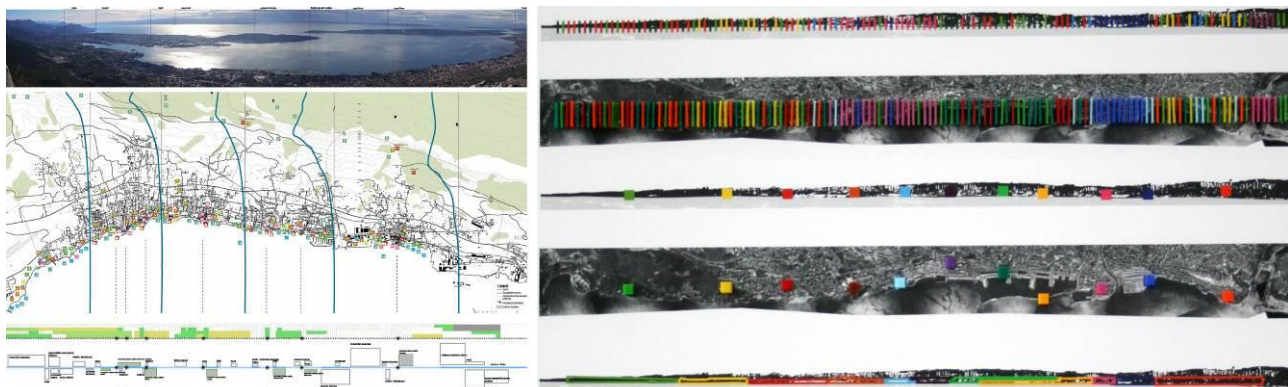
In Kaštela – the linear city between the city of Split and Trogir – urban promenade as real lungomare was suggested.[20] It is very important project because its linear structure is very hard to organize and because of it Kaštela are divided into 7 segments without the sense of one city. Public space that would be gained is the best possible way of connection to achieve this. Minimal interventions are needed for the beginning part and after that it is up to users and community to make an effort for improvements in different parts and places which is the main difference from the serious strategically organized interventions in Toronto. More like Toronto, project in Rijeka deals with the problems of the largest port city in Croatia.[21] Its coast is almost nowhere accessible for the public and now when the most of the industrial buildings are shut down revitalisation is necessity. In Master thesis for the coast of Rijeka it was attempted to put it into realization by organizing coast in frames of Waterfronts with different ration of interventions inside of them.


Fig. 6: Waterfronts in the Mediterranean Croatia. Promenade project for the linear city of Kaštela – author: Batina Iva, project for the coast of the city of Rijeka – author: Marija Peranić (footnote 20, 21)

In continental Croatia waterfronts are a part of relationship between Rivers and Cities. Two larger cities in this Region are the special cases of this relation. Capital city was until 1960's situated between river Sava and mountain Medvednica with little connections to the river. When the city crossed the river a new part of the city was created in the spirit of modern urbanism. Today still this isn't the city at the river but the city cannot ignore that a river is running through it. That's way one Master thesis of Landscape Architecture tried to establish the logical connections of the city and the River without ruining the relationship between them in the way it has been for centuries.[22] And in the East Croatia Osijek is very specific city situated only on one river bank of Drava. Another Master thesis deals with this type of city by saving the landscape for the time

5 CASE STUDY: URBAN LANDSCAPE OF THE CITY OF SPLIT

Here is an example of how urban boundaries can be non effective in the urban planning of region and the city. The subject of research is the Mediterranean city of Split. It is topographically a peninsula which ends with another peninsula called Marjan.[24]

Long ago when Split was just a small settlement, in the north on the Jadro river delta there was the ancient city of Salona, which was a Greek harbor and later a grand Roman city. Salona is the real beginning of the city of Split. In the late 4th century AD Diocletian's Palace, was built on the site of a former village. This royal palace was (and still is) a unique Roman building large in scale and situated on the periphery of Salona and is now part of UNESCO World Heritage list. In 6th century AD residents of Salona fled from the Avars´ invasion settling in the old royal palace which soon grew into a medieval burg. That is the story of Split´s origin. The growth of the city was slow and gradual during a long period of time. As opposed to the centuries of slow growth, during the 20th century the city of Split rapidly widens its built territory. Back than Solin with the archeological park Salona was administrative part of the city of Split as its distant periphery. Today (when Solins is indeed periphery of Split) it is not the case, boundaries are separated, Solin is town and the city of Split is now peninsula where a huge urban expansion in the 20th century leaves the city with very few urban open spaces except with a huge landscape area of the Marjan peninsula.

Fig. 7: The City of Split: peninsula city, Diocletian Palace, Diocletian Aqueduct, Salona roman amphitheatre (footnote 24)

5.1 Connections beyond Boundary

Marjan park-forest is the most precious part of landscape in the city surroundings. It is the space of walkability, recreation, culture and strong history and due to that if was an impulse for designing an urban landscape of the city of Split as a Master thesis assignment. With the motto of graduate work: the future of the city will be created on the periphery as the core is taken by the history, this research and design aims to connect two cities (Split and Solin) in a logical way – beyond boundaries – connecting Marjan park-forest, Diocletian's Palace, City and archeological park Salona.

[24] MARIĆ, Tamara: Landscape Planning of Split Urban Peripheries – Walking Choreography,Visual Illusions and Waiting Areas. Master Thesis, 2011, Faculty of Architecture, University of Zagreb, mentor: Prof. Bojana Bojanić Obad Šćitaroci, PhD.

Marjan landscape is the formula for how public spaces should be formed and designed only in urban character in order to achieve a healthier city with healthier inhabitants. Also reversed, with this kind of approach to the city planning, awareness about the Marjan peninsula values and problems can be induced. And with time more attention would be given to the forest and the coast of Marjan as a consequence of a Mediterranean lifestyle with more tourists actually visiting the city of Split instead of just passing by and through the city.

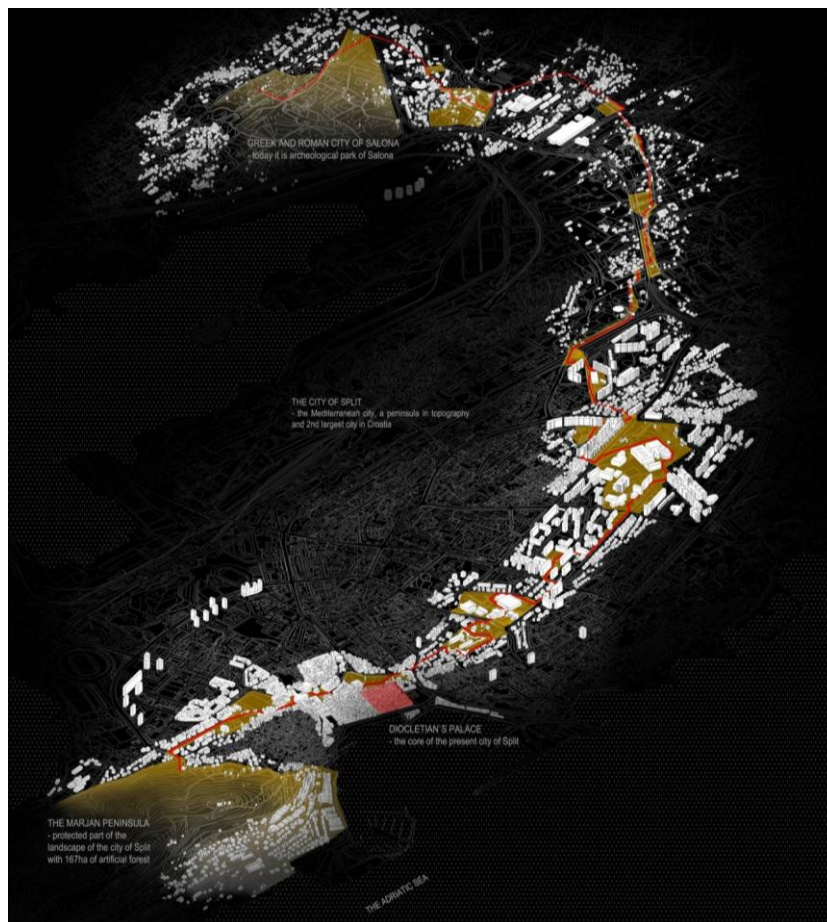
Fig. 8: The City of Split Interventions: new usage, elements of shades and new Park of Aqueduct (footnote 24)


Fig. 9: Linear Landscape of The City of Split – author: Tamara Marić

In order to carry out this concept, linear space was divided into five urban areas between the Marjan peninsula and Salona Park: 1) the historic and social nucleus with Diocletian's palace 2) Gripe fortress connected with Gripe sports and commercial centre 3) residential areas 4) university campus 5) contemporary periphery along road entry to the city of Split. In every area suitable interventions were proposed considering urban existing conditions and master plan. It is necessary to make small interventions in public space of the core (Diocletian's Palace, the fortress) and in the residential areas around its museums, schools, parks, grove, avenues, and sight-seeing points, such as: considering other purposes, ways of using the space, planting trees, or changing path material. In the city core re-using and re-designing public space is necessary and economically acceptable intervention. In residential areas it is necessary to create places of

shade and "soft facade" in order to activate open spaces in-between the buildings. By creating and adapting these places, the landscape would come to life and neighbourhoods would accomplish great walkability with many health, environmental, and economic benefits. On the other hand, only one large intervention is enough to connect Marjan and Salona all the way and for that in the periphery – the Aqueduct Park was proposed. It is a cultural park along the Diocletian aqueduct remains, from the University campus to Salona as an amplifier of the importance of the Diocletian's Palace. Interventions are mapped and visualized and connections are designed through solution of public transport line, bicycle route and places of waiting at the viewpoints.

5.2 Resulting urban landscape – The Pulse of the City of Split

This Mediterranean city landscape of history, urbanism, society and culture – The Pulse of Split – connects the city core (Diocletian's Palace) with the periphery and with its historical core, the Greek and Roman city of Salona. It also links the Marjan peninsula on one side and its present archaeological park Salona on the other. At the same time it passes through all historical levels of the city urban development, which gives different features to the landscape. By this it has joined towns making it possible to stay as two administrative units but united around the same interests for the future.

Indeed, urban landscape here becomes the pulse – the heartbeat of the city because it connects everything important about this city with a contemporary approach to landscape space as a walkscape thus reminding the city of the things it has forgotten about.

6 VALORIZATION: "LANDSCAPE IN-BETWEEN, WHY AND WHAN?"

In this research contemporary projects have been explained through categorisation in three themes: airscapes (highline projects as a part of it), linear parks above and along the existing and active traffic and infrastructure, and waterfronts. All three have in common that they give public land for the public good by transforming public space into vivid public places for the citizen and tourists. In this way landscape is seen as opportunity for regeneration or/and city development and better growth. Many projects belong at least partially in more than one of these types, by which they show how this categorisation is not mutually exclusive. Highlines are in one way linear parks but on the former infrastructure of transportation, now becoming infrastructure of different kind – infrastructure of walkspace and walkscape. Linear parks category includes projects of greater area and systems of urban landscapes along either diagonal or linear corridors. Sometimes it can be in relation to the water element in the city (Madrid Rio) becoming also waterfront which gives it higher value and justification. Waterfronts are project which are not only placed on the shores but also planned and designed primarily as relation to the sea, river, canal or lake.

These categories are compared to the projects for the Landscape Architecture Workshop and Master Thesis in Croatian cities at the Faculty of Architecture in Zagreb. Projects have been chosen carefully so that they can be compared with classification above, but bearing in mind the scale, reach and possibilities of Croatia. Therefore the division is not taken literally, but is carefully and purposely adjusted. In airscape example of Brač it is shown how lungomare can be a variation of this category. Infrastructural re-use is in Croatian scale between highlines and linear park category, because bigger linear parks would not be economically possible in Croatia, at least for now, but even more importantly they are not necessary or a priority due to large number of National Parks and other protected landscapes at the state level. Werfronts are shown through more projects because they are in Croatia a very important and delicate topic. Also here landscape of water itself is a way of connecting the parts in a unit, we just need to make this connection happen in a positive way.

These project proposals are developed by students under the mentorship of Prof. Bojana Bojanić Obad Šćitaroci, PhD. at the faculty during one semester and the idea is to show to the public administrations how they can use and direct their urban and regional planning or design to improve tourism, living and nature. Most of the projects have been presented to public (Brač, Zadar and Rijeka) and reactions from the inhabitants were excellent. In Bol on Brač lungomare airscape was presented together with the exhibition in the summer program.[25] In Zadar the office for space planning was interested in this project and they have taken it into consideration. Other projects have been carried on in the workshops, for example in Split

---

[25] http://www.boljani.info/images/stories/2011/poster-smanjeno.jpg [28.2.2013.]

workshop called Marjan 2011,[26] in Dubrovnik workshop the research work of Dubrovnik surroundings (Kaštela and Pelješac including) was presented and further developed. In Kaštela there was an international workshop dealing with lungomare promenade called 7 Bisera Kaštela-Croatia.[27] It is difficult to make an impact on the administration of cities but the attention was turned to the problems and possible direction for solutions were shown.

7 CONCLUSION

Important part of this research was to show how boundaries are necessary, but they can be limiting in the process of urban planning. It offers also a possible solution for this conflict in the form of using landscape architecture in planning in a way that it explains how landscape can, especially urban landscape define new boundaries. As well it is shown how can landscape be a help to urban planning without changing the boundaries. This is the reason why urban landscape is beginning to be a method in urban planning and the theme of urban designs of the cities from the end of the 20th c. since when new theories have been arising in form of Landscape Urbanism and Ecological Urbanism.

This new theories see landscape as a potential for new urban revival of the cities giving them contemporary more human image. Rediscovery of neglected and ignored city space and their redesign and reaffirmation is shown on types of projects giving the correlation between examples in practice and study projects at the University of Zagreb. Highline, like the one in New York, and promenade, like student project in Kaštela, connect parts of the cities or different communities in one whole, like in airscape of Brač. New landscapes along and above infrastructures show us how to connect peripheries and the city (Madrid Rio) or one region (wider surroundings of Dubrovnik). Waterfronts connect urban and natural landscape making attractive new public places and it is very important topic in planning of the Croatia and in the world in general.

Case study of urban landscape of Split illustrates how boundaries can become a problem for design or/and development of important historical and urban parts leaving an archaeological site of world importance to be gradually destroyed by spreading suburban areas of town Solin and not using the space adequate to its potential. City landscape of Split has been seen as a solution for this problem as a way to connect Split and Solin (centre and periphery) without administrative changes. This urban landscape would give more value to the world heritage Diocletian's Palace connecting it with Salona and other historical places with contemporary image for the whole city and its periphery.

Landscape can be a tool in urban planning when city or region need a new image, promotion or healthier space. It is necessary to use landscape as a connection when it is about areas with strong historical and cultural heritage or natural environment, where urban landscape design can properly make this places usable in non violate form.

Le Politiche Temporali Urbane tra Pianificazione e Inclusività Sociale: il Caso dei Piani Territoriali dei Tempi e degli Spazi della Regione Puglia in Italia

1 ABSTRACT

Con l'inizio della rivoluzione informatica, la discontinuità generatasi con il pensiero prospettico di matrice rinascimentale e le nuove esperienze sensoriali e percettive di tipo interattivo, in cui il parametro "tempo" diviene dominante rispetto al parametro "spazio", consentono di supporre che esso possa diventare il nuovo fondamento dell'architettura contemporanea, decretando il passaggio dalla progettazione degli "spazi" a quella dei "tempi". I tentativi di unire tempo, architettura e città, che lascerebbero già intravedere l'avvento di nuove tipologie architettoniche e urbane, nascono principalmente dal bisogno di rispondere a necessità fondamentali per il benessere dei cittadini, tra cui l'esigenza di una città "inclusiva" dei bisogni sociali dei suoi utenti diversificati per età, sesso, etnia e livello culturale.

Il caso studio presentato riguarda le poltiche sociali della Regione Puglia, eccellente modello di riferimento per il sud dell'Italia: la L.R. n. 19/2006 "Disciplina del sistema integrato dei servizi sociali per la dignità e il benessere dei cittadini e delle cittadine di Puglia" e la L.R. n. 7/ 2007 "Norme per le politiche di genere e i servizi per la conciliazione vita-lavoro in Puglia" hanno sostenuto la nascita di un sistema di governance delle politiche di genere, che includono le politiche temporali urbane alla base del Piano Territoriale dei Tempi e degli Spazi (PTTS) della città, strumento pianificatorio ad indirizzo strategico con l'obiettivo di rispondere concretamente ai bisogni di conciliazione vita-lavoro delle famiglie in contesti locali. Presentato a livello di Ambito Territoriale Sociale (ATS), il piano si attua per mezzo di Studi di Fattibilita dei PTTS (n. 28 studi avviati per altrettanti ATS su n. 45 ATS presenti), il cui fine è quello di implementare azioni spazio-temporali, diffondere la mobilità sostenibile, promuovere la conciliazione dei tempi di vita-lavoro e la rivitalizzazione sociale dei contesti urbani e, per mezzo delle Banche del Tempo, promuovere l'uso del tempo per fini di solidarietà sociale.

La rilevanza assegnata alla mobilità sostenibile nelle politiche temporali urbane della CE viene recepita a livello regionale dai PTTS, le cui direttive si integreranno a livello locale con i Piani Urbani di Mobilità Sostenibile (PUMS), introdotti con la L.S. n. 340/2000. In Puglia sono in corso la formazione di una rete ciclabile regionale integrata con la rete delle infrastrutture per la mobilità e una serie di iniziative didattico-comunicative per la diffusione, tra giovani e studenti, di pratiche per l'uso della bicicletta e per gli spostamenti a piedi, nel pieno rispetto dell'ambiente per una migliore qualità della vita.

2 TEMPO, ARCHITETTURA E CITTÀ

Il concetto di "spazio", che ha dominato la teoria e la pratica dell'architettura dei secoli scorsi, sembra stia per cedere il passo al concetto di "tempo", che, seppur presente, non ha quasi mai determinato in modo sostanziale sino ad oggi le scelte alla base del progetto architettonico e urbano. La crisi della "modernità" classica e l'avvento di quella che viene definita "nuova modernità"[3] avrebbe generato il cambio di paradigma dalla società industriale a quella elettronico-informatica, aprendo la strada a nuove sperimentazioni teoriche e progettuali, in cui il tempo sembra configurarsi come il nuovo parametro della progettazione architettonica all'interno della città contemporanea dell'era dell'informatica.

2.1 La questione del tempo

Il "tempo" è essenzialmente questione esistenziale e filosofica, prima ancora che progettuale. Nella storia della filosofia si sono avvicendate diverse visioni e concezioni a tal riguardo: tempo come causalità, tempo come coscienza e tempo come possibilità.

---

[1] Autrice del paragrafo "La mobilità sostenibile in Puglia".
[2] Autrice dei paragrafi "Tempo, Architettura e Città" e "Le politiche sociali Puglia Regione Puglia".
[3] Z. Bauman: Modernità liquida. Bari, 2002.

Il concetto di tempo come causalità (tempo oggettivo) ha origine con Aristotele, per il quale il tempo è l'ordine misurabile del movimento, e arriva sino a Newton, che distingue un tempo assoluto (tempo di durata) da un tempo relativo (tempo lineare), e infine a Kant, secondo il quale l'ordine di successione temporale coincide con l'ordine di causalità, decretando il pasaggio alla concezione moderna del tempo. La concezione del tempo come coscienza (tempo soggettivo) nasce, invece, con Plotino e Sant'Agostino e giunge sino a Hegel, che considera il tempo come intuizione del movimento e del divenire, approdando ad un'idea in cui il tempo si riduce alla coscienza pura. Dopo Hegel, il concetto è ripreso da Bergson, per il quale il tempo vissuto equivale alla durata della coscienza, e da Husserl, per il quale il tempo coincide con la coscienza nel tempo presente. La concezione del tempo come possibilità (tempo progettuale), infine, viene formulata da Heidegger: il tempo si riduce a struttura delle possibilità, secondo una rivalutazione del ruolo del futuro in favore di un tempo che è possibilità e progettualità. Grazie anche a Einstein e alla sua teoria della relatività, il tempo cessa di essere "necessità" per diventare "possibilità", di più ordini e di più tempi.

Tra le varie interpretazioni e definizioni del tempo esposte, particolarmente attuale risulta essere quella di Husserl, che sviluppa il discorso sul tempo a partire da una fenomenologia della coscienza interna, secondo cui il tempo non è creato dalla coscienza, ma coincide con la vita della coscienza, ed è elemento sempre presente, anche quando non percepito, che rende possibile lo svolgersi degli eventi e la loro percezione e da cui ha origine il mondo spazio-temporale. Dopo Husserl, anche il filosofo Maurice Merleau-Ponty, esponente della fenomenologia francese del Novecento, sostiene le qualità fenomeniche del tempo in opposizione alla concezione di tempo lineare, dicharando in tal senso che il tempo è una "rete di intenzionalità" e "non è una linea". In continuità con tali visioni, le teorie odierne che forse rappresentano di più il tempo sono quelle che si basano su concetti derivanti dalla tradizione fenomenologica, che abbandonano il concetto di tempo lineare, rinunciando all'idea di un tempo unico in favore di nuovi modelli (tempo ciclico, simultaneo, ecc.), e presuppongono una "coscienza del tempo" (fenomenologia della coscienza di E. Husserl) e una consapevolezza di "qualità" del tempo (fenomenologia urbana di K. Lynch.).

2.2 Spazio e Tempo in Architettura

Nel 1941 viene pubblicato negli Stati Uniti il libro dal titolo "Spazio, tempo e architettura: lo sviluppo di una nuova tradizione", in cui lo storico svizzero Sigfried Giedion analizza, parallelamente alla storia dell'architettura, l'evoluzione delle concezioni di spazio e tempo, portando all'attenzione del dibattito architettonico di quel periodo il tema del "tempo" in architettura. Egli sostiene, infatti, che alla base dell'architettura contemporanea vi sia una concezione di tipo spazio-temporale, affermando che, dopo i postulati della geometria euclidea e cartesiana e della prospettiva quattrocentesca basata sullo spazio a tre dimensioni, agli inizi del Novecento si affermano le teorie del fisico A. Einstein e del matematico H. Minkowski sullo spazio a quattro dimensioni,[4] per giungere, infine, agli spazi dinamici generatisi con l'invenzione dell'automobile, che integrano il "movimento" alla concezione architettonica contemporanea.

Dopo Giedion, è, infatti, l'urbanista francese Paul Virilio a sostenere che l'avvento della velocità, dell'elettronica e dell'informatica segna i nuovi confini dello spazio e dei suoi rituali d'accesso: non più porte ma sistemi di ascolto elettronico, non più recinti ma superfici-limite, interfacce, in una "città sovraesposta", in cui la velocità abolisce la nozione di dimensione fisica e "l'architettura urbana deve ormai venire a patti con l'aprirsi di uno spazio-tempo tecnologico". Agli inizi degli anni Settanta il filosofo Michael Foucault afferma che la storia è finita ("La storia è discontinuità", Microfisica del potere, 1977), sostenendo che la storia era fatta di frammenti e eventi sparsi e che non esisteva più un discorso sulla storia nè l'unità dell'esperienza, ma solo pluralità, del soggetto e degli eventi (M. Cacciari, F. Rella, M. Tafuri, G. Teyssot, Il dispositivo Foucault, 1977). Negli stessi anni, sulla scia delle affermazioni di Foucault, il filosofo Gilles Deleuze anticipava alcuni dei temi centrali nella sperimentazione progettuale contemporanea: le sue teorie hanno introdotto nella pratica architettonica termini come affiliazione, spazio fluido e stirato, piega e flessibilità. Eppure, nonostante gli assunti diversi e i diversi esiti formali, esiste ancora un elemento che accomuna le esperienze della fine del XX secolo e non consente ancora di parlare di avvento di una nuova era in architettura ed è la permanenza della prospettiva. Giedion sosteneva che la prospettiva viene superata nel movimento artistico del Cubismo, a differenza di quanto affermato da Franco Purini, secondo il quale, invece, il Cubismo non si sarebbe mai veramente liberato dagli schemi prospettici, ravvisando una

---

[4] A. Einstein, Sulla elettrodinamica dei corpi in movimento (1905) e H. Minkowski, Space and Time (1908).

sostanziale continuità della presenza della prospettiva per tutto il Novecento, anche nel decostruttivismo, poiché la negazione del punto di vista unico moltiplicato in una pluralità di nuovi punti di vista, in realtà non segnerebbe la fine della prospettiva come forma simbolica, così come teorizzata da Erwin Panofsky (La prospettiva come forma simbolica, 1926). E' solo con l'architettura digitale che si può cominciare a parlare di discontinuità con il pensiero prospettico di matrice rinascimentale. Superato, infatti, il rapporto tra l'uomo e la realtà creato dallo spazio prospettico, la rivoluzione digitale sostituisce alle entità classiche della prospettiva delle entità indirette, in base alle quali al segno subentra un'informazione, con il risultato che le immagini non sono più definite dalla distanza ma dalla prossimità dello schermo, che però si fa inaccessibile in un rapporto di presenza/assenza e si configura come "digital divide", muro che ormai divide due epoche umane, quella passata da quella futura.[5] La rivoluzione informatica rappresenta sicuramente uno degli aspetti più imponenti della contemporaneità, tra i quali il nuovo valore della discontinuità e il fenomeno dell'interattività stanno generando nuove esperienze percettive, in cui il parametro "tempo" diviene dominante rispetto al parametro "spazio". Il nuovo ruolo del tempo, che nell'architettura digitale si lega alla questione della percezione sensoriale e individuale, mentre nell'architettura reale si esprime già nell'attenzione per la progettazione di alcuni edifici e degli spazi e dei tempi della città, consente di supporre che possa diventare il nuovo fondamento dell'architettura contemporanea, decretando il passaggio dalla progettazione degli "spazi" a quella dei "tempi".

2.3 Nuove città per nuove società

I tentativi di unire il tempo all'architettura e alla città nascono principalmente dal problema di sincronizzare i tempi degli edifici con quelli della città e questi con quelli degli abitanti, un problema che in definitiva esiste da sempre, ma che l'accelerazione temporale del digitale sembra aver accresciuto in modo esponenziale.

Nel 2005 il gruppo di ricerca olandese composto da B. Leupen, J. Van Zwol e R. Heijne presenta la propria ricerca in un testo intitolato "The 4th dimension: Time-based Architecture", riportando all'attenzione del dibattito contemporaneo sull'architettura il tema del "tempo" nel progetto architettonico.[6] Nella storia dell'architettura olandese, l'elemento "tempo" rappresenta un fattore di continuità, che a partire dalla prima metà del XX secolo, quando J. Brinkman e J. Van den Broek già affrontavano il tema dell'abitazione flessibile, attraversa l'opera di H. Herzberger con i suoi "edifici polivalenti" sino ai progetti più contemporanei di MVRDV e di R. Koolhaas (OMA), in cui l'architettura prende forma dal programma temporale e il tempo sociale, grazie a politche di welfare integrate alla cultura del progetto, si traduce in architettura e economia.[7]
Fig.1: OMA, Yokohama Terminal Airport (2002), Schema n. 1 – Diagramma delle analisi delle ore di punta, Schema n. 2 – Diagramma temporale della costruzione del programma.

Studi più recenti affermano che vi sono già architetture temporali latenti "dentro architetture spaziali che già esistono ma che, attraverso la progettazione architettonica temporale, vengono rifunzionalizzate, reinventate, ricostruite per contenere tutti i tempi dell'abitare". I nuovi media, che includono simultaneità e ubiquità, e i nuovi mezzi di trasporto sempre più veloci, in grado di deformare le coordinate spazio-temporali, mutano il

---

[5] F. Purini: Digital Divide. In: AAVV, Architettura e cultura digitale, a cura di L. Sacchi e M. Unali, Milano, 2003.

[6] Il concetto di "time-based" deriva dal mondo video e cinematografico e introduce nella progettazione architettonica gli strumenti per il controllo dinamico della forma e del tempo.

[7] Gli edifici Time-Based sono concepiti come polivalenti, parzialmente permanenti e modificabili, semi-permanenti o smontabili e hanno tutti alla base un modello concettuale per l'utilizzo di uno stesso spazio per usi differenti in tempi differenti, coniugando il tema della flessibilità con quello del tempo. B. Leupen, R. Heijne, J. van Zwol, Time-based Architecture, Rotterdam, 2005.

rapporto con gli spazi in cui si vive e iniziano a delineare una città contemporanea che "sfida le dimensioni del tempo per prefigurare le nuove morfologie urbane e tipologie architettoniche".[8] Se, dunque, il processo di destrutturazione della concezione spazio-temporale della modernità tende ad estremizzarsi sempre più, si profilano all'orizzonte nuove strategie di riappropriazione e ridefinizione dello spazio-tempo vissuto, attivate dai soggetti nelle loro pratiche quotidiane. Comprendere, infatti, il modo in cui oggi si articola il rapporto tra spazio e tempo, consente non solo di trovare risposte ai problemi dell'architettura, ma equivale anche a dotarsi di un dispositivo per l'interpretazione di alcune dinamiche molto complesse in atto nella città e nella società contemporanea: il problema della sicurezza e il governo dell'incertezza, la ridefinizione dei confini tra pubblico e privato, l'impatto delle nuove tecnologie sulle pratiche quotidiane, l'accelerazione dei ritmi della vita, la conciliazione dei tempi vita-lavoro, le differenze di genere, l'inclusione sociale. Il luogo in cui queste dinamiche si manifestano è il "quotidiano", fenomenologicamente inteso come "risultato delle pratiche di appropriazione e trasformazione degli spazi urbani", ed è in quel "quotidiano" che possono trovare una soluzione. Se ci si sofferma sulle pratiche prodotte da tali luoghi, più che sui luoghi stessi, ci si accorge che non esistono più uno spazio e un tempo uniformi, ma una "rete" disomogenea di tempi quotidiani che si interseca con spazi diversi all'interno della città. Il significato di tali relazioni spazio-temporali, inoltre, non è uguale per tutti i soggetti che ne fanno esperienza, ma varia a seconda del ceto sociale, del genere e dell'appartenenza etnica. Attraverso la crescente attenzione per le pratiche della vita quotidiana è in atto oggi un percorso di rivalutazione in positivo delle "differenze", che se in passato erano considerate questione privata, oggi appaiono centrali per la promozione di nuove forme di azione sociale finalizzata al recupero del valore della socialità e al dialogo con le istituzioni politiche, e per il recupero del ruolo del "pubblico" rispetto al "privato", grazie al quale diventa possibile rispondere a necessità fondamentali per il benessere dei cittadini, tra cui l'esigenza di una "città inclusiva" dei bisogni sociali dei suoi utenti diversificati per età, sesso, etnia e livello culturale.[9]

3 LE POLITICHE SOCIALI DELLA REGIONE PUGLIA (IT)

Sullo sfondo del difficile contesto economico internazionale, le politiche attuate in Italia negli ultimi anni per fronteggiare lo stato generalizzato di crisi hanno spesso avuto l'effetto di penalizzare ancora di più la condizione della fasce sociali più deboli, con il conseguente aumento del fenomeno della disoccupazione e del lavoro precario e il peggioramento delle condizioni sociali e della qualità di vita della popolazione.

La Regione Puglia, raccogliendo la sfida posta dalle difficoltà di un sistema economico fortemente instabile, ha inteso promuovere nuovi momenti di riflessione e sperimentazione con cui avviare uno sviluppo economico e sociale più equo e inclusivo. Con la programmazione dei fondi europei 2007-2013, infatti, è partita "una stagione nuova per l'esigibilità dei diritti sociali e del diritto al benessere e alla dignità di tutti i cittadini e le cittadine pugliesi", grazie all'attuazione di politiche integrate basate sui bisogni degli attori sociali, sullo sviluppo di nuovi settori produttivi, sulla crescita delle risorse immateriali e sull'attenzione allo sviluppo del capitale sociale territoriale. La carenza della normativa regionale in termini di esigibilità dei diritti ha imposto l'elaborazione di due nuove e importanti leggi: la L.R. n. 19/2006 "Disciplina del sistema integrato dei servizi sociali per la dignità e il benessere dei cittadini e delle cittadine di Puglia" e la L.R. n. 7/2007 "Norme per le politiche di genere e i servizi per la conciliazione vita-lavoro in Puglia" i cui principi base sono "Dignità delle persone, Universalità dei diritti, Valorizzazione delle potenzialità e delle risorse delle persone e delle famiglie, Equità nella distribuzione delle risorse, dei poteri e delle responsabilità tra i sessi, Rispetto delle identità e Valorizzazione delle differenze di genere, cultura, e religione". Tali leggi hanno sostenuto la nascita di un sistema di governance delle Politiche di genere, che includono le Politiche temporali urbane, all'interno delle quali trovano espressione misure che valorizzano i "processi di costruzione di dinamiche di inclusione, benessere e integrazione sociale" e promuovono "una pianificazione territoriale in grado di favorire la qualità della vita di donne e uomini". Tra queste le principali sono le Politiche di sostegno alle genitorialità e di conciliazione, i Piani dei Tempi e degli Spazi, i Patti sociali di Genere, la Carta per le Pari Opportunità e l'Uguaglianza nel Lavoro, il Fondo pubblico-privato per il sostegno alla flessibilità del Lavoro.[10]

3.1 Le politiche temporali urbane in Europa e in Italia

Nel 2000 la Comunità Europea dà una prima definizione delle politiche temporali nella Risoluzione 218/2002 sulla partecipazione equilibrata delle donne e degli uomini all'attività professionale e alla vita familiare (GUCE n. C 218 del 31 luglio 2000): "Le Politiche temporali urbane indicano un insieme di azioni mirate a migliorare la qualità della vita dei cittadini e la qualità urbana, attraverso la progettazione e la realizzazione di interventi sui tempi e gli orari della città. Lo scopo di questi interventi è una migliore conciliazione dei tempi familiari, dei tempi di lavoro e dei tempi per sé, una più efficace organizzazione degli orari dei servizi pubblici e dell'uso spaziale e temporale della città". Tra i vari Paesi che hanno seguito tali indirizzi, l'Italia è stato il primo a dotarsi di una legislazione specifica per la conciliazione dei tempi di vita-lavoro, avendo contribuito ad alimentare il dibattito europeo intorno al tema delle politiche temporali.[11] Con l'iniziativa di legge popolare "Le donne cambiano i tempi", infatti, la Sezione Femminile del P.C.I. nel 1989 si interessò per la prima volta alle tematiche relative alla conciliazione dei tempi di cura parentale, agli orari di lavoro ed al tempo per sé, proponendo di intervenire in tre direzioni: l'organizzazione dei tempi delle città, il coordinamento dei servizi di interesse pubblico, l'offerta di servizi organizzati in base agli orari. Le prime leggi nazionali sono la L. n. 142/1990 "Ordinamento delle Autonomie Locali" e la L. n. 125/1991 "Azioni positive per la realizzazione della parita' uomo-donna nel lavoro". A queste segue la L. n. 53/2000 "Disposizioni per il sostegno della maternità e della paternità, per il diritto alla cura e alla formazione e per il coordinamento dei tempi delle città", che al Capo VII – "Tempi delle Città", dispone che le Regioni definiscano con proprie leggi "norme per il coordinamento da parte dei comuni degli orari degli esercizi commerciali, dei servizi pubblici e degli uffici periferici delle amministrazioni pubbliche e la promozione dell'uso del tempo per fini di solidarietà sociale". Essa obbliga i Sindaci di città con più di 30.000 abitanti a predisporre un Piano Territoriale degli Orari, a istituire un Ufficio Tempi e a individuare un Dirigente in materia (art. 24) e a istituire un Tavolo di concertazione delle Istituzioni cittadine per l'attuazione dei progetti contenuti nel Piano (art. 25).

3.2 La programmazione della Regione Puglia: i Piani Territoriali dei Tempi e degli Spazi (PTTS)

In attuazione dell'art. 22 (Compiti delle regioni) della L. 53/2000, la Regione Puglia ha emanato la L.R. n. 7/ 2007 "Norme per le politiche di genere e i servizi per la conciliazione vita-lavoro in Puglia", che pone a fondamento delle strategie di sviluppo regionale e territoriale l'affermazione di una nuova cittadinanza basata sulle differenze di genere e la partecipazione attiva della stessa e definisce al Titolo II – "Coordinamento dei tempi delle città" i compiti di Regione, Province, Comuni per la progettazione e l'attuazione dei Piani degli Orari, istituendo anche un Gruppo di Lavoro Interassessorile e un Tavolo permanente di Partenariato sulle politiche di genere. Preceduta dalla L.R. n. 19/2006 "Disciplina del sistema integrato dei servizi sociali per la dignità e il benessere dei cittadini e delle cittadine di Puglia" (art. 28 – "Conciliazione dei tempi di vita e di lavoro e armonizzazione dei tempi delle città"), tale legge è seguita dal R. R. n. 21/2008 "Regolamento per la predisposizione e l'attuazione dei Piani territoriali degli orari e degli spazi e per la costituzione, la promozione e il sostegno delle banche dei tempi", che definisce criteri e modalità per la concessione di contributi per promuovere la progettazione e l'adozione dei Piani Territoriali dei Tempi e degli Spazi, e dalla D.G.R. n. 1267/2009 "Linee guida regionali per la predisposizione degli studi di fattibilità per la progettazione dei Piani dei Tempi e degli Spazi".

Il Piano Territoriale dei Tempi e degli Spazi è definito come uno "strumento di pianificazione territoriale, volto a razionalizzare l'organizzazione dei tempi della città e a migliorare le condizioni di fruizione quotidiana dei servizi, attraverso la qualificazione dei programmi di azione per lo sviluppo economico, lo sviluppo urbano sostenibile e l'inclusione sociale, al fine di sostenere le pari opportunità fra uomini e donne e di favorire la qualità della vita attraverso la conciliazione dei tempi di lavoro, di relazione, di cura parentale, di formazione e del tempo per sé delle persone che risiedono sul territorio regionale, anche temporaneamente" (R.R. 21/2008, art. 2). Esso si configura dunque come strumento pianificatorio ad indirizzo strategico con l'obiettivo di rispondere concretamente ai bisogni di conciliazione vita-lavoro delle famiglie in contesti locali. Presentato a livello di Ambito Territoriale Sociale (ATS), essendo quello il

---

[11] "La prima ricerca europea in materia di politiche temporali è stata promossa nel 1997 dalla Fondazione europea per il miglioramento delle condizioni di vita e lavoro, con sede a Dublino. Lo studio riconosceva l'origine italiana delle politiche dei tempi e l'innovazione delle stesse nel panorama delle politiche di genere". A. Pozzi: Un focus sulle politiche di conciliazione temporale. In: Mutamento Sociale n. 15, 05/2007, Milano.

contesto che presenta maggiori ostacoli per la gestione della famiglia e della città, il piano si attua per mezzo di Studi di Fattibilita, il cui fine è quello di implementare azioni spazio-temporali, diffondere la mobilità sostenibile, promuovere la conciliazione dei tempi di vita-lavoro e la rivitalizzazione sociale dei contesti urbani, e per mezzo delle Banche del Tempo, il cui fine è promuovere l'uso del tempo per fini di solidarietà sociale.

Lo Studio di Fattibilità definisce e descrive le strategie e le linee d'azione finalizzate alla redazione del PTTS attraverso la creazione dell'Ufficio dei Tempi e degli Spazi della città, l'analisi del contesto di riferimento, i meccanismi di costruzione del partenariato istituzionale, l'individuazione delle risorse finanziarie e umane per la fattibilità economica del piano, la strategia di comunicazione. Il PTTS, invece, deve necessariamente contenere l'analisi dell'ambito territoriale di riferimento, esigenze e criticità, finalità e obiettivi, misure previste (linee d'azione), target dei destinatari, risorse per le misure previste, partenariato attivato, cronoprogramma e piano finanziario delle attività, modalità di integrazione con i Piani di Zona e i Piani di Distretto, modalità di raccordo con la pianificazione territoriale ai vari livelli, modalità di gestione, controllo e monitoraggio, azioni di informazione e comunicazione. I Modelli di Intervento contenuti nelle Linee Guida, indicativi e non esaustivi delle iniziative attivabili, prevedono le seguenti Linee di Azione: Orari delle scuole, Orari dei servizi pubblici comunali, Orari del commercio e dei pubblici servizi, Orari dei servizi di trasporto pubblico locale, Orari dei servizi dedicati all'infanzia, Miglioramento dell'accesso ai servizi attraverso gli sturmenti della società dell'informazione, Formazione degli operatori delle amministrazioni pubbliche da parte delle provincie e sensibilizzazione dei cittadini (linea d'azione trasversale). Attraverso tali Azioni i Comuni coordinano e amministrano gli orari dei servizi pubblici, compresi gli uffici centrali e periferici delle amministrazioni pubbliche, gli esercizi commerciali e i pubblici servizi, le attività di trasporto, socio-sanitarie, di formazione e istruzione, culturali, sportive, turistiche e di spettacolo. Per i contributi agli studi di fattibilità sono state stanziate risorse complessive di € 3 milioni a valere sull'Intesa Famiglia Dipartimento Politiche Famiglia. Gli ambiti sociali che hanno già elaborato e presentato lo studio di fattibilità tra il 2010 e il 2011, rispondendo all'Avviso Pubblico pubblicato sul BURP della Regione Puglia n. 194/2009, sono n. 28 su n. 45 ATS presenti.

3.2.1 Lo Studio di Fattibilità "Abitare i tempi e gli spazi della città di Bari"

Il caso qui esposto riguarda lo Studio di Fattibilità per la redazione del Piano Territoriale dei Tempi e degli Spazi presentato dall'Ambito Territoriale Sociale della città di Bari il 30 giugno 2012. La città di Bari, capoluogo della Regione Puglia, a partire dal 2007 ha promosso e sviluppato con la Provincia e altri trenta comuni, sulla base di importanti modelli nazionali e internazionali, il Piano strategico Metropoli Terra di Bari, nell'intento di avviare la definizione degli scenari futuri dell'area metropolitana e la pianificazione della stessa nell'ottica della sviluppo sostenibile di medio e lungo periodo.

Nell'ambito di tale contesto, la visione alla base del Piano Territoriale dei Tempi e degli Spazi per la città di Bari contempla il miglioramento dell'abitabilità del tempo urbano, in favore della conciliazione dei diversi spazi di vita dei cittadini e di un maggiore coordinamento tra attori istituzionali e sociali.

Il processo di avvio dello studio di fattibilità ha previsto, infatti, due momenti fondamentali: l'analisi dei fabbisogni della cittadinanza e la partecipazione degli attori sociali. Ai fini dell'analisi conoscitiva dei bisogni del territorio oggetto di studio, si è resa necessaria un'indagine sugli utilizzi di tempo e spazio nella città. L'analisi è stata fatta su un campione di popolazione per mezzo di questionari (n. 320 questionari compilati) specifici per fasce d'età su argomenti relativi alle esigenze di accesso ai servizi pubblico-privati e alla mobilità urbana. I fabbisogni emersi sono stati raggruppati in quattro macrocategorie: mobilità pubblica sostenibile (potenziamento del trasporto pubblico, attenzione per le utenze deboli, potenziamento di bike e car-sharing), conciliazione vita-lavoro (flessibilità nell'orario di entrata a scuola, ampliamento della fascia oraria di apertura degli sportelli pubblici), accessibilità ai servizi pubblici (più efficiente comunicazione del comune con i cittadini, orari di apertura dei negozi più vicini alle esigenze dei cittadini, aperture domenicali degli esercizi commerciali), qualità urbana (nuovi spazi verdi, spazi per la cultura.). La modalità partecipativa della progettazione del piano ha previsto l'attivazione di focus-groups su base territoriale nelle circoscrizioni che hanno coinvolto il Terzo Settore, di forum urbani presso la sala consiliare del comune di Bari alla presenza di rappresentanti istituzionali, l'invito alle Asl e allle parrocchie.

Sulla base dell'analisi di contesto e delle proposte scaturite dagli incontri con gli attori sociali, è stata costruita l'architettura del PTTS, secondo una visione strategica articolata in quattro Linee d'azione, da attuarsi per mezzo di progetti sperimentali.

Le azioni strategiche sono:

Linea di azione 1 – Mobilità sostenibile urbana, con l'obiettivo di incentivare e implementare il Trasporto Pubblico Locale (TPL) e le modalità di spostamento collettivo, ridurre l'uso dei mezzi di trasporto privati, ridurre l'impatto ambientale. Progetti: TPL Bari, Car-pooling e sharing, Rete ciclopedonale Biciplan, Mobilità scolastica.

Linea di azione 2 – Conciliazione vita lavoro, con l'obiettivo di pianificare e regoalre gli orari e la fruizione degli spazi, garantire maggiori servizi e più qualificati per le fasce più deboli della popolazione, promuovere l'attivismo dei cittadini nella solidarietà. Progetti: Micronidi familiari, Coordinamento metropolitano delle Banche del Tempo, Albo dei lavori di cura, Commercio in rete.

Linea di azione 3 – Accessibilità ai servizi pubblici, con l'obiettivo di rafforzare le capacità delle istituzioni nell'erogazione dei servizi, rafforzare le competenze entro l'amministrazione sulle politiche di conciliazione e di organizzazione spazio-temporale, istituire un dialogo permanente di confronto tra Amministrazione e cittadini sugli usi del tempo e dello spazio. Progetti: Giornata del cittadino, Portale e-Gov, Ufficio dei Tempi e degli Spazi, Formazione PA.

Linea d'azione 4 – Qualità urbana, con l'obiettivo di aumentare la presenza di verde urbano, istitizionalizzare un luogo che possa favorire il dibattito urbano ed educare alla città. Progetti: Urban Center, Greening Project.

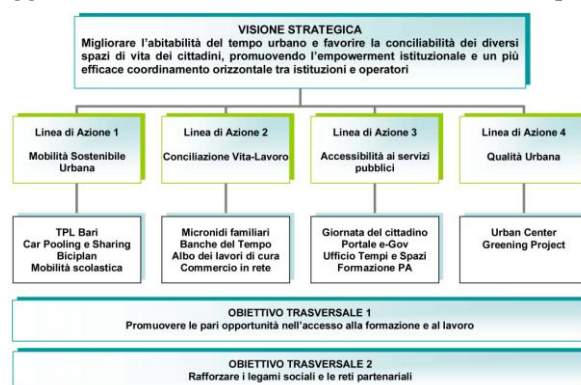
Il governo del Piano è affidato ad un Ufficio del Piano dei Tempi e degli Spazi, la cui struttura organizzativa ha il compito di attuare i PTTS e di istituire una Consulta dei Tempi, composta da soggetti rappresentativi del territorio, per il monitoraggio ciclico e l'animazione del dibattito sulla qualità urbana.


Fig.2: L'architettura del PTTS dell'Ambito Sociale della città di Bari.

4 LA MOBILITÀ SOSTENIBILE IN PUGLIA

L'obiettivo globale della politica di coesione della Puglia cofinanziata dal FESR per il periodo 2007-2013 è quello di favorire la piena convergenza della Regione in termini di crescita e occupazione, garantendo la sostenibilità del modello di sviluppo. Nell'ambito di questa strategia generale un riguardo particolare è stato dato ai temi della mobilità urbana sostenibile e dello sviluppo degli attrattori culturali, in quanto il sistema insediativo della Regione Puglia ha causato la perdita di identità dei centri limitrofi ai capoluoghi e lo spopolamento e declino economico dei centri minori. A questo si è accompagnato il declino demografico delle città centrali, determinato dai processi migratori verso le corone urbane dovuti sia ai differenziali di prezzo e alla scarsa offerta di alloggi pubblici, sia alla scarsa qualità urbana (inquinamento, criminalità, congestione, degrado, carenza di luoghi della socialità e di servizi di assistenza). Siamo in presenza di un'armatura urbana policentrica, nella quale da un lato sono assenti grandi agglomerazioni metropolitane con problemi di congestione e relative diseconomie esterne, dall'altro sono presenti sistemi di piccole città legate da consolidate relazioni reciproche e notevole affinità di risorse e problemi. Di conseguenza da un lato il sistema di trasporto risulta deficitario oltre che sul versante della intermodalità, della interconnessione su scala regionale e sovraregionale, anche su quello della qualificazione dei servizi collettivi di base, dall'altro il turismo regionale risulta ancora eccessivamente incentrato sulla valorizzazione delle risorse naturali nei

mesi estivi, mentre la domanda di turismo culturale risulta piuttosto limitata, anche a causa di un'offerta poco valorizzata e incapace di attrarre flussi turistici destagionalizzati.

4.1 Piano urbano della mobilità sostenibile

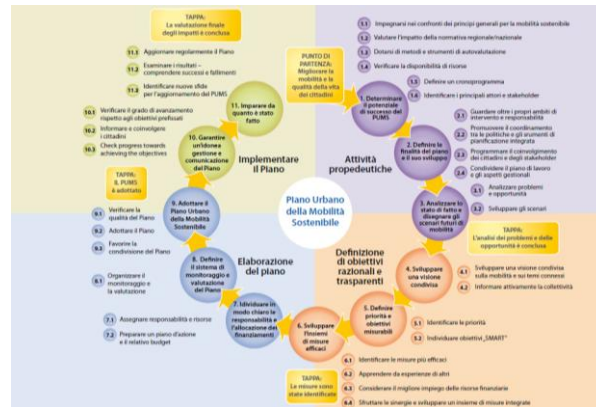
Il Piano Urbano della Mobilità Sostenibile è un piano strategico, costruito su strumenti di pianificazione esistenti, che tiene conto dei principi di integrazione, partecipazione e valutazione per soddisfare i bisogni di mobilità attuali e futuri degli individui al fine di migliorare la qualità della vita e l'attrattività dell'ambiente urbano. Una città impegnata nella pianificazione della mobilità sostenibile è vista come una città innovativa a cui fare riferimento e contribuisce a fornire una migliore immagine di se stessa. Pianificare la mobilità concentrandosi sulle persone e sui luoghi piuttosto che sulle auto ed il traffico comporta innegabili benefici per l'ambiente e la salute, anche in termini di riduzione di inquinamento termico ed acustico e di consumo di energia, ed aiuta a mitigare i cambiamenti climatici.


Fig.3: Schema del PUMS.

Il piano è basato su una visione dei trasporti e della mobilità di lungo periodo che comprende l'intero agglomerato urbano e include tutte le forme e i modi di trasporto pubblico e privato, passeggeri e merci, motorizzato e non motorizzato, circolazione e sosta, e che mira ad aumentare l'efficienza ed economicità delle forme di trasporto presenti sull'intero agglomerato urbano, pubbliche e private, passeggeri e merci, motorizzate e non motorizzate, di circolazione e sosta. È uno strumento caratterizzato da una visione chiara, da obiettivi e traguardi misurabili e da un approccio integrato e partecipativo. Il coinvolgimento dei cittadini e degli altri portatori di interessi è un aspetto fondamentale lungo tutto il processo di Pianificazione per capire perchè alcuni gruppi di cittadini dovrebbero essere coinvolti e quale l'influenza che potrebbero esercitare. Solo così le decisioni relative a specifiche misure di mobilità urbana sostenibile, come per l'appunto lo stesso PUMS, possono ottenere una significativa "legittimazione pubblica".

Nello sviluppo di un Piano Urbano della Mobilità Sostenibile, la visione spazia necessariamente oltre gli ambiti dei trasporti e della mobilità e considera opportunamente aspetti sociali, economici, ambientali e politico-istituzionali, nell'ambito di una strategia complessiva di sviluppo sostenibile. La rilevanza di un Piano Urbano della Mobilità Sostenibile è tale da necessitare la guida dell'Assessorato ai Trasporti e alla Mobilità del Comune di riferimento e il coinvolgimento di altri uffici e dipartimenti comunali e regionali nel processo di pianificazione (urbanistica e sviluppo del territorio, sviluppo economico, ambiente, servizi sociali, salute, sicurezza). Un approccio integrato che tiene conto di strumenti e politiche di diversi settori, livelli amministrativi e autorità limitrofe e tenta di risolvere i deficit di integrazione e cooperazione per perseguire innovazione e miglioramento. Tale visione strategica deve essere specificata con obiettivi concreti, fornisce una descrizione qualitativa del futuro urbano desiderato e serve ad orientare lo sviluppo di adeguate misure di pianificazione.

La selezione delle misure non deve basarsi solo sull'efficacia ma anche sull'economicità e su un'analisi dei costi e dei benefici dei trasporti, che tenga conto dei più ampi costi e benefici sociali. Soprattutto in un periodo di budget limitati per la mobilità e i trasporti urbani, è fondamentale legare le ricadute delle misure e degli interventi alle risorse spese. Questo aspetto richiede una opportuna valutazione delle opzioni con una particolare attenzione alla qualità dell'aria e agli impatti derivanti dalle emissioni di gas serra. La Commissione Europea nel Libro Bianco sui Trasporti (2011) ha rimarcato l'importanza di internalizzare i costi esterni di tutti i modi di trasporto applicando principi comuni alle specificità di ciascun modo.

4.2 Le reti ciclo – pedonali

In Puglia è in atto una forte campagna di comunicazione, sensibilizzazione e informazione innovativa su tutto quello che attiene la bicicletta, mezzo economico e flessibile: l'uso delle piste ciclabili, il rispetto delle regole in città, il bike sharing, la realizzazione di momenti di condivisione e animazione territoriale utili alla diffusione della cultura sulla mobilità ciclabile. Esistono ben 1653 km di possibili percorsi per cui sostanziale diventa il potenziamento della rete ciclabile regionale integrata con la rete delle infrastrutture per la mobilità, mediante la realizzazione di opere specifiche, quali piste e corsie ciclabili, ciclovie, itinerari ciclopedonali, segnaletica, misure di moderazione del traffico, finalizzate ad indurre un'andatura più lenta che consenta la circolazione in sicurezza e libertà di pedoni e ciclisti.

Decidere di incoraggiare la gente ad abbandonare l'auto e utilizzare la bicicletta comporta delle responsabilità in termini di scelte politiche e strategiche, finalizzate a decongestionare il traffico e la sosta e a permettere al cittadino di andare in bici con tutti gli strumenti necessari, a livello infrastrutturale e non solo. Per questo è in corso il programma "Crea-Attiva-Mente" che si sviluppa attraverso due direttrici principali: il Progetto "Mente locale", per il recupero degli immobili a servizio del TPL, al fine di trasformare i luoghi non vissuti, o vissuti in modo sfuggente, in fucine di sperimentazione di buone pratiche per la mobilità sostenibile e la valorizzazione dell'ambiente; il Progetto "Cicloattivi", per lo sviluppo della mobilità ciclistica e la tutela degli utenti deboli della strada. Sempre nell'ambito di "Crea-Attiva-Mente" alla fine di gennaio è stato pubblicato il bando del Progetto "PugliApedali" con il quale si intende valorizzare e sviluppare l'impegno delle amministrazioni locali e il coinvolgimento di imprese, associazioni ed enti del no-profit pugliesi per la promozione della mobilità sostenibile e per lo sviluppo turistico del territorio.

Inoltre, la Regione Puglia ha partecipato, in qualità di Lead Partner, al "Progetto CYRONMED" – Cycle Route Network of the Mediterranean, che ha permesso di realizzare un interessante manuale di buone pratiche, il "Vademecum della ciclabilità", con il fine di incoraggiare i Comuni e le Province ad indirizzare le loro scelte verso una mobilità sempre più eco-sostenibile. La Puglia compare in ben 5 itinerari: Via dei Pellegrini: Londra – Roma – Brindisi; Via Adriatica: Delta del Po – Leuca; Via dei Borboni: Bari – Napoli; Alta via dell'Italia centrale: Dal Parco del Gargano alle Foreste Casentinesi; Via dei Tre mari: Otranto – Taranto – Sapri; Variante ionica Torre Lapillo – S. Maria di Leuca.

Fig.4: Gli Itinerari del Progetto CYRONMED

Il progetto CYRONMED ha contribuito a modificare il modo di concepire i piani di intervento infrastrutturale e a far entrare, all'interno della programmazione e della pianificazione regionale, il tema delle reti ciclabili e della loro integrazione modale con le altre reti trasportistiche. Tali indicazioni sono state recepite dal Piano Regionale dei Trasporti e dal Piano Paesaggistico Territoriale Regionale che considerano la rete ciclabile regionale come infrastruttura essenziale per lo sviluppo della mobilità sostenibile, mentre il DRAG (Documento Regionale per l'Assetto Generale) ha introdotto i piani delle reti ciclabili sulla viabilità di competenza tra i contenuti della Pianificazione Territoriale di Comuni e Province.

Sono numerose pure le iniziative di sensibilizzazione e le attività e gli interventi di educazione, formazione e comunicazione per la diffusione della mobilità sostenibile, a cui si affianca la realizzazione di percorsi casa-scuola per bambini (Piedibus e Bicibus), per incentivare gli spostamenti quotidiani a piedi con il coinvolgimento dei cittadini più giovani e degli studenti di tutte le scuole di ogni ordine e grado. L'Assessorato alle Infrastrutture e alla Mobilità della Regione Puglia, in collaborazione con Legambiente

Puglia e l'Anci Puglia, ha recentemente presentato alla stampa il dossier sui "Comuni Bicicloni", nato proprio con l'obiettivo di fotografare lo stato della mobilità sostenibile nei Comuni pugliesi e di costruire un primo database da integrare gradualmente per incentivare l'uso delle biciclette nelle città come forma di mobilità ordinaria. Fra i Comuni grandi e piccoli che sono all'avanguardia in questo processo di trasformazione che parte dal basso, emerge Bari, attiva già da anni sul fronte della mobilità sostenibile e dotatat anche di un mobility manager nell'organigramma dell'amministrazione comunale. Oltre a possedere il servizio di bikesharing (intercettabili in ormai più di 20 punti) e numerosi cicloparcheggi nell'ambito del Progetto "BiciPlan", si distingue per la realizzazione di un piano della mobilità con interventi infrastrutturali riguardanti il completamento e il potenziamento dei sistemi di offerta dei trasporti su rete ferroviaria e rete stradale e del sistema di parcheggi, la sperimentazione del trasporto ON DEMAND, mediante l'utilizzo di alcune mini-navette elettriche già di proprietà dell' AMTAB. L'Amministrazione locale sta anche puntando sulla promozione del Progetto Car-Pooling & Car-Sharing, per chi, per diverse esigenze, proprio non riesce o non può lasciare a casa l'auto. Il primo necessita di mezzi di proprietà degli stessi utenti della strada e il secondo di dotazione di parco mezzi, di solito sostenibili, auto o minicar elettriche. In entrambi i casi per l'avvio, non servono spese per l'attivazione di portali o strumenti particolari.

5 CONCLUSIONI

Le esperienze degli ultimi decenni nell'ambito della pianificazione territoriale hanno evidenziato che le principali trasformazioni strutturali e culturali delle società contemporanee sono sempre accompagnate da importanti cambiamenti nell'utilizzo dei tempi e degli spazi di vita, che spingono verso nuovi utilizzi del territorio e del tempo e generano nei cittadini nuove aspettative di qualità della vita e di maggiore coinvolgimento nelle scelte pubbliche. Un governo del territorio interessato non più solo all'organizzazione e alla gestione dello spazio, ma che integra nelle sue scelte di base anche le esigenze di tutte la fasce sociali, il bisogno di sicurezza, la cultura, la formazione, i tempi, la mobilità sostenibile, è un governo che si avvia verso un nuovo modello di politica. La Regione Puglia ha raccolto la sfida posta dalla crisi economica in atto e, attraverso le poliche sociali, di genere e temporali che sta attuando, insegue la visione di una città a misura di donne e uomini, in cui promuovere sempre la qualità della vita e in cui il valore del Tempo possa essere considerato come il bene più prezioso da utilizzare per sè e in favore degli altri.

7 RINGRAZIAMENTI

London After the Spectacle Year, Who Claims Which Space and Who Gets it?

Judith Ryser

(Judith Ryser, CityScope Europe, London, judith@urbanthinker.com, www.urbanthinker.com)

1 ABSTRACT

This aim of this paper is to look at the lull after an exceptional 'year of spectacles' in London and how the development industry is pursuing property-led growth with government support. Their spatial strategies are discussed in the context of alternative scenarios for urban change, proposed by Erik Swingedouw in terms of the 'post-political city'[1] and by Henri Lefebvre in his writings on the paths to difference[2] and the right to the city.[3]

2 ABOUT THE POLITICS OF SPACE

A generation apart, but in what could be arguably considered pre-revolutionary conditions, Henri Lefebvre and Erik Swyngedouw were/are reflecting on an alternative to the global, neo-liberal, capitalistic model of urban change, its underlying social relations and governance. Lefebvre wrote the "Differentialist Manifesto" (Le Manifeste Differentialiste) in 1970 after his involvement in the protests of May 1968 in Paris. His concern is with the hegemony of the global model which confounds growth with development, and he explores possible alternatives of paths rather than end-state models for the production of 'urban' space.[4] Also preoccupied with the dominant model of (urban) governance and prospects for alternatives Swyngedouw uses 'police' ('le police'- the existing social order), 'politics' (la politique) and 'the political' (le politique), terms he borrowed from Jacques Ranciere[5] to critique what he perceives as the post-political, post-democratic period following the global financial crisis of 2007.

Both Lefebvre and Swyngedouw are focusing on theoretical deliberations about the nature of urbanisation, the former from a philosophical, historic and political-economy point of view, the latter from a geographic-environmental and political science perspective of reinstating urban justice, equality and freedom.[6] They both analyse and denounce the hegemony of the dominant model of society (the new order as moral and political order[7] – the neo-liberal order[8]) and explore alternative urban transformations. Lefebvre is reconstructing 'difference' as a way of gaining a universal sense of alternative paths toward differentiated urban social relations.[9] For him, the modern world – progress – this chaos – starts to make sense if one distinguishes among conflicts and confrontations, "the titanic struggle between homogenising powers" (which have access to enormous means) and "differential capacities".[10] Swyngedouw, through identifying

[5] 'the police', the urban policy order, – 'la police', 'le policier' – is the organisation of society where everyone has an assigned place. 'Politics ' – 'la politique', is a process of emancipation. 'The political' – 'le politique', is the place of encounter of the two heterogeneous processes above, one governmental, the other emancipatory. These terms are proposed by Jacques Ranciere, cf. e.g. Au Bords du Politique. Osisris. 1990. La Fabrique Editions 1998, Folio 2003. They are taken by number of current thinkers about the post-political city.

the 'non-part', the part of society with no properly defined place within it, is using the universal as a starting point to re-politicise public civic space.

The simultaneous generation of scarcity and abundance is another theme they have in common. They adopt a different take though on social movements and their effectiveness in bringing about fundamental societal transformation and urban change. Lefebvre is more optimistic about their possible contribution to urban change than Swyngedouw who, in his more recent writings, sees them as an inherent part of the existing, in his view deficient urban governance which has inbuilt instruments to tame or absorb them. They both refer to human rights, and the right to the city, as well as to utopia as the ultimate imagined path towards change, again in a slightly different light. Perhaps these rather abstract critical explorations of urban justice may shed some light on the production of space in London in the current contradictory and divisive climate of austerity.

3 LONDON, THE 'SPECTACLE CITY'

There exists a political consensus that 2012 was an exceptional year for London. It found itself in a permanent state of pageant and delivered a plethora of world class spectacles which may well have masked the effects of the crisis at the heart of London's financial sector and the hurt of scarcity. Epitomising the society of spectacle, London had been groomed for exceptional celebration to attract spectators from all over the world.

*1_dia London Spectacle city: Queen's diamond jubilee celebrations, source: http://static.guim.co.uk/sys-images/Guardian/Pix/pictures/2012/6/3/1338744517609/The-Thames-Diamond-Jubile-054.jpg

In rapid succession London staged the Queen's Diamond Jubilee, the Olympic Games, the Cultural Olympiad, the Gay Pride Parade and the international Frieze art fair, besides numerous global political summits, premieres of films with the fastest ever return on investment, while the Lord Mayor and the Mayor of London were rivalling with fireworks. Did the vertiginous speed and ephemerity of events, instantly diffused worldwide, indicate the path from spectacle society to digital society, from the real to the virtual world which, according to Michel Serres,[11] is transforming the perception as well as the experience of space and time?

---

[11] Michel Serres. 2012. Petite Poucette. Manifeste, editions Le Pommier.

2_dia Thames with Shard and City skyscrapers, source: http://medias.photodeck.com/889602a8-22b3-11e1-bd22-8147863a0125/View %20from %20Tower %20Bridge %20panorama2_pr_xlarge.jpg

A counterpoint to this trajectory into digital society is the material urban development which London has completed during that time in its traditional physical environment: the 'Shard', the highest skyscraper in Western Europe designed by 'starchitect' Renzo Piano,[12] and, equalling the Victorians, major transportation infrastructure like the multimodal interchange in Stratford near the Olympic site and work on the new east-west Crossrail to ease commuter traffic. Besides the Olympic mega-buildings themselves, all these material changes took place in the context of the Mayor of London's expansionist ambitions laid down in the new London Plan.[13]

The mayor, together with corporate business and other key stakeholders in London insist that 'the show must go on'. The consensus model evoked by Lefebvre and Swyngedouw as well as by the latter's urban populism have certainly been a contributing factor to keeping London among the key world cities, retaining and attracting foreign visitors, the best talent and global inward investment. London continues to benefit from the lion's share of public finance, despite austerity measures imposed by the Chancellor of the Exchequer which are hitting the lower paid Londoners hard.

How can London keep this momentum going when the economy is hovering around no growth and austerity measures are likely to stay in place for the foreseeable future? Despite London's job losses, including in the financial sector, unemployment is far higher in the north of the country. Those experiencing hardship remain unconvinced that London should continue to be privileged, and they doubt London's claim to be the economic engine of the nation and the necessary driver of recovery everywhere else. Therefore, the question of who would benefit from London's continuous growth and who would lose out remains at the forefront of current political debate.[14] This does not prevent the governance lobbies from demanding a world-class hub airport[15] and more high speed rail[16] to guarantee London's competitiveness in the global market.

4 AFTER THE 'FIREWORKS'

The 2011 census data revealed the contrast between London's rapid population growth, well above expectations, and stagnation in other parts of the country. The available maps of the economically active population in England and Wales, or of car ownership illustrate the difference between the north and the

south.[17] Spatial analyses of this data by the Greater London Authority show growing unevenness and divergence also within London. Overall, London's population increased by one million in 10 years from 7.17 million in 2001 to 8.17 million in 2011.[18] For the first time, the indigenous British population was in a minority with 44.9 %. London Boroughs with a high immigrant population were among the fastest growing ones, where household sizes are larger than average, and overcrowding tends to be higher.
4_dia London population growth 2001 – 2011, source: Greater London Authority, Datastore

5_dia Legacy area and its nebula, source: ‚Design for London', GLA

Although no income data maps are available, it is known that London Boroughs with high numbers of immigrants constitute the poorest parts of London. The East End has been traditionally a reception area. The boroughs there have a significantly higher proportion of social housing and pressure for affordable housing remains intense. Encouraged by the changes brought about by the Olympic Games, symbolised by one of the

biggest new shopping centres in Europe,[19] the local mayor of Newham is not keen to maintain a large disadvantaged population and sees an opportunity to obtain a greater social mix in the development foreseen on the Olympic site. He resists the potential influx of poorer residents who will no longer by able to afford their social housing elsewhere, especially in central areas when the housing benefits will be capped in spring 2013. Quite the reverse, he welcomes housing for high income households which is expected to be provided by private developers, once they have managed to get hold of land[20] from the London Legacy Development Corporation (LLDC). This new successor agency of the Olympic Park Legacy Company[21] is now in charge not only of the development of the Olympic site but of many areas around it where it has inherited public land holdings and for which it has become the planning authority with compulsory purchase powers, substituting for local authorities.[22]

The mayor of Newham most certainly follows the dominant growth model and has little time for the alternative local social movements which are demanding a different development model for themselves.[23] In this sense, Swyngedouw could well be right with his interpretation that small scale, fragmented groups who attempt to produce an environment for a different lifestyle are being side-lined or displaced by what he calls post-political 'policing'. A current deal under discussion is a large university campus which University College London (UCL)[24] is planning on the site of an existing social housing estate still inhabited.[25]

Why UCL is not willing or able to build on available brown field land, for example on the Olympic site, or in the nearby recently established Enterprise Zone in the Royal Docks[26] with prime sites on waterfronts and where a new university campus has been established recently[27] may be explained by the hegemonic growth model, rather than by alternative possibilities of generating genuine socio-economic development in this impoverished area.

Can Lefebvre's concepts, elaborated in the Production of Space,[28] shed some light on these current and intensely conflicting development choices? He proposes a unitary theory of physical, mental and social space which simultaneously represents the political, implies concealing ideology, and embodies technological utopia. His dialectic approach to the continuous interplay between human action and space rests on a

conceptual triad, comprising 'spatial practice', 'representations of space' and 'representational spaces'. Would his concept of social space produced under the capitalist system, which has to encompass biological reproduction (the family), the reproduction of labour power (the working class) and the reproduction of the social relations of production (constitutive of capitalism) leave room for at least some alternatives to the currently dominant, negotiated rather than planned development process?

He most definitely includes this possibility when he discusses 'from the contradictions of space to differential space' and refers to 'alternative society' and 'counter-culture'.[29] Not only does he acknowledge the existence of such alternative movements from the bottom-up – protest, ecological, communal – because they "allow to break the barriers of the forbidden", but he also considers them as an inherent part of the dialectic of spatial practice and a necessary force of the dynamic of the production of space. What remains debatable is the extent to which such local movements are able to remain part of the urban process in the longer term. The conflicts around the Olympic site show clearly divergence, or at least the will to differentiation, the claim to 'being other', which represents in its own way a universal right to the city for all parts of the differentiated society, so very present in the East End of London. The jury is still out on medium term 'footholding', let alone the long term establishment of culturally, economically and socially diverse groups alongside each other and the 'habiter' produced by the dominant model of growth. For the time being at least this is an outlook which runs contrary to the gentrification process in the making on and around the Olympic site.

5   URBAN 'MOMENTS', SINCE THE ECONOMIC BANKING CRISIS 2008

London's transformation as a global city has been divided for some time into international, development-led physical growth, accompanied by socio-economic polarisation. The latter is becoming apparent in hardship which is creeping from the bottom of society up the social strata. It is also expressed in physical change of London's urban space and, in particular, in its representational spaces. During the recurrent phases of economic crisis these trends become more visible. It could be argued that the current, post-spectacle moment is somewhat different as it compounds the aftermath of an exceptional state of profligate expansion with its inherent characteristics of economic downturn, moreover in a different context of polity, of Swyngedouw's 'polic(y)ing', or Lefebvre's 'political space'.

When governance is strong and firmly top-down, supported by outstanding resources, it would seem logical that the dominant model of growth would increase its hegemonic position. To some extent this appears true, at least on the surface. The development industry exercises a central place in London's urban change. Very large sites, often 'brown fields', meaning with discounted land values, are made available to the development industry, frequently with direct and indirect subsidies. The Olympic site is a point in time, as were Docklands three decades ago. The public good, or what is left of it, is negotiated not regulated ex ante, while the private interest, with property rights at its heart, is given a free reign. Paradoxically, two questions come to mind. Why do such developments take almost a generation to get realised, and why would this process leave any room for alternative manoeuvres?

For Swyngedouw at al,[30] "the search for competitive development has become the leading objective of the new urban polic(y)ing … to reassert the position of cities in the consolidating global economy". This is certainly London's political position. Even if one would agree with Swyngedouw's notion of post-democracy, during which "urban regeneration is increasingly framed in a common and consensual language of competitive creativity, flexibility, efficiency, state entrepreneurship, strategic partnership and collaborative advantage",[31] the ensuing development process is neither homogeneous, nor continuous, nor universal. Precisely, because such potential regeneration sites are so large, so derelict, so unmanageable, in such unfashionable locations, they are prone to infiltration, to what Swyngedouw terms 'the political', which enables contesting, resisting, dissident groups to invade such spaces, appropriate them at least temporarily, and apply their own projects to them, with their own creativity, flexibility and entrepreneurship. The timeframe is of the essence in this cat and mouse process, but the hegemonic system is learning and pre-

---

empting, hence the blue fence around the Olympic site, surmounted by electrically charged razor wire. Despite all these precautions, some artists managed to 'infiltrate' what happened on the site. One of them, Jom Woodall, was monitoring the development process with three cameras day and night and created an audio-visual history of the present for all the other displaced people to see and to act upon.[32]

Opposed to that, the development industry had to create its own narrative. Arguably these narratives are reflecting Lefebvre's differentiation, albeit from the top-down rather than across socio-cultural groups. The narrative of the Olympic Games was global and guided by the International Olympic Committee (IOC) and its culture. London's second financial city, Canary Wharf, took this opportunity to revive its narrative, by benefiting from the proximity of the global exposure which the Olympic Games offered East London. The largest private property owner on the Isle of Dogs produced new masterplans,[33] revived its construction efforts, diversifying into luxury housing, shopping malls and other commercial premises, in competition or as a reinforcement of the constructions which emerged on and around the Olympic site.

7_dia Canary Wharf extension, Wood Wharf (project) in the London Docks, source:
http://en.wikipedia.org/wiki/File:Wood_Wharf_Development.jpg

The City of London Corporation exposed its own narrative at the Cultural Olympiad, under the banner of 'Developing City'.[34] At a lavish exhibition and during breakfast talks the City promoted its long term future of 2050, green and sustainable, by colonising the Thames – the only still protected, truly generous open space in London – with 'green' islands to accommodate the 'developing city' and satiate its space bulimia. This fascinating self-projection took place in an unfinished new building, one of many located at the very heart of the City, above a tributary river of the Thames where excavations uncovered important Roman ruins. The City Corporation's self-image was portrayed as 'the resilient city', quite appropriate considering that it has managed to preserve its medieval, pre-democratic status and will continue to do so, unchallenged. This self-representation shows that the homogeneity and the hegemony of the dominant growth model adopts various forms of 'police', although their generic 'raison d'etre' is congruent with the dominant, speculative, free market development model.

Detached from use value or need for such types of buildings, and regardless of economic crisis or politics of austerity, the process which drives exchange value of real estate pushes property development ahead relentlessly, despite the detrimental effect of glut on rents. The production of space in this case is the

reflection of the workings of the political economy, a material expression of the capitalistic post-political state. The City of London, like many CBDs accommodating capitalist financial centres is the concrete expression of this hegemonic process. There, skyscrapers multiply, compete with each other's heights, are periodically stopped in their track for lack of debt finance, get destroyed to make way for ever higher densities, simultaneously driven by increasing land values while pushing them up in turn.

The West End does not look idly on and builds and builds, according to slightly different drivers, but as integral part of this hegemonic meta-system of real estate-led, albeit often fictituous economic growth. Clearly, in places with such high densities there is no idle land available for spontaneous, temporary uses. Besides, confined to just one square mile the City is easier to 'police' than hundreds of hectares out of sight and civilisation in the East End, until they are recuperated by the same hegemonous growth model.

9_dia Olympic site, aerial view http://www.londonlegacy.co.uk/mayoral-development-corporation-to-move-to-westfield/

6   WHERE NEXT?

Even when there is saturation, overproduction, glut, and a few property companies are going bankrupt it is not for long. The economic cycle will recover eventually, so cranes lie idle just for a while, debts will be

written off, and the momentum will be reactivated. As land is finite, especially urban land and land in places of centrality, competition is fierce, so any less lucrative use of land will need to be displaced according to the logic of this system. For that reason, there is little chance that those who were displaced from the Olympic site will find new housing when it will be produced eventually. It will be well out of there reach financially, and they will have settled elsewhere for it will take a very long time to develop this site, especially as no time limit is imposed on this free market property development process, despite taking place on land which was purchased with the public purse and owned by the public sector. Moreover, privileged accessibility – high speed rail interchanges and fast connections to international airport hubs are attractors for the mobile international business class and of little use to deprived local neighbourhoods dependent on local, often unskilled employment.

Unfortunately, the opportunity of spectacle does not present itself everywhere and other areas, in the West End for example, come up with different solutions. Under the pretext of scarcity local authorities aim to displace low income people, the unemployed, the disabled from high land value sites, away from their social support structures to other cities in the north of the country. They attract global excess capital to the most expensive sites instead where gated condominiums, most of them staying empty, are erected. The scarcity programme reveals itself as a powerful spatial segregator.

11_dia Bar 25 Berlin, source: http://www.tip-berlin.de/kultur-und-freizeit-stadtleben-und-leute/countdown-bar-25-berlin

Where does this process belong in Lefebvre's analysis of the production of space and in Swyngedouw's post-political, post-democratic condition? For the former, it may not correspond to his idea of differentiation which underlies his dialectic. For the latter, the variations of the hegemonic model may simply confirm its resilience and staying power, and may make total social change even more remote. In these circumstances, is there any possibility of alternative urban development, of greater diversity, of a post-democratic return to democracy or, better perhaps, an advancement towards a post-post democratic model, in the form of assemblages between innovative and creative productions of space? Is it possible to imagine a post-post political scenario, considering that both Lefebvre and Swyngedouw conceive the production of space as fundamentally political? Meanwhile, where does this leave what regulates the city de facto, what produces the urban space at present? Will it be just more of the same? With perhaps minute forgotten spaces which

may be colonised differently, at least on a temporary basis, like in Berlin, where obviously pressure on land is not comparable with London – a world city and seat of global finance?

7 CONCLUSION: SOME HOPE?

"Differentialism is not a system. Is it a matter of debate on difference? No. It is about living. Not about thinking but being differently". This is how Lefebvre ends his differentialist manifesto. Are there examples of such different ways of living? Two urban situations come to mind in London, Coin Street on the Southbank of the Thames[35] and Bromley By Bow Centre,[36] an island of communal calm and serenity in the middle of the cosmopolitan London East End kaleidoscope. Both these urban spaces are resilient, as they have lasted for more than two decades against all mainstream odds. They started very much in terms of 'spatial practice', to the point of making things, of building their own world with their internal resources and with what the hegemonic system was discarding.

12_dia (left) Coin Street, London. 13_dia (right) Bomley by Bow centre, photos Judith Ryser

It could be argued that by now they form an integral part of the urban fabric, albeit slightly different from mainstream places if observed with a critical eye. They produced a representational space of their ideal of 'living differently'. Their spatial praxis over time was also influenced by 'the politic', as they reinvented how they were going to materialise their wanting, thinking, doing things differently, as consenting individuals towards a common goal. Their self-managed collective decisions guided them in inventing their representations of space and the way they constructed and, most importantly, are living their representational spaces.

Longing for the Ordinary – the Meaning of Authentic Places in the North-American Metropolis

Jorick Beijer

(MSc Jorick Beijer Department of Urbanism, Faculty of Architecture Delft University of Technology, post@jorickbeijer.nl)

1 ABSTRACT

Under pressure of advancing technology, rapid growth and globalisation, the Northern-American metropolis changed radically over the last 50 years. The cityscape of American cities such as New York, Los Angeles, Chicago and Houston represent fascinating processes of urbanisation. They became regional metropolises with extended post-suburban neighbourhoods and dispersed centres (Soja, 1989). Infrastructure in its broadest meaning eroded our orientation on physical presence and the meaning of proximity (Harvey, 1989). This regional urbanism serves an anonymous network society, and it does not include public space as we were used to know it. It resulted in a public realm that lost its scale, not only geographical and in time, but especially in the scale of human interaction (Koolhaas, 1995). Paradoxically – or not? – we see a growing desire for the romantic city, authentic spaces and ordinary places. This manifests itself in all kind of simulations of the past. Feelings of authenticity are tried to be reproduced in contemporary city centres, city extensions and shopping malls. But is that the ordinary space we long for? And what determines a sense of authenticity? Does the contemporary metropolis needs authentic places after all?

Building on the theme of the REAL CORP 2013 conference, this paper explores theoretically and conceptually how the compression of time and space relates to humans desire for authenticity, and the seeming disability of modernist planners in preserving it. The literature review aims to give an oversight of the various concepts of authenticity from a philosophical and conceptual point of view and to outline critiques on the commercialisation of public space in the North-American Metropolis. The review will offer a meaningful contribution to the debate of contemporary city development versus the connotation of authenticity in citizens daily live. This use of theory and philosophy, as basis for debate, is relevant for the originally technocratic-oriented planning discipline. Although it might feel uncomfortable at first, selected writers are beyond doubt constructive in broadening our view on the consequences of modernistic planning regimes concerning the issue of authenticity.

In this review I will outline two perspectives on the concept of authentic place, and two critiques of contemporary placemaking. The two concepts, defined by David Harvey (1996, 2000) and Doreen Massey (1993, 1994) originate (and criticize) the meta-concept of philosopher Martin Heidegger who argued that the construction of that place is one of the existential necessities for people to define themselves in relation to the material world (Heidegger, 1971). David Harvey criticizes Heideggers argument and elaborates on what he calls 'rootedness', a reactionary sense of place. Doreen Massey elaborates further on that, arguing for the redefinition of place as an inclusive and progressive site of social life. Michael Sorkin (1992) was one of the first to critique the heavenly 'disneyfication' of the public realm of the city, describing another layer that is driven by endless consumerism. Finally Sharon Zuking (2009) brings the discussion of authenticity back on Jane Jacobs and develops an argument for the restoration of the city's soul.

2 FAREWELL OLD CITY

Now we since the 1960's have witnessed 50 years of modernisation and transformation in the Western metropolis, the question of authenticity slowly seems to come back in. The vast development of infrastructures repeatability speeded up ordinary life and transformed the city into a increasingly generic urban fabric. The implementation of the North-American freeways from the 1950s onwards for instance, radically questioned the concept of distance and the meaning of central places. But also non-tangible infrastructures as the internet changed daily life in the metropolis. It eroded the meaning of place and distance, and by that – discrete and concrete – changed the perception of city space fundamentally. Nowadays people increasingly are longing back to the 'old city'. Profit driven developers have no difficulties in fulfilling this desire for romance. Faked authenticity then manifests itself in all kind of simulations of the past, in cosy stucco apartment blocks, Italian village like shopping malls and city extensions.

3 DEFINING SPACE AND PLACE

To put this literature review in the right perspective, first we define the rather vague concepts of space and place. Space is a more abstract concept then place. When we speak of space we tend to think of outer-space or the spaces of pure geometry. Spaces have areas and volumes, places have space between them. The Chinese geographer Yi-Fu Tuan linked space to movement and place to pauses:

What begins as undifferentiated space becomes place as we get to know it better and endow it with value (....) The ideas 'space' and 'place' require each other for definition. From the security and stability of place we are aware of the openness, freedom and threat of space, and vice verse. Furthermore, if we think of space as that which allows movement, then place is pause; each pause in movement makes it possible for location to be transformed into place (Tuan 1977:6).

4 META CONCEPT: SPACE AS THE HUMAN CONSTRUCT

Martin Heidegger can help us understanding the importance of ordinary public spaces. Heidegger argues that a fundamental element in the construction of a place is the existential necessity for people to define themselves in relation to the material world. He contended that human beings originate in an alienated condition and define themselves, among other ways, spatially. The creation of 'place' roots them in the world, their homes and localities becoming biographies of this creation (Heidegger, 1971).

One of the difficulties in clarifying the relation between space and place is, not only that the two are necessarily connected, but that this concept for years tended to be understood only spatially. In such, place is most often treated as either a certain position in space or else as a certain portion of space. This way of understanding place is itself tied to a particular conception of space as identical with physical space, as it is articulated within the system of the physical sciences – articulated in terms of the measurable and the quantifiable. Heidegger comments on the modern concept of space and the way it has come to dominate the idea of place, stating:

"For us today space is not determined by way of place; rather, all places, as constellations of points, are determined by infinite space that is everywhere homogeneous and nowhere distinctive" (Heidegger 1971:249).

The concepts of place, and of space, that are at issue for Heidegger cannot be assumed to be identical with any narrowly physical conception, nor can it be assumed that place can be taken as derivative of space, or as identical with spatial location, position, area, or volume. In this respect, place should not be assumed to be identical with the "where" of a thing. Although this is one sense of place, it is not the only or the primary sense – place also refers us to that open, cleared, gathered "region" or "locale" in which we find ourselves along with other persons and things (Cresswell, 2004).

Central to Heideggers philosophy is the notion of 'dwelling': the basic capacity to achieve a form of spiritual unity between humans and the material world. Through repeated experiences and complex associations, our capacity for dwelling allows us to construct places; to give them meanings that are deepened and qualified over time with a continuous flow of nuances. For Heidegger 'dwelling' was the very essence of existence, the things that makes humans humans. Heidegger used the illustration of a farmhouse in the German Black Forest to make this point:

"Here the self-sufficiency of the power to let earth and heaven, divinities and mortals enter in simple oneness into things, ordered the house. It places the farm on the wind sheltered slope looking south, among the meadows close to the spring. It gave it the wide overhanging shingle roof whose proper slope bears up under the burden of snow, and which, reaching deepening down, shields the cambers against the storms of the long winter nights. It did not forget the altar corner behind the community table; it made room in this chamber for the hallowed places of childbed and the 'three of the dead' – for that is what they called a coffin there; the Totenbaum – and in this way it designed for the different generations under on the character of their journey through time. A craft which itself is sprung from dwelling, still uses its tools and frames as things, built the farmhouse" (Heidegger 1971: 160).

Place as dwelling then is a spiritual and philosophical endeavour that unites natural and human worlds. A properly authentic existence to Heidegger is one rooted in place.

5 PLACE AS EVENT

5.1 Imagined rootedness

David Harvey in his work critiques Heideggers concept of seeing place-as-dwelling as the 'locale of the truth of being' – the thing that makes humans humans (Harvey, 1996). Harvey points out that Heideggers thinking was heavenly influenced by the time-space compression in the Germany that was becoming a war state. It was this terror that forced Heidegger to withdraw from the world into his Black Forest farmhouse, a situation that for Harvey is hard to relate to:

"For example, what might the conditions of 'dwelling' be in a highly industrialized, modernist and capitalist world? We cannot turn back to the Black Forest farmhouse, but what is it that we might turn to? The issue of authenticity (rootedness) of the experience of place [...] is a difficult one. To begin with... the problem of authenticity is itself peculiarly modern. Only as modern industrialization separates us from the production and we encounter the environment as a finished commodity does it emerge" (Harvey 1996:302).

Cresswell (2004) argues that it is not possible any more for large numbers of modern dwellers to retreat to farmhouses in the Black Forest or anywhere else. He links Harvey's critique on Heidegger to the contemporary efforts to make places more distinctive and visible and to provide a sense of pride and belonging. As Harvey notes this takes often the form of 'heritage' where a sense of rootedness in the past and in place is provided for the consumption of locals and tourists. Something that we nowadays can easily refer to – for instance the San Diego 'Gas Lamp district' (fig. 1) – an urban area being cleaned up and marketed as a form of heritage. Signposts appear with kitschy 'old' maps and detailed histories. All of this we can relate to as a search for authenticity and rootedness. In his text Harvey refers to the work of Yi-Fu Tuan when he borrows the argument that being rooted in place is a different kind of experience from having and cultivating a sense of place:

"A truly rooted community may have shrines and monuments, but it is unlikely to have museums and societies for the preservation of the past. The effort to evoke a sense of place and of the past is now often deliberate and conscious" (Harvey 1996:302).

Fig. 1: San Diego Gas Lamp District – 2012 (by author).

Harvey continues by stating that place is often seen as the locus of collective memory, an argument he shares whit among others Christine Boyer (1994). This locus, being a site where identity is created through the construction of memories, linking a group of people into the past.

"The preservation or construction of a sense of place is then an active moment in the passage from memory to hope, from past to future. And the reconstruction of places can reveal hidden memories that hold out the prospect for different futures" (Harvey 1996:306).

This construction of imagined places is important to Harvey, he would later dedicate the book Spaces of Hope entirely to the theme (Harvey, 2000). Harvey portrays in both of these works place as a deeply ambiguous facet of modern and postmodern life.

On the one hand investments in place can play a role in resisting the global circulation of capital but on the other it is often quite an exclusionary force in the world where groups of people define themselves against threatening others, who are not included in the particular local expression of place.

5.2 The sense of place

Doreen Massey's paper 'a global sense of place' (1994) is in many ways a response on Harvey's way of thinking, a response that hinges on a redefinition of place as an inclusive and progressive site of social life (Cresswell, 2004). Her plea is for a new conceptualization of place as open and hybrid – a product of interconnecting flows, of routes rather than roots. This extroverted notion of place calls into question the whole history of place as a centre of meaning connected to a 'rooted' and 'authentic' sense of identity; forever challenged by mobility.

Harvey's critique on Heidegger was already echoed by Doreen Massey in her paper 'power geometry' (Massey, 1993). Although her work has also been important in bringing ideas of place and space to greater prominence in contemporary theory, nevertheless, Massey explicitly criticizes what she takes to be the "Heideggerian view of Space/Place as Being" and raises a variety of objections to such an account (Malpas, 2007), claiming that:

"There are a number of distinct ways in which the notion of place which is derived from Heidegger is problematical. One is the idea that places have single essential identities. Another is the idea that the identity of place – the sense of place – is constructed out of an introverted, inward-looking history based on delving into the past for internalized origins... Another problem with the conception of place which derives from Heidegger is that it seems to require the drawing of boundaries... [Another aspect of] the Heideggerian approach, and one which from the point of view of the physical sciences now looks out of date, is the strict dichotomization of time and space..."(Massey 1993:64).

Massey describes a twofold problem with the definition of place as a merely static and rooted reaction to a dynamic and mobile world. First she argues that it may be the case that people do need a sense of place to hold on to – to be 'rooted'. Secondly Massey sees the flow and flows of global movement not necessarily as anxiety provoking. The reactionary sense of place that troubles Harvey is for Massey marked as problematic by at least three interconnected ways of thinking. Being: the idea that places have single, essential identities, the idea that the sense of place is constructed out of an introverted inward-looking history and the conception of place as something that requires the drawing of boundaries (Massey 1994). In her paper Massey describes Kilburn, a neighbourhood of London where she lived for years. Her description is a celebration of diversity and hybridity, an evocative mix of people of multiple ethnicities living and working side by side:

"While Kilburn may have a character of its own, it is absolutely not a seamless, coherent identity, a single sense of place that everyone shares. It could hardly be less so. [...] Moreover, not only does Kilburn then have many different identities (or its full identity is a complex mix of all these) it is also, looked at in this way, absolutely not introverted. It is [...] impossible even to begin thinking about Kilburn High Road without bringing into play half of the world and a considerable amount of British imperialist history [...]. Imagining in this way provokes in you (or at least in me) a really global sense of place" (Massey 1994:174-175).

Massey's Kilburn is, in her words, a 'meeting place' where a particular 'constellation of social relations' comes together in place. Her observations of Kilburn draw towards a – what she defines – new extrovert, progressive and global sense of place. This definition of place is marked by:

(1) Place as process

(2) Place as defined by the outside

(3) Place as site of multiple identities and histories

(4) A uniqueness of place defined by its interactions

Reviewing the outlined perceptions of place by Heidegger, Harvey and Massey it seems important to notice the very local context in which they developed there concepts or to what context they refer. Heidegger uses the complete, romanticised and slightly naive, isolation of the Black Forest farmhouse. David Harvey refers

to Guilford, a place that sees itself under threat from difference and seeks to create clear boundaries to distinguish itself from the threatening outside. Massey's Kilburn on the other hand is a place of radical openness, in this perspective it is not surprising that her considerations are different. Where Harvey sees place as too reactionary, Massey's context allows her to suggest that it is okay to seek identity in place because that identity is never fixed and bounded.

6 THE CONTEMPORARY DEBATE.

6.1 See you in Disneyland

Michael Sorkins book 'Variations on a Theme Park' (Sorkin, 1992) was one of the most critical contributions with great impact on the discussion on urban renewal at the moment of publishing. In the early 90s he was one of the first to draw a problematic conclusion: in a predominantly suburban America, Disneyland was one of the few places where real urbanity can be experienced on a manner that is not threatening.

A safe place where all the infrastructure is organised well, where everything works and where everything is neat, where reigns an utopian ethos of pleasant living. According to Sorkin it is no wonder that private developers have taken Disneyland as an example for their new projects. Around the world, Disney is the benchmark (Sorkin, 1992).

Sorkin abhors this Disneyfication. The illusion of parochialism and universal happiness for all, based on an almost completely passive way of leisure – a world without work – is his problem. For Sorkin even worse is the lack of freedom of choice, a result of cutting away everything that might disturb people – nonconformity, the aberrant. His most fundamental objection, however, focuses on the lack of democracy, of real citizenship. Sorkin uses television (another popular 90s phenomena in urban critical theory) as a metaphor:

"[...] the structure of this city is a lot like television. TV's main event is the cut, the elision between broadcast bits, the seamless slide from soap opera to docudrama to a world from our sponsor. The 'design' of television is all about erasing differences among these bits, about asserting equal value for all the elements in the net, so that any of the infinite combinations that the broadcast day produces can make 'sense'. The new city likewise eradicates genuine particularity in favour of a continuous urban field, a conceptual grid of boundless reach" (Sorkin 1992:xii)

Sorkin argues that what is missing in the city is not just a matter of any particular building or place, rather the spaces in between, the connections that make sense of form. Liberated from its 'centres' and edges – due to advanced infrastructures – and by a new world order bent on a 'single citizenship of consumption (Sorkin, 1992), the new city threatens an unimagined sameness even as it multiplies the illusory choices of the TV system. Sorkin sets out three characteristics that mark this city, and outline his book. First is the scattering of stable relations to local physical and cultural geography, the loosening of ties to any specific space. Second is the obsession with 'security', both technological and physical. Third is the realm of the city turning into one of simulations, the city as theme park. Universal Studio City Walk functions then as a great example, being the ultimate fusion of being completely isolated – heavenly monitored and an extreme constellation of the fictive.

Comprehensively Sorkin elaborates on the relation that he sees between Disney Land and the garden city, both in organization as in scale. Their location on the urban perimeter, at the intersection of highways and their strict internal order – radiating from a strong centre the parks are thematically zoned. Whereas the ground plane is dedicated to the pedestrian circulation, its perimeters and airspace are the terrain of extensive and expressive transport systems: trains, monorails and aerial gondolas. He sees it as a particular way of urbanism, one that accelerates trends that are everywhere noticeable. According to Sorkin the problems addressed by 'Disneyzone' are quintessentially modern: crime, transportation, waste, the relationship of work and leisure, the transience of populations and the growing hegemony of simulacrum (Sorkin, 1992)

Sorkin argues in extent that like world fairs, theme parks offer 'intensifications of the present, the transformation of the world by an exponential increase in its commodities. And for Sorkin the motion is essential in this experience, movement is ubiquitous and central:

"Getting there, then, is not half the fun: it's all the fun. At Disneyland one is constantly poised in a condition of becoming, always someplace that is 'like' someplace else. The simulations referent is ever elsewhere, the

'authenticity' of the substitution always depends on the knowledge, however faded, of some absent genuine. Disneyland is in perpetual shadow, propelling its visitors to an unvisitable past or future, or to some (inconvenient) geography" (Sorkin 1992:216)

Sorkin links Disneyland to an existing city. Los Angeles. Where historic themes describe the city's own self-description. The genius of the city resides – according to Sorkin – not simply in dispersal but in juxtaposition. The Disney visitor seeks and delights in the relationship between what he or she finds and its observes back home.

"In the Disney utopia, we all become involuntary flaneurs and flaneuses, global drifters, holding high our lamps as we look everywhere for an honest image [...] Like television, it is a machine for the continuous transformation of what exists [...] into what doesn't [...]. It's a genetic utopia, where every product is some sort of mutant" (Sorkin 1992:232).

6.2 The death and life of authentic urban places

What was considered a 'typical', 'authentic', 'original' district was taken over by representatives of the wealthy middle class and everything that initially was so appealing – particularly the mixing of the population and the creative atmosphere – has disappeared. In Amsterdam this process of gentrification occurred for instance in the Jordaan: for long being a typical Amsterdam neighbourhood, but whereas nowadays all 'real Jordanezen' moved to periferal Purmerend or Almere. New York is the biggest offender of them all, the anonymous blogger Brooks of the Lost City blog viciously described Bloomberg's city as:

"homogeneous, anodyne, whitewashed, suburban, toothless, chain-store-ridden, ordinary, exclusive and terribly, terribly expensive. A town for tourists and the upper 2 %. He took a world-class capital of culture, individuality and independent endeavour and turned it into the smoothest, first-class, gated community Houston ever saw" (Brooks 2010).

Sharon Zukin in 'Naked City: The Death and Life of Authentic Urban Places' focuses on urban change that manifest in specific neighbourhoods. Building on the argument of Jane Jacobs but in the same time critiquing it (Zukin, 2009). To this end she analyses accurately what has happened in a few famous New York neighbourhoods like Williamsburg, East Village and the area around Union Square, but also a former no-go area as Harlem. Zukin distinct a pattern: ramshackle neighbourhoods get discovered by squatters, artists, immigrants and undergo a metamorphosis. There are then attractive shops with local products, restaurants with exotic foods and there is a dynamic, cosmopolitan atmosphere. The 'authentic neighbourhood' is born.

Jacobs showed a world that was disappearing in the time she wrote about it (Jacobs, 1961). There are no housewives any more who spend all day monitoring the street and talking with the grocer on the corner. Existence is mobile and has become hectic, we have barely the opportunity to deeply root into our neighbourhoods. Zukin argues that authenticity refers to the 'look' and 'feel' of a place, as well as the social connectedness that place inspires:

"Yearning for authenticity reflects the separation between our experience and of space and our sense of self that is so much part of modern mentalities. Though we think authenticity refers to a neighbourhood's innate qualities, it really expresses our own anxieties about how places changes. The idea of authenticity is important because it connects our individual yearning to root ourselves in a singular time and place to a cosmic grasp of larger social forces that remake our world from many small and often invisible actions" (Zukin 2009:220).

Zukin shows that cities are subject to the market and therefore sensitive to changes in appearance, taste and fashion. Whether we like it or not, Zukin argues, our preference for designer clothing, healthy food and audiovisual toys dispels vulgar and cheap eats tents and mass stores. Likewise, our desire to live in the large former warehouses ensure that such buildings are restored and made suitable for habitation. But this applies to everything that formerly sat dispelled and disappears. 'Authentic' is then a buzzword, obsolete before you know it.

7   REACTIVATING THE ORDINARY

Recreating a sense of urban vitality means that one does not just introduce 'publicness' as what would be 'places to meet'. As argued before, it requires a deeper understanding of the city. The goal would be to keep working on the locus of the city and one might completely has to rediscover or reactive it. It are the

singularity of residuals from the former city with its civic events, failed attempts and its particular natural setting. All those have an intrinsic order and logic, but require an almost simple way of looking to the city. Turning this understanding into a laboratory, I have been working on a project that reactivates and reconnects urban spaces in Downtown Los Angeles (Beijer, 2013).

Los Angeles downtown's rich diversity of 'theme districts' lacks continuity in the experience of the public realm. Great micro-environments are of a distance from each other that is too far to walk, while downtown at the same time is utterly inconvenient to drive. Empty plots and big parking lots are opportunities for further intensification and when located around interesting zones, public parks and other means of public transport - they can serve as location for monorail stations. Hereby the laboratory is not about the monorail in itself. Building on Los Angeles' rich history of exaggeration, the rendering of this exploration plays in the realm of optimistic utopia.

Instead of homogenising the urban landscape and turning the diversity into an nondescript themepark, the monorail helps to manifest the various identities and characters. Just by being an nondescript generic element itself that only connects great micro spheres. Overlaid histories from 1888 to 2011 (fig. 2) of the historic 'hotspots', show the arguments of this thesis. Attractive and meaningful spaces don't just suddenly appear, most of them are residuals from earlier urban ecologies. Former time frames are mapped (grey tones) on the next phase (purple), questioning the relation between morphology, centrality and infrastructures.

Rendering a future where ordinary and authentic places are not just a gimmick or only get articulated through decorative shells. But a future where the ordinary place is one of historic existence. Intrinsic logic that one conceives through feeling it, realizing it without the oppressive demand to consume it.
Fig. 2: The historic layering of contemporary hotspots (purple), from 1888 to 2011 in Los Angeles (by author).

8 CONCLUSION

One of the difficulties in clarifying the relation between space and place is, not only that the two are necessarily connected, but that this concept for years tended to be understood only spatially. Then Heideggers overarching philosophical notion of 'dwelling' is an interesting perspective. Dwelling as a basic capacity to achieve a form of spiritual unity between humans and the material world allows us to construct places, give them meaning and nuance them. Harvey portrays place as a deeply ambiguous facet of post-modern life. The reconstruction of places thus can reveal hidden memories that hold out the prospect for different futures. Harvey points out that investments in place in the same time often can be quite an

exclusionary force in the world where groups of people define themselves against threatening others who are not included in the particular local expression of place.

The sense of being rooted in place, argued by Harvey is something we find back in Massey's work. But she is able to bring it closer to life in the complexity of the metropolis. Massey points out that the problematic definition of place as a merely static and rooted reaction to a dynamic and mobile world. She argues that people might do need a sense of place to hold on to – to be 'rooted' – but to her the flows of global movement not necessarily have to be seen as anxiety provoking. Whereas the notions of people as Heidegger, Harvey and Massey remain rather abstract, the concrete critique by Sorkin and Zukin clearly points out the problematic paradox the public domain of the metropolis is in. Sorkin argues that what is missing in the city is not just a matter of any particular buildings or places, rather the spaces in between, the connections that make sense of forms. Sorkin abhors the thematisation of public space; the illusion of parochialism and universal happiness for all and the lack of freedom of choice.

Existence became mobile and increasingly hectic and Zukin argues that we barely have the opportunity to deeply root into our neighbourhoods. Zukin argues that authenticity refers to the 'look' and 'feel' of a place, as well as the social connectedness that place inspires. She makes the argument that longing for authenticity reflects the separation between our experience and of space and our sense of self, that is so much part of modern mentalities. Though we think authenticity refers to a neighbourhood's innate qualities, it really expresses our own anxieties about how places changes. And then we can try to grasp the meaning of ordinary, authentic places in the city. A recommendation would be to start with leaving the city the city. Commercial driven urban development led to a public domain that became private, visualising a complete lack of democracy, of real citizenship. The thematisation of the street partly deluded the city by decorating it with false notions of romanticism, but also by making it increasingly exclusive and unjust.

The goal would be to keep working on the locus of the city, the collective memory. Rediscovering the singularity of residuals from the former city with its civic events, failed attempts and its particular natural setting. The preservation of a sense of place is then an active moment in the passage from memory to hope, from past to a better future.

L'altra faccia dell'economia: gli street vendors e l'uso dello spazio urbano nell'area metropolitana di Cagliari

Roberta Floris, Anania Mereu

1 ABSTRACT

L'attività del commercio ambulante ha svolto un ruolo di primaria importanza nell'evoluzione della definizione concettuale dell'economia informale: oggi, nell'era della globalizzazione, tale fenomeno rappresenta una fetta importante dell'economia sia nei paesi in via di sviluppo sia nei paesi sviluppati. Gli attori principali del settore informale sono gli street vendors, i quali occupano spazi urbani nello svolgere la loro attività di vendita, caratterizzata per lo più da alimentari e oggettistica varia.

Tale fenomeno è un aspetto " poco esplorato" dal punto di vista della pianificazione urbana. Questo infatti fa parte di quella faccia della città globalmente riconosciuta in quanto facente parte della vita di tutti i giorni, ma mai compresa sino in fondo per la complessità della sua natura. Anche in piccole realtà quale è quella di Cagliari, è possibile riscontrare la presenza dei venditori ambulanti.

Dopo un breve excursus sullo stato dell'arte, il paper analizza il fenomeno circoscritto all'area metropolitana di Cagliari, interagendo direttamente con gli attori protagonisti. Infatti parte importante della metodologia seguita è stata la conduzione di interviste dirette previa realizzazione di un questionario semi-strutturato, a specifiche categorie: venditori informali locali, venditori informali stranieri, venditori formali.

Dai dati raccolti è emerso un quadro di problematiche che influisce non solo sulla tipologia dei rapporti tra attori dell'economia informale e dell'economia formale ma anche sull' occupazione dello spazio urbano.

2 INTRODUZIONE

L'attività del commercio ambulante ha svolto un ruolo fondamentale nella storia della definizione concettuale dell'economia informale.

Con il termine economia informale si intendono quegli aspetti dell'economia del Paese che, seppur a fini legali, non vengono dichiarati, in tutto o in parte, ai pubblici poteri. L'economia informale rappresenta una sorta di ammortizzatore sociale per i problemi legati alla disoccupazione e una possibilità di sopravvivenza per quella parte della popolazione più vulnerabili o già in condizioni di povertà (Zurru,2005).

Sia chi si occupa di paesi in via di sviluppo che di paesi in paesi a capitalismo maturo, descrive il commercio ambulante come un meccanismo fondamentale di sussistenza per le persone senza alcuna possibilità di guadagnarsi un posto negli spazi formali dell'economia o come uno strumento di contrasto contro le logiche dominanti del sistema capitalistico moderno.

Il commercio ambulante ha quindi la peculiarità di risultare quel settore escluso dall'economia formale; in termini di capitale è caratterizzato da basse barriere all'entrata, la conduzione è prevalentemente familiare con livelli tecnologici quasi totalmente inesistenti (Bellanca,2008).

L'immagine immediata che può suscitare la vendita ambulante è quella di un mondo caotico, animato da un numero difficilmente stimabile di attori. Questi, fondamentalmente mossi dal forte bisogno, decidono di vendere qualcosa per strada, in competizione con gli altri attori, per conquistarsi qualsiasi spazio urbano che possa garantire la possibilità di racimolare le risorse utili alla propria sopravvivenza giornaliera. Al fine della sopravvivenza uno spazio di vendita vale l'altro per qualsiasi ambulante. Ciò comporta una disposizione caotica degli attori nello spazio urbano ed una forma complessiva dello spazio fisico occupato che riflette la capacità dei singoli attori di gestire al meglio le proprie risorse.

In passato gran parte degli spazi dove avvenivano le transazioni erano subordinati a rigorosi controlli istituzionali, e gran parte della letteratura storica fa rimandi continui alla centralità e specificità degli spazi fisici per l'attuazione delle transazioni economiche, definendo i meccanismi di limitazione che forze sociali e politiche comportavano per la libera azione economica dei singoli.

La localizzazione fisica del mercato appare un elemento intimamente legato alla sua esistenza: i mercatini locali posti alle porte della città e le fiere rappresentano le prime forme di localizzazione fisica del mercato; quando raggiungevano un certo livello di importanza, venivano contrassegnate anche dall'identità temporale, con la definizione di una precisa cadenza periodica per le vendite. L'elemento chiave di questo processo diviene così il luogo in cui avvengono le transazioni: lo spazio urbano (Bagnasco, 1988).

In questo lavoro si analizzerà il settore del commercio ambulante nella città di Cagliari dando particolare attenzione alla dimensione dello spazio urbano.

I temi dell'indagine sono stati trattati con metodologia qualitativa in due momenti: nella prima fase esplorativa e di ricostruzione del contesto, tramite una mappatura del fenomeno in città e la conduzione di interviste agli attori chiave; nella seconda fase come approfondimento dei risultati più complessi e problematici emersi dal questionario. Nei paragrafi che seguiranno verrà spiegata nello specifico la metodologia adottata. Il censimento degli street vendors di frutta e verdura principalmente, ha consentito di disegnare la disposizione spaziale quotidiana degli ambulanti e la forma urbana complessiva di questo mercato irregolare, come pure alcune caratteristiche socio anagrafiche degli attori protagonisti (Angioni, 1982).

La continuità temporale delle transazioni economiche irregolari viene concepita in questo paper come problematica, privilegiando un tipo di analisi orientata all'ottenimento del dato spaziale: il luogo di lavoro diviene infatti uno spazio urbano occupato in modo irregolare per la vendita irregolare.

3 EVOLUZIONE DEL COMMERCIO AMBULANTE

3.1 Il mercato alimentare storico

Lo scambio delle merci è stato da sempre uno degli elementi essenziali del processo evolutivo umano, ne sono state testimonianza le più antiche civiltà. Successivamente l'agricoltura, sistema produttivo primario, ha innescato il processo di passaggio dal nomadismo alla stanzialità e, con esso, ha messo in evidenza le variegate esigenze legate alla conservazione dei prodotti eccedenti, a quelli da consumare e a quelli destinati allo scambio di altri beni (Roma, 2001).

Da tale primitiva organizzazione è scaturita la necessità di strutture per il deposito delle merci e di spazi atti a contenerle per essere successivamente utilizzate, barattate con altre o vendute. Queste esigenze hanno dato vita ai mercati e ai primi commercianti: i mercanti.

Il mercato ha sempre rappresentato un punto di riferimento per quel ruolo di relazione e di scambio che ne costituisce dalle origini il substrato portante, imponendosi come simbolo non solo del commercio dei prodotti, ma anche come spazio di relazione e di scambio delle diverse culture locali (Anderson, 1996).

Nonostante l'evoluzione dei tempi e gli inesorabili processi di cambiamento e di trasformazione che hanno mano a mano interessato le città, il mercato ha continuato a vivere, adattandosi e modellandosi secondo le esigenze imposte dai moderni ritmi di vita.

3.2 Il commercio ambulante nella società post-moderna

Pur essendo specificatamente regolata dalla legge, la gran parte della vendita per strada di beni quali quelli alimentari, frutta e verdura, si svolge in città in modo abusivo. Ma a differenza di tante altre attività sommerse, per poter svolgere normalmente la loro attività, gli attori necessitano di ampia visibilità per la domanda, generando nei confronti delle istituzioni tese al controllo e alla repressione dei fenomeni di irregolarità. A fronte di questa enorme possibilità repressiva è evidente che un commercio ambulante abusivo viene istituzionalizzato nella vita sociale della città, quale mercato che si è affermato come spazio quotidiano di relazioni contraddistinto da proprie regole specifiche.

Il commercio ha quindi creato spazi che generano nuovi rapporti sociali secondo un modello sempre più avulso da quello diretto che un tempo intratteneva il "consumatore-cliente e il venditore-amico", basato essenzialmente su un rapporto personale e di fiducia, caratterizzato da un approccio del tutto impersonale che riflette la diversa organizzazione commerciale: ieri per ramo merceologico, tipico dei negozi specializzati a conduzione familiare, oggi con un assortimento vario riposto negli scaffali dei moderni complessi commerciali.

In tale nuovo contesto gli Enti Locali sono chiamati a risolvere i problemi relativi alla convivenza del dualismo commerciale attraverso una politica volta allo sviluppo delle medie strutture di vendita e alla qualificazione del commercio ambulante.

L'esistenza di questo mercato irregolare è possibile in città grazie al controllo dello spazio di vendita. La spazialità delle aree di mercato è contenuta all'interno di particolari quartieri, vie e piazza, ed è regolata da norme informali, prodotto di relazioni sia tra i diversi attori economici, sia tra questi e quelli politico/organizzativi. (Bagnasco, 1986)

L'estrema facilità di intraprendere l'attività di vendita e i bassi costi iniziali ne fanno un ambito frequentatissimo. Ma se l'ingresso al settore appare abbastanza semplice, non possiamo dire la stessa cosa riguardo la permanenza al suo interno. Questo perché l'occupazione dello spazio non è una condizione che può dirsi definita una volta per tutte; i decisori politici infatti garantiscono l'uso della superficie di vendita agli ambulanti per la loro sopravvivenza tramite una concessione elastica, vincolata da strutture normative informali abbastanza rigide ed utilizzata "strumentalmente" come merce di scambio per ottenere consenso politico; ne consegue che certi spazi vengono concessi e altri negati perché ciò che è in gioco sono i diritti degli altri cittadini e il decoro della città (Roma,2001).

L'immagine che gli attori politici vogliono fornire alla città, influenza anche l'operato degli organismi che devono tradurre operativamente questo elemento: la Polizia Municipale. In tal caso, alla forza del diritto alla sopravvivenza, quale elemento che orienta l'azione dei vigili urbani, si affianca il deficit organizzativo interno, che limita l'applicazione letterale della legge e consente un uso illegale degli spazi agli ambulanti.

4 LA FORMA URBANA DEL MERCATO IRREGOLARE

La vendita di prodotti e oggettistica varia che avviene per la strada, è un fatto talmente quotidiano da apparire normale e quindi parte integrante della vita quotidiana della città. La presenza degli ambulanti diventa quindi una cosa utile e scontata e capace di soddisfare i bisogni economici di una vasta clientela (Bagnasco, 1988).

Nonostante questa attività possa essere svolta in modo regolare, in spazi e tempi ben definiti, l'esperienza di qualsiasi cittadino richiama la presenza diffusa in diverse zone della città di street vendors abusivi.

Così, per la mancanza di autorizzazione di vendita, per il mancato pagamento della concessione del suolo, per la vendita di prodotti non previsti dalla tavola merceologica comunale e per la mancanza di rilascio al cliente di qualsiasi ricevuta fiscali, un numero considerevole di street vendors viene tagliato fuori dal sistema di regole che disciplina l'attività.

Altro problema da non sottovalutare sono le continue proteste e lamentele dei negozianti stanziali nei confronti degli abusivi, visti come concorrenti sleali.

La particolarità del commercio ambulante è che, a differenza di altre attività irregolari, per esercitare la propria attività hanno bisogno di visibilità. Esporre i propri prodotti in uno spazio pubblico, come marciapiedi strade e piazze è la condizione primaria per poter lavorare: la visibilità della postazione deve quindi essere massima(Zurru, 2005).

Come verrà ben esposto nel paragrafo che segue, nella città di Cagliari questo tipo di vendita si effettua nei giorni feriali in spazi bene delimitati e circoscritti all'area dei mercati rionali; nei giorni festivi invece le piazze e una quota rilevante del quartiere di Sant'Elia vengono occupate dalla vendita di beni alimentari.

Per cui ogni tipologia di street vendors è definito un singolo spazio e quindi un proprio angolo di visuale. Le mappe che seguiranno consentiranno di capire meglio la complessità spaziale del fenomeno.

5 METODOLOGIA ADOTTATA E MAGGIORI RISULTATI OTTENUTI

Dall'analisi bibliografica del fenomeno, e dalla sua proiezione nel contesto metropolitano di Cagliari, sono emerse una serie di zone caratterizzate dalla presenza degli ambulanti, che hanno mutato nel tempo la loro forma: per esempio, alcune aree in cui prima si riscontrava la presenza degli street vendors ora risultano essere non occupate, altre che prima erano caratterizzate da una disposizione lineare e continua dei venditori ambulanti ora risultano averla frammentata, altre ancora invece sono di recente occupazione.

Fig. 2: Mappatura venditori informali internazionali intervistati e foto.

Ciò mostra come tali aree siano in continua evoluzione sia per il cambiamento di scelta sul dove svolgere l'attività da parte dei venditori, sia per l'intervento del Comune al fine di salvaguardare l'immagine e il funzionamento di alcuni aspetti cittadini quali ad esempio il decoro e la circolazione fluida delle auto.

Per avere un resoconto, almeno parziale, dell'evoluzione delle aree interessate dalla presenza di venditori ambulanti, la prima parte della metodologia è stata quella della mappatura del fenomeno in alcune zone dalla posizione urbana favorevole allo sviluppo di tali attività informali (Zurru, 2005).

Una è l'area di Piazza San Michele – Is Mirrionis, uno dei quartieri popolari di Cagliari, un'altra è quella della Località Is Bingias, in prossimità del mercato civico di Pirri e infine quella del quartiere della Marina, nel centro storico della città, e del Centro Commerciale "Le Vele", sito nel comune di Quartu Sant'Elena.

In prima istanza la mappatura mirava a identificare la disposizione spaziale dei venditori ambulanti ed è stata completata mediante un'analisi visiva e fotografica supportata delle seguenti informazioni reperite:

- l'età approssimativa e genere del venditore;
- la tipologia di merce venduta,
- il grado di complessità tecnologica (complessità attrezzatura) a supporto della vendita;
- il numero di addetti alla vendita.

A titolo esemplificativo si riportano qui sotto due tra le mappe realizzate; la Figura 1 mostra la posizione occupata dai venditori informali e formali intervistati nell'area di Is Bingias, la Figura 2 rappresenta la mappatura dei venditori informali intervistati nell'area di San Michele con alcune foto esplicative.

Al fine di ottenere risultati il più possibile realistici, parte integrante della metodologia è stata l'elaborazione di due differenti questionari semistrutturati: uno per la categoria dei venditori informali locali e stranieri, e uno per quella dei venditori formali (Zurru, 2005).

Obiettivo principale del questionario era quello di ottenere informazioni riguardanti i benefici economici del lavoro svolto, il rapporto tra questo e l'area in cui esso viene esercitato, nonché eventuali variazioni logistiche e tipologiche dell'attività svolta e le esigenze lavorative di tali venditori.

Per quanto riguarda invece i venditori formali locali, è stata condotta un'intervista con l'intento di individuare: gli impatti che la presenza di venditori informali nelle vicinanze delle attività formalizzate può determinare sui guadagni nonchè sull'immagine di tali attività, gli impatti sulla città, ed eventuali situazioni problematiche. Sono stati intervistati 9 venditori informali e 9 venditori formali locali nella zona di San Michele, altrettanti nella zona di Is Bingias, mentre nei quartieri di Marina, del Poetto, di San Benedetto e del centro commerciale "Le Vele" sono stati intervistati 28 ambulanti internazionali. Complessivamente sono state condotte 64 interviste.

6 DATI REPERITI

6.1 Tipologia delle merci vendute e grado di tecnologia adottato

Per quanto riguarda le interviste condotte ai venditori informali locali e ai venditori formali è utile considerare i dati separatamente per le due aree di San Michele e Is Bingias, dato che si tratta di aree molto differenti per posizione occupata. I risultati ottenuti complessivamente sono i seguenti:

Venditori informali		
	Area Is Bingias (Tot. Intervistati 9)	Area San Michele (Tot. Intervistati 9)
Genere	Donne 5 Uomini 4	Donne 3 Uomini 6
Età	Tra i 35 e i 54 anni 7 Superiore ai 54 anni 2	Tra i 25 e i 34 anni 1 Tra i 35 e i 54 anni 5 Superiore ai 54 anni 3
Numero addetti alla vendita	Un addetto 8 Due addetti 1	Un addetto 7 Due addetti 2
Tecnologia usata per la vendita	Furgone e bancarella 4 Macchina e bancarella 2 Ape Piaggio 3	Furgone e bancarella 2 Macchina e teloni 2 Ape Piaggio e teloni 3 Bagagliaio auto 1 Tavole e cassette 1
Tipologia merce venduta	Frutta e verdura 3 Abbigliamento e calzature 3 Piante 2 Biancheria per la casa 1	Frutta e verdura 3 Abbigliamento e calzature 3 Oggettistica varia 2 Pupazzi e libri 1
Provenienza merce venduta	Italia Cina Olanda Belgio	Italia Cina
Clienti abituali	Residenti del quartiere Passanti Turisti	Residenti del quartiere Passanti Turisti

Vantaggi	Vicinanza al mercato civico Brevi distanze dalla propria abitazione Quartiere residenziale Centralità della zona	Zona di passaggio Quartiere popolare Brevi distanze dalla propria abitazione
Svantaggi	Assenza di parcheggi Assenza di vigilanza	Assenza di servizi (parcheggi, acqua corrente)

Table 1: Risultati interviste ai venditori informali locali

Venditori formali		
	Area Is Bingias (Tot. Intervistati 9)	Area San Michele (Tot. Intervistati 9)
Genere	Donne 5 Uomini 4	Donne 4 Uomini 5
Età	Tra i 25 e i 34 anni 1 Tra i 35 e i 54 anni 7 Superiore ai 55 anni 1	Tra i 35 e i 54 anni 7 Superiore ai 55 anni 2
Merci	Alimentari 2 Cartoleria 1 Abbigliamento 3 Articoli da regalo 1 Gioielleria e bigiotteria 2	Alimentari 3 Cartoleria 1 Abbigliamento 2 Articoli da regalo 1 Ferramenta 2
Clienti abituali	Residenti del quartiere Passanti Turisti Venditori ambulanti Altri negozianti	Residenti del quartiere Passanti Turisti Venditori ambulanti
Vantaggi	Centralità della zona Vicinanza ai venditori informali locali	Ambiente tranquillo (pacifica convivenza)
Svantaggi	Assenza di parcheggi Problema della vigilanza	Disordine Cattivo aspetto della zona Intralcio del passaggio nelle vie principali

Table 2: Risultati interviste ai venditori formali

Per quanto riguarda i risultati delle interviste ai venditori internazionali, la tabella che segue mostra quelli complessivi:

Venditori Informali internazionali	
	Viale Marconi – San benedetto – Marina – Stampace (Tot. Intervistati 28)
Genere	Donne 1 Uomini 27
Età	Minore di 18 anni 1 Tra i 18 e i 24 anni 9 Tra i 25 e i 34 anni 13 Tra i 35 e i 54 anni 5 Superiore ai 55 anni 0
Nazionalità	Senegal 18 Bangladesh 9 Ghana 1
Merci	Accendini Fazzoletti Cd Abbigliamento e calzature contraffatte Oggettistica (Cover telefoni, occhiali da sole, souvenirs) Bigiotteria
Provenienza merci	Cina Italia Bangladesh Africa Nessuna risposta India
Piano di lavoro	Macchina Buste/borsoni Teli Cartone e cassette Tavole di compensato
Clienti abituali	Passanti Turisti Parcheggiatori Residenti del quartiere Altri venditori ambulanti Negozianti
Vantaggi	Passaggio di persone
Svantaggi	Fenomeni di razzismo Assenza servizi

Table 3: Risultati interviste ai venditori informali internazionali

L'analisi visiva e fotografica, nonché quella svolta mediante la somministrazione del questionario semi-strutturato ha permesso di ottenere una serie di dati che vengono riassunti qui di seguito. Per quanto riguarda i venditori informali locali dell'area di Is Bingias, essi hanno un'età media di 50 anni, leggermente superiore a quella dei venditori di San Michele (45 – 50 anni), ma di molto più elevata rispetto a quella dei venditori informali stranieri (25 – 28 anni). A Is Bingias è presente una buona rappresentanza femminile, superiore a quella della zona di San Michele, rappresentanza che risulta annullarsi quasi completamente tra i venditori informali internazionali.

Per quanto riguarda le merci vendute, in entrambe le aree di local street vending troviamo frutta e verdura, abbigliamento e calzature. A Is Bingias si vende anche biancheria per la casa e piante, mentre nella zona di San Michele oggettistica varia, pupazzi e libri. I venditori stranieri invece si limitano alla vendita di oggetti e di abbigliamento. La provenienza delle merci è all'incirca la stessa per i venditori locali: principalmente da Cina e Italia.

Per i venditori internazionali è più varia e come ci potremo aspettare in parte proviene dall'Africa e dall'India. Come attrezzatura a supporto della vendita, a Is Bingias solitamente per il trasporto usano o il furgone o l'Ape Piaggio o la macchina, mentre per la vendita allestiscono delle bancarelle con tavole.

A San Michele si possono riscontrare gli stessi mezzi di trasporto, mentre per l'esposizione della merce si usano metodi, oltre alle bancarelle, meno tecnologici tipo teloni e cassette per terra, o addirittura direttamente il bagagliaio dell'auto.

Per i venditori stranieri la tecnologia di vendita è ancora meno avanzata di quella già menzionata in quanto caratterizzata principalmente da teli e buste e solo qualcuno dispone di una macchina per il trasporto. I clienti abituali sono solitamente residenti del quartiere, passanti e turisti, per tutti i venditori informali, ma per i venditori stranieri possono essere annoverati tra i clienti anche i parcheggiatori .

Per quanto riguarda i venditori formali, essi presentano caratteristiche simili nelle due aree considerate: il numero di donne e uomini all'incirca si equivale, l'età media è compresa tra i 35 e i 54 anni.

Le merci vendute sono abbastanza varie; il maggior numero di attività è rappresentato da negozi alimentari e di abbigliamento, da cartolerie, da articoli da regalo, da gioiellerie e da ferramenta. I clienti abituali sono principalmente, come per i venditori informali, residenti del quartiere, passanti e turisti, ma anche venditori ambulanti e altri negozianti.

6.2 Gli impatti riscontrati

Ulteriori dati ricavati hanno permesso di individuare una serie di elementi importanti che hanno permesso di comprendere meglio la complessità del fenomeno. Quasi sempre quello del venditore ambulante è l'unica fonte di sostentamento della famiglia, infatti gran parte delle persone intervistate e/o osservate svolgevano la loro attività singolarmente.

La disposizione spaziale in cui viene svolta l'attività di vendita viene leggitimata seppur con le dovute restrizioni e in certi casi tollerata dalle Autorità e dalle Amministrazioni Locali. Essa innesca una serie di situazioni che hanno immediata ripercussione in termini di vendita. La maggior parte dei venditori locali intervistati, la ritiene strategica nonchè la migliore in cui possano vendere, in quanto, si trovandosi in quartieri abitati principalmente da persone di ceto basso o medio-basso, la clientela non manca mai e costantemente acquista prodotti a prezzi più accessibili.

Rappresentando essenzialmente dei luoghi di passaggio o luoghi in prossimità di attrattori come importanti attività commerciali, per coloro che dall'hinterland cagliaritano si spostano verso il centro della città e viceversa diviene più facile fermarsi per acquistare qualcosa.

Tra gli aspetti negativi conseguenti l'occupazione di spazi urbani per la vendita informale il problema più sentito è sicuramente la scarsa presenza di parcheggio nelle immediate vicinanze, che determina necessariamente una clientela inferiore rispetto a quella che si avrebbe qualora gli automobilisti potessero sostare più facilmente.

Altro problema è la scarsa presenza di servizi igienici sia per i venditori sia quelli necessari per ripulire la zona occupata, dopo lo svolgimento dell'attività.

In ultima istanza, per quanto riguarda le relazioni tra i venditori informali locali e i venditori formali, molto spesso si manifesta una sorta di collaborazione indiretta tra essi e inoltre dalle interviste è emerso come i

negozianti regolari considerino un vantaggio avere nelle vicinanze venditori informali che svolgono la loro attività in quanto essi attraggono una maggiore clientela.

7   CONCLUSIONI E POSSIBILI INTERVENTI DI MITIGAZIONE

La vendita ambulante abusiva appare un settore economico strutturale nella nostra soictà, in quanto piena dimostrazione della rivendicazione del diritto di sopravvivenza reclamabile da qualsiasi cittadino. Il diritto alla sopravvivenza degli street vendors viene riconosciuto non tanto come diritto civile ma come diritto umano.

É proprio il tentativo di salvaguardare i diritti di tutti, in concorrenza tra loro (quelli degli ambulanti, dei cittadini e dei negozianti) che orienta il comportamento politico e organizzativo, in una sorta di concessione elastica all'esercizio di vendita: alcuni luoghi vengono concessi altri proibiti.. anche in quei luoghi che vengono concessi il diritto alla vendita informale non è un scontatoma strettamente dipendente dalla policy altalenante.(Zurru,2005)

In questo spazio irregolare tutte le relazioni sono messe in gioco giorno per giorno, tutto è altalenante, ma nonstante la sua precarietà la struttura dell'informale regge oramai da diversi anni; gli ambulanti continuano ad occupare certi spazi e a caratterizzare certi luoghi urbani e a tessere startegie relazionali che consentono la persistenza del mercato sommerso nella sua fisicità.

Nei paragrafi precedenti è emerso come il coinvolgimento degli attori chiave ha avuto innanzitutto un'utilità strumentale, perché ha permesso di ottenere informazioni sul contesto locale e definire alcuni punti di intervento di intervento. Inoltre il coinvolgimento della comunità dei venditori abulanti e non ha avuto anche un ruolo costruttivo, perché ha permesso agli attori di decidere autonomamente secondo quali priorità verranno gestiti i processi di trasformazione territoriale dello spazio urbano che gli riguarda e di appropriarsi di una strategia di intervento.

Le possibili soluzioni, emerse dal confronto diretto con gli attori protagonisti sono le seguenti:

- L'aumento dei controlli da parte delle autorità vigilanti in modo che non vengano occupati senza nessuna autorizzazione ulteriori spazi pubblici ed eventuale modifica degli spazi attualmente concessi, al fine di evitare un ulteriore aggravamento del problema dell'intralcio del passaggio delle auto e del disordine. Sarebbe opportuno che tutti i venditori possedessero una licenza di vendita e dichiarassero ai fini fiscali i propri guadagni; questo porterebbe la maggior parte dei venditori a cessare con la propria attività in quanto, posti dinnanzi all'obbligo di una regolarizzazione, non riuscirebbero a sopravvivere, rappresentando questa l'unica fonte di guadagno familiare.

- La creazione di spazi appositi per i venditori informali con annessi sevizi igienici, contribuire a migliorare l'aspetto delle zone considerate: dalle interviste infatti è emerso tale deficit e la realizzazione di questi servizi potrebbe contribuire a migliorare l'aspetto delle zone considerate, permettendo agli ambulanti stessi di ripulire e tenere ordinata l'area al termine della giornata di vendita.

- la Creazione di nuovi parcheggi o concessione di aree per svolgere l'attività di vendita che siano servite da parcheggi, in modo tale che coloro che intendono acquistare prodotti dai venditori informali possano sostare tranquillamente, riducendo di conseguenza il problema del traffico veicolare.

La pianificazione urbana, all'interno di un contesto postmoderno deve essere fondata sulla conoscenza del fenomeno e capire chi tenere in considerazione quale soggetto che conosce. La conoscenza viene socialmente costriuta e richiede la validazione di una comunità di soggetti che conoscono. I processi politici e culturali fanno parte del costituirsi di quella comunità.

L'approccio consiste nella necessità di una negoziazione che sia specifica rispetto al contesto. Negoziare significa che tutti i protagonisti del processo di pianificazione, siano essi decisori o beneficiari delle strategie, conoscano una varietà di modi di conoscere e cominucare. Un modello basato sulla pianificazione esperta, che definisce l'interesse pubblico attraverso una deliberazione nazionale non è adatto ai nuovi contesti multculturali (Sandercock, 2004). Una pianificazione più democratica e culturalmente inclusiva deve attingere a molti modi di conoscere e deve sviluppare una sensibilità che sia in grado di individuare quali siano i modi più utili per conoscere e in quali circostanze metterli in atto.

Dall'esperienza sintetizzata in questo paper, emerge come le conoscenze siano state acquisite verso il dialogo, attraverso il confronto con l'esperienza dei veri attori protagonisti e con la lettura specifica delle testimonianze concrete.

Metrics of Assessing Affordable Living

Justyna Karakiewicz

(Professor Justyna Karakiewicz, University of Melbourne, Parkville, VIC 3000 Australia, justynak@unimelb.edu.au)

1 ABSTRACT

Providing good-quality, appropraiate and affordable housing for all in most of urban places around the world is a major challenge. Politcal leaders such as mayors, governors and other politicians struggle to develop mechanisms to satisfy the requirements for even basic provisions in both developed and developing countries. The problem is global but the answers are very culturally specific and the types and locations of new dwellings shapes our cities. While choices are made with the intention to alleviate poverty and improve quality of life, outcomes observed suggest that some solutions drive occupants even futher away from affordable life.

2 INTRODUCTION

A city is a direct reflection of its inhabitants, where the design directly influences the living conditions of the people. Modernist urban strategies call for cities to be disassembled into detailed component parts, where each part is optimised for a specific purpose (Geertman & Stillwell, 2002). Such strategies promote separation and segregation; this in turn has led to remoteness and loneliness of many inhabitants, detracting from the quality of urban life.

Master plans are a feature of a modernist planning approach (Sandercock, 1990). Typically, master plans are a description of a resolved city in which change is not part of the picture. The rigidity of this approach fails to respond to the dynamic evolution of the context. Consequently, a move away from prescriptive master plans has been observed (Riddell, 2003). In place of plans based on geometric properties (zones), performance specifications encapsulating observed or desired behaviours have been described resulting in a variety of outcomes (Hopkins, 2012). However, there is an urgent need to investigate new forms of description, prediction, and intervention in the design process particularly for affordable social housing. What is required is a different mind-set by architects and urban planners.

It is important to point out that when designing affordable social housing the focus should not be limited to the provision of affordable housing, but rather the provision of affordable living. Usually, we understand affordability as "inexpensive; reasonable priced," which is the definition in the Oxford Dictionary as illustrated with the sample phrase in this source as "affordable home." An etymological dictionary will show that "affordability" derives from "forward, onward, to put forth, to contribute, advance, accomplish." Therefore, the notion of enabling outcomes and creating opportunity could be a guiding characteristic of design.

3 AFFORDABLE LIVING AND THE HOUSE WE CAN AFFORD

We all need housing and we prepared to pay a significant proportion of our income towards it. But what we desire and what we can afford are two very different things. Each time we start looking for the place to live, disregarding our social status, we very soon come to realization that we cannot afford, what we want. We need to compromise and translate our wishes to wishes that we can afford. We make decision base on elimination of features that we can live without, constantly checking if what 'I want' is the same as what 'I need'. We make choices by ranking what is important to us. Far too often we realize that we are not in control of our decision on where and how to live. Homes located near opportunities for work, entertainment or good schools all seems to be too expensive, and we need to decide whether is better to have smaller house or live further out and commute. And the tighter is our budget the smaller amount of choices, and therefore those who are poor often have no choice at all. Most of them will end up in housing, which is affordable, but the living is not. Since this housing types will be located at the periphery of the city or in more central areas but economically devastated where work, schooling and even safety are chronically limited. Far too often affordable housing is very far from opportunity. And the reason behind it maybe that housing is most of the time treated in isolation. And this does not only refers to affordable, or social housing, developers, architects, planners, and politicians treat housing as separate element to other part of the city.

Housing is undoubtably the most important component of a city and therefore should not be treated in isolation. Furthermore affordable housing should be approached not as a product to house the poor or a container for undesirable elements, but as a framework for enabling social processes of complexity facilitated by the adaptability of a particular form. And this is what this paper is all about.

3.1 Market Feedback

In November 2011 the Grattan Institute issued a report on "Getting the housing we want", written by Jane-Frances Kelly, director of Cities Program at the Grattan Institute. The report clearly identified a mismatch between the housing Australian say they want and the housing that is provided. The report tested a hypothesis that housing demand and housing stock do not align. The Grattan Institute interviewed 700 residents of Melbourne and Sydney in order to identify their housing preferences. The results are very surprising, not because it is very clear from the report that housing in Australian cities do not match the choices and trade-offs that people would make if they could, but because it illuminates the choices and compromises people make when selecting their homes.

The data from the survey illustrated a substantial shortage of semi detached houses and apartments. In the introduction to the report we read:

New supply is not reducing the mismatch, and there are barriers to delivering more of the housing people say they want. These include difficulty of land assembly and preparation, the risk and uncertainty of planning systems, and the cost of materials and labour for building over three storeys. Indeed, the incentives facing developers and builders are skewed away from infield development, and towards building more detached houses at the edge of our cities" (Kelly et al, 2011b).

The biggest problem with infield development is that developers are unable to provide the type of housing, which people want for the price that they can afford, without loosing all possible profits. The opportunities to make profit at the edge of the city, by developing greenfield sites are to strong to be rejected by developers and the sprawl continues together with unaffordable life styles.

New developments at the edge of the cities require new infrastructure, roads, utilities, etc. Most of the time the densities of these developments cannot support public transport, schools, and commercial activities and therefore residents are force to commute and drive in order to reach shops, utilities, schools, clinics, etc. The time, energy, cost of fuel and car maintenance are often forgotten when calculating initial cost of new home they choose to live. Most of the time, we all look at the price of the house and not the cost of living there.

The Grattan Report states that the average cost of commuting from outer-suburbs in Melbourne is more than $500 a week and $300 a week for inner-suburbs. For people living in the CBD areas of Melbourne is anything between $0-50 (BITRE, 2011). A simple mortgage calculation for what you need to pay for the loan of $300 000, at interest rate at 7.5 % for the loan period of 25 years is equal to $511 per week, which means that one can spend extra $ 300 000 to buy accommodation which does not require commuting. The challenge is to identify how commuting can be afforded at $500 a week, yet the threshold of a higher down payment on the more expensive home is beyond many, hence the trap of higher ongoing costs.

The 2008 Housing Affordability Report from the Australian Conservation Foundation and the Victorian Council of Social Service we read that on average, low-income earners spend greater proportion of total weekly household budget on energy, water and transport, 8.44 percent, than wealthier households 5.99 per cent. Dodson and Sipe (2005) show that oil and mortgage vulnerability is worsening each year. People on low incomes are therefore forced to live in outer-suburbs where they are more vulnerable to increasing petrol prices and hence to increases in interest rates or rental prices.

The question is why people choose to live in outer-suburbs where the life is most of the time unaffordable? What are the main drivers in decision-making processes? Can they choose to move to the inner suburbs instead and live more affordable lives? The answer most likely will be "no".

3.2 Problems with inner suburbs

One of the biggest problems with increasing development of housing within inner suburbs is the resistance of existing residents and their fear of change. The residents in established inner-suburbs are extremely resistant to change. Any suggestion of population growth or increase of density brings anxiety and fear to the community. Even people who understand benefits and necessity of population growth they want all the

benefits without making any changes to the way they live. And most of the people cannot see any benefits from having more households in their neighbourhoods. Therefore any new developments within inner suburbs are very problematic.

But there is another problem in inner suburbs related to residential mobility. Australian Bureau of Statistics 2008 suggests that residents who own their homes are almost 30 % less likely to move compared with private tenants. Furthermore, those with mortgage over 20 % are also less likely to move (Andrews, 2011). There are many barriers that prevent people from moving and therefore utilizing existing housing stock more efficiently. The most cited factors are usually transaction costs, the amount of choices available within the same area, real estate commissions, and preferential treatment for home ownership in asset tests for welfare (Leigh, 2011). People often choose to stay in their original property even if down-sizing, or reduction in commuting time due to different job opportunity, would have been good enough reason too move (Henry, 2009). Leigh (2011) believes that a 10 % reduction in stamp duty would possible increase people mobility by over 2 %. This in turn may increase house prices by 1.6 %. Henry (2009) suggests that stamp duties should be replaced by land-tax based on the value rather than size of holding. The same idea is repeated in Australians for Affordable Housing (HousingStressed.org.au) publication titled: Addressing Housing Affordability in Australia: A 4 point plan for the next 5 years (2012). Unfortunately stamp duties are part of Australian tax system and are very unlikely to be abolished. The stamp duties in Victoria (Melbourne) reached 5 % in 2011 (Larocca, 2011). What is also unfortunate that the first paragraph in Addressing Housing Affordability in Australia we read:

Australians for Affordable Housing are proposing a four point plan that will deliver 30,000 new affordable housing units each year and lift 250,000 households out of housing stress (HousingStress.org.au, 2012)

In the same report we read about how we can increase the supply of affordable rental housing and build more affordable housing through an Affordable Housing Growth Fund. Affordable Growth Fund is proposed as "banded" model. The three bands are described below.

- Band A provides a deep subsidy to ensure rents are set below 25 % of household income and provide secure tendencies, similar to current public housing model.

- Band B provides a mid level subsidy to secure dwellings at least 20 % below market rent, for example further investment in the National Rental Affordability Scheme or programs that assist households in private rental market to secure long term leases with stable rents.

- Band C includes funding to enable low cost home purchase schemes for low to moderate income households, for example shared equity schemes and community land trusts (National Affordable Housing Summit Group, 2008).

The report ends with a suggestion that $3.5 billion over 5 years should be spent to build a minimum of 150, 000 new properties and to assist over a quarter of a million households move out of housing stress. Unfortunately if implemented this scheme will provide housing at the peripheries, since land at affordable prices is only available at the edge of the city and therefore poor people will become poorer and vulnerable people will become more vulnerable. To sum it up one may say that as long as we keep on solving problems of affordable housing in isolation, we will be creating more problems and instead of bringing people out of poverty, we will be putting them in poverty again and again.

4 A DEFINITION OF AFFORDABILITY

Until 2006 the definition of Affordable Housing was rather limited. Definition used by the Victorian Government in response to the Melbourne 2030 Audit did not take into account indirect cost of assessing access to employment, services and facilities as well as household expenditure on utilities such as water, gas, and electricity. In 2006, however, a paper prepared by the National Affordable Housing Forum defines affordable housing as housing which is reasonably adequate in standard and location for lower or middle income household and does not cost so much that a household is unlikely to be able to meet other basic living costs on sustainable basis. It goes further to suggest the requirements for reasonable accessibility to work opportunities, services, and facilities. It also includes consideration of cost of transport. In 2008 Housing Affordability Report, there is also strong suggestion to the Victorian Government to consider index of housing affordability that includes the broader concept of affordable living. If Government adapts this

definition of affordable living as a guiding principle in delivering affordable housing, than affordable housing will no longer be able to end up at the city edge, the periphery.

5 THE HOUSING WE WANT

In another report from the Grattan Institute, The housing we'd choose, we find illuminating data that suggests that, in addition to the problem on having mismatch of the housing we want and the housing we have, we also have very strong ideas about how we want to live, which could make provision of affordable housing in Australia close to impossible (Kelly et al, 2011a). The report suggests that the dream of owning your own home is still automatically associated with detached house on the big plot of land:

We're born and bred in Australia – we're ingrained and conditioned to have that attitude towards detached home.

At the same time, people very clearly describe their concerns about apartments. Most of Australian see apartments as the way of housing people who cannot afford to live in the house. The fear of not owning the land on which your household is located is probably one of the major reasons why apartments are still not considered as first choice. The problems associated with them include: lack of outdoor space, proximity of neighbours (next door, below and above), privacy, overlooking, overhearing, and lost of control. All of the above are preconceptions, which are impossible to get rid of. Furthermore it is impossible to suggest that you may have less noise and less overlooking and in some cases plenty of outdoor spaces if you decide to live in apartment.

One of the most interesting finding from in Grattan report was answer to the question posed to 706 people: What matters most when you choose housing? The survey included 57 variables, divided into four broad categories and presented in groups of eight. Each participant of the survey was asked to identify one variable that matter most and one that mattered least to their housing choice from the group of 8. The four categories were: dwelling features (number of rooms, presence of a garage, whether house was detached), safety and security (safety for people and property, secure parking, away from jails), convenience and access (near family and friends, proximity to work, access to health and services), attractiveness of environment (near the park, a particularly clean and unpolluted area, a natural environment that is attractive).

The most popular answer to the question: What matters most when you choose housing? was the number of rooms. Little traffic congestion in the area came as the least important feature. Proximity to work, school or facilities did not rank highly, indicating that people assume that they are going to drive in order to satisfy their daily living requirements. Safety for people and property came as second most important variable. It will be interesting to find out how people visualize this "safety". Do they prefer to live in gated communities, with guards at the gate, or behind tall fences, with secure locks on the doors, or apartments with security guards?

Most interviewed people preferred large dwellings, and as mentioned before detached houses were the most popular, followed by semi-detached (not commonly available in Melbourne). People valued proximity to the city and most prefered to be closer to the center rather than far away. But if the choice was between living in the city in an apartment and living in a big house away from the city, most of the respondents chose a house.

It is therefore not surprising that 74 % of Australia's housing stock is in detached houses. This has changed very little in the past 30 years; in 1976, detached houses comprised 78 % of the stock. Melbourne's built area has nearly doubled in the past 30 years and may double again in near future; as with many citeis, we cannot afford or sustain the horizontal expansion. The cost of infrastructure associated with development of detached houses, the cost of road building and provision of facilities, utilities, schools, nurseries, and jobs cannot be achieved without making dramatic changes to the way we choose to want to live. If we don't change the affordable housing will be put even further away and will make lives very unaffordable. If we try to provide affordable living instead of affordable housing we will need to not only change the perception of what is desirable but also the structure of land allocation. The problem we are now facing is that we don't have exciting alternatives. It is the time we come up with some new ideas, which will allow people to dream about better futures.

5.1 Detroit versus Medellin

There are many lessons that we could learn from countries around the world. Over past 50 years developing countries were always looking to the West for ideas and inspiration and examples of better quality of life. But this is changing now and the best lessons we can learn are no longer from the West but rather from developing countries.

In the first half of the 20th century a very large, poor workforce was attracted to the US city of Detroit to support the boom of automobile industry. These workers came from the South looking for a better quality of life, but since they were the lowest paid workers housing them became significant problem. There was no affordable housing to accommodate them. Landlords saw opportunity for business and started to subdivide apartments into small units, providing minimum spaces and getting maximum profit. Most of the migrant population from the South was black. Most of the original population was white and did not welcome blacks into their neighbourhoods. The moment black people move in to the area the white population started to move out. The prices of the housing stock started to go down but this did not stop landlords to keep on increasing the rent values. And since there was never a shortage of people willing to rent, the landlords didn't bother with maintenance and upkeep. The tenants themselves preferred to send their money back home where they came from to secure their future when they returned. As a result, the areas where the migrant population lived slowly degenerated. Those who had a little extra money moved out to more desirable areas, to be replaced by more who had none. Within few years the areas of town previously occupied by middle classes and considered, as desirable places to live became the places to be avoided. After the automobile industry collapsed, huge parts of Detroit became deserted. Today land value in these areas is close to zero (Brugmann, 2010).

With an opportunity to benefit from improvements made, residents will respond differently. We can contrast Detroit with the example seen in developing countries in South America, where the value of land in favelas rises the moment a migrant worker claims a piece of land for a shelter. Favela dwellers typically cannot afford to construct anything significant at the start, but slowly and gradually they are able to build their capital. If they start earning some money by running small business or scavenging, they invest it in their house and in their business. Often they will latter extend their house in order to accommodate tenants, supplementing income that is again used to improve their house or to invest in business. Through this slow evolution is observed the incremental development and improvement in such areas of informal housing. This is very different to the conditions we observed in Detroit. In Detroit the moment the first migrant worker moved in, the value of the land decreased. In favela the moment the migrant worker moves in the value of the land increases. There is another substantial different between the two. As oppose to Detroit favelas do not offer affordable housing, they offer affordable living. Residents of favelas run their businesses from their homes, the work, shop, entertain each other in the same place. Their quality of life may be very poor but they can see opportunities and the way out of poverty. And what we can observe over and over again in favelas in places in Colomboa such as Medellin and Bogota as well as in other cities in South America where action brings people out of the poverty; meanwhile in the developed world, we still follow the same trap of putting people into poverty.

We can not only observe the phenomenon of people being housed in so called affordable house but not being able to afford to commute to work, or even in some cases to afford to come for the interview. We can also observed how inner city areas next to social housing and consider less desirable to live in. it is obvious that we have to rethink our affordable housing models on many levels.

6   AFFORDABLE FUTURES

Renzo Piano noted in an interview with Peter Buchanan:

What architecture and planning suffer from is a desperate lack of imagination. We need to think about more alternatives and where we might be going, and of new paradigms. We have all sorts of possibilities open to us, and we don't have the imagination to conceive of and use them. What we need now is brainstorm and dream: to stop trashing the world we need culture that is more deeply satisfying. […] There's terrible dearth of real imagination in thinking about the environment. Most ideas are not exciting. And we are not going to stop people trashing the world unless they are exciting about the alternative. That's the problem. People are not dreaming up sufficiently exciting alternatives." (Piano, 1999, pp 71-72)

Profound societal change has happened in recent history. At the beginning of the twentieth century, when the effects of the Industrial Revolution were choking cities and the solution was identified of encouraging people to move out of cities, into the new idea of suburbs, London Underground came up with series of posters advertising all the advantages of suburban life. Ebenezer Howard's Hampstead Garden Suburb offered people the luxury of dreaming about better futures away from pollution of the industrial city. Railways offered a means to move easily back and forth from suburb to workplace. Yet the public had to be introduced to the idea and convinced of its benefit. An advertising campaign sold the message and sold the dream.

It is important that we can inspire people once again and allow them to dream about alternative futures. Ebenzer Howard managed to sell the idea of the suburban house very well but this was over 100 years ago. It is time we came up with ideas for the 21st century and leave behind models which are not sustainable and which lead us to unaffordable life styles. So what might these new alternatives be?

If we seek an alternative to building affordable housing in the areas where the consequence will be unaffordable living, we will have to look for an alternative aprroach. This approach could start with re-conceptualization of affordability. If affordability is to be considered as the opportunity for a better quality of life, then we may want to start with looking for sites not at the edge of the city but closer to the center. In the first instance, this may seem impossible to achieve since the land prices in Central Melbourne, as in may cities, are unaffordable and unavailable, if we look a little bit harder and slightly out of the box, the reality is different and full of opportunities. Central Melbourne has substantial pockets of land created by two different grid systems intersecting, creating odd and triangulated sectors of land that are either used by car parks, planted with struggling shrubs or just left as traffic islands. There is no curent perceived value to these pockets sites, they are seen as elements of the road structure.

We propose that such left over land can be reconceptualised. In our proposal, we illustrate how such remaindered land can benefit the surrounding areas, bring better road structure and specific benefits to the local communities, by creating opportunities to create affordable housing in the middle of the city that will have all ingredients of affordable living. There are other opportunities related to mix use and, air rights and mix-price housing, where rich and poor can live together in the same location. We have numerous examples from the past. It has been done in ancient Rome, in 18th and 19th century Paris and London, manifesting a range of different forms and configurations. We seek to terminate approaches that keep repeating our 20th century mistakes instead of looking for new 21st century ideas, which can bring back our cities to the new century full of hope, dreams, and opportunities and therefore affordable lives for all.

Mobile Embedded Climate Sensing 2.0

Benjamin Allbach, Sascha Henninger

(Dipl.-Ing. Benjamin Allbach, Fachhochschule Kaiserslautern – University of Applied Sciences, Dept. of Engineering and Dept. of Building and Design, Morlauterer Straße 31, 67657 Kaiserslautern, benjamin.allbach@fh-kl.de)

1 ABSTRACT

Mobile technologies and communication techniques are developing rapidly. Mobile information systems offer access to information resources and services via "end-user terminals," which are mobile (e.g. cellphones, netbooks, notebooks, PDAs, etc.) and can work in nearly every location. These techniques have a huge influence on the relationship of time and space. We are more and more surrounded by computers which we do not even notice anymore. While driving we are e.g. assisted by a brake assist system, or by intelligent trash cans. These small computers which are built into everyday items are called "embedded computers" and are often interconnected with each other. In literature they are also called "ubiquitous computing" and "pervasive computing". These "embedded computers" can be used to gain knowledge and gather data. Because of the amount of the individual measurement stations it would be possible to gain exceptionally precise and special data without ignoring the valid concerns for information privacy. Cellphones are widespread in the population. These mobile devices already have various sensors. For example, most cellphones have sensors for location, temperature, speed and acceleration, brightness, and many more. Furthermore, it is possible to save permanently various data. Additionally, it is possible to connect a computer or microcontroller in order to increase the amount of sensors or to design them individually. Dreams, as they are presented to us by science fiction literature, like the "Tricoder" (Star Trek 1966), are already realizable.

The aim of this paper is to present the possibilities of smartphones for climate research. It should offer the notable capabilities of smartphones to gather climate data only by using the standard built-in equipment and sensors, which applications can handle these data and how the data can be processed further. Besides, it will be demonstrated how smartphones can be enhanced with the help of microcontrollers in order to create various "sensing scenarios." So a prototype of a microcontroller will be introduced, which was especially developed and adjusted to gather data of the urban climate. Additionally, the accuracy and validity of the data gathered by these microcontrollers will be compared to the data from common measurement instruments in order to analyze how useable they are.

2 INTRODUCTION

The climate, the weather, the city, and the human organism are complex interconnected systems. Though, research is required to analyze the relation between the city, the climate, and the physical health of human beings. Various single measurements try to establish a connection between the influencing factors. "Urban sensing" and crowdsourcing are means to gather various novel and special data. "Urban Sensing" as a new type of measurement could be a very good method of observation for planners. The individual human being or his or her carried equipment can be used as a measurement instrument for "Urban Sensing." A combination of stationary and mobile sensors is also possible [cf. Campell 2006]. "Urban Sensing" in combination with Web 2.0 or Web 3.0 respectively, is a new possibility to gather and analyse data. These data, which can be determined actively as well as passively, have a yet an unpredictable value for urban design and climatology. The possible usage could be separated into three fields: personal scenarios, social scenarios, and public scenarios. A personal scenario could be the monitoring and analysis of one's own vital functions. In a social scenario, data of a fixed group of people could be gathered and handled by social networks like "Flickr". In a public scenario, there is not be any limit and the whole population could take part of it [cf. Srivastava; et al., 2006:1F]. One advantage of this data collection is the possibility of monitoring huge areas over a long period of time [cf. Hof, 2007:1]. Mostly, out of financial reasons, this is not possible with the classical methodology of counting or measuring. Also the already existing ubiquiority of mobile devices is important for the accuracy of data [cf. Goldman; et al., 2009:4FF]. Several microclimatic factors could influence the well being of the people and out of this reasons they are an important basis for urban planning. Numerical simulations such like "ENVI-met" coould help to gain a better understanding of microclimate. It allows to analyze and anticipate various planning scenarios and their

consequences for the microclimatological aspect. Data required for the simulations are mainly determined by means of field surveys and measurements at certain locations by various individuals. Out of this reason, data collection of an urban area is expensive as well as time consuming [cf. HELDENS; HEIDEN, 2010:170F].

Nowadays, cartography and planning is widely influenced by the internet. The users as well as the creators of maps are affected. The net-based cartographical data processing is only just developing and can be regarded as the beginning of a new era in the field of cartography [cf. HERMANN; ASCHE, 2001:3FF]. In 2006 a new trend emerged: Neogeography. Typical areas of this new geography are the geotagging of videos and photos, e.g. by uploading them to "Flickr", and the "Open Streetmap Project." The radical change in cartography is supported by the absolute availability of the technologies, the possibility to include geodata of various sources, user participation following the Web 2.0 idea, and grassroots and free democratic geodata [cf. Unigis, 2010]. New technologies like smartphones, mobile internet, embedded systems, and augmented reality (AR) offer an enormous potential for this kind of monitoring. The gathered data can be digitalized and processed, e.g. by a Geographic Information System (GIS), and new types of maps could be created. Augmented reality (AR) can also be used for urban sensing. Exemplarily, the diploma thesis "Augmented City Kaiserslautern" by ALLBACH (2010) describes how virtual tags can be blended into the real world as an information carrier. The active tagging of objects in the real world offers a comprehensive database for planners and scientists. New projects and their acceptance can be analyzed. Nuisances like noise, dirt, heat, problems with a special type of ground covering, or insufficient accessibility could be identified in a new way and through the uploading of pictures and voice recordings be further documented [cf. ALLBACH 2010, 2011]. A lot of different phenomena, e.g. the rising emission of carbon dioxide and its effects on the global climatic system or the distructive consequences for the ozone layer due to the anthropogenic emission of FCKW, are only discovered after new measurement techniques have been field-tested. Furthermore, weather and climate monitoring has probably been established just as long as humankind. It has constantly developed alongside with other technologies and the human society. Because of the importance, climate monitoring must always be adapted to the current state of technology.

So, a next step in this development is using the availability of mobile phones and tablet computers for the climate monitoring. Due to the low costs of the so-called microcontrollers, it is possible to improve one's own devices or even develop completely new ones.

3 SMARTPHONES AS SENSOR UNITS

Depending on the technological area, new products are developed and updated at a very high level. We are surrounded by computers which support and guide us. And because of a permanently increasing processing power the barrier, which was again and again prophesized by Moore's Law, was never met up to now. Every year the producers of smartphones create new devices and the scope of operation of these is steadily increasing. Networks and clouds have a huge significance, but have not yet reached the peak of their development. For instance, the changes in the Middle East (Arab Spring) had shown the power and potential of Web 2.0/Web 3.0. As an example, "Facebook" was used as a kind of navigator device for the revolution. The Tunisian online activist "FOETUS" stated in an interview for Technology Review that a revolution always takes place on the street, and the street offers a huge potential in combination with "Facebook" [STIELER, 2011].

Though, it could be interesting to measure and monitor the environment with daily carried gadgets. One of these gadgets is a mobile phone or a smartphone respectively. These modern phones have a variety of sensors. They can be used to monitor the movement of the users (tracking), which is done via GPS or wireless LAN. Additionally, there are sensors for acceleration and absolute positioning as well as a compass and they can determine the altitude via GPS. User can save pictures, audio recordings, and texts and enhance them with their current position (GeoTagging). Since ambient noises can be recorded it is possible to conduct noise measurements. There are already projects which try to use "Urban Sensing" and indicate what can already be done by smartphones. "Noisetube" (http://noisetube.net) is a system for the monitoring of noise. "Waze" (www.waze.com) is a mixture of crowdsourcing, geotagging, traffic information system, and real time map. Users are enabled to inform each other about traffic jams, accidents, and other problems. Because data could be collected in real time and it is also possible to send the data directly to the system, this program is interesting for planners. Another aspect which might be fascinating for planners is the possibility to monitor areas like nature protection areas or new development sites. Many new phones offer the possibility

to adapt the brightness of the screen automatically to their surrounding. This sensor could be used to measure brightness. In combination with the absolute position sensor it is possible to identify how the phone is positioned and why a certain amount of light is registered by the sensor. After the nuclear catastrophe of Fukushima, Japan, the company SoftBanks developed a smartphone with an integrated Geiger tube (Pantone 5 Softbank 107SH). The camera and the included sensor is also an interesting device and it was already attempted to create a Geiger tube by using this sensor. Since the light consists of photons and since gamma rays are photons which have a higher energetic value, the sensor in the camera can detect them if one covers the lens with black adhesive tape. The application "Thermos" (http://www.thermos-app.com/) makes it possible to measure the air temperature by covering the lens. It might also be possible to use the internal temperature sensors of the cell phone measuring the air temperature. At the moment, producers consider to add an infrared sensor next to the camera sensor which could make various tasks possible, e.g. taking someone's temperature.

Following a concluding research it is verified that nearly all included sensors can be activated and read-out. Partly, this is prevented by the producers and has to be bypassed. However, smartphones lack crucial sensors for the complete measurements of climate parameters. Additional devices have to be connected via USB, Bluetooth, or wireless LAN. But these additional devices allow the execution of new sensing scenarios in order to measure the local climate. Even human biovital functions and medical conditions could be measured, e.g. blood sugar level, pulse rate, temperature, blood oxygen, air humidity, and skin temperature. Since 2012, the company Netatmo advertises the development of the first personal weather station application which includes a sensor for air quality (www.netatmo.com). This includes various climate sensors and connects them to a smartphone which allows a rudimentary urban sensing. However, this product has different flaws and a multitude of needed sensors are missing. A huge flaw of the available products is that measurements cannot be conducted simultaneously and the sensors are not interconnected. Most of the available "single sensing solutions" do not offer the possibility to access the measured data. Out of this reason, it is not possible to merge the data with the data measured by additional devices and process them in a single application. At present most producers favor their own closed system. It is not possible to combine the single devices into one specific system. Meanwhile, it is detectable that the sharing of crowdsourcing or biovital data in social media networks is appealing to the users (e.g. covered distance, energy consumption, time needed, overcome altitude). Nevertheless, it would be desirable that the producers enhance their closed systems for the possibility of exporting data.

4   A MICROCONTROLLER AS A CENTRAL UNIT FOR CLIMATE MONITORING

In order to overcome the described weaknesses of the available products, especially for the measuring climate parameters, the idea for the development of a new measurement device was born. Basicly, this will be a microcontroller and the various sensors, connected to it. Of course, the idea for a stationary weather station in combination with a microcontroller and sensors is not really new. There are a lot of projects [e.g. HAAKE-ERFURT.DE; CAMPBELL SCIENTIFIC; PRODATA] monitoring the weather. Commercial weather stations are using sensors and some kind of microcontrollers measuring the meteorological conditions. However, the weakness of all products is that they lack at least in monitoring the urban environment or special sensors are missing and cannot be connected to the base unit of the controller. These requirements are: simultaneous measurements of different weather values and biovital functions at the same time, transportable, battery powered, low cost/affordable, modular built and expandable. This is why a a new measurement device is still needed for a urban climate monitoring and for analysing the relationship between the urban area, the climate, and the physical health of human beings. If it could be possible to create one device which measures all climate data and biofital function at the same time, this would lead to a faster, more accurate, cheaper, and easier way for monitoring the connections of the urban ecosystems complex. The measuring of climate conditions and immediate bodily reactions could lead to new insights into the complex urban ecosystem which might change the planning process.

So two alternatives emerged: How should the device be constructed and how could data be stored and processed controlled?

The smartphone will be the central unit, controling and regulating the single sensors as well as the storage of the data and its localization. Furthermore, it should transmit and visualize the data. An application will be

created to serve as a graphical interface. This system must be regarded as cost-effective, because the storage unit, data connection, and sensors are already part of a smartphone.

The other possibility is that a microcontroller could be the central unit and the different sensors will directly be connected to it. Likewise, the microcontroller is responsible for the storage of the data. By means of various enhancements the microcontroller will be able to send the data to a smartphone, to another system, or the possibility for an upload to the internet. A SD card could be used as a storage unit and data could be exported to a GIS. Of course, the usage of a microcontroller as the central unit does not exclude the usage of a smartphone for the controlling and storage of the data.

The prototype of the climate measurement instrument will follow the second possibility and uses a microcontroller as a central unit. The main function of this new device is measuring climate data (figure 1). Additionally, it will be able to record various biovital functions. This combination of detecting climate as well as biovital data could help to analyze the urban ecosystem more precisely. Because the weather ist permanently changing, it is hardly possible to process and present these data statistically correct and to gain how far these are influencing the human body. Important data of the body are the age, the adaptability of the organism, illnesses, gender, and stamina. Both, the human body and the climate system are so complex that it is complicated to conduct a scientific researches of them [cf. TRENKLE, 1992:21].
Fig. 1: Microcontroller as central unit.

5 BIOCLIMATOLOGICAL COMPLEXES

In order to have a better understanding of the aspects, which are going to be measured by the microcontroller, a brief description of the humanbiometeorological complexes is given. There are four bioclimatic complexes, which control the function of the human organism and influence the thermal regulation:

1. Thermal complex

2. Photo-actinic complex

3. Air chemical complex

4. Neurotropic complex

The thermal complex deals with the influence of daily and annual impulses (e.g. heat and cold) on the organism and its ability to regulate its temperature independently from outside influences. Physical (blood circulation, perspiration) and chemical (basal energy rate) processes adapt the temperature to the surrounding

environment. The thermal regulation of the body is influenced, for instance, by clothes, activity, shade, wind, and indoor air conditioning. Based on the comfort equation by FANGER (1972) a bioclimatic model was developed by JENDRITZKY (so-called Klima-Michel-Modell). This model describes the thermal environment conditions which are important for the human being and includes influences like clothes, activity, heat emission and absorption. A model for the calculation of the body temperature was developed by HÖPPE in 1984 [cf. TRENKLE, 1992:21FF].

The actinic or photo-actinic complex describes the influence the radiation of the sun on the human organism. We can confirm that the visible light, about 46 % of the total radiation, influences our psyche. It influences our activity, efficiency, and mood and is also important for our apperception, our hormonal balance, metabolism, and furthermore influences our biorhythm. Ultraviolet radiation is of crucial biological importance. Ultraviolet radiation can be divided into UVA radiation (315 – 380 nm), UVB radiation (280 – 315 nm), and UVC radiation (100 -280 nm). UVA radiation can lead to a change of the melanin in our skin. For instance, this can be used medically as a cure for psoriasis. UVB radiation also influences the melanin in our skin, but over a longer period of time. It is also responsible for erythema and it has a lethal effect on bacteria. UVC radiation has also a lethal effect on bacteria. However, it also causes skin cancer and the destruction of cells. Infrared radiation only reaches the biosphere with a low intensity with less biological influence.

The air chemical complex analyzes the influence and reaction of natural and anthropogenic air pollution on the human organism. Various noble gasses and micro elements are part of the natural air quality components. Carbon hydrate (CH_4), carbon monoxide (CO), nitric oxide (NOx), ammonia (NH_3), and hydrogen sulfide (SH_2) can be emitted during the decay of organic substances. During natural incidents like volcanic eruptions or huge forest fires, the emission of sulfur dioxide (SO_2), nitric oxides (NO_x) and other solid and liquid aerosols reaching the atmosphere. There are also airborne particles emitted by the flora, which can influence the human organism (e.g. pollen can lead to allergic reactions) [cf. TRENKLE, 1992:32FF]. Anthropogenic air pollution like dust, soot, and the waste products of the industry (sulfur dioxide (SO_2), carbon monoxide (CO), nitric oxides (NO_X)) as well as traffic exhaust of carbon monoxide, hydrocarbons, and mainly nitric oxides effect the air quality negatively. The consequences and the duration of the harmful substances within the atmosphere depends upon their physical qualities, disposition to undergo a chemical reaction, concentration, and the atmospheric terms of exchange. For instance, soot absorbs various carcinogenic and toxic substances. Pure sulfur dioxide, if absorbed by the mucosa, complicates the expiration of phlegm, which leads to a narrowing of the bronchia, which, in return, causes tussive irritation. Nitric oxides can also narrow the bronchia and cause nausea, headaches, and exhaustion. Additionally, viruses and bacteria more easily cause illnesses when the defense mechanisms of the organism are weakened due to a limited oxygen supply. Ozone, and other photooxidates can cause headaches and attack the mucosa and complicate the breathing. If during clear and calm weather conditions the air exchange is hindered this results in an accumulation of noxious substances, which lead to serious respiratory and cardiovascular diseases, [cf. TRENKLE, 1992:36FF].

The neurotropic complex analyzes the influence of different climate and weather situations on the human organism. Such influences could lead to neurotropic reactions. All humans are affected by weather stimuli, but only a healthy and adapted organism automatically is able to adjust the metabolism, the temperature, and the circulation to them. The sympathetic and the parasympathetic nervous system are keeping the nervous system in the interbrain in balance. For a long time, physicians have observed that e.g. neuritic or rheumatic are prone to hurt during special weather conditions and it was detectable that under certain conditions physiological and biological reactions were taking place. [cf. TRENKLE, 1992:47FF].

6 MICROCONTROLLER AND SENSORS TO ANALYZE THE BIOCLIMATOLOGICL COMPLEXES

All these complex relations could be analyzed with one device and therefore we defined the following requirements for the device:

- Modular structure and portable format
- Recording of the location of the measurement
- Detecting of local climate data

- Measuring biovital functions
- Selective and constant measurement during movements

Relevant climate parameters are air temperature, air pressure, air humidity, surface temperature, including the distance from the ground, emitted heat to the left and to the right of the device, including the distance to the emitting surface, UV value, brightness (LUX), ozone (O_3), carbon dioxide (CO_2), sulfur dioxide (SO_2), carbon monoxide (CO), nitric oxide (NO_x), and particulate matters ($PM_{2.5}$ and PM_{10}). Relevant data for the biovital functions are pulse and heart rate, airflow, temperature, oxygen level in the blood, and skin resistance. Due to the modular structure and additional sensors it is possible to gather various data in the future. The listed sensors will allow us to create a kind of 'ambient atmosphere'/'ambient climate' which is recorded at a specific geographical position. Because the emission of heat from constructions is of importance in the urban environment, the device will not only measure the emitted heat from the ground, but also from its nearby surroundings. This could be enhanced by measurements to the front and to the back of the device. The measurement of the emitted surface temperature will be enhanced by a sensor to locate the distance to the surface object from where the heat is emitted (Figure 2).
Fig. 2: Microcontroller measurement of the emitted temperature and distance to the surface by the microcontroller.

7 EMBEDDED SENSING – PROTOTYPE

While developing the prototype various models were conceived:

(1) Developer model

(2) Hand held model

(3) Belt

(4) Backpack

(5) Integrated into the clothes

© Allbach 2012

Fig. 3: Model of the various measurement devices.

The developer model is a connection of microcontrollers and sensors. The second model is a hand held device similar to a remote control or the "Tricoder" from Star Trek. In the future, the hand held model could be used in schools, projects, and workshops in the field of natural sciences. Pupils could be able to discover their environment with such an device and could experience and record nature and the weather conditions as well. The third model is placed in a belly bag. The forth model is carried in a backpack. The fifth model is an integration of the devices into the clothes in order to create a kind of wearable computer. However, also a smartphone and a backpack could be described as wearable. But the best solution would be to integrate all sensors complete and invisible into the clothes. The measurements will be individualized, inconspicuous, discreet, and permanent. As a result, the instruments can offer the most pristine "ambient-climate"/"ambient atmosphere" data. Partly, the equipment even adapts to the shape of body, can be washed and bended. But of course, this model is the most expensive one.

The first measurements with the microcontroller had demonstrated that it can compete with the common measurement instruments (Figure 4). The laggardness of the sensors has to be taken into account just like in any other measurement of the climate. More precise measurements have to be conducted and the spread for standard factory models has to be considered.

All models have their advantages and disadvantages: e.g. costs, portability, and accurateness of the measurement. The belly pack and the backpack are very similar, but the backpack has a higher contact area with the body which could lead to increased sweating at the back and to measureable bodily reaction. A hand held model could also lead to problems during longer measurements, because this might wear out the muscles of the arm.

Problems all models share are the dependence of a power source and the reaction time of the sensors. Some problems are specific for certain sensors. The anemometer, for instance, must record wind speed during a constant movement, but the measurement can be distorted by the movement and the reaction time of the sensors. Though, it might be able that an ultrasonic sound anemometer or a heat wire anemometer could be

used to solve this problem. Last but not least, measurements of precipitation cannot be done out of technical reasons.

A major test of the hardware is done during "Projekttage für Schülerinnen" at the University of Applied Science, Kaiserslautern, Germany. For two days, pupils tried to create a simplified weather station out of microcontrollers with identical wiring and sensors. The used sensors are: barometer, light sensor, water sensor, sound sensor, and a combination of air humidity and air temperature sensor [cf. THEATO 2013]. The procedure, programming, electric circuit, management of the individual parts, and wiring was predetermined by the author. The test or workshop, respectively, confirmed that the sensors already work accuratly (even if they are rather cheap and not labeled as very precisely).
Fig. 4: First measurement results of the air temperature and a comparison to common measurement devices.

8 CONCLUSION

Smartphones, urban sensing, and other new technologies are becoming part of climate monitoring. However, these technologies are still under development and are confronted with various problems and the current measurement results must be regarded with suspicion. Nevertheless, since we have to assume that there will be plenty of measurement stations in the future, it might be possible that the sheer amount of measurements will result in kind of "wisdom of crowds." Especially, the approach monitoring the climate bottom-up is an interesting alternative to the generally known top down monitoring. It follows the principal of "we are all affected by climate and weather, so we will monitor it together." At the moment, smartphones are limited in their use as measurement instruments due to the lack of important sensors. But this will change in future. It is already possible to conduct amazing measurements (e.g. the cell phone as a Geiger tube). If the sensors of the smartphone do not suffice, they can be expanded by a microcontroller and its sensors. The new generation of microcontrollers follows the idea of Web 2.0 and appeals to new users due to its improved handling. The new technologies make is possible that a prototype can be created which can easily be expanded and adapted to special purposes, due to its modular design. This device is rather cheap and will allow us to conduct new forms of climate measurement and urban sensing. For instance, the urban area could

be explored by groups of people and the gathered data could be analyzed with regard to climate and biovital values. A new possiblity of monitoring climatological effects within inhomogeneous urban structures is using mobile measurements devices. The advantage of this type of methodology is a high density of measurements, which could be mapped spatially. Although, mobile air temperature and air humidity measurements had been practiced for a long time, especially in the field of applied urban climatology. However, most of the mobile measurements are performed by using individual mobile measurement instruments and the results have to be written down manually. Other methods like a special car, which is able to gather various climate values, is very expensive and is also not able to gather biovital functions. A new devise, based on microcontroller, could help planners and scientists. It could close the gap between various single measurements and an expensive professional car. This device uses a new approach to research the interconnections between climate, city, and human beings and might offer new insights, showing us new interdependencies, but it does not replace the traditional measurement methods!

1 ABSTRACT

Modernity is not only the theme of the world development,but also the main feature of China's development nearly 100 years. It have contributed to the economic development, as well as formed an unstable system of internal city, especially on non-core area of city. The modern process constantly changes the driving force of development, rather than continues as a linear, with different interpretation of the modernity in different periods. On the spatial dimensions, the non-core area reflected different modern characters from core area that have enormous influence and powerful attraction. It changed from the original stable structure to a kind of mosaic state as the collage. With the influence of industrialization and information, the non-core area has always been formed by the changing economic and political power. Important here in this context is that the urban system is viewed not as a static structure ,but as a system in flux, characterized by interdependencies and uncertainties about the nature and the direction of change. This creates a doubt that emphasis on the factors what promote the unending changing of Non-core area and made it became a kind of unstable space.

To demonstrate the reality of the modernity of non-core city area, we choose one special area of shanghai— Suzhou River area, which has a synchronous development history of Shanghai but has not became the core area still now, to explore the inner force what promote the reform and the reconstruction of here. Under the power and economical influence, the both side of Suzhou River was enveloped by increasing intensity, to meet the need of modernity. This changing have also made this area lost its natural scene bit by bit, like the never stop flow of the river.

At the beginning of this paper, we introduce the general features of modernity, which displays the different characteristics on the spatial dimension and temporal process. Then, through the case study of the Suzhou River area, we present a real scene of the modernity in china. It reflected the stable and flowing characteristic of non-core areas which do not have enough developmental potential to prevent the unending change. The history has been divided into three periods, we analyse the background of the politics & economy, main forces and promoters of development, the specificality of spatial character and social situation on each period. Obviously, when we talk about modernity, we should not only pay attention to its present, but also look back upon history and look forward to future.

2 MODERNITY

2.1 The characteristic of modernity

'Modernity', 'The painter of modern life is the transient, the fleeting, the contingent; it is the one half of art, the other being the eternal and the immutable.' Baudelaire wrote in his essay. similarly, Berman's description: There is a mode of vital experience – experience of space and time, of the self and others, of life's possibilities and perils – that is shared by men and women all over the world today. I will call this body of experience 'modernity'. To be modern is to find ourselves in an environment that promises adventure, power, joy, growth, transformation of ourselves and the world – and, at the same time, that threatens to destroy everything we have, everything we know, everything we are. We shall leave aside the question why modern life might be characterized by this, but that the condition of modernity is not generally disputed.

If modern life is indeed so suffused with the sense of the fleeting, the ephemeral, the fragmentary, and the contingent, then a number of profound consequences follow. To begin with, modernity can have no respect even for its own past, let alone that of any pre-modern social order. The transitoriness of things makes it difficult to preserve any sense of historical continuity. If there is any meaning to history, then that meaning has to be discovered and defined from within the maelstrom of change.Modernity, therefore, not only entails

a ruthless break with any or all preceding historical conditions, but is characterized by a never ending process of internal ruptures and fragmentations within itself.

Raban describes an essential aspect of urban life as 'Aesthetic practices and judgements fragmented into that kind of 'maniacal scrapbook filled with colourful entries that have no relation to each other, no determining, rational, or economic scheme,'. Where, in all of this, could we look for some sense of coherence, let alone say something cogent about the 'eternal and immutable' that was supposed to lurk within this maelstrom of social change in space and time?

But what promote the modernity change all the time .Marx provides one of the earliest and most complete accounts of capitalist modernization.Marx insists, there is a single unitary principle at work that underpins and frames all of this revolutionary upheaval, fragmentation, and perpetual insecurity. The principle resides in what he calls, most abstractly, 'value in motion' or, more simply, the circulation of capital restlessly and perpetually seeking new ways to garner profits. By the same token, there are higher-order co-ordinating systems that seem to have the power – though in the end Marx will insist that this power is itself transitory and illusory – to bring order to all this chaos and set the path of capitalist modernization on a more stable terrain.

2.2 Modernity on the time process and spatial dimension

On the time process, modenity Show the different game rules at different periods. The development of modernity is not a liner process. The change from Fordism to flexible accumulation trigger the transform from industry to post-industry development. The more flexible motion of capital emphasizes the new, fleeting, ephemeral, fugitive, and contingent style in modern life, rather than the solid values implanted under Fordism. To the degree that collective action was thereby made more difficult – and it was indeed a central aim of the drive for enhanced labour control to render it thus – so rampant individualism fits into place as a necessary, though not a sufficient, condition for the transition from Fordism to flexible accumulation.

And on the spatial dimension, it also has different characters of modernity between core area and non-core area. On Non-core area, the lack of original stable social elite system and capital accumulation system leads to their constantly changing status.Capital investment here will not face many obstacles for infringing upon the interests of other elite groups. So non-core areas are usually

2.3 China's situation

International and Globalization have had direct or indirect impacts on China's economic and urbantransformations. From the global perspective, China's economic reform is more than simply a transition from central planning to a "market economy with Chinese characteristics" as Deng Xiaoping envisioned, although this trend has been clearly evident. On the other hand, socialist countries' shift away from state socialism can be seen as part of the massive global change in the mode of regulation and the regime of accumulation that began in the advanced capitalist states. Viewed on this way, China's urban transformation involves not just one but several global processes occurring simultaneously that have affected the production of space, urban consumption and the circulation of capital, people and technology.

Each of these shifts has strongly impacted one or more aspects of the social, economicand spatial structures of the Chinese city. The consequences of such restructuring processes are manifested in new urban realities that together constitute a new urban mosaic and spatiality for China which, despite lingering elements of the past, is visibly very different from that of the pre-reform era. The new urban realities have been created by the transfer of massive amounts of global and domestic capital to the built environment. The sunken capital is spatially fixed, and as usual, the spatial fixity of the newly reconfigured urban elements ensures their existence for at least decades to come until they become dilapidated, dated or are otherwise rendered unfit for the city. As long as it exists, the existing spatiality of the city will have reciprocal effect on the forces of economic and urban transformation that created it in the first place.

3   THE MODERNITY HISTORY OF SUZHOU RIVER DISTRICT

Shanghai,as China's earliest open port city,establishes and led the development of China's modern industry, in the frontier of the China's modernization. Among this city, there is a river, winding flow over 5000 yearsr, breed almost more than half of the ancient Shanghai.Then, she spend 100 years "build" the initial frame of

international metropolis of modern ShangHai. It's the Suzhou River, the downstream of WuSongJiang, flows through Shanghai downtown reach into the Huangpu River. It also be called "Suzhou Creek" by British and American who find its superior geographical position very suitable for a inland shipping port. Due to Shanghai's role as trade port, the coast of suzhou river started her urbanization process，with the expansion of the foreign settlement, from the the east mouth to the west gradually. Since the 1930s,Suzhou Creek became an important shipping route. For more than one hundred years, the process of urban rapid development together with human influence have controlled this area. It covered by the need of social and economic structure change. The modernity history of suzhou river district reflect the moderniazation of Shanghai, it also became the typical representative of the course of Chinese modernity.

Fig. 1: The position of the Suzhou River and the area for research.

Suzhou river area is located on non-core areas of city, although some part of it adjacent to the downtown area of Shanghai , it reflect the unrest and unending redevelopment condition that different with core area which always have the stable capital accumulation and elite relationship. In the push of modernity，the region has experienced several evolution.On early period,the colonial economy,national industrial economy and warehousing on both sides of Suzhou river estuary area created the suzhou river coast's early brilliant. After the funding of china , Industry, Shipping and Business get further development,sustained the economy property of both side of river. It became the important areas for Shanghai to expend mordern industrial development. But at the end of last century, the shipping commerce and industry along Suzhou River receded. With relocation of the industry in Shanghai city center to the suburb, the economic hollow phenomenon of Suzhou River region after withdrawing from industrialization is conspicuous. Plus the water pollution, Suzhou River region declines. But at the turn of this century as the river water and the nearby areas underwent comprehensive treatment along with the rise of creative industry and the redevelopment, Suzhou River region will be hot cake once more. Below is a brief account and analysis of the development background in three periods, the driving force, changes of spatial and social structures, which reflect the features of modernization in Suzhou River region.

3.1 The early stage

The development along the bank of Suzhou River started from the land to the southwest of the junction of Suzhou River and Huangpu River. After the Opium War, George Balfour, consul of the British Consulate in Shanghai, thought highly of this land, which was not far from Shanghai and which served as a strategically important rear. Upon being taken as the British concession, this area started the construction of economic facilities, with various foreign firms making investment here. With the Bund being the center, the construction extended westward.   Based on the spatial pattern, cultural, recreational, and public facilities were gradually established, making this area a comprehensive business residential zone. In the 1930s, the area between the Garden Bridge of Shanghai and the north bank of Henan Road developed into a sophisticated business and residential area. The area along the eastern section of Suzhou River thus became a cluster area of foreigners and businessmen in Shanghai.

However, with Henan Road as a boundary, there appeared two situations along the bank of Suzhou River, particularly the area in the southern bank: in the east stood tall and spacious western buildings; in the east lied low and clustering Chinese constructions. There was a massive flow of refugees due to the war. The concession took the opportunity to build a large number of houses and sell them to the Chinese. As a result,

the concession gradually turned to a place where the Chinese and foreigners lived together, showing an evident divergence in the spatial pattern.

In the 1920s and 1930s, a great number of quay sheds emerged along the riverbank. After Shanghai opened its ports, British businessmen stopped opium trafficking and focused on the trading of raw silk and tea. The light industrial products produced in the upper reaches of Suzhou River were also transported here for storage. As a result, lots of transit sheds and warehouses were built in the 1920s. When it comes to the 1930s and 1940s, numerous Chinese and western banks built frame-structured capped warehouses made of reinforced concrete and without girders, at the back of which the old lanes were renovated into the new-style Shikumen (literally "stone gate") houses.

Fig. 2: The old Suzhou Greek as a hustling trade port

During this process, there formed three obvious sections along Suzhou River: the first section is the Bund between the estuary and the bridge of Henan Road, which is a "golden district" with foreign consulates, parks, foreign banks, churches, post offices, etc.; the second section is the quay between Henan Road and the present Shimen Road, which is a "storehouse business zone" with numerous transit sheds and warehouses; the third section is the "storehouse industrial zone" in the west of Shimen Road with a cluster of large enterprises.

It cannot be denied that Suzhou River area is developed with a capitalistic promotion. External capital inflow changed the original farming culture, and attracted many nonlocal population, and changed the social environment here. Though it's the beginning of the one-hundred history of Suzhou River, similar stories happened from then on.

3.2 The Industry period

3.2.1 The background of Industry development

The formation of Shanghai modern industrial, originated from the first opium war of china, is push forward by Treaty of Nanjing , which signed to western country,that Shanghai was forced to open the treaty port. After the treaty, the Western Imperial Powers made Shanghai as the center to achieve the trade aggression of China, this is the fisrt important cause that accelerateShanghai modern industrial development. The other cause is the power from the China's national entrepreneurs. These entrepreneurs hope to increase the comprehensive national strength of China through the development of industry. So such industrial development has been the support by the national patriotic groups and the government of at that time.

From 1860s, foreign businessmen began to open factories in China, mainly north to Suzhou River and west to Huangpu River. It stimulated people of insight to develop national industries. With the ideal of "saving the nation by engaging in industry", national capital in Shanghai started. With shipping advantage connecting rivers, seas and the mainland, Suzhou River became an earlier national industry center of China. Along the river west to Xizang Road, many factories were built. By 1920s, there were dozens of big spinning mills, flour mills, oil pressing mills, and engineering works along the banks; according to statistics, in the 21 flour mills of the city, 18 flour mills along Suzhou river produced 90 % flour of the industry. Big chemical companies and 70 % of small and medium-sized dye works located along Suzhou River. By 1949, there were 1914 factories and companies in Huxi Industrial Zone, and many of them are important in their industries in China. By the reform and opening-up, Huxi Industrial Zone was an important old industrial zone and the

most important textile industry center of Shanghai. Therefore, Suzhou River is the birth place of Shanghai's national industries.

Almost one hundrend years, Shanghai modern industral development bit by bit, began with the passive pushof the war, go through the main construction after the founding of new China, then undergo the rapid development after since the reform and opening-up of china. Then shanghai became the main industrial cente of china.among.

The industrialization development of Suzhou river area was supported by the government, and here both private and state-owned collective economics seeks the benefits of industrialization development. At this time, the development of Suzhou River was promoted jointly by the government and private enterprises.

3.2.2   The specificality of spatial character & social situation

Industrial expansion caused heavy environmental pollution

After the founding of the nation, Shanghai gradually changed to a single industrial center city. By expanding existing factories and building new factories, the industry developed faster, especially after the great leap forward in 1958. According to the investigation in 1936, there were more than 2200 factories in Shanghai, and in the 2039 factories in urban area, there were 1186 factories in midstream and downstream area of Suzhou River, accounting 58 % of the urban factories. These factories were administrated by seven bureaus including textile, machine and electricity, light industry, metallurgy, chemical industry, instrument, and manual, and especially the chemical industry, metallurgy and machine and electricity account more significant of the urban factories.

The industrialization along the river developed with more poor-efficiency, high-energy, high-pollution and water-consuming papermaking, chemical and casting companies, at the same time, as a poor area of Shanghai, Suzhou river area has the most immigrate population. Emission of industrial waste and sanitary sewage made Suzhou River heavily polluted. With more reeling mills, flour mills, iron factories and paper mills, Shanghai's industries and commerce grew. As freight volume increased, then function of Suzhou

River as inland transportation was enhanced, and many timber docks, fruit docks, rice docks and rubbish docks were built along the river. Soon, the river became black and smelly, fish and shrimp disappeared, and Suzhou River became a stinking river.

In 1930s, a reporter Dong Ping wrote in his book Interviews of the Slum: Suzhou river of Shanghai rotted like a dead snake. From Caojiadu to Fanwangdu, the erosion was too heavier too be recognized that the water polluted by sludge became terribly black and stinking.

Fig. 3: The early factories and river pollution after industrial boom

A lot of shanty towns

Textile mills and textile machinery factories spread along the Suzhou River in Shanghai. Women from other cities worked in textile mills while men in the textile machinery factories. They came batches after batches with fellow villagers and relatives, then slowly gathered and built private houses which are now villages. Consequently on the wastelands, ruins, cemeteries, garbage sites and places including both sides of the Suzhou River and other river banks, there appeared a variety of shanty towns. And during the Anti-Japanese War, a large number of civil houses were destroyed in Shanghai eastern downtown area   and batches of displaced refugees poured into the shanty towns, setting up rows of houses on the remaining empty lands.

According to then social bureau's incomplete statistics, shacks totaled 50000. After the civil war, ruined peasants from the rural war zones swarmed into Shanghai for survival, thus shanty towns saw another large expansion of residents.

Till the 1940s, Shanghai traditional shanty towns basically formed: by referring to then social bureau's incomplete statistics, poor migrants and refugees especially from Jianghuai watershed built or rent cheap shacks on the north shore of Suzhou River, both sides of railways and the surrounding wild wastelands, which gathered and later became urban slums besieging Chinese downtown   and concession inside Shanghai. And the reason why these refugees crowded here was because on the one hand the Chinese downtown's protection, on the other the industrialization here can provide lots of jobs. Shanghai municipal authorities once tried to control the spread of shanty towns, but the clearing and settlement measures   cannot stop the influx of refugees as well as the their demands and determinations of building shacks.
Fig. 4:. A lot of shanty towns packaged by industrial plant

3.2.3   The influence of modernity on Industrial period

Industrialization is considered to be the contributor to the progress of modernity. In the period of industrial prosperity, a large amount of capitals flood into the Suzhou River Area and many people are attracted to live here, which rapidly boost the modernization progress in this region. This is also one of the important approaches for China and other cities in the world to advance their modernity. In addition, what else does industrialization leave for cities? The previous farmlands are replaced by factories in a flash. The original social system of agricultural civilization is gradually disappearing, instead, there are full of workers from different regions and of different backgrounds. They care neither the history of this land nor the continuity of such history. Just like the capitalists making investment and development here, they are also interest-oriented. Therefore, these lead to the region's unstable future. The industrial recession and serious environmental pollution will reduce the value generating by the region. Bothe investors and workers hope to seek better living space without any attachment. It is just this kind of industrial modernity that separate people from space and become independent to each other.

Obviously, it is capitals that promote all the reforms in the boom period of the Suzhou River Area. Since Suzhou River is located at the edge of the core zone, plenty of land is the foundation for the concentration of industrial factories, and sparse farmlands serve as the unstoppable social basis for the rapid development of industrial agglomeration. Generally speaking, capital investment here will not face many obstacles for infringing upon the interests of other elite groups. This explains why non-core zones are usually more unstable compared with core zones in the modernization process.

The essence of capital lies in its pursuit of maximized interests. The intervention of capital turns agricultural civilization into industrial civilization. The pursuit of capital without any control has completely ignored the ecological environmental value, which turned the Suzhou River into a heavily polluted black river. Moreover, the large population introduced for the purpose of industrial construction has also upgraded the social and space structure in this region. A large number of shanty towns are scattered among the factories, which is a problem for future urban development.

3.3 The Post-Industry period

3.3.1   The background of redevelopment

Around 1995, Shanghai started a strategy of withdrawing from the secondary industry and progressing into the tertiary industry. It replaced contaminative manufacturing industry with service sectors. With the changes of history, a large number of flour mills, paper mills and old warehouses built in the industrial age near Suzhou River were abandoned. The once bustling industrial space gradually silenced. On the other hand, the cleaning of heavily polluted Suzhou River gained the government's attention and support to improve the overall image of the city and develop urban waterfront areas. Thus, the city space near Suzhou River stepped into a new stage of development.

By analyzing the region's early development after withdrawing from industrialization, spontaneity and chance could be clearly found in the early agglomeration. During this period, the water quality was poor and surrounding environment terrible, while the main reasons why creation practitioners concentrated could be attributed to the charm of architectural art for architects, the intrinsic history of buildings, laid-back environment as well as cheap rent. The agglomeration contributed to the spontaneous concentration of art warehouses, communities along Suzhou River, which gradually developed to a scale.

With the later startup of environmental renovation project, this place became the hot cake for a new round of real estate investment. Of the real estate along Suzhou River from 1998 to 2002, the western section was originally industrial land later turned into residential land while the middle section was originally storehouse land converted into residential land and renovated. After reconstruction in several early years of new century, old warehouses and factory buildings along the banks were demolished to a large extent.

Because the overall cost of the Suzhou River renovation project was huge, Shanghai municipal government could not depend only on the government finance to appropriate such a large sum of money. Therefore, the capital for the treatment of Suzhou River could only be obtained through attracting investments from developers. There was nothing wrong in inviting outside investment and let capital involve in the renovation of Suzhou River. When the water became clearer, and small swimming fishes reappeared in the river, from the government and media to the residents living near Suzhou River all cheered for it. However, with the proceeding of the investment attraction job and the constant involvement of capital and power, new contradictions started to appear. First, eager for quick success and instant benefits, and haunted by political achievement consciousness, local government approved some of the projects that even themselves felt inappropriate. Second, the planning of Suzhou River lagged, but the real estate development along the river were proved before the planning, which led to a disordered state.

Although the land redevelopment of the region along the Suzhou River had started, its pace significantly lagged behind the water body treatment and lagged behind the other parts of the city. The reason was that under the condition of market economy, the major force that drove the development and construction of the city was real estate developers. And the success or failure was the key factor for the developers to make decisions about development activities. Even the redevelopment of common areas had the problems of high cost and complicated implementation links and operating procedures which make the success or failure of development difficult to predict, the riverside areas had more odious environmental conditions (including black and dirty river water and unpleasant smell.) which could not be solved with the power of individual developers. Because of the huge risks, most of the developers took a wait-and-see attitude and did not dare to rashly get involved in. The government, on the other hand, did not have enough capital, which led to the lag of land redevelopment of the riverside areas. Therefore, in the nearly 20 years of development after 1995, the Suzhou River Area did not form a unified development pattern. Instead, bits and pieces of creative industrial development zone and high-grade residential areas appeared.

3.3.2   The specificality of spatial character & social situation

Creative Industry Development along Suzhou River

Along Suzhou River, creative industry agglomeration forms a creative industry band along the river gathering area, like pearls threaded into one string. In early times, Suzhou River banks attracted a lot of artists and creative personnel to engage in creative activity. Along the Suzhou River from west to east, influential creative industry parks listed by the Shanghai government are concentrated here such as Zhoujia Bridge creative center, M50 and Laosihang warehouse. This creative industry band spans several

administrative regions, forms a group of creative industries feature design, animation, games, media and advertising, and reflects the integration of warehouse culture and riverside culture. Creative activities with creative personnel as the main body gather along the river. The historic buildings rent for self use initially by the artists and creative personnel are gradually leased to other studios. Creative cluster areas form through large-scale investment and creative enterprises settle down as a result of friends' or clients' introductions, so this tightens the social network relationship between enterprises. Therefore, Suzhou River region constitutes the synonym for creative industry as well as culture and art industry, also a must for foreign visitors to hunt for old Shanghai's culture.

Fig. 5: The distribution of the creative industry along Suzhou river area

High-grade Close Residential

The profit-chasing of capital is quite manifesting in the coastal development of Suzhou River. With the constant listing of new houses in market, the Suzhou River area has been divided into blocks by land agents. Property developers lose no time to hang out the banner of Private Garden, the intention of which is quite obvious. They want to take possession of Suzhou River which belongs to the public by themselves. At the same time, most of the new districts alongside the Suzhou River are characterized by Two High and One Low, namely high density, high volume rate and low greening rate. The motivation of property developers is to maximize profit, so they are constantly decreasing the distance between the building and Suzhou River and increasing the height of buildings. Suzhou River will become the Building Canyon in city.

Fig. 6: The image of High-grade Close Residengtial along the riverside that made the river landscape into private

At the same time, independent high-grade residential districts cut off social connections between areas and turn them into groups with no relationship with each other. The high-grade residential and the hardly developed shantytowns around turn up alternatively. Fraternization of social structure and privatization of riverside space become the new social space characteristics alongside the Suzhou River. People who have lived there for half of their life have to move. The public life involving turning coal ball furnace, cooking, eating, chatting, bowl washing and playing cards has also been dissolved.

3.3.3 The influence of modernity on Post-Industrial period

The industrial transformation in Shanghai has brought an end to the era of capital accumulation when industrial mass production was prevalent. What come as a consequence are land economy and a kind of production method that lay emphasis on individuals, diversity and flexibility. As a result, real estate development and creation industry come to the historical stage of a new round of modernization development. Without stopping for a rest after the industrial era, the Suzhou River area sees large amounts of capitals flooding into the area again. With the success in wastewater treatment several years ago, bulldozers are approaching to the old warehouses and factories along the bank of the river. This area once again becomes an ideal destination for investment pursued by estate agents. The development of upscale closed regions and the establishment of creation studios have turned today's Suzhou River area into a place that is combined with private possessions and architectural canyon. Located in Shanghai, the River is affiliated to the capital rather than Shanghai residents.

The intervention of capital separates not only the Suzhou River area alone, but also the old residents living along the bank of the river. The comprehensive improvement of the Suzhou River also involves the relocation of tens of thousands of residents. The social structure of original residents is crumbled. This is another great change of space and social structure in this region pushed by the capital. The stable essence that capital pursues profits in this region has not been fundamentally changed, while the characteristics of modernity such as transience, flowage and separation are still on the stage in this region. In the post-industrial era, the capital accumulation methods have been changed to a new round of flexible capital investment, which separate this region into many independent capital territories and further result in a fragmented urban space.

3.4 Stable and flowing of Suzhou River area

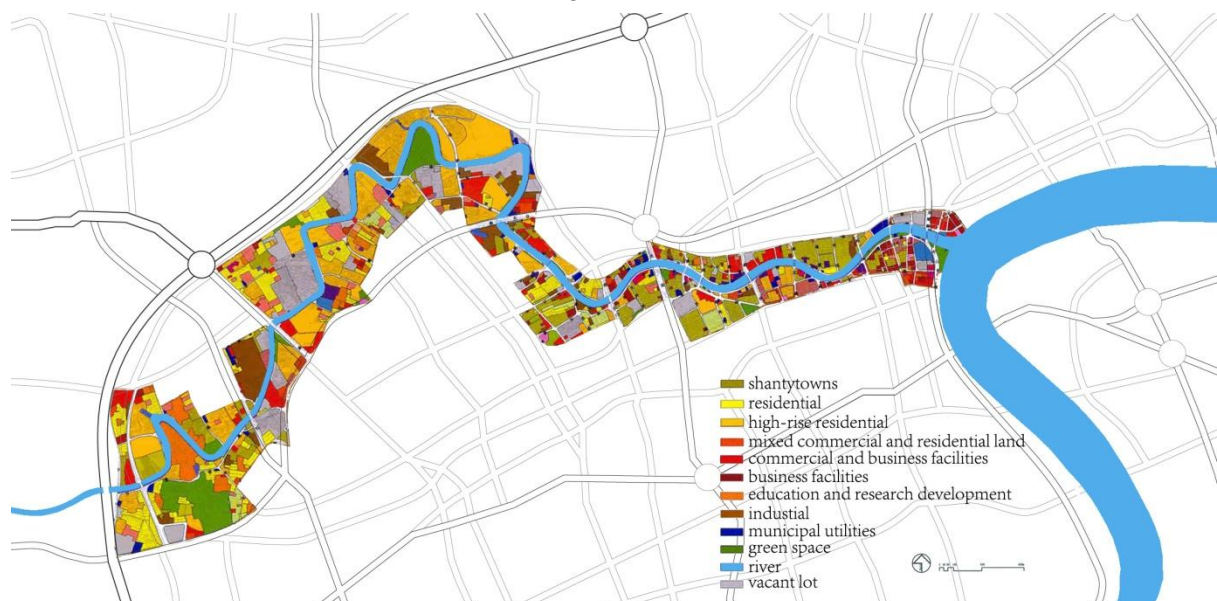
The development of the Suzhou River area is a continuously upgrading history. From commodity logistics in the colonial period, to the large scale modern industrial development, and to the post-industrial upgrading, the Suzhou River area has seen great changes in its space and social structure. The earliest colonial banks, warehouses and ports were transformed into factories with fumes everywhere in short period of time. The banks of the river were filled with large numbers of factories and scattered shanty towns. But industrialization cannot keep its story going. With Shanghai's industrial development becoming a history, Suzhou River used to be abandoned due to the heavy pollution. But later, with the post-industrial development, it becomes hotbed for the creation industry, informal economies and a new round of estate development. At the same time, people here are changing along with the ups and downs of capital investment. Located in the non-core zone, it lacks the strong and stable society root and capital accumulation. Therefore, the area located at the edge of the core zone is, on the one hand, an ideal destination for investment, and the most volatile region on the other.


Fig. 7: The fragmentatized land use of suzhou creek area

In all the transience, flowage, separation and accidents, the only stable thing is the continuously emerging impetus of capital. Both the colonial investment and the later alliance of government and estate agencies are the powerful alliance of political and capital elites who deem urban space as the capital growth machine. Finally, under the continuous stimulation and erosion of capital, urban space becomes an aggregate for value investment. Independent urban functions and closed residential apartments form a fragmented collage here.

4 CONCLUSION

Modernity shows the features of transience, flowage, separation and accidents. "Change" becomes the everlasting element of modernity. In the pursuit of modernity, cities are faced with constant changes. People and space are separated into two mobile entities. The location sense of space has been greatly removed. It is the essence of profit pursuit that pushes the city's constant change and become the only stable thing in all the changes.

The each stages of China's modernization are influenced by the push from capitals from different kinds of promoters. From the earliest foreign colonial capital flooding, to the national capitals and the later state-owned collective capitals, then to the combination of post-industrial national investment and private investment, all these show the impetus of the alliance of capital and political elites acting on modernization progress. On this process, the daily living space of common people was placed at an inferior position. This is also one of the essential characteristics of modernity development.

The development of Suzhou River is a special but typical case represented a common phenomenon in the modernization of non-core urban zones. The lack of original stable social elite system and capital accumulation system leads to their constantly changing status. This district was firstly opened up by the foreign capital, and then achieved rapid urbanization and population accumulation with the development of industrialization. But as the value decline of this kind of scale accumulation, the original investment capital and population began to flee. Then the new capital will get involved to find scattered investment values on the wasteland. Neither the government nor capitalists are capable of carrying out an all-round large-scale reform. Therefore the city is transferred into a fragmented state becoming a piece of collage. This is described as a post-modernity, which is only a new round of modernity "change", a continuity of its stable essence of "profit pursuit".

1 ABSTRACT

The biggest part of economic activity worldwide is already happening in cities, and the share of urban dwellers is rising continuously: by 2030 almost 5 billion people will be living in cities. Prof. Hans-Jörg Bullinger, the former president of the Fraunhofer Society said: "Cities are responsible for up to eighty percent of global greenhouse gas emissions. Whoever is the first to find the key to Morgenstadt [future cities], in other words a system approach to redesigning existing and newly emerging cities that are sustainable and enhances the quality of life, will chart the way for what may be the largest future market for the next few decades."

To tackle the this challenge, the Fraunhofer Society launched an innovation network called Morgenstadt: City Insights. For this system research initiative, 12 Fraunhofer institutes work together to analyze innovative solutions for a sustainable city. For this goal we developed a holistic research approach to analyze the city system in its interdependent structure. The following paper is an extract of the Morgenstadt: City Insights project description and the general research desig (Schatzinger et al. 2012; Fraunhofer-Institut für Arbeitswirtschaft und Organisation IAO 2012). We will describe in this paper the need for a systematic and holistic approach in city analysis and illustrate a possible research approach to do so.

2 INTRODUCTION

The urban knowledge economy is facing a tremendous transformation that will affect our society technologically, organisationally and systemically. Not only will individual technological sectors, such as energy or mobility, be affected but because the implementation of these sectors were highly cross linked, especially in cities and urban regions, the change in one sector will affect all others and the urban system itself as well. Particularly with regard to the reconstruction of the energy supplies, a holistic and systematic analysis of the city as the central anthroposphere of the modern society will be a critical success factor for future development. The challenge for a liveable and sustainable city will be the upcoming decisions regarding the long-term strategic orientation in the city. To achieve this goal it is essential to consider the interdependence of the involved sectors, as well as discernible trends, and adjust flexibly to future variances.

The trends that are essential for future city development towards a sustainable city and can already be seen today are: urbanization, rising resource consumption, demographic change, climate change, mobility, information and communicatio technologies, and civic participatio (Bundesregierung Deutschland 2012). Since 2007 more than 50 % of the world population live in an urban area. The urbanization process will lead to more than 70 % of urban residences in the next three decades (Heilig 2012). Together with the increase of the world population to 9.2 billion people, the population shift from the rural to urban areas will double the need for urban living space. The demographic change in the western civilizations will change the urban structure to a more elderly friendly city that requires new regulation and accommodation concepts. Even in a shrinking society such as Germany, the resource consumption of our growth oriented economy will lead to a higher consumption per capita. The climate change will force the society to rethink this growth strategy. Here the urban regions are the problem and the solution at the same time (Glaeser 2012). Today the urban regions are responsible for about 80 % of the CO_2 emissions (WWF 2010). but one can already see the potential of these regions to be an important part of the solution because of the scaling effects. In highly urbanized countries the metropolitan areas have a lower CO_2 balance per capita than the rural areas. One of the many reasons is the change in the mobility system. The traffic collapse in cities like London and New York, but also the rethinking process of more and more young people who don't see a car as a status symbol, leads to an increased demand for public transportation systems. These systems are especially profitable in high density areas where enough people use the system. The public transportation systems as well as vehicle sharing models and electro mobility will change the way we travel in the next decade to a more sustainable mobility. This will require new urban structures that have the potential to change the city to provide more

quality of life in the city. A lot of these trends require more sophisticated information and communication technologies. The increasing digitalization of our habitat by mobile internet and spatial cross linking of real time information allows an intelligent reconstruction of existing systems and offers the opportunities to create new approaches. These new approaches for a Smart City will already be developed in numerous research projects, but the potential according to sustainable urban development are still unexploited. One of the new opportunities is increased civic participation. Major projects in urban areas provoke socio-political discussions of a more and more informed population that wants to be part of the political process. Information and communication technologies can be an option to gain a sustainable consensus through population

If we take a look at these enormous change dynamics while taking the low adaption rate of the cities into consideration, then it becomes clear that a singular change of single fields of action and planning areas can't be a solution according to the challenges the urban areas are facing. To tackle long-term sustainable strategies we have to synchronize the long-term and short-term innovation cycles, which are still developed independently (e.g. the fast development of the ICT sector versus the long-term life cycles of the transport infrastructure). Therefore, Fraunhofer launched the research initiative Morgenstadt – Future City with the goal to develop a consistent model for a sustainable urban development strategy that takes not just one sector into account but all, especially interdependent connections between the sectors. We understand Morgenstadt as a vision of a sustainable and liveable city. Therefore, we do not address only an urban center, but future cities will be more an interrelated structure of the city with their urban surrounding region.

The strategic focus of this project lies in discovering systemic approaches that successfully respond to the increasing problems of the selected technology fields in leading cities (see Figure 1). By detecting and analyzing innovative but already field-tested approaches, we evaluate their feasibility for new and complex environments and demands for an urban future. To verify this we pool expertise to develop smart and individually customized strategies together with our network partners, aiming at the future requirements for further concepts' efficient implementations. Adapted to distinct functions and consumers, unique but holistic and trans-sectoral solutions should be anticipated to meet future urban challenges and shape tomorrow's sustainable cities.

Figure 1: Exemplary overview on existing global best practices for sustainable city solutions

3 PROJECT APPROACH

The goal of the Morgenstadt: City Insights project is to identify the status quo and establish a starting point for the research and development of innovations for urban systems. For this we will develop a systematic understanding of the investigated cities and describe a generalized fundamental model of the urban city system based on the investigated cities.

In the past, one of the greatest challenges in researching cities has been how to manage the high level of complexity inherent to urban systems. Sector-specific analyses conducted by experts of various disciplines allows for in-depth research into specific individual areas of interest. This type of research results in highly specialized solutions for individual areas of application within the city, which represent only isolated solutions within specific fields that do not fit into the city system context as a whole. Innovative facades, local energy production via solar panels, electric vehicles and the ubiquitous availability of information via smart phones are impressive examples of such an approach, and have undoubtedly been successful. In order to analyze and shape sustainable city systems, however, a detailed inspection of individual sectors as well as a systematic analysis of the city as a whole is necessary. Therefore, the project structure is defined by three work packages. The first preliminary research module is the preparation of a global survey on existing urban solutions and detailed studies on future cities. This is followed by a second in-field research module covering in-depth studies in the jointly identified leading cities worldwide. The project will be completed by a third research module compiling the results, comparing the cities and developing a prototype model of an urban system. To achieve this, the project analyzes the following eight most important technology sectors of the city of tomorrow with respect to best practices, ground-breaking pathways and existing challenges and innovation barriers that have to be overcome. As facilitator to the organization of city-systems, governance represents a key-scope of the analysis. In addition, the field of security, representing a genuinely cross-sectional system of importance for all other sectors, will be analyzed in detail.

Mobility

How can the masses of people in tomorrow's cities be moved most effectively while at the same time assuring quality of life and zero impact on the environment? Highly efficient mass transit systems, like in Hong Kong, or emission free mobility-on-demand solutions represent some of the ground-breaking solutions to be analyzed and developed further.

Energy

The future city will not depend on fossil energy. Renewable energies, energy efficient technologies and communicating energy grids will become the drive-train of tomorrow's cities. But where will the energy be produced? Today, energy-plus-houses already produce more green energy than they need. Integrated community energy solutions that link houses, wind- and solar parks, biomass sites and electric vehicles can be a starting point for an integrated urban energy system of the future.

Communications

Technologies already exist that enable communication between devices, buildings, vehicles and people. Geographic information processing, wireless internet and smart-phone technology possess almost infinite potential for the development of smart solutions for urban systems. Some cities like Qatar or Mannheim already try to make use of this potential and thereby provide the framework for innovative business- logistic- and transportation processes.

Buildings

There are several ground-breaking technologies that allow buildings to communicate with their environment, to produce more energy than they consume and to work with light, biomass and air from the local environment. In a future city these technologies will be integrated into systems that allow groups of buildings to create closed cycles of energy- and material flows and to shape the micro climate of a city.

Production and Logistics

The big challenge of future urban systems is the smart and sustainable use of resources. Full integration of advanced recycling, recovery and reuse techniques into urban material flows and the holistic use of cradle-to-cradle systems for production, services and consumption will be imperative for the sustainable megacity of tomorrow. This also implies innovations in product design with a highest possible share of biodegradable

materials or recyclable product concepts. Smart city logistics complete a resource efficient production chain for sustainable distribution of goods within our cities.

Governance

A new urban paradigm needs efficient governance concepts that enable participation and acknowledge the complexity of systems innovation. Frontrunners like Zurich, Copenhagen, Amsterdam or Sydney are already working with systems that integrate citizens into decision structures and create smart collaborations between city administrations, innovative companies and research institutes.

Security

The resilient city of the future will integrate security concepts and systems at the design stage of urban planning and policy implementation, therefore ensuring the capability to identify and dominate emerging risks as well as to effectively manage catastrophic situations and quickly return to normal status. New smart and multifunctional protection technologies and materials complemented by sophisticated planning tools will ensure the security of the future urban system while not affecting the civil liberties of its citizens.

Urban Water Infrastructure

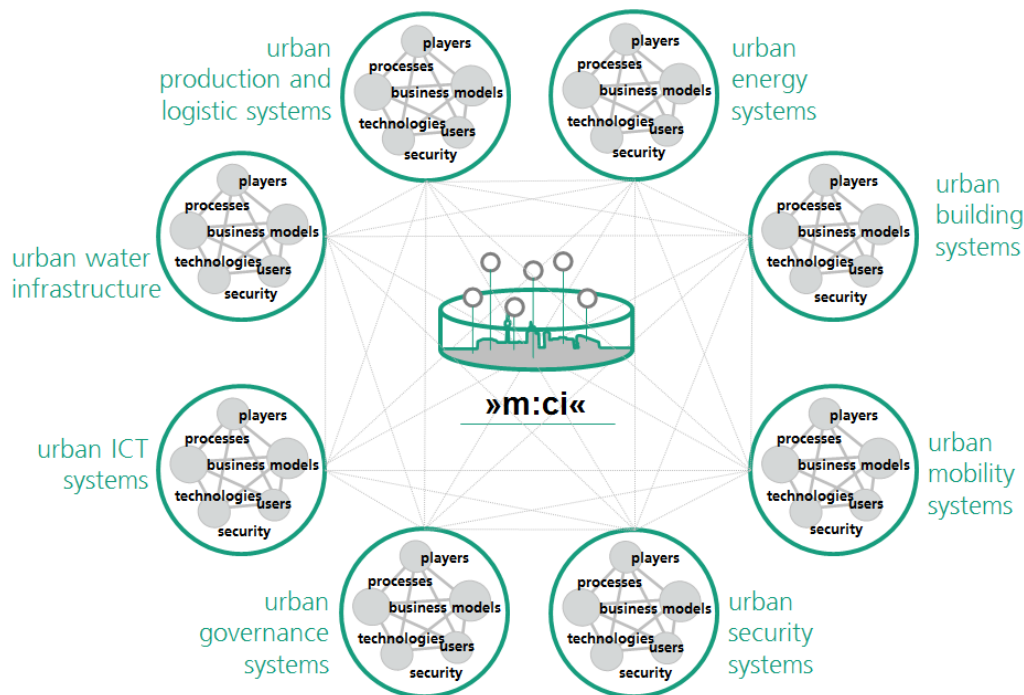
Full integration of advanced water treatment, recovery and reuse techniques into urban systems will be imperative for the sustainable city of tomorrow. This implies innovations in the water supply and sanitation sector with a highest possible share of recovery of energy, water and nutrients and interlinkage to other sectors for most efficient resource reuse.


Figure 2: Determination of the main urban systems as relevant drivers for sustainable cities.

In addition, both the research design and the data collection need to establish the foundation that will enable the transfer of solutions such as future system innovations. In order to achieve this, we developed an approach entitled City Insights Engineering (CIE) at Fraunhofer. In four consecutive steps, based on the analysis of currently existing urban system solutions, this approach is designed to generate exemplary processes for the transfer of successful solutions, as well as to facilitate the development of additional solutions for the sustainable transformation of cities.

City Insights Engineering is a long-term concept which aims to systematically build on the data collected within the Morgenstadt: City Insights project. Morgenstadt: City Insights thus represents the starting point for a long-term, systematic research of cities. In Phase I (analyze) the focus will be the analysis of the current situation in the city as well as the holistic and sector-overlapping analysis of existing Best Practice examples in the according city. In Phase II (explore) we analyze the prospective development of each Best Practice Example with the sector specific scientific methods. We further assess the frame conditions of the according

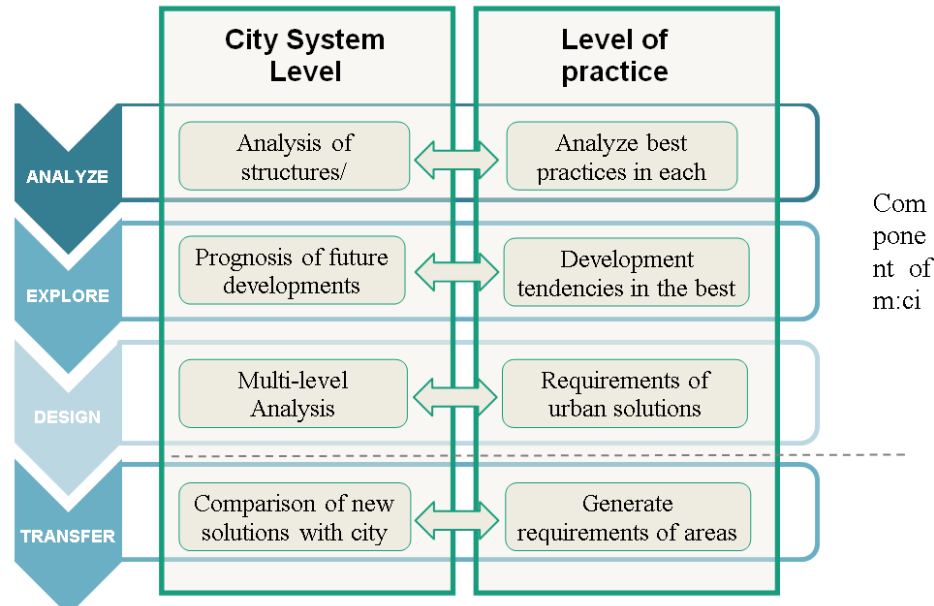
field of application for each best practice example. Both phases take place before and during the particular field trips in the according cities. In Phase III (design) we will focus on the definition of requirements for the analyzed best practice examples. For this we will perform a multi level analysis of actors, business models and use processes. A very important aspect will also be the interdependent interrelation of the individual players in the different sectors. In the last phase, Phase IV (transfer), we analyze the city's independent systematic relationships and effects.


Figure 3: Application of the research approach to both levels
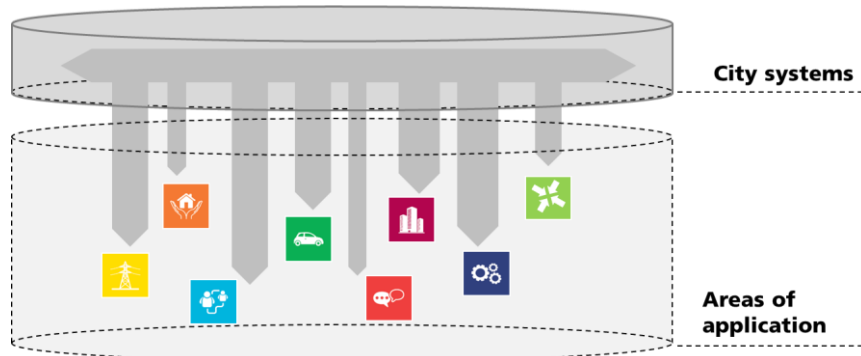

Figure 4: System analysis of cities on two levels

To link the data and information, which are generated on both levels, a transdisciplinary research approach is necessary. With such an approach, relevant actors on the city level, processes and structures, as well as general drivers of the city system as a whole can be identified, analyzed and described. Alongside a continual dialogue between the transdisciplinary City-Team, two workshops (the so called Morgenstadt Labs in each of the investigated cities) represent the most important transdisciplinary element within the Morgenstadt: City Insights project. These are transdisciplinary workshops in which Fraunhofer researchers analyze, reflect upon and transform their findings and hypotheses into additional research questions.

3.1 From sectors to areas of applications

To achieve the set goals of the Morgenstadt: City Insights project we have to come from the individual sectors to a comprehensive model of the city with all its subsystems and components. For this we divide the research process into seven phases which are shown in Figure 5. By taking apart and interpreting existing practice examples and exemplary sustainable solutions, the research design shown in this figure attempts to recognize and describe systemic interconnections between various key drivers. While at first different sectors such as mobility, energy or ICT are still considered individually to make an initial structuring of the current practice examples possible, the final result of the current research phase will present new multidisciplinary areas of application which can provide valuable information on promising technologies, industrial markets,

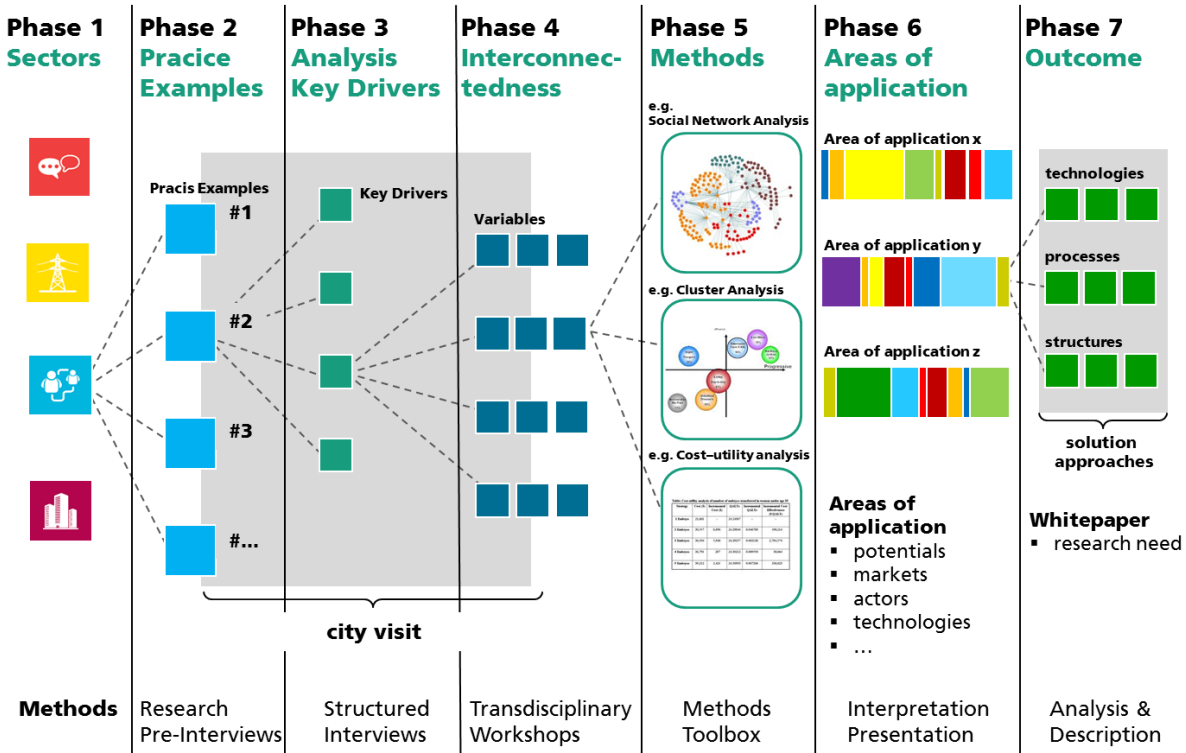
forms of cooperation, implementation processes and business models. The research process within the CIS model is shown in Figure 6.


Figure 5: Overview of the research process from sectors to areas of application

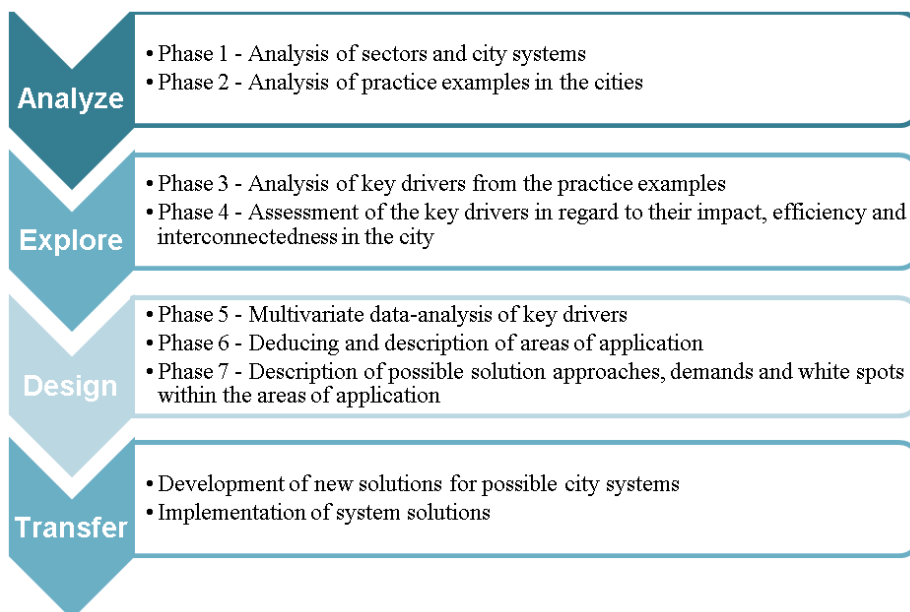
The two-week research stay in the cities themselves provides the opportunity to analyze the practice examples in a transdisciplinary and coherent manner and to understand each within its particular context. The practice examples will be broken down into key drivers which, in a joint venture with additional experts, will be evaluated regarding their future effects (for example technical, process-related, regulatory or other changes in the future) and then compiled into new areas of application in regards to the entire city system. This will be done with the help of appropriate scientific methods such as Social Network Analysis, Cluster analysis, SWOT Analysis, or cost-utility analysis.


Figure 6: City Insights Engineering model with integrated research process

3.2 Structure of the research stays within the cities

After the preparatory phase, a team of Fraunhofer experts (the City Team) will travel to the city, to spend at least two weeks on-site answering and developing upon the existing research questions.

In the first week, each City Team member will interview experts from within their particular sector, analyze practice examples and outstanding sustainable solutions within that sector, and document and interpret the data collected. Interviews can be conducted individually, however, researchers aim at conducting them in a two-person team. At the same time, each City Team member will formulate hypotheses regarding the current and future suitability of the solutions they are researching. Near the end of the first week, the entire City Team will participate in a joint one-day workshop: the Morgenstadt Lab I. The purpose of this workshop is to discuss and verify the insights and hypotheses gained during the first week with the other Fraunhofer experts looking at different sectors. The goal is to analyze and describe success factors that are relevant to all sectors on a city level. Patterns and structures at work within the city can thus be understood.

The second week is dedicated to deepening the data collection phase. Using the insights resulting from the Morgenstadt Lab I, additional interviews, analyses, and observations will be conducted within each of the sectors. The interviewees may include new individuals; however, the goal is primarily to deepen the questions and to consult the original interviewees on these questions as well. All data collected will be documented immediately. The Morgenstadt Lab II is scheduled for the end for the research stay. The same procedure will be applied as in the Morgenstadt Lab I. In addition, previously defined urban framework conditions will be discussed in terms of their relevance to the city in question. The goal is to capture and document the most important key drivers on a city level.

4 NEXT STEPS

The first work package of the Morgenstadt: City Insights project consists of the research of global best practices and the definition of leading cities in the field of urban sustainability. With the desktop research, we evaluated more than 50 cities and extracted 80 best practices. The result is a catalog of existing approaches towards improving urban sustainability (Fraunhofer IAO et al. 2012). The aim of this research was not only to identify inspiring and trendsetting solutions for future cities, but also to find examples of cities that are already performing extraordinarily well in terms of linking sustainable solutions from various fields and thereby creating a systemic approach towards becoming a sustainable city. Many of the solutions under analysis were shown to be relevant not only for one specific sector but also for the city system as a whole, featuring several important cross-linkages with other sectors. Trendsetting energy solutions often rely on innovative ICT systems, as do mobility systems that aim to reduce emissions and enhance traffic flow. Building standards, transport regulations or carbon finance approaches cannot function without sound governance and long term planning reliability.
Figure 7: Morgenstadt: City Insights research process

We therefore selected 12 cities by more than 26 quantitative and qualitative indicators with 35 trendsetting solutions that were comprehensively described in the catalog. From these 12 cities we selected, together with our partners, six cities (Freiburg, Berlin, Copenhagen, New York, Tokyo and Singapore) that will be analyzed in field excursions by Fraunhofer researchers in the next six months. In the field excursions, a Fraunhofer expert from the according sector will do narrative expert interviews with experts from the to be examined best practices and the government in the according city. With these interviews, we assess the essential frame conditions and key actors at the city level and relate them to the project level. Each practice example will than be analyzed within a holistic framework, researching data on finances, resources,

technologies, processes, structures and outcomes. Therefore, each practice example is assessed with the same extensive template. Because each researcher comes from a different science sector, the transdisciplinary labs are very important. The environment where we bring together all the results from the interviews in the different sectors and analyze them together in a hypothesis generating process is the Morgenstadt Lab, which is based on the collaborative consulting methodology.

We further define one to three essential indicators per practice example that clearly show us the success of the practice example in terms of enhanced sustainability. The indicators are defined with reference to our Morgenstadt definition of sustainability. These indicators will be assessed based on quantitative data that corresponds to the indicators. Success factors can be certain financial innovations, organizational structures, strategies, single actors, etc. Each success factor is assessed with the same template. The most important success factors for each practice example will then be correlated on a time-scale with the defined indicators. In order to find out about greater leverage points for each city, all success factors of all practice examples in one city will then be related to each other. Finally we will analyze the success factors and frame conditions for each city and bring them into an interdependent model. The comparative analysis will then relate all data assessed within the 6 cities with each other by applying a variety of mathematical, logical and statistical methods.

The first city, Freiburg, was already investigated in February. We are going to analyze the adaptability of our research concept before we start the other city investigations. We expect the first results of the field trips in June 2013 and the final results by December 2013.

Neighbourhoods' Future Created by Combined Stakeholder Engagement

Katharina Söpper

(Dr. Katharina Söpper, Vienna City Administration, Municipal Department 18 Urban Development and Planning, Rathausstraße 14-16, 1082 Vienna, katharina.soepper@wien.gv.at)

1 ABSTRACT

Spaces in cities are manifold. Of particular interest for quality of life are neighborhoods. Blighted local areas undergo enhancement processes in various ways, which differ in success and sustainability of enhancement. This is often based on the stakeholder structure supporting the process. Different models display various levels of governmental as well as non-governmental involvement and collaboration of both groups often bears difficulties. How both can be useful and what model would combine the different stakeholders most effectively, is analyzed in the present work. The U.S. approach of Community Development Corporations (CDCs) displays advantages by gaining private funding and partners. Whereas, the German model guarantees enhancement processes even in areas where bottom-up initiatives and engaged nonprofit organizations are missing. In the interest of the neighborhood and the whole city, collaboration would be the best way; however, it seems that local actors have to take a leading part as experts of the local situation. The named results can also be transferred to the city context as they are neither limited to the neighborhood area nor to the studied countries.

2 GOVERNMENTAL AND NON-GOVERNMENTAL NEIGHBORHOOD ENHANCEMENT

Approaches for enhancement of distressed neighborhoods exist in almost every industrialized country. Programs differ, however can be divided into governmental-based and non-governmental-based approaches.

Governmental-based approaches are based on governmental created, lead, and funded programs. Local stakeholders take part as supporter on the neighborhood level, following the government's rules. In contrast, non-governmental approaches are bottom-up processes, getting started by local citizens, nonprofits or other area stakeholders. They define their own rules and goals and work on the enhancement of their neighborhood. Nevertheless, additional governmental funding is used during the non-governmental approach as well, which leads to the part-adaption of local goals according to governmental regulations.

Dissatisfying results often evolve from merely governmental programs sustained with governmental funding and tailored to governmental objectives and measures often using the same mission for every neighborhood that is part of the program. Such an overall program hinders covering local needs with adequate measures. Hence, local stakeholders do only play a minor role in the government's game. Participation processes exist, but are limited to strongly regulated procedures where citizens and other participants have to match with. Particular needs or desires are tough to cover while following the governmental based program.

In addition, governmental support is often limited in terms of time and money. Due to the goal of fair distribution of enhancement measures governments often limit their time and money budget. This way allows the approach to cover as many areas as possible since funding, that ends in one area will be available to another area afterwards. Time restriction often follows the idea of activating local potentials. Time restricted provision of money combined with the goal of building self-supporting structures is seen as adequate approach by the government for gaining local support and independent structures. The idea of long-term support without local contribution has to get avoided.

Therefore, the local community should get involved at an earlier time point and take over after the governmental incentives end. An example of such missing self-supporting structures after the governmental funding period is the German 'Soziale Stadt' ('Socially Integrative City') program. Being a successful enhancement program in general, the 'Soziale Stadt' program struggles by gaining necessary local support during the funding period, which leads to the end of most of the projects after the governmental funding ends. Short term extra time does not lead to long-term achievement yet.[1]

3   EXAMPLES OF EXISTING RELATIONSHIPS

Based on research on two examples of redevelopment approaches, the following results could be gained. The two examples are: the 'Soziale Stadt' program in Germany and Community Development Corporations (CDCs) in the United States of America (U.S.). The German program is governmental-based and currently struggling due to governmental funding cutbacks. New instruments and methods for more self-supporting neighborhood enhancement, even with reduced governmental funding are needed. Therefore, CDCs were chosen as second example. This approach is initiated by local stakeholders and follows a local mission. Governmental funding exists as well, however it is seen as additional in contrast to the initiative funding.

Both examples are based on collaboration processes, but they are generated from two different ends of the stakeholder spectrum.

3.1 Collaboration Generated by Governmental Stakeholders – 'Soziale Stadt'

The German federal program 'Soziale Stadt' is part of the main urban development promotion program. The program consists of local, mainly investive projects in clearly defined neighborhoods and is funded by the government. The combined funding model consists of one-third federal and two-thirds 'Länder' and municipality support. Local redevelopment offices and their professional staff are the center of the local engagement. The time frame of five to ten years yields the challenge of building self-supporting structures and the sustainment of successful projects.[2]

The German model 'Soziale Stadt' can be described as collaboration generated by governmental stakeholders. The following table displays some advantage as well as disadvantages evolving from this kind of collaboration structure.

advantage	disadvantage
reliable funding (governmental share)	cutbacks due to governmental financial situation
distinctive program regulations	minor flexibility, due to governmental regulations
long history of redevelopment efforts	same program for every neighborhood
even neighborhoods without local initiatives get supported	time-restriction versus long term effort
local redevelopment offices as strong local stakeholders and starting point for local network building	governmental funding can hinder private funding engagement
local initiative can apply for governmental program	reliable partners for time after governmental funding cannot be found in time
	imbalance is particularly problematic once the government starts to retreat from the enhancement process
	local businesses do not feel attracted by program
	local nonprofits contribute but do not lead
	missing acceptance of local actors as partners
	regulations and rules come one-sided
	power as well as resources are alloted to one partner only
	common goals are missing

Table 1: Advantages and disadvantages of 'Soziale Stadt'

The reliable governmental funding is one of the biggest advantages of the German model 'Soziale Stadt'. However, governmental funding faces cutbacks as well, the governmental share can be seen as important starting point for local initiatives. This governmental first step also allows distressed neighborhoods without initiatives to get an enhancement process started. Would these neighborhoods rely on a local leading private partner there might be no partner strong enough to take the first step. Due to the long history of redevelopment efforts in Germany, the approach is proven to be reliable and even successful. The process was reviewed as well as adapted over time. The core instruments of the 'Soziale Stadt' program are

---

[2] BMVBS 2012; Centre for Knowledge Transfer 'Social City' 2008; Franke 2011; Franke 2005; Lahner, Zimmermann 2005

'Quartiersmanagements' meaning local neighborhood offices. These offices are paid by the government and build the local hubs for every activity. These low key meeting places are often successful in gaining partners for redevelopment efforts (even if their contribution might be time-restricted). Moreover, the German program also includes the chance for local initiatives to apply for the governmental funding if there was a initiative build by the neighborhood without governmental support at first.

The German model displays disadvantages as well. Recent cutbacks of the governmental funding hit the project areas hard, since they cannot cover this shortfall by private funds. Moreover, the governmental money comes with regulations attached, which means minor flexibility for local projects. Therefore, every neighborhood receives governmental money following the same rules and the same enhancement program, due to the federal regulations. Local singularities cannot be covered. Although the neighborhood revitalization has to be seen as long term effort, the governmental funding program is time restricted. Private engagement often is discouraged by the governmental regulations which can hinder private funding support. The largest challenge for the 'Soziale Stadt' program is gaining long term private partners. These local non-governmental partners are necessary for continuing the redevelopment effort after the governmental funding ends. However, due to the one-sided activities lead and paid by the government, they feel as participants more than as partners. In particular, local businesses do not feel attracted by the governmental lead program and miss flexibility. Local nonprofits contribute to the efforts started by the program but are no leading partner. In general, common goals for redevelopment combining governmental and non-governmental stakeholders are missing.

As shown above, German redevelopment efforts depend on governmental funding as starting point for neighborhood enhancement. This is based on the German understanding of the state and the role of the particular citizen as well as existing legal structures. In Germany, redevelopment of local areas is part of the so called 'Fürsorgestaat' (welfare state) and its measures have to be coordinated and paid for by the government. Local citizens do not feel personally responsible for their neighborhoods compared to U.S. neighborhood citizens. Therefore, governmental funding will still remain a necessary component of redevelopment efforts in future times.[3]

advantage	disadvantage
governmental and private funding is used in a combined way right from the beginning of the community development effort	first steps have to take place without governmental support at all
government is an important partner as sponsor	(economical) weak neighborhoods might not be able to get initiatives started on their own
no substantial dependency on governmental funding	more powerful actors might overrule silent inhabitants
stakeholders act as partners in a mutual undertaking	
designated long-term mission	
local projects are conducted by local people	
closer connection of the projects to the neighborhood since goals are based on neighborhood demands	
activation processes have to be intense, due to dependence on private money	
more long-lasting projects may be realized and funded	

Table 2: Advantages and disadvantages of Community Development Corporations

3.2 Collaboration Generated by Non-governmental Stakeholders – 'Community Development Corporations'

Alternatively, neighborhood enhancement can start on the local level and involve local stakeholders as leading part. This is the case in U.S. Community Development Collaborations (CDCs), which are founded by the neighborhood itself and additional funding is provided proportionally by the government.

Crucial for Community Development Corporations (CDCs) is their founding process, which takes place without governmental influence, but with local stakeholders only (citizens, businesses, nonprofits, etc.).

---

[3] Franke 2011; Schönig 2011

Professionals as well as local people without respective professional background work at the installed local offices. Local projects take place in collaboration with local partners (citizens, shop owners, large businesses, banks, nonprofits, etc.). Even funding is organized locally, supported by donations, and complemented by governmental funding (grants, etc.). No time restriction exists for CDCs, since they work with five-year plans and a long-term mission. This model has several advantages over the model described above.[4]

Community Development Corporations gain sufficient support from neighborhood citizens, nonprofits, foundations, banks, and local businesses, in particular since they are established by stakeholders from the neighborhood itself and part of its staff also comes from the area. First steps have to take place without governmental support at all. Locals are partners right from the beginning and additional governmental funding is combined with private local funds. Collaborations on the local level have to be built, and common projects have to be phrased prior to applying for governmental support. Nevertheless, the government is an important funding partner, but no one-sided independency evolves. The program follows a designated long-term mission and local projects are conducted and mainly paid by local stakeholders. These locally based and funded initiatives know local problems better and are closer to their neighborhood and residents, as well as participants and collaborators. Therefore, the program creates a closer connection to the neighborhood as well as an intense participation and activation process, since the money has to be collected from local partners. This leads to more long-lasting projects in the neighborhoods and all involved stakeholders act as partners in a mutual undertaking.

Disadvantages can be named for this program as well, since it can also be problematic that the first steps of the enhancement process have to be taken without governmental support at all. Thereby, (economical) weak neighborhoods might not be able to get initiatives started on their own. Moreover, more active participants might hinder other (more silent) potential partners from getting heard and getting involved.

3.3 Collaborations

It has to be stated that the paper focuses on the way the collaboration was generated, meaning who indicated the collaboration process. Of course, way and intensity of collaborations differ independent from their initiation process. Much good and fruitful collaborations exist in the 'Soziale Stadt' areas in Germany as well as in CDC neighborhoods in the U.S.; same with unsuccessful enhancement processes in both countries.

As result of the conducted research above, the following main goals for successful collaboration are stated: combined governmental and non-governmental funding, partnership instead of participation, long term collaboration, local based projects.

3.3.1   Combined governmental and non-governmental funding

As the examples show, the combination of governmental and non-governmental funding makes neighborhood enhancement efforts strong and reliable. The mutual contribution to redevelopment efforts prevents from one-sided dependency and one-sided goals. Reliable governmental funding shares should be combined with a share of private funding. The private part should be gained through partnership instead of participation (see below). This common funding model displays the common approach as well as the common responsibilities all partners share. Depending on the cultural background of the country the leading partner can be private or governmental.

Using the U.S. and German example combined funding means: U.S. redevelopment approaches like Community Development Corporations (CDCs) avoid one-sided dependency by the combined use of governmental and private funds. Governmental money is only provided, if private funds are present, too. Thereby, projects only come to life if the private share (up to 50 %) is guaranteed, as well. Such an approach could also be useful for German redevelopment, instead of providing governmental money for projects that lack private funding. This method would be helpful to make projects more self-supporting and stop one-sided dependency on governmental money. Moreover, the search for private funding support could be an important part of the activation strategies in the neighborhood. Existent project funding should not comprise only the building or installation of the project, but also include maintenance and service periods in the future,

---

[4] Accordino 2007; Brophy, Shabecoff 2001; DeFilippis 2008; Grogan, Proscio 2000; Peterman 2000; Rubin 2000

as it is the case in the U.S. model. Such an approach would prevent projects from taking place, for which no budget for future maintenance exists, as has happened in German 'Soziale Stadt' projects sometimes.

3.3.2 Partnership instead of participation

Gaining partners for the common undertaking of enhancement is crucial. Following the combined funding model, local actors should be seen as partners instead of participants. The difference between these two ways of collaboration lies in the guiding role. If local stakeholders only participate on the governmental effort, they are not responsible for the outcome and most important they are not able to influence the goals of the undertaking. Obtaining a participant brings support for the already existent project. Obtaining a partner brings someone in who shares the same idea and the same level of responsibility for the project. Partners in redevelopment define their common goals together and contribute in the same way. This seems the more promising way of neighborhood enhancement than the one-sided German model.

Regarding the 'Soziale Stadt' approach and U.S. CDCs partnership means: In the U.S., citizens are perceived not only as participants, but also as funding partners. Local inhabitants should be asked for support (money or manpower) if governmental money has to be complemented. Working with a combination of governmental money and private funds forces CDCs to get local stakeholders on board early and to build partnerships with the residents. Incentives are given for people to donate time and money by providing them influence on the decision making process and on implemented projects, which they pay or work for. Such more interactive participation processes and the building of partnerships rather than hierarchical structures between the office and the neighborhood including more co-determination for the people would most likely improve German approaches, as well.

3.3.3 Long term collaboration

Moreover, the collaboration should follow long term goals. Since neighborhood enhancement is a long term challenge and improvement cannot be reached during a few years, the collaboration needs to phrase long term goals together. Working together on future projects brings in more commitment by the singular partner. Reliable planning horizons attract private partners most. In addition, governmental partner need to be interested in a sustainable enhancement of their city areas instead of short term success, which is fading away after the redevelopment program left.

The German redevelopment program shows how problematic situations can get, if the governmental money is withdrawn from the area before sustainable enhancement took place. In contrast, the U.S. approach never sets a deadline, but uses long-term missions combined with 5-year implementation plans.

3.3.4 Local based projects

Working on the city and neighborhood level always comes with particular challenges and situations. These situations differ from area to area. Therefore, it is very important to be aware of different challenges and particular needs existent in the neighborhood. This particular situation can be understood best by working with local stakeholders and obtaining local partners. The goal of redevelopment efforts needs to be, establishing local projects, based on local ideas, and (partly) funded by local partners. Neighborhood stakeholders are manifold, beginning with inhabitants, businesses, nonprofits and so on. The more local input the project consists of the more likely it will be successful.

German 'Quartiersmanagements' contribute to a local view on projects and are able to gather local ideas. Nevertheless, the U.S. local redevelopment offices are more active in gaining local partners and in getting in touch with as many local stakeholders as possible. In particular business and nonprofit partners need to be contacted more in Germany. Common projects will lead to a common effort on local enhancement.

4 NEW RELATIONSHIPS

The question about the neighborhoods future and the role combined stakeholder engagement plays on this behalf was answered for the local level using the example of neighborhood enhancement. However, this research results can also be transferred to the city level as well as an to an international context.

4.1 Neighborhood Enhancement by Different Relationships

The chosen examples show that neighborhood enhancement always depends on the general understanding of the role of a country's government. Strong dependence on the government comes along with comprehensive governmentally lead support programs for the neighborhoods, whereas more individualistic societies do not depend as strongly on the government.[5] Thus, no model fits every country since the context has to be taken into account. Nevertheless, neighborhood enhancement has to take place between partners. Neither can the government improve the situation on its own, nor can the local area start projects entirely without governmental support. Consequently, new relationships have to be built. Ideas and engagement have to be contributed by the neighborhood, whereas organizational and monetary support has to be provided by the government and the local partners alike. Eventually, the neighborhood – accompanied by the government – decides about its future. Non-governmental stakeholders could and should play an important role in redevelopment efforts in the future, if they are seen as partners and provided with necessary power and responsibility. In addition, the engagement of citizens and business has to receive more appreciation.

4.2 Ways of Stakeholder Engagement and their Importance on the Future of Cities

The presented research used redevelopment as an example and manageable research area, but its results are important for the city context as well. Many cities of the world face increasing numbers of challenges combined with a decreasing amount of governmental money available. Accompanied by the newly established understanding of citizen and private stakeholder engagement this should lead to a new way of dealing with the cities' challenges.

City governments will not be able to create their future on their own. Many new stakeholders are about to claim their share of the city and its future. Although, the government will still play an important role in securing the common good and fair living conditions for every inhabitant, planning projects will be shared ventures in future times. How collaboration between these stakeholders can take place and what needs to be aimed at has been described above.
