If the cities' future will be based on shared efforts of all city stakeholders using combined governmental and non-governmental funding, if it is build upon partnership instead of participation, if it reaches for long term collaboration, and if it works on local based projects, the future challenges might not be that frightening anymore.

1 ABSTRACT

Like in many other developing countries under globalization and structural change processes, Turkey has experiencing great deal of changes in its urban structures fort the last two decades. Among them urban regeneration is one of the highly debated planning issues in the last decade. In addition to major structural changes like integration of urban fringe to the core, de-industrialization, urban sprawl and re-invention of the city center as cultural domain; planning issues such as renewal of historical areas, disaster mitigation planning in risk prone zones, and re-development of brown field areas have put a complex agenda in urban planning practice.

In the recent decade, the central government in Turkey has issued several legal planning tools to enable urban regeneration projects in Istanbul and in many other cities. However, in many cases these legal arrangements were acted as ad-hoc solutions for case-specific urban regeneration projects and the empowerment of some central state organizations such as State Housing Authority (TOKI) and Privatization Authority (OIB) in plan making process have caused fragmentation in urban planning process in Turkey.

In this paper some selected urban regeneration cases will be scrutinized in order to explain the current actors and their roles in plan making process. An assessment will be made on the effects of Neo-liberal approaches to current planning issues in Istanbul and a discussion will follow about the possible outcomes of fragmentation in urban planning practices.

2 CONCEPT OF URBAN TRANSFORMATION

During recent years, like in many other countries, there have been several discussions in Turkey on the phenomenon of urban transformation. Urban transformation varies between nations with respect to proposed vision, objective, strategies and employed methods. The focal point of discussions is that urban transformation cannot be restricted with the transformation of a physical space but needs to embody cultural, social, economical and environmental aspects as well.

Within this framework urban transformation is acknowledged to be a comprehensive vision and action that aims to provide permanent solutions for the economical, physical, social and environmental urban problems witnessed in a transformed region (Thomas, 2003).

Urban transformation is basically conducted to reintegrate outdated, battered, bedraggled, nonfunctional and economically worn-out regions within the large texture of city. It refers to the whole set of strategies and actions followed to improve economical, social, physical and environmental urban conditions via implementing comprehensive and integrated approaches.

In a different saying, it implies re-improvement and regeneration of an outdated economical activity, revitalizing of a nonoperational social function; in ostracized regions enabling reintegration with larger society; reestablishing the harmony in regions where environmental quality or balance is lost (Roberts, 2000).

2.1 Concept of Urban Transformation during post-1980

A closer look at the historical development of urban transformation reveals that the breaking point of this phenomenon coincides with the 1980s. A definition of the phenomenon of urban transformation calls for a better grasp of globalization, competition and sustainability concepts that collectively impacted planning strategy as of the 1980s.

Having existed and acknowledged before the 1980s urban transformation first referred to transformation of unsanitary urban conditions of laborers in major European cities particularly after the Industrial Revolution as well as physical transformation of cities wrecked in the aftermath of the First and Second World Wars. It was perceived as rehabilitation of unsanitary urban conditions or restructuring of battered urban textures. In

the preceding years of 1980s urban transformation in the narrowest sense implied a transformation of physical space; however in subsequent years it gained new dimensions by virtue of changes from traditional marketing strategy towards strategic spatial planning.

Context and meaning of transformation changed in a way to encompass transition to information technologies, urban competition, sustainability, governance, social facts, social belonging, localness and ecological features.

As a consequence, phenomenon of urban transformation initiated by Industrial Revolution and extended till the 1980s was defined as reconsidering physical battering caused in urban land by rapid urbanization, spatial change in the city, population density in urban lands and relevant factors. However in the aftermath of 1980s it has been dealt within a conceptual structure in which the union of physical, economical, social, environmental and technological relations has been questioned and transformation has been analyzed within the framework of this interrogation.

2.1.1   Different Dimensions of Urban Transformation

Urban transformation includes in itself four key dimensions which all complement one another; planning of physical space, social facts, economical features and legal/administrative structure. Physical space dimension relates to transportation connections of the region in which urban transformation is implemented, housing stock it preserves, technical substructure and social equipment capacities and environmental problems. Planning dimension involves spatial plan, development and change of transformation zone. Social dimension embodies access to public services such as health and education, crime, social exclusion, public and private sector partnership, participation of locals and volunteers. Economical dimension implies boosting the quantity and quality of employment opportunities and created added value in selected region and its vicinity (Kokturk, 2007). Legal/administrative dimension integrates structure of local decision mechanisms, relations with local community, participation of interest groups and actors playing role throughout the process.

2.1.2   Targets of Urban Transformation

By definition concept of transformation has effect on the structure of city and physical, environmental, social and economical future of urban settlers. Hence in all planning activities, a multidisciplinary approach that integrates sociologists, planners, architects, engineers, economists, legal practitioners, historians, landscape architects should be adopted. Treating qualified lands as merely transformation of physical space brings about the rise of problems throughout the implementation of project which in turn delays the completion of project or even causes an annulment.

From this point of view, urban transformation is required to be planned to serve five key objectives (Roberts, 2000).

A direct relation should be established between physical conditions of the city and social problems. One of the most influential factors in the dilapidation of urban lands is social deterioration or societal collapse. Urban transformation projects should prioritize the underlying reasons behind social deterioration and propose preventive suggestions against societal collapse.

Urban transformation should meet continuous, physical change need of many elements constituting urban texture. In other terms urban transformation project should enable re-improvement of urban components in accordance with new physical, social, environmental and infrastructural needs emerging in the rapidly enlarging texture of city.

It should hold a local economical development approach boosting urban welfare and life quality.

Aside from physical and social deterioration, one of the most significant reasons wrecking urban lands is the loss of economical vitality in these regions. Urban transformation projects are required to develop strategies that shall revitalize economical flourish in urban components that are in the form of physical and social wrack. In these projects employment opportunities and increase in added value should be sine qua non condition to prioritize.

Strategies that enable the most effective use of urban lands and prevent undesired urban sprawl should be implemented. Urban growth should promote compact city.

Urban transformation projects should possess one or several of these targets in accordance with the problems, threats, opportunities and potentials of particular urban region.

2.2 Relation between Urban Transformation and Urban Projects

Activities directed towards the actualization of targets identified with urban transformation should be treated as a process. In that case the process in urban transformation projects are;

in line with Urban Development Vision

within the framework of Strategic Spatial Planning approaches

identified by Urban Project

defined by Implementation Program and Tools.

What is the focal point in present research is that urban projects are crucial toolsin urban transformation projects. However it would be a misleading and incorrect approach to claim that phenomenon of urban project is merely a reorganization of physical space. It is required to integrate with the project throughout different stages the multi disciplines that encompass different dimensions of urban transformation. Urban projects mostly focus on urban components that have been discriminated by industrial city and become nonfunctional under current conditions. Urban projects also can take stage in a wide range of domains such as recovery of old industrial and port areas in idle status; building of techno-parks, amusement parks, housing zones demanding modern technological infrastructure and international capital; polishing old urban housing zones by adding new prestige. Hence in urban interventions, urban projects act as crucial planning and design tools. Urban components constituting the subject of urban projects can posses "public space" or "private space" quality. Urban projects of which main objects are public and private space can thus initiate with itself a process of urban transformation. Therefore it is a must not to reduce urban projects to merely physical space but handle it collectively with the other components of space.

In its modern sense concept of urban transformation refers to a comprehensive restructuring approach directed towards overcoming social, economical and spatial wracks triggered in cities by the dynamics of post-Fordist era in particular and problems of post industrial period developmental stages (Sökmen, 2003). What deserves particular attention at this point is the kind of planning approach urban transformation concept and subsequent urban project approach are associated with.

2.2.1 Implementation Forms of Urban Transformation

Urban transformation is a wide-scope concept including in itself the implementations aimed towards renewal of present urban structure. Different forms of implementation enclosed in urban transformation are as outlined below:

Renewal: Urban renewal activity takes stage according to the needs of urban spaces having passed to deterioration and wrecking process because of the development and change of urban functions and socio-economic structuring. Renewal is defined as restructuring after demolishing some or all buildings in areas of which living and sanitary conditions cannot be improved because of both settlement design and status of existing structures.

Urban Renaissance: Urban renaissance basically focuses on the process witnessed in the transformation of London in Britain. It generally advocates establishing harmony amidst economical competition, minimizing social exclusion and environmental protection (Gibson&Kocabas, 2001).

Rehabilitation: Rehabilitation is rehabilitating via rearrangement a wrecked building or set of buildings of which density has increased due to several recent additions and modifications but of which original quality is still preserved. It implies reopening to use of old urban texture and wreckage lands by making use of partial renewal.

Preservation-conservation: Preventing the loss of physical structure that reflects a society's ancient social and economic conditions and cultural values because of the experienced changes and developments (Erden, 2003). Union of urban texture with modern life is defined as rehabilitating cultural assets by virtue of economical and functional conditions beneficial for society. The concept involves two kinds of approaches; preservation with the original quality or conservation with limited changes.

Revitalization: Urban revitalization is by eliminating social, economical and physical impacts triggering deterioration in urban regions passing to period of collapse to re-strengthen and revitalize the land via reintegration with the urban system.

Redevelopment: Developing within a new planning design the urban textures of which economical and structural qualities are too deteriorated to conduct renewal.

Improvement: A public action type aimed towards unplanned development of a whole or part of city; manipulating development to gain societal benefit and establish relation between functions and land use.

Clearance: Defined as removal of unsanitary conditions in houses and other buildings within regions in which low-income groups are densely populated. The process is described as "Slum-Clearance" in Western world.

Brownfield development: Joining new activities and structures into an existing structure in any region.

Refurbishment: Indicates revitalization of historical lands by using landscape components and urban furniture that play crucial role in the acquisition of urban image and character.

Aside from above defined implementation forms of urban transformation projects, there are several implementation forms known by different names or formed by the combination of several of the ones above. Selection of implementation forms within an urban transformation project varies with respect to physical, social and economic structure of particular region and legal framework effective on the treatment of particular issue.

3 URBAN TRANSFORMATION PROJECTS IN TURKEY

Urban transformation phenomenon in Turkey though bears similarities to developed Western states, also exhibits substantial divergences which stem from economical and political facts surrounding Turkey as well as historical past and social and cultural structure of the nation.

In the West a set of intervention methods has been developed so as to deal with a variety of urban transformation problems. In Turkey on the other hand the most emphasized dimension in urban transformation is change of informally developing housing zones (slums etc.) (Türel 2005). In Turkey, State Housing Authority (TOKI) acts on behalf of general public during urban transformation processes and fuels the transformation in these domains. Presently TOKI is the most powerful and effective central government authority in urban transformation within Turkey. Other participating public actors are Ministry of Environment and Urban Planning, Ministry of Culture and Tourism and Municipalities. Additionally in recent years projects implemented by real-estate development agencies have been seated in the first rows on public agenda. In relation to the quality and location of urban transformation, international organizations and agencies such as UNESCO, ICOMOS can also play role in urban transformation projects within Turkey (Kocabas, 2006, Dincer&Enlil&Evren, 2009).

Modern cities in Turkey face several urban transformation problems ranging from developing earthquake-resistant urban spaces, conservation of natural, historical and cultural heritage, legalizing and rehabilitating informal and low quality of life in urban lands. In Turkey urban transformation is generally reduced to merely transformation of physical space thus social, economical and environmental dimensions of transformation have been neglected. In Turkey response to urban transformation problems have been, rather than political interventions within the scope of a definite plan and program, based on market conditions; 'ad-hoc' solutions of community; mutual interactions between central and local administrations.

In Turkey urban transformation projects implemented during post- 1980 in particular have received much criticism on accounts of being allegedly the kind of projects creating uncontrolled urban sprawl, deterioration of cultural, historical and natural assets, non-industrialization, ignoring environmental sustainability, reflecting non-local features, climbing social inequality, social exclusion and polarization, providing a limited spatial quality (Ercan, 2011).

3.1 Legal Dimension of Urban Transformation in Turkey

In Turkey, cities have been transformed in this framework of urbanization problems; however the introduction of urban renewal concept in urbanization and planning practice in Turkey coincides with the 1970s and its utilization as an implementation tool in planning corresponds to the 1980s.

Regulations and practices concerning urban transformation have for a long time been conducted within the framework of effective legislations and legal provisions (Genc, 2008). Therefore unlike Western states which adopted multi-dimensional, comprehensive political practices, techniques and methods, corporate and financial structure there have been ad-hoc solutions and practices that are nonrelated and developed by different administrative units only when a necessity emerged. In its current form it can be argued that there is a fragmented structuring within the relevant legislation.

In addition to these developments, fueled by EU membership process too, there have been major legal regulations involving urban transformation issue as of year 2000 in certain public administrative reforms. Amongst them the most fore grounded regulations are;

Date	Law No	Law Title* *(in abbreviated format)	Scope with respect to Urban Transformation
1966	775	Illegal Housing Prevention Law	Preventing unplanned structuring via illegal housing prevention
1984	2981	Law on Buildings Violating Construction and Illegal Housing Prevention Law	Indirect implementation of urban transformation projects via Improvement plan
1984	2985	Mass Housing Law	Regulations to meet housing demands
1985	3194	Construction Law	Regulations on Construction Plan preparation and approval
1994	4046	Privatization Law (Article 41)	Amendment in Article 9 of Construction Law, granting planning and approval authority to Privatization Administration
1997	4232	Privatization Law (Article 4)	Amendment in Article 9 of Construction Law,
2004	5104	North Ankara Transit Urban Transformation Project Law	Legal regulations on private project lands
2004	5162	Amendment in Mass Housing Law	Amendment in Article 4, in transformation lands granting planning and approval authority to TOKI
2004	5226	Amendment in Cultural and Natural Heritage Conservation Law	Definition of Renewal Land and renewal projects
2005	5393	Municipality Law	Pursuant to Article 73 of the Law urban transformation and development projects are approved.
2005	5366	Law on Battered Historical and Cultural Real Estate	Selecting the neighborhoods dominated with battered historical and cultural assets as renewal zones,
2010	5998	Amendment in Municipality Law	Amendment in Article 73, Scope of urban transformation and development project is widened.
2011	644	Body and Missions of the Ministry of Environment and Urbanism	Pursuant to Cabinet decree, authority to plan and approve for all the lands under the rule of central administration, authority to identify the procedures and principles concerning urban transformation practices
2012	6306	Law on Transforming Disaster Risk Zones & Regulation on implementation of Transforming Disaster Risk Zones	Identification, planning and setting implementation procedures for disaster risk zones, -Identification of Risk Buildings in an Earthquake Risk Report, -Pursuant to Cabinet Decree identification as **risk zone**

Table 1: In Turkey Major Legal Regulations involving Urban Transformation issue

Main factors influential in the emergence of legal regulations aimed so far to direct urban transformation in Turkey throughout historical process can be listed as below;

Illegal Housing Prevention Zones:

Squatter houses (illegal houses, slums) refer to the housing style addressing to low income groups of which residential demands could not be met through legal methods. In Turkey the system basically addressed to the former rural settlers that migrated to cities in the aftermath of rapid urbanization process witnessed in post Second World War era. In Istanbul, Illegal Housing Prevention Zones practices were developed in Sarıgöl – Yenidoğan and Tozkoparan districts by Municipalities of Gaziosmanpaşa and Güngören pursuant to 775 no Law in addition to Ayazma and Kayabaşı Mass Housing Zone applications within the borders of Başakşehir Municipality are the most significant samples. The objective of this law is to prevent unorganized public housing that emerge due to rapid urbanization on public urban lands and providing organized housing areas for the needy citizens via mass housing practices in the selected zones. Nonetheless the positive outcomes obtained by these practices have been confined to total urban development phenomenon witnessed in Turkey during the last four decades. In years squatter housing has turned into a way of grabbing advantage-though informally- from urban development rents thus owners of squatter houses rejected to be involved in such formal arrangements.

Renewal Zones:

In renewal zones proclaimed pursuant to 5366 no Law, the aim is to plan the neighborhoods in which historical and cultural assets are densely populated. Publicly known as Tarlabaşı Project, Sulukule Project, Fener Balat Project these projects are the leading examples of renewal lands within the borders of Istanbul. Basically these are the regions situated in city center and favored by middle and low income groups till recent times on accounts of their proximity to former industrial zones and its subsequent connection with city center afterwards. However the new objective is to renew these regions in accordance with non-industrialization phenomenon experienced gradually in the central zones in Istanbul and at the same parallel to the rediscovery of cultural, touristic and aesthetic identities in particular spots within city center. This legal regulation aiming to improve urban standards of particular zones through physical renewal and life quality of settlers failed to envisage an intervention with the accompanying social and economical processes. Consequently former inhabitants in the course of time migrated from their original settlements (gentrification) as they failed to adopt new economical and social conditions (Ergun, 2004; Uysal, 2012). In the course of time this movement has turned into a tool aiming to present for the taste of new urban middle class and global tourism investors through aestheticization of historical urban identity elements in particular regions reflecting historical identity of the city.

Cabinet Decree	Official Gazette No	Official Gazette Date	Renewal Land
2006/10172	26122	28.03.2006	Beyoğlu (Cezayir Blind and its vicinity, Tophane District, Galata Tower neighborhood, Beyoğlu Municipality Building and its vicinity, Bedrettin Neighborhood)
2006/10299	26147	22.04.2006	Fatih (Fatih – Kürkçübaşı Area Bulgurpalas, Atikmustafapaşa Neighborhoods, Fatih Balat Karabaş – Tahta Minare Neighborhoods, Hatice Sultan – Neslişah Neighborhoods)
2006/10455	26186	02.06.2006	Tuzla (Tuzla Köyiçi)
2006/10501	26206	22.06.2006	Eminönü (Süleymaniye, Hacıkadın, Kalenderhane, Mollahüsrev, Hoca Gıyaseddin, Sarıemir, Yavuz Sinan, Demirtaş Neighborhoods)
2006/10502	26207	23.06.2006	Zeytinburnu (Zeytinburnu Wall Isolation Band)
2006/10961	26318	13.10.2006	Fatih (Haraççi Kara Mehmet, Yali, Küçük Mustafa Paşa, Hüsambey, Kasap İlyas, Haci Hüseyin Ağa, İmrahor, Arpa Emini, Şeyh Resmi , Hatice Sultan, Ereğli, Kürkçübaşi, Cerrahpaşa , Davut Paşa, Atik Mustafa Paşa, Fatma Sultan, Çakirağa, Kirkçeşme, Neslişah , Haci Evhattin, Haci Hamza, Canbaziye, Balat Karabaş, Tahta Minare, Abdi Subaşi, Veledi Karabaş, Beyazitağa, Molla Aşki, Sancaktar Hayrettin Neighborhoods)
2007/12375	26588	20.07.2007	Eminönü (Nişanca, Sultanahmet)
2007/12429	26597	29.07.2007	Fatih (On İmrahor Neighborhood 2384 No Block previous parcel no "11" has been changed as "L")
2007/12893	26737	25.12.2007	Eminönü (Old Bazaar and its Neighborhood)
2008/14349	27074	04.12.2008	Tuzla (İçmeler, Kamil Abduş Lake and its Neighborhood)
2010/405	27586	20.05.2010	Eyüp (Nişanca, Cezrikasım Neighborhoods)

Table 2: Renewal Lands Proclaimed in Istanbul

- Law on the Transformation of Disaster Risk Zones:

As a natural consequence of unorganized and uncontrolled urbanization natural disasters, mostly earthquakes, bring about even greater damages. In cities devastating effects of earthquakes become even deeper due to population boost, land use, defects in structures, insufficiency of substructure and services, environmental problems. Pursuant to 6306 no Law it has been aimed to consolidate risky structures or demolish then reconstruct an earthquake-resistant building (Ozcevik, 2007). As stipulated under this law loan supports are provided for the house owners in risky structures and contractor's in-charge.

A substantial portion of Turkey is situated in first degree seismic belt. As an outcome of the rapid urbanization process witnessed during the last four decades not only the emergence of comparatively low-quality urban settlements has been observed but also the emergence of zones with dense housing textures that are non-resistant to earthquakes. This legal regulation not only aims to minimize the losses in the face of a potential earthquake but also to improve unorganized settlings. Nonetheless at this point a market-centered political approach which ignores the fact that urban physical improvement's basic aim is to create safe urban lands -which in fact is the inherent mission of ruling government- is once again utilized. Thus through

reallocation of urban rents, settlement density in these zones is multiplied to create new demands of houses/trade zones. In that case urban land improvement which is theoretically true in legal regulation fails to be valid in practice. Because of market-centered approach selected as the tool, it remains under the shadow of problems concerning more permanent infrastructure and urban equipment zone standards that emerge parallel to the rise in urban density.

Cabinet Decree	Official Gazette Nr.	Official Gazette Date	Disaster Risk Zones
2012/3791	28434	7 October 2012	Esenler (Atışalan Airport and Atışalan Tuna Neighborhoods)
2012/3786	28457	4 November 2012	Beyoğlu (Örnektepe and Sütlüce Neighborhoods)
2012/3901	28457	4 November 2012	Beyoğlu (İstiklal Neighborhood)
2012/4125	28534	20 January 2013	Sarıyer (Fatih Sultan Mehmet Neighborhood -Armutlu)
2012/4163	28538	24 January 2013	Sarıyer (Çamlıtepe-Derbent Neighborhood)
2012/4160	28539	25 January 2013	Zeytinburnu (Sümer Neighborhood)
2012/4099	28540	26 January 2013	Gaziosmanpaşa (Merkez Neighborhood)
2013/4254	28551	06 February 2013	Sultangazi (Cumhuriyet Neighborhood)
2013/4258	28551	06 February 2013	Küçükçekmece (Kanarya Neighborhood)
2013/4257	28552	7 February 2013	Küçükçekmece (Fatih Neighborhood)

Table 3: Proclaimed Risk Zones in Istanbul

- Urban Transformation Zone

Pursuant to Article 73 of Municipality Law in proclaimed urban transformation zones such as Sumer Neighborhood (Zeytinburnu, Istanbul) the objective is to construct new living spaces fulfilling demands of modern way of life. However in the regulations sticking to Municipality Law municipality's approach on transformation zones is the determinant force.

- Regulations conducted within the scope of 3194 no Law

Master and tentative plans conducted within the scope of Construction Law and applications conducted via increasing structuring density in housing lands and introducing minimum parcel size are within this framework. Transformation phenomenon experienced in former villages that were once part of rural land but became an integrated part of urban settlement parallel to the expansion of cities is best illustrated in Mahmutbey Village (Bağcılar). Another critical zone on public agenda is Fikirtepe (Kadıköy) urban transformation project. Fikirtepe is situated in a location that was once in the periphery of city but became an integrated part of urban settlement and gained increasing land ratings. In addition there are various urban transformations depending on construction parceling plans. İstinye, Ferahevler (Sarıyer) can be given as an example to these zones but it should be analyzed in a more comprehensive study. Aside from housing transformation practices, in construction plans aimed towards industrial zones, resolutions for industrial transformation are also taken. An example for industrial zone transformation projects is Kartal Sub Center Urban Transformation Project designed by well known architect Zaha Hadid. This project also brought about with itself a good deal of public controversies.

- Zone-Specific Laws:

Urban transformation projects can also be implemented via laws released specific to transformation zone and scope. In addition to the earliest 2004-dated regulation released specific to city of Ankara, 2012-dated projects of Kazım Karabekir, Inkılap, Hekimbaşı Neigborhoods (Ümraniye, Istanbul) and Şerifali Farm (Ataşehir, Istanbul) are such laws. Aside from that as regards transformation of port areas regulations on Galata Port and Haydarpaşa Port are particularly noteworthy.

Table 4: In Turkey Major Actors in Urban Transformation Zones and Scope of Urban Transformation

As clearly evidenced in the tables above, after 2005 in particular, within the framework of neoliberal policies, a significant fragmentation has been experienced in urban planning system. One of the most significant indicators is that Cabinet which is the most authorized executive board of central government holds determinant role in the identification of urban transformation zones (Lovering&Turkmen, 2013). Another salient indicator is that compared to municipalities, central government agencies are more effective in urban transformation.

4 CONCLUSION

In the light of all above-given explanations and investigations it is feasible to outline key outputs and problems concerning urban transformation practices in Turkey as below;

- In Turkey there is an absence of definite legal framework outlining urban transformation. Instead, legal regulations are released merely specific to individual conditions. Provisions on regulations are identified pursuant to Cabinet Decree issued in Official Gazette that characterizes them as legal tools of central government. However, in many cases, there need to be location-specific regulations, which must developed by local governments to enable public support in urban areas with different problems.

- There are no clear-cut standards in the detection of Urban Transformation Zones. The scientific criteria followed in the identification of border are ambiguous. Political and economical choices play role in the emergence of this ambiguity.

- Other than the building regulations on earthquake prevention there are no definite implementation guidelines / implementation tools in the preparation of Urban transformation projects. There is no adequate and applicable planning tool concerning construction activities in built-up area.

- Urban transformation projects basically focus on the development of physical space and estimated rise in land value. Revenue sharing contracts of TOKI have become a component of project process in particular. However, as the main objects of urban renewal, risk reducing in earthquake zones and developing new urban public facilities to increase spatial standards were ignored in many cases to rise the value of urban land.

- In urban transformation process there is an approach that fails to fully integrate and even excludes current social structure in the transformation zone. Since urban transformation is treated outside the scope of issues such as taxing policies, it embodies features that rise social inequality.

- In the relocations of industrial areas etc. within urban transformation zones, the required socio-economic measures are missing. A process that particularly fails to get integrated with employment opportunities and created added value is experienced.

- The urban transformation process merely focuses on building generation and marketing; however in addition to buildings, employment opportunities, transportation, urban service areas should also be collectively treated.

- Central and local politics play dominant role in urban transformation projects. Central government authorities such as TOKI have gained further strength with legal regulations; thus local administrations constituted by elected representatives and bearing great potential in creating urban transformation models within a participatory process have fallen backwards.

1 ABSTRACT

Welche Chancen bieten mobile Augmented-Reality-Anwendungen (AR), die vor Ort virtuelle Objekte – hier eine Straßenraumgestaltung – in eine reale Umgebung proji¬zieren, um Partizipationsprozesse, beispielsweise bei der Planung eines Shared Space, zu verbessern? Im Vergleich zu herkömmlichen Perspektivskizzen fehlen bislang umfangreiche Erfahrungen zum Partizipationsprozess mit betroffenen Bürgerinnen und Bürgern. Eine empirische Untersuchung des Shared-Space-Projektes „Alleegasse" in Hartberg liefert erste Ergebnisse hierzu, welche im Zuge des Projekts „Zielgruppenspezifischer Einsatz von Augmented Reality und Web 2.0 in partizipativen Verkehrsplanungsprozessen" gewonnenen wurden. Gefördert wird dieses Projekt vom Bundesministerium für Verkehr, Innovation und Technologie (3. Programmlinie von „ways2go"). Der Mehrwert dieser empirischen Untersuchung besteht darin, dass konkrete Praxiserfahrungen im bürgernahen Umgang mit beiden Darstellungsmethoden gemacht werden. Die Einsatzmöglichkeiten von mobilen AR-Anwendungen und Perspektivskizzen werden im Zuge von Beteiligungs¬prozessen untersucht und Handlungs-empfehlungen abgeleitet.

2 EINLEITUNG

2.1 Ausgangslage

Planungsprozesse werden zunehmend komplexer: Einerseits äußern Betroffene, deren Unterschiedlichkeit sich in der Vielfalt der Gesellschaft widerspiegelt, ihre Anliegen, Wünsche und Meinungen zunehmend vehementer, und andererseits nimmt die Bedeutung der Privatwirtschaft mit einem unternehmerischen Kalkül bei vielen Investitionen zu. Relevante Akteure weisen somit sowohl unterschiedliche Ziele, Interessen, Erwartungen, Motive etc. als auch ein unterschiedlich profundes Planungswissen auf. Somit steigen die Kommunikationserfordernisse in Planungsprozessen, um Konflikte zu versachlichen, festgefahrene Debatten wieder in Gang zu setzen und einen Konsens zu erzielen. Mit innovativen Visualisierungstechnologien, wie z.B. mobiler Augmented Reality („erweiterte Realität", lat.: augeo: vergrößern) kann es gelingen, Beteiligungsverfahren zeitgemäß auszurichten, um Planungsqualität und Akzeptanz von Straßenraumgestaltungen durch bürgerschaftliche Partizipation zu steigern. Die Informationsvermittlung mit AR-Anwendungen kombiniert Methoden der Visualisierung und e-Partizipation. Die visuelle Aufbereitung und Präsentation von heterogenen Planungsdaten, die Erstellung von 3D-Stadtmodellen und die Möglichkeit, diese mit externen Informationssystemen zu verknüpfen, eröffnet eine Vielzahl an Möglichkeiten von neuer Wissensgenerierung (vgl. Zeile 2010).

Gerade zu Planungsbeginn, wo planungsrelevantes (Vor-)Wissen ge¬sammelt wird, sollte der Bürger bzw. die Bürgerin verstärkt bei der Ideenfindung, beim Sammeln von Informationen, Evaluierungen von Alter¬nativen einbezogen werden. Die steigenden Partizipationswünsche der Bürgerinnen und Bürger können somit erfüllt werden, was letztlich die Sicher¬heit, Legitimität und Transparenz der Planung erhöht (vgl. Märker 2005). Die Verbreitung von mobilen AR-Anwendungen als unterstützende Visualisierungsmethode in Bürgerbeteiligungprozessen wird durch die rasche Weiterentwicklung von neuen Informations- und Kommunikationstechnologien, wie z.B. Smartphones und Tablet-Computern, forciert. Mit AR wird die Synthese von Realität und Virtualität beschrieben, wobei die reale Umgebung mit virtuellen Elementen überlagert wird. Azuma 1997 nennt die drei Charakteristika von AR:

- Kombination von realer und virtueller Welt,
- Informationen stehen dreidimensional zueinander in Bezug,
- Darstellung der Informationen in Echtzeit.

Die besondere Stärke von mobilen AR-Anwendungen liegt neben der Möglichkeit, komplexe und umfangreiche Inhalte zielgruppengerecht und flexibel darzustellen, vor allem in der besserern Begreifbarkeit und Erlebbarkeit von Information vor Ort, beispielsweise im Rahmen von gemeinsamen Begehungen von Bürgerinnen und Bürgern, Planerinnen und Planern sowie Politikerinnen und Politikern.

AR-Visualisierungen sollen Barrieren der Informati¬onsübermittlung und -aufnahme vermindern. Gerade in der Straßenraumgestaltung, wo üblicherweise komplexe Inhalte einem sehr hetero¬genen Publikum in unterschiedlichen Planungsphasen und mit unterschiedlichen Zielsetzungen vermittelt werden müssen, eignet sich diese neue, flexible und ergänzende Form der Partizipation zur leichten Wissensvermittlung, wodurch die Legitimität und Transparenz in der Straßengestaltung gesteigert wird (vgl. Nash 2010, Zeile 2010, Hagen 2006).

2.2 Fragestellungen und Zielsetzungen

Welche Chancen bieten mobile Augmented-Reality-Anwendungen (AR), die vor Ort virtuelle Objekte – hier eine Straßenraumgestaltung – auf eine reale Umgebung proji¬zieren, um Partizipationsprozesse verbessern? Es fehlen im Vergleich zu herkömmlichen Perspektivskizzen bislang umfangreiche Erfahrungen zum Partizipationsprozess mit betroffenen Bürgerinnen und Bürgern. Eine empirische Untersuchung[1] im Rahmen des Shared-Space-Projektes „Alleegasse" in Hartberg liefert erste Ergebnisse. Verglichen werden die Darstellungsarten AR und Perspektivskizzen als unterstützende Werkzeuge im Partizipationsprozess, wobei sich folgende Fragen stellen:

- Welche Personen präferieren AR oder Perspektivskizzen?
- Wie werden AR und Perspektivskizzen im Zuge einer Informationsveranstaltung von den Bürgerinnen und Bürgern beurteilt?
- Wie gut eignen sich mobile AR-Visualisierungen und Perspektivskizzen zur Wissensvermittlung?
- Wie nehmen unterschiedliche Verkehrsteilnehmerinnen und Verkehrsteilnehmer (Fußgänger, Pkw-, ÖV-Nutzerinnen und ÖV-Nutzer) relevante Planungsinhalte (z. B. Parkplatzangebot, Fahrradweg, Abmessungen) wahr?

2.3 Anlass und Situation in Hartberg

Das Stadtzentrum bzw. der historische Altstadtbereich von Hartberg zeichnet sich durch die hohe Qualität seiner baulichen Struktur und den geschlossenen, dichten Charakter des öffentlichen Raums aus. Bemerkenswert ist die architektonisch in wesentlichen Teilen geschlossen erhaltene Gebäudekulisse, die durch hochwertige moderne Ergänzungen bereichert ist und sich durch die Veränderung des Lebens über mehrere Jahrhunderte das Potenzial erhalten hat, unterschiedliche Funktionen aufzunehmen und der Stadt eine unverwechselbare Identität zu geben. Dies drückt sich auch darin aus, dass Hartberg den Titel einer citta slow (=langsamen Stadt) führt.

Hartberg erscheint als vitales Zentrum, dessen intakte Ortsstruktur mit beachtlichem touristischem Wert bis heute wichtige Handelsfunktionen sowie ein reiches gastronomisches Angebot im Stadtkern vereinigt. Hier spielt die günstige Erreichbarkeit für Bürger und Gäste eine wichtige Rolle. Von der Hartberger Bevölkerungen teilweise als problematisch wahrgenommen wird die Rolle des motorisierten Verkehrs im Ortszentrum. Auch die Frage des ruhenden Verkehrs muss aufmerksam betrachtet werden, um – im Einklang mit den zeitgemäßen Wünschen der Bürgerschaft – den öffentlichen Raum im Stadtzentrum immer mehr als Raum für Begegnungen, den Aufenthalt und das alltägliche Leben vor Ort in Erscheinung treten zu lassen und so die Lebensqualität im Stadtzentrum von Hartberg weiter zu steigern.

Um den Raum neu beleben und inszenieren zu können, bedarf es einer neuen Planungskultur, die eine möglichst konsequente Form von Partizipation entwickelt. Damit Bürger vor Ort den Raum neu beleben können, müssen sie sich untereinander darüber verständigen, welches Leben sie vor Ort führen wollen. Erst auf der Basis eines derart entwickelten sozialen Leitbildes kann dann der räumliche Entwurf entstehen, und erst dann wird in den gestalteten Raum der Verkehr integriert. Bei der Übertragung des sozialen Leitbildes in

den räumlichen Entwurf ist es wichtig, über Bilder des neuen Raums eine präzise Verständigung zwischen Laien (Bürgern, als Experten vor Ort) und Planern (Architektinnen und Architekten, Stadt- und Verkehrsplaner, als Experten für die Raumwirkung) zu erzielen. Dabei können unterschiedliche Methoden verwendet werden, von der perspektivischen Handskizze, die eine präzise Andeutung des Entwurfs im Raum gibt, bis zur computerunterstützten Simulation, die sich der Technik der mobilen Augmented Reality bedient. Welche Methode verschafft dem Laien den bessern Zugang zum Planungsprozess bzw. zur Planung?

3   TESTFALL HARTBERG „ALLEEGASSE"

Das Projekt Alleegasse zielt auf die Ausbildung einer neuen Altstadtkante im Bereich der Alleegasse ab. Als Konzept zur Schaffung von Parkmöglichkeiten am Rande der Altstadt leistet es einen wichtigen Beitrag zur Altstadterneuerung und -erweiterung. Das Projekt integriert das Verkehrsgeschehen in die Struktur des Stadtraumes unter Berücksichtigung der sozialen Lebensverhältnisse. Neben Parkflächen soll ein attraktiver öffentlicher Raum entstehen, der so lebendig gestaltet ist, dass er von allen Bürgern gern genutzt wird und ein ausgewogenes Nutzungsverhältnis aller Verkehrsteilnehmer zulässt.

3.1 Vorgehensweise

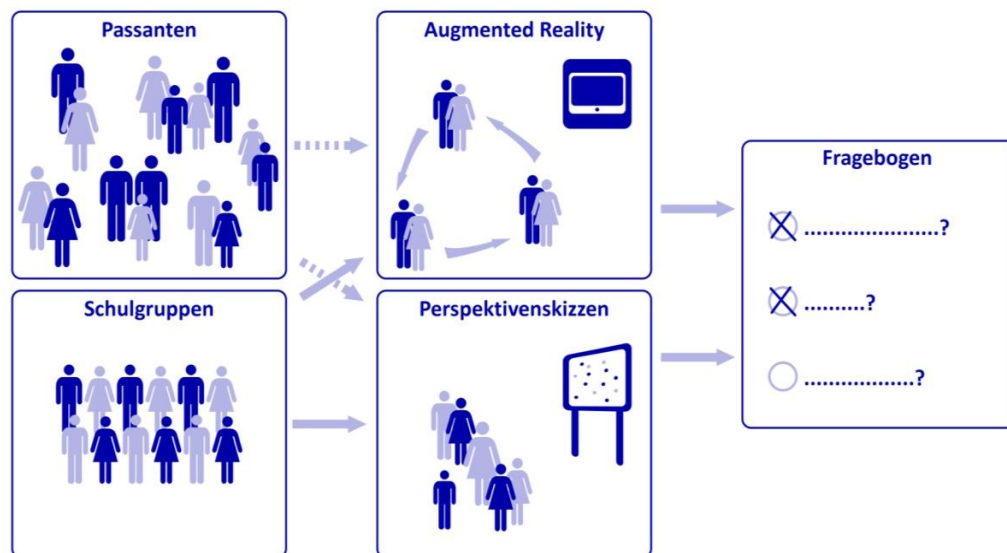
Am 9.11.2012 fand von 10:00 bis ca. 17:00 Uhr der Testfall Hartberg statt. Unmittelbar neben dem Projektgebiet wurden in der Fußgängerzone Passantinnen und Passanten angesprochen, ob Sie an einer Projekteinführung interessiert sind und eine Vorstellung des Entwurfs wünschen. Die Testpersonen konnten – mit Ausnahme einer Schulklasse – selbst wählen, ob Ihnen der Entwurf mittels AR oder anhand von konventionellen Perspektivskizzen erläutert werden soll. Die Perspektivskizzen sind auf einer Schaufensterscheibe befestigt, wobei die Teilnehmerinnen und Teilnehmer ausschließlich dort Projektinformationen erhielten. Demgegenüber liefen die Teilnehmerinnen und Teilnehmer der AR-Gruppe mit Tablet-Computer eine vorgegebene Route unter Verwendung der AR-Anwendung ab. Beide Testgruppen erhielten zum Projekt die gleichen Inhalte in gleichem Umfang präsentiert, nur das Visualisierungsmedium variierte. Abschließend füllten die Testpersonen einen Fragebogen aus, der neben soziodemographischen Merkmalen (Alter, Geschlecht, Bildungsstand etc.), das eigene Mobilitätsverhalten und insbesondere die Beurteilung der vorgestellten Darstellungsmethoden erfasst (siehe Abbildung 1).


Abbildung 1: Ablauf des Testfalls

Folgende Rahmenbedingungen sind bei der Auswertung sowie Interpretation der Ergebnisse zu berücksichtigen:

- Zufällig arbeiten und/oder wohnen alle Testpersonen in der Stadt Hartberg.

- Aufgrund des kühlen, nebligen, jedoch niederschlagsfreien Wetters traten keine starken Blendeffekte am Display der Tablet-Computer durch Sonneneinstrahlung auf. Die Begehungsroute war so festgelegt, dass Bauarbeiten nicht behindert wurden und dennoch ein guter Überblick des Bauvorhabens gewährleistet war.

- Durch die vordefinierte Auswahl des Info-Standortes (Fußgängerzone unmittelbar neben Projektgebiet) und der Begehungsroute kam es zu keinen Kommunikationseinschränkungen z.B. durch Verkehr, Baulärm etc.

- Aufgrund der Größe der Stadtgemeinde Hartberg wurde davon ausgegangen, dass die Beteiligten in der Regel das Projektgebiet kennen. Bisher hat es keine präzisen Informationen über den aktuellen Projektstand für die Bevölkerung gegeben. Mit Ausnahme von einigen Mitarbeitern der Stadtgemeinde wurde also allen Testpersonen etwas Neues und teilweise Überraschendes vermittelt. Diese „Ein-Weg-Kommunikation" zwischen Planern und Bürgern verfolgte somit hauptsächlich das Ziel der Projektvorstellung.

3.2 Spezifizierung der beiden Darstellungsmethoden

Tabelle 1 spezifiziert die beiden im Testfall zur Anwendung kommenden Darstellungs¬methoden und zeigt einen beispielhaften Auszug der Darstellungen. Die Erläuterung des Planungsvorhabens erfolgte für die AR-Gruppenteilnehmerinnen und Gruppenteilnehmer mit einer 3-D-Visualisierung am Tablet-PC und für die Gruppe mit herkömmlichen Planungsdarstellungen mittels eines Grundrisses und fünf Perspektivskizzen. Beim Vergleich beider Darstellungsmethoden ist festzustellen, dass die AR-Visualisierung einen geringeren Level of Detail (LOD) aufweist als die Perspektivskizzen.
	Mobile Augmented Reality	Perspektivskizzen
Darstellungs-grundlagen	3-D-Visualisierung[2]	1 Grundriss 5 Perspektivskizzen
Level of Detail (LOD)[3]	ca. 1-2	ca. 3
Ortsbezug	Begehung auf vorgegebener Route	fixer Standort
Dauer der Informierung	ca. 10 min	ca. 10 min
Projekt-beschreibung		
Darstellung (Auszug)		

Tabelle 1: Spezifizierung beider Darstellungsmethoden

---

[3] vgl. Zeile 2010

4 ERGEBNISSE

4.1 Stichprobenzusammensetzung

Tabelle 2 zeigt, die Zusammensetzung der Stichprobe hinsichtlich Geschlecht, Alter und Bildung. Es nahmen überwiegend jüngere Personen mit geringer bzw. noch nicht abgeschlossener Ausbildung am Testfall teil.

	Absolute (relative) Häufigkeiten
Geschlecht	
männlich	39 (54 %)
weiblich	33 (46 %)
Alter	
≤ 18 Jahre	45 (62 %)
19 – 30 Jahre	5 (7 %)
31 – 45 Jahre	7 (10 %)
46 – 65 Jahre	12 (17 %)
≥ 66 Jahre	3 (4 %)
Ausbildung	
VS od. HS	45 (62 %)
Lehrabschluss	10 (14 %)
Matura	11 (15 %)
FH	4 (6 %)
Uni	2 (3 %)
Gesamt	72 (100 %)

Tabelle 2: Stichprobenzusammensetzung (gerundete relative Häufigkeiten)

4.2 Teilnahmegründe

Abbildung 2 zeigt, dass mehr als die Hälfte der Probanden (59 %) Veränderungen in ihrem Umfeld interessant finden. Dieses starke Interesse stellt eine wichtige Voraussetzung für Partizipation dar und ist umso beeindruckender, da nur 19 % selbst vom Planungsvorhaben, z.B. als Anrainer, betroffen sind. Für den Einsatz von neuen innovativen Darstellungsmethoden zur Vermittlung der Planungsinhalte spricht, dass ca. ein Drittel der Probanden (32 %) den Einsatz neuer Technologien wie Augmented Reality interessant finden. 24 % der Teilnehmerinnen und Teilnehmer arbeiten in der Gegend, haben ein prinzipielles Interesse an Beteiligungen oder nehmen am Testfall im Zuge ihrer Ausbildungen (Schulklasse) teil.
Abbildung 2: Gründe für die Teilnahme an der Begehung (n=72)

4.3 Aktivierung der Teilnehmerinnen und Teilnehmer

Den teilnehmenden Passanten stand es mit Ausnahme einer Schulklasse mit 13 Schülerinnen und Schülern frei, auszuwählen mit welcher Darstellungsmethode sie über das Projekt informiert werden wollen. Im Falle der wahlfreien Teilnehmerinnen und Teilnehmer wird untersucht, ob sich die beiden Gruppen hinsichtlich soziodemographischer Merkmale (z.B. Geschlecht, Alter, Ausbildung etc.) unterscheiden.

Tabelle 3 fasst die Zusammensetzung der beiden Gruppen hinsichtlich Geschlecht, Alter und Ausbildung zusammen. Augmented Reality spricht vor allem männliche Personen bis 30 Jahre an. Hingegen können mit Perspektivskizzen vorwiegend Personen über 30 Jahren aktiviert werden.

Zwischen Bildung und Auswahl der Darstellungsmethode ist kein eindeutiger Zusammenhang erkennbar. Die geringen Gruppenunterschiede sind vermutlich auf die Alterszusammensetzung der Teilnehmerinnen und Teilnehmer zurückzuführen.

Planungsrelevantes Vorwissen bzw. die Auseinandersetzung mit 3-D-Visualisierungen der Teilnehmerinnen und Teilnehmer wird erhoben, indem befragt wurde wie häufig die Personen mit 3-D-Planung und 3-D-animierten Computerspielen (Autorennen, Stadtsimulationen etc.) zu tun haben. Es zeigt sich, dass Personen, die häufig mit 3-D-Planung zu tun haben, stärker in der Gruppe „Perspektivskizzen" vertreten sind. Andererseits präferieren Personen, die häufig 3-D-Computerspiele spielen, die Augmented-Reality-Visualisierung für die Erklärung des Planungsvorhabens. Erwähnenswert ist der relativ hohe Anteil (56 %) von häufigen 3-D-Computerspielerinnen in der Schulgruppe und deren geringes Vorwissen (15 %) bezüglich 3-D-Planung.

	wahlfreie Teilnehmerinnen und Teilnehmer		gebundene Teilnehmerinnen und Teilnehmer (Schulklasse)
Aktivierung nach…	Augmented-Reality	Perspektivskizze	Augmented-Reality und Perspektivskizze
Geschlecht männlich weiblich	59 % 41 %	50 % 50 %	54 % 46 %
Alter <= 30 Jahre > 30 Jahre	90 % 10 %	37 % 63 %	100 %
Ausbildung Volks-, Hauptschule od. Lehrabschluss Matura, FH od. Uni	76 % 24 %	67 % 33 %	100 %
Gesamt	n=29	n=30	n=13

Tabelle 3: Zusammensetzung der beiden Gruppen (gerundete Häufigkeiten)

4.4 Stellenwert von Partizipation

Es zeigt sich: Aktive Beteiligung in Form von Mitmachen, Diskutieren und Mitgestalten ist weniger wichtig im Vergleich zum passiven Informationsgewinn über die Gestaltung von Straßen und Plätzen. Nur 53 % im Vergleich zu 71 % messen der aktiven Beteiligung eine hohe bzw. sehr hohe Bedeutung zu (siehe Abbildung 3). Zurückzuführen ist dies wahrscheinlich darauf, dass eine aktive Beteiligung einen höheren persönlichen Aufwand und Einsatz erfordert. Insgesamt ist das Interesse der Teilnehmerinnen und Teilnehmer für Partizipation jedoch hoch.

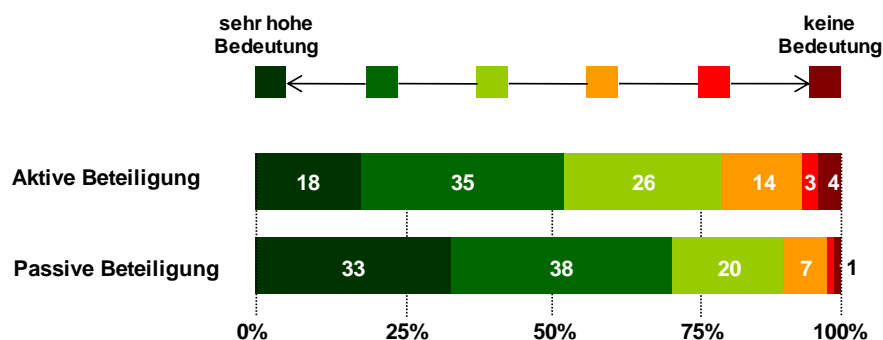
Beim Gruppenvergleich beider Darstellungsmethoden zeigt sich, dass für die Teilnehmerinnen und Teilnehmer der Gruppe „Perspektivskizzen" das Mitmachen, Diskutieren und Mitgestalten bedeutsamer (64 % sehr hohe und hohe Bedeutung) als die Teilnehmerinnen und Teilnehmer der Gruppe „Augmented Reality" (36 % sehr hohe und hohe Bedeutung) wahrnehmen.


Abbildung 3: Bedeutung von aktiver Beteiligung und passiver Innformation zur Gestaltung von Plätzen und Straßen (n=72)

4.5 Vergleich von AR und Perspektivskizzen

4.5.1 Mittelwertvergleich

Zur Beurteilung der beiden Darstellungsmethoden werden die Mittelwerte einzelner, vorab festgelegter Beurteilungskriterien verglichen. Die Beurteilungskriterien weisen ein Antwortspektrum von 1 bis 6 auf, wobei 1 eine sehr positive Beurteilung und 6 eine sehr negative Beurteilung bedeutet. Dementsprechend signalisieren niedrige Mittelwerte Defizite und hohe Mittelwerte Stärken der Planungsmethoden. Die Frage, ob signifikante Unterschiede zwischen den Planungsmethoden auftreten, wird statistisch mittels „t-Test" beantwortet.

Statistisch können keine signifikanten Mittelwerteunterschiede nachgewiesen werden, wobei die Gründe hierfür offen bleiben müssen. Methodisch betrachtet können eine zu geringe Stichprobengröße und/ oder eine zu grobe Skalierung der Antwortmöglichkeiten zu nichtsignifikanten Ergebnissen führen. Trotzdem sind aus den Ergebnissen qualitative Hinweise ableitbar, welche Kriterien besser bzw. schlechter beurteilt werden.

Abbildung 4 zeigt, dass sowohl Augmented Reality als auch Perspektivskizzen sich für partizipative Planungsprozesse eignen, was sich durch die durchwegs positive Beurteilung der Kriterien bestätigt. Die Mittelwerte einzelner Beurteilungskriterien variieren zwischen Augmented Reality und Perspektivskizzen kaum. Über alle Bewertungskriterien ergibt sich für Augmented Reality ein Gesamtmittelwert von 2,1 und für Perspektivskizzen von 2,0. Für eine niederschwellige Vermittlung von Planungsinhalten spricht, dass beide Darstellungsmethoden sehr verständlich sind und die Teilnehmerinnen und Teilnehmer kaum überfordern.

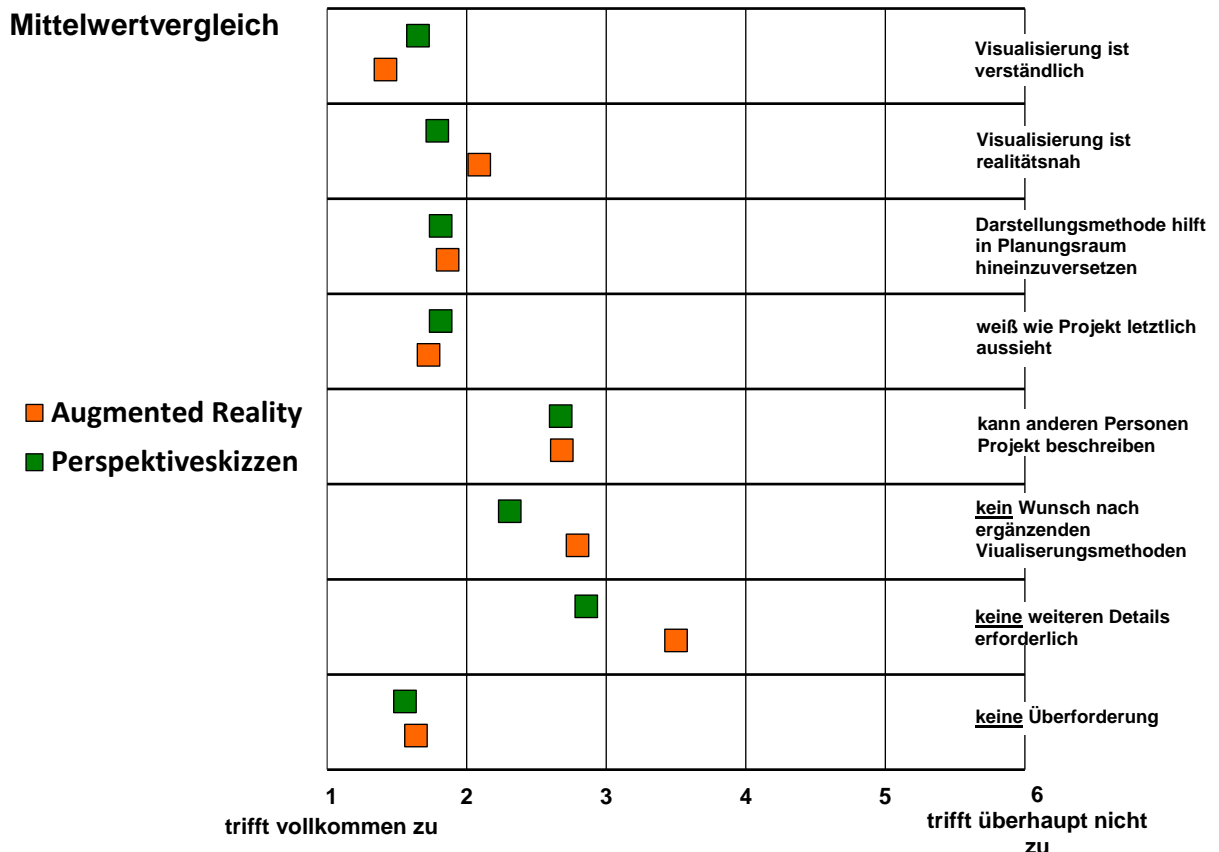
Teilnehmerinnen und Teilnehmer beider Darstellungsmethoden wünschen sich vor allem ergänzenden Visualisierungsmethoden (z. B. Karten, Skizzen oder Modelle) und weiteren Details bzw. Informationen zum Projekt. Dies trifft vor allem auf die Gruppe „Augmented Reality" zu. Zusätzlich fällt es den Teilnehmern – im Vergleich zu den weiteren Kriterien – schwerer, anderen Personen (z. B. Familienmitglieder, Freunde) das Projekt zu erklären. Die geringere Realitätsnähe von AR im Vergleich zu den Perspektivskizzen erklärt sich u.a. durch den geringeren Level of Detail dieser Darstellungsmethode.


Abbildung 4: Mittelwerte von Beurteilungskriterien differenziert nach AR und Perspektivenskizzen (n=85)

4.5.2   Vermittlung von Wissen

Des Weiteren wird untersucht, ob sich die beiden Darstellungsmethoden hinsichtlich der Vermittlung von Wissen eignen. Hierzu erfolgt eine subjektive und objektive Beurteilung.

Subjektive Beurteilung: Abbildung 5 zeigt, wie die Teilnehmerinnen und Teilnehmer subjektiv ihre Wissenserweiterung beurteilen. Der Großteil aller Teilnehmerinnen und Teilnehmer gab an, neues Wissen über das Planungsvorhaben gewonnen zu haben. 52 % der Teilnehmerinnen und Teilnehmer der Gruppe „AR" und 43 % in der Gruppe „Perspektivskizzen" erweiterten ihr Wissen stark.
Abbildung 5: Subjektive Beurteilung der Wissenserweiterung für AR (n = 36) und Perspektivskizzen (n = 36)

Objektive Beurteilung: Zusätzlich zur subjektiven Einschätzung der Teilnehmerinnen und Teilnehmer werden mit Hilfe eines „Wissenstests" beide Darstellungsmethoden objektiv hinsichtlich der Anzahl richtiger Antworten beurteilt. Mit projektspezifischen Fragen wurde festgestellt, inwiefern planungsrelevantes Wissen in Abhängigkeit der beiden Darstellungsmethoden vermittelt wird. Zuvor wurde jedoch noch ein Toleranzbereich für die einzelnen Fragen festgelegt, innerhalb dessen die Antworten   „richtig" sind. Informationen z. B. zur Parkplatzverfügbarkeit und der Anzahl der Bäume waren zum einen in beiden Darstellungsmethoden ersichtlich, zum anderen wurde bei der Projektbeschreibung verbal darauf hingewiesen. Tabelle 4 zeigt die richtigen Antworten der Teilnehmerinnen und Teilnehmer je Wissenfrage. Generell zeigt sich, dass mit zunehmender Konkretisierung und bei Fragestellungen mit keinen vorgegebenen Antwortmöglichkeiten der Anteil richtiger Antworten drastisch sinkt. Die Einschätzung der Längen- und Breiten des Bauvorhabens sowie der genauen Anzahl von geplanten Park¬plätzen und Bäumen fielen den Befragten schwer. Grundlegendere Planungsinhalte werden jedoch von mehr als vier Fünftel der Teilnehmerinnen und Teilnehmer richtig beurteilt. Im Unterschied zur subjektiven Beurteilung der Wissens-erweiterung (siehe Abbildung 5) schneiden Teilnehmerinnen und Teilnehmer in der Gruppe „Perspektivskizzen" etwas besser ab.

Fragestellung	Augmented Reality	Perspektivskizzen	Toleranzbereich
Beim Planungsvorhaben handelt es sich um… …eine Fußgängerzone *…ein für alle ein Verkehrsteilnehme gemeinsam genutzten Raum* …Durchfahrtsstraße	richtige Antwort: 84 % weiß nicht: 2 %	richtige Antwort: 91 % weiß nicht: 7 %	siehe kursive Antwortmöglichkeit
Ist Parkplatz für Autos vorgesehen? *...ja* …nein	richtige Antwort: 93 % weiß nicht: 2 %	richtige Antwort: 98 % weiß nicht: 0 %	siehe kursive Antwortmöglichkeit
wenn ja → Wieviele Parkplätze sind vorgesehen? (offene Frage)	richtige Antwort: 8 % weiß nicht: 0 %	richtige Antwort: 17 % weiß nicht: 0 %	40 bis 60 Parkplätze
Wie viele Bäume sind geplant? (offene Frage)	richtige Antwort: 7 % weiß nicht: 18 %	richtige Antwort: 7 % weiß nicht: 16 %	7 bis 9 Bäume
Wie lange groß schätzen Sie die Abmessungen (Länge und Breite) der Bebauungsfläche ein? (offene Frage)	richtige Antwort: 14 % weiß nicht: 5 %	richtige Antwort: 25 % weiß nicht: 38 %	Länge: 150 bis 250 m Briete: 15 bis 25 m

Tabelle 4: Wissenstest differenziert nach AR und Perspektivskizzen und Toleranzbereich richtiger Antworten (n=72)

Für den Testfall Hartberg konnte nicht nachgewiesen werden, dass unterschiedliche Verkehrsteilnehmer (z. B. Fußgänger, Radfahrer, ÖV-Fahrgäste, Auto-Fahrer) auf Planungsinhalte fokussieren, die ihr eigenes Mobilitätsverhalten betreffen. Beispielsweise kann nicht bestätigt werden, dass Autofahrerinnen und Autofahrer im Vergleich zu Radfahrerinnen und Radfahrern, Fußgängerinnen und ÖV-Fahrgästen die Parkplatzsituation realistischer einschätzen.

5 FAZIT UND AUSBLICK

Der Mehrwert dieser empirischen Untersuchung anhand des Testfalls Shared-Space Hartberg besteht darin, dass konkrete Praxiserfahrungen in Planungs- und Beteiligungs¬prozessen zu den Darstellungsmethoden mobile Augmented Reality und Perspektivskizzen gewonnen werden. Es zeigt sich, dass

- sich die Beteiligten für Veränderungen in ihrem Umfeld interessieren und insbesondere Diskutieren, Mitgestalten und Mitmachen eine hohe Bedeutung für sie hat,
- überwiegend jüngere und männliche Teilnehmer AR-Darstellungen favorisieren und damit als Zielgruppe besser angesprochen werden können,
- beide Darstellungsarten AR und Perspektivskizzen für Partizipationsprozesse grundsätzlich geeignet sind, wobei sich die Ergebnisse in der Wahrnehmung des Entwurfsprojekts Shared Space „Alleegasse" bei beiden Darstellungsarten nur geringfügig unterscheiden und
- für die Informationsvermittlung am Projektbeginn ein geringer Detailierungsgrad der Darstellungen (Level of Detail) ausreicht.

Unabhängig von der Darstellungsmethode zeigten sich überwiegend positive Reaktionen darauf, dass überhaupt informiert wird sowie über die erkennbare Qualität des Gestaltungsentwurfs. Am Rande der Projektvorstellung entstanden spontan Diskussionen unter Bürgern von Hartberg.

Zukünftig sollten mobile AR-Anwendungen im Bereich der Partizipation vor Ort dahingehend weiterentwickelt werden, dass

- diese einfach, nutzerfreundlich und somit selbständig zu bedienen,
- zusätzliche Informationen abrufbar und
- die zugrundeliegenden 3-D-Visualiserungen modifizierbar sind.

New Geographies of Self-Organisation

Cecilia Scoppetta

(Cecilia Scoppetta, PhD., Sapienza University of Rome)

1 ABSTRACT

Moving from both contradictions in EU policies between territorial cohesion and competitiveness, and the comparision between different conceptualisations of territory, and in the light of the ongoing territorial and political rescaling processes, notions such as "autonomy", "self-organisation", "active territoriality" and "territorial heritage" as a common good are introduced, in order to propose a general rethinking of the concept of "marginality", and to suggest a possible way in which non-paternalistic but really shared sustainability can effectively be achieved at the local level.

2 RESCALING AS A PROCESS OF RE-TERRITORIALISATION

2.1 Actually existing neo-liberalism, and the (assumption of) "local trap"

Although (officially) guided by a political process rather than by market forces, the EU construction is part of the broader phenomenon of globalisation. In this sense, EU territorial policies can be interpreted as a local compensation for global neo-liberalism (Allmendinger, 2000), i.e.: the redistributive tool used in advanced capitalist societies. An example is given by EU agricultural policies – a clear example of protectionist (non-liberalist) policy – that can be seen as a form of mitigation of unbalances due to neo-liberal strategies, whose principles, however, remain undiscussed, as shown by decisions on communications, airlines or energy (Marshall, 2012), which highlight a trend towards an increasing polarisation. As EU policies focus on cities as nodes and high-speed railways as inter-connections, such trend towards polarisation clearly mirrors the dominant representation given by the network metaphor (Castells, 1996) that has emerged from the deep structural changes occurred in Western economies/societies since the end of the 70s as „a powerful and pervasive image within which framing every interpretation of contemporary complexity/territory" (Scoppetta, 2009), so that networking, together with governance and rescaling (often interrelated), has been one the main path explored in various and converging research fields (Scoppetta, 2012).

A tendence in summarising the three interrelated issues – networking, governance and rescaling – by using the generic term "globalisation" exists, and this does not offer a fruitful insight into the ongoing re-articulation of politics at different spatial level as described by Brenner (1999; 2000) since it inevitably ends to fail focusing on territory (on its social/historical/political/economic complexity), without which the phenomenon of rescaling (Swyngedouw, 1997; Brenner, 2000; 2001; 2004; Brenner & Theodore, 2002b; Gualini, 2006) cannot be understood at all. In other words, Badie's „death of territory" (1995), due to de-territorialised flows of globalisation, seems to be nothing but a fashonable narrative which, in the reality, has no substantive truth (Elden, 2005). Even governance, if detached from territorial specificity and „path-dependence" (Brenner et al., 2010b), ends to be the Offe's (2008) „empty signifier", as it does not allow to understand the distinctive ways in which the „actually existing neo-liberalism" (Brenner & Theodore, 2002a) is translated at the local level, i.e.: the real local changes it produces in terms of public policies and discourses, emerging spatial configurations, social impacts and economic outcomes, democratic processes, and power coalitions (see: Brenner et al., 2010a; 2010b; Peck et al., 2009; Brenner & Theodore, 2002a; on certain aspects of the Italian specificity, see: Tocci, 2009; Cremaschi, 2007). Therefore, if detached from territory (i.e.: from the local), neo-liberalism itself – „a keyword for the "prevailing pattern of market-oriented, market-disciplinary regulatory restructuring",, (Peck et al., 2009 in: Brenner, 2010b) – remains nothing but a „rascal" concept (Brenner et al., 2010a; 2010b) leading to a temptation to assess localised territorial policy developments as conforming to international trends through the assumption of power asymmetries in terms of weakness of local governments (or local social actors) in the face of „external and more powerful actors" (Robinson, 2011), such as corporations, NGOs and other transnational organisations.

Such a homogenising idea of an uniform „smooth space [not territory] of Empire „ – which, differently from the „striated space of modernity", can be intended as an „ou-topia, or really a non place", where there is „no place of power" as „it is both everywhere and nowhere" (Hardt & Negri, 2000; 2004) – tends to hide the varieties of local forms, hybrids and peculiarities of neo-liberalism at different sites and scales as well as the particular and contextualised ways in which scale itself consists of the product of political struggles (i.e:

exactly the reason for which the issue of territorial rescaling needs a deeper critical inquiry to be necessarily focused on territorial differences). It is not a coincidence, however, that one of the hallmarks of neo-liberal politics themselves is the appeal to supposed external constraints of the global economy, which are generally represented as being objective, abstract, and quasi-natural forces that are autonomous from political decisions and independent from human control.

2.2 Territorial differences, and different approaches to territory

In this sense, what Brown and Purcell (2005) advocates as the „local trap", contrasting the idea of a more sustainable environment as an outcome of more localised policies, mirrors the Agnew's urging (1994) in trascending the „territorial trap" as a problematic and intellettually constraining assumption. As well-known, such viewpoint is strictly connected to the Anglo-Saxon political-economy and economic-geography tradition, according to which the territory is interpreted as the spatial expression of the modern national state. But, as scholars such as Cox (1991) and Agnew and Corbridge (1995; more recently, also: Brenner, 2004) observed, such equivalence of territory and state is highly questionable, and reasons to believe that the mainstream political and legal conception of territory as the passive spatial recipient of the state is the fruit of a modernist discourse can be easily found in the fact that the state can never fully reach total exclusion of others spatial functions and practices.

Furthermore, differences and specificities can be found in the construction and in the meaning itself of the European modern national states, especially in countries, such as Italy, with a long foreign domination in which power was legitimised from outside. In particular, in certain regions (such as Sicily or, more generally, the South of Italy), power was historically intended as costantly negotiated between the central (often perceived as an enemy) and the local level, the latter constituted by a small elite of landowners whose key-role was given by a feudal pyramidal model of power relation based on submission and violence that paved the way to the emerging of criminal organisation, such as the Sicilian mafia, as (violent) intermediator between a strong local power based on land ownership and an inevitably weak national state. In the Italian case, the latter, in fact, could not promote a land reform untill 1950 (Lupo, 1993). Thus, the Sicilian example challenges the mainstream view of territory as the hard fact which merely provides the visible support for invisible social ties as it clearly shows how territory rather is precisely the effect of a specific pattern of social and power relations. Territory, therefore, can be thought not simply as a bouded space, but as the political form of the type of conceptualisation of space that makes boundaries possible. Then, the Westphalian state – which is very different, for example, from the Italian unitary state emerging from struggles for Independence – is only a variant within an existing spatial-political configuration, rather than the ontological shape that is often presumed to be. In these sense, the demise of one specific historical territorial configuration does not means the end of territory as such, but rather an evolution.

Different approaches, sources and traditions in studies on territory exist, such as the French or Italian human geography. Raffestin (1980), for example, has developed his conception of territory as space mediated through power, in which "space" is a pre-existing reality that becomes "territory" through various political mechanisms, strategies, interventions and representations, and the state itself – as also Lefebvre (1980) notes – is only one actor among the others, since territory is social relation produced and transformed through continual struggle, a site of contested processes. As argued by Soja (1989), each concrete spatiality is an arena of struggle.

Sereni's studies on the Italian landscape (1961) constitute an example of a broad Braudelian approach coming from a Marxist tradition, which considers territory as the result of „the inter-relation between history and nature" becoming „also aestetically perceiveble" through landscape (Calzolari, 1999). Introducing nature in discourses on territory means underlining the ways in which nature itself is worked and collectively transformed into a social construct. The Italian (federalist) patriot and philosopher Carlo Cattaneo (1925) in 1840 describes the Val Padana (the wide Po Plain) as a „by-product" of human activities, practices, strategy and „projects" (Corboz, 1983) – an archive of inhabitants' daily life – rather than a gift from nature: „since human fate has been to live by working hard, each civilised region can be distinguished from wild ones by the fact it becomes an immense repository of human labour. It is for the reason that nine-tenths of our country is not derived from nature, but from our own hands: ours is an artificial homeland". According to such non-Anglo-Saxon approaches, the territory is something different from the static, fixed and ossified object of the Anglo Saxon literature. On the contrary, it implies a different idea of territory as a highly

complex product of a co-evolution of both people and places, the result of a long standing process of civilisation (Magnaghi, 2000, 2001; see also: Dematteis, 1985), a collective product/construct that can be rather expressed through the Deleuze's and Guattari's (1980) cyclic movements of de-territorialisation and re-territorialisation defining the relationship between the territoire and the milieu (or Umwelt) it territorialises.

Thus, if framed within an idea of „active territoriality" (Dematteis, 2001; Dematteis & Governa, 2005; Governa, 2007) territory – as space constantly crossed by de-territorialising and re-territorialising tendencies – may be intended as aimed at a (self)sustainable and durable local development, where identity consists of sharing a common project and landscape is „a manner of seeing" (Farinelli, 1992), the Humboldtian "haze" describing not „what exists", but making possible „what could be" (id.), what „could allow for the unexpected, that could promote change, even revolution" (id.).

3 EU TERRITORIAL POLICIES BETWEEN COHESION AND COMPETITIVENESS

3.1 Territorialising the European social model

A further result of introducing nature in discourses on territory consists of the possibility of better separate the latter from the rigid idea of modern national state since environmental features are congenitally uncomfortable with boundaries. Furthermore, environmental issues seem to be usefully able to both summarise the three main elements – networking, governance, and rescaling – of the (apparently) de-territorialising metaphor and re-connect them to the territory. A river, for example, undoubtedly constitutes a network that can be intended as both physical and immaterial, given the social, economic, cultural relationships between opposite banks. Controlling its floods or building dams or bridges implies a certain degree of governance, at least in the form of coordination. Considering a river basin instead of different national states implies a territorial rescaling. It is not a coincidence, therefore, that the environment is one of the major pillars of EU policies, as the entire EU project has always been defined, although indirectly (Scoppetta, 2012), by space and territory because its primary intent is to override boundaries, be they legal or physical impediments to the free movement of good, people, services, and capital.

Such territorial dimension of EU policies is expressed by the concept of "territorial cohesion" as well as by the development of a non-binding programme – the ESDP, European Spatial Development Perspective – that mirrors the EU understanding of spatial planning. The subtitle of the ESDP, „Towards Balanced and Sustainable Development of the Territory of Europe" (CSD, 1999), clearly illustrates the importance attached the pursuit of balance – i.e: alleviating spatial differentiation among EU territory – in order to ensure that „the three fundamental goals of European policy", identified as economic and social cohesion, conservation and management of natural resources and cultural heritage and more balanced competitiveness, „are achieved equally in all the Regions of the EU" (id.). In fact, „people should not be disadvantaged by wherever they happen to live or work in the Union" (CEC, 2004). Such approach is aimed to give „a territorial dimension of the European social model" (CEC, 2009), by expressing the latter into spatial form and incorporating concerns about spatial protection by calling for „a just distribution of opportunities in space" (Faludi, 2007; see also: Davoudi, 2005). In political terms, such European social model – based „beyond the diversity of the Member States' social systems, on a common core of values" (Council of the EU, 2000b) – can be referred to the Delors's European vision, expressed in both the 1994 White Paper on Social Policy (CEC, 1994) and the Lisbon Presidency conclusions (Council of the EU, 2000a) before being more fully articulated in an annex to the Presidency Conclusions in Nice in 2000 as „characterised in particular by systems that offer a high level of social protection, by the importance of social dialogue and by services of general interest covering activities vital for social cohesion" (Council of the EU, 2000a).

Therefore, the concept of territorial cohesion implies an integrated and holistic approach that clearly demonstrates key cultural concerns. On the one hand, a key contribution of the German Government to the ESDP (Faludi, 2001) consists of the concept of "quality of life" that can be translated into " equivalent living conditions" to be achieved through spatial planning as a regional act. On the other hand, the focus on access to services of general interest reflects the French "aménagement du territoire", i.e.: the interest in pursuing redistributive policies within a regional context. Anyway, „Europeans", Faludi argues (2006), „are rooted in the soil […]. In their desire to live where they have for generations they deserve public support". Furthermore, territorial cohesion should also include a visionary element, since spatial visions „must

conceive of town and cities and regions, indeed of the territory of the EU as a whole, as more than places of production". Territories, in fact, „need to be conceptualised as cohesive […]. People should want to attach themselves to territories. Indeed, where the process is conducted in transparent fashion, the very act of visioning territories and their future can contribute to this feeling of attachement" (Faludi, 2007).

Thus, although undoubtedly European planning traditions are diverse (CEC, 1997; Nadin & Stead, 2008) and proponents have offered no explanations of how the social model itself is affected by concrete practices in spatial planning (Gualini, 2008), territorial cohesion permeates EU spatial policies at least as a normative claim that the European social model should encompass a core of shared values, which, when spatialised, would promote spatial justice. An example is given by the European Landscape Convention – whose surprising emphasised spreading within the Italian academic context appears as particularly suspicious, since landscape is a particularly negletted issues within the Italian territorial context… – focusing on a strong place-based approach in order to enlarge participation and governance, to re-built social relationships, sense of community and local identity, and to strenghten legitimacy, democratisation, and social justice.

3.2 Cohesion vs. competitiveness?

But, in the light of the current dominant network metaphor, the major aim of the Lisbon Agenda – developed in 2005 after the 2000 Lisbon Strategy was perceived to have run out of steam – consists of competitiveness and growth of the economic and productive system through the enforcement of strategic and innovative sectors by focusing on the so-called "territorial excellences". This means that cohesion funds are currently the financial incentives of the "jobs and growth" Lisbon Agenda that focuses on inter-urban competitiveness as a primary virtue in the context of neo-liberal development, and on a growth-first perspective based on the naturalisation of market logics that implies a "locking-in" in terms of an austere public sector, and funding provision on the basis of economic potential rather than social needs (Peck & Tickell, 2002).

This re-packaging takes place within the broader context of sustainable development (CEC, 2005) characterising the EU Sustainble Development Strategy (CEC, 2001; Council of the EU, 2006) as a long-term complement to Lisbon's medium-term goals. This means that cohesion and sustainability are indicated as tools for the achievement of growth-oriented objectives, so that the decrease of regional differences, that constitutes the main indicators of imbalances, become crucial in the achievement of cohesion. The latter, in turn, is seen as a tool for competitiveness. Therefore, the idea of "balanced development" – proposed in documents such as the ESPD or the Amsterdam Treaty – still remains, but such vision is interpreted as functional for global competitiveness: in other words, without levellig richness and accessibility (to infrastructures, to knowledge) it is impossible to compete on the global market. Despite the focus on economic development and growth, this broader framework enables territorial cohesion to maintain ist grasp on balance, co-ordination and sustainability, even while economic development seems to be in explicit ascendancy.

Both the spatial planning and the cohesion strand continue to be reflected in policy documents, and the contested definition reflects the political and cultural investments of different actors in the debate. The 2009 Sixth Report on Economic and Social Cohesion, for example, summarised the Commission's interpretation as „the goal of territorial cohesion is to encourage the harmonious and sustainable development of all territories by building on their territorial characteristics and resources" (CEC, 2009). This satisfies both strands: it refers to „harmonious and sustainable development", which can be understood to entail balance and coordination – and, consequently, the ESDP – while the reference to „building on territorial characteristics and resources" refers to the liberal economic paradigm's use of territorial endogenous advantages to promote economic development (CEC, 2008). By relying on the idea of territory to try to resolve the dissonance between competitiveness and redistribution, the Commission echoes OECD policy by emphasising the role of place-based policy approaches in capitalising on territorial assetts and locational advantages such as knowledge, skills, specialisation, and proximity between economic agents.

Thus, a contraddiction is to be highlighted here, and the crucial question concerns the ways in which such divergence between competitiveness and cohesion is tackled. Undoubtedly, a strategy focusing on territorial excellences risks to weaken and further marginalise those territories that are already considered as spatially or economically peripheral. Territorial development, indeed, is not a neutral process, as it involves interests and strategies that can also be conflicting, and the implementation of development policies can paradoxically generate further and different imbalances.

4 RETHINKING PERIPHERAL TERRITORIES

4.1 Marginality

"Marginality" has been a key-term for the conceptualisation of the Italian territory. Both the partition between mountains and non-mountains regions, given by the physical geography (see: Becchi et al., 1989), and the North/South dichotomy – given by historical reasons and originated by a vast literature on the so-called "questione meridionale" ("Southern question"), which comprised seminal works by Giustino Fortunato, Saverio Nitti, and Antonio Gramsci – have constituted the typical representation of the Italian territory (see: Lanzani, 1996) and the main approach to regional development in the decades from the formation of the national state (1861) until the Fifties. Backwardness and regional unbalances became dominant in public and scientific discourse and, especially in the case of the Southern Italy, the latter was fully mirrored in (mainly top-down) public policies that, in turn, paradoxically ended reproducing precisely those problems they were aimed to contrast, as once the Cassa per il Mezzogiorno – the first development agency introduced in Italy following the political and social debate on the agrarian reform – had been established, the territorial disparity came to be seen as a matter of the fact. In fact, its ambitious top-down regional development plan was explicitly devoted to the South of Italy as an entire homogeneous "backward region". As marginality was intended in terms of lack of both capital stock and spatial accessibility, the Cassa per il Mezzogiorno systematically addressed the question of both infrastructure provision and re-distribution of resources without any reference to the economic effects of allocation choice and to possible endogenous entrepreneurial actors and activities. Furthermore, as within the rigid North/South dichotomy the development model was given by big firms (e.g.: FIAT) of the industrial North, a number of "poles of industrialisation" were established in order to stop the massive internal and external emigration.

In a certain sense, the quantitative and economic criteria used for the allocation of EU structural funds – population, density, age structure, GDP, employment, education, spatial accessibility, and so on – mirror the rigid and static concept of marginality that was at the basis of the Italian development policies of the Fifties. What results is a too simplified image, which is inadaquate to effectively represent the real articulation of contemporary European local contexts, as it cannot capture the profound transformations occurred in the relationships and inter-dependences between urban and rural areas as well as the new territorial hierarchies given by the broader rescaling due to the phenomenon of globalisation. Thus, a more complex and dynamic approach to peripheral territories and to development issues seems to be needed.

In this sense, interesting suggestions are given by the Italian case. In the late Seventies the innovative and more articulated territorial representation of the so-called "Third Italy" (Bagnasco, 1977), comprising the regions of Central and North-Eastern Italy and mirroring an emerging economic landscape, was introduced by social scientists. This stimulated a profound theoretical change that led to the subsequent shift to the category of "local systems" as the manifestation of original local trajectories of industrialisation, and, therefore, as units for analysing territorial performance. This, in turn, led to formulate the concept of "industrial district" (Becattini, 1979; 1987; 1989; 1990; 1991; 2000) as spatially bounded relational density arising at the local level both directly (through deliberate exchange of matter and information) and indirectly (through external economies, spillovers and spin-offs) thanks to local cultural features and learning mechanisms given by a cognitive proximity.

Such advancements clearly showed the inadequacy of the previous representations of marginality, based on terms such as "depressed areas", "rural areas", "inner areas", "forgotten areas", "inactivity", "inability to adapt", "resistance against changing" (see: Becchi et al., 1989). These terms, in the reality, describe the features of a large part of the Italian territory, as it is largely maden by mountain areas and by small municipalities with a population of 5.000 or less (70,4 % of the total Italian municipalities) that are currently experiencing a progressive out-migration leading the total resident population to decrease (from 10.590.728 in 2001 to 10.349.962 in 2011 according to ANCI, 2011). And these are precisely the features that, in the long-run, have allowed the permanence of what Magnaghi (2000) calls „territorial heritage", and that may now not only find an economic use (Calafati, 2004; 2006) but also constitute the basis for conceptualising an interesting alternative "slower" development pattern.

4.2 Autonomy, and slowness

Despite marginal local systems – even though their contribution to the GDP may be negligible – perform a fundamental role in the social and ecological stabilisation of the territory, their distinctive features are little studied, and the need of a broad rethinking of marginality still remains neglected and undervaluated. The proposed reformulation of the issue – through the identification of new and more effective interpretative categories – would allow the abandonment of a restrictive concept of "unbalance", unidirectionally centred on the idea of economic growth, and would favour the construction of more complex, dynamic and pluralistic geographies of development, within which marginal territories may actively participate (and not merely survive) by usefully suggesting a possible alternative perspective.

The proposed rethinking of the role of marginality within development processes is to be framed within the recent trend towards the so-called „decroissance" (Grinevald, 1979; Latouche, 2005, 2008), also due to the ongoing global economic crisis, which includes the search for innovative parameters for measuring development such as the Hicksian income (maximum sustainable consumption), MEW (Measure of Economic Welfare), HDI (Human Development Index), GNH (Gross National Happiness) (see: Brooks, 2008), GPI (Genuine Progress Indicator) (Daly & Cobb, 1994), ISEW (Index of Sustainable Economic Welfare) (ibid.). Beyond the „natural capital", the latter considers inequal distribution of income, unpaid houseworks, costs for education, health, commuting, car accidents, pollution, loss of rural areas or wetlands, long-term environmental damages, distruction of non-renewable resources, and so on. Further transversal indicators refer to the relationships between human settlements and environment (e.g.: the carbon or entropy estimation), or to a shift of lifestyles, such as in the case of the justice estimation (in which the way of consuming is referred to justice for future generations). Participation, genre, and inter-generational estimations are to be added. All these parameters highlight the inadequacy of traditional categories, but they still remain linked to an economic approach to well-being, while further indicators focusing on territory seem to be more effective: from carrying capacity to ecological footprint; from „environmental space" (or „ecospace" or „environmental utilisation space") to concepts such as „resilience", „emergy", „exergy" (see: Pareglio, 2010). Finally, we also have an indicator for measuring „happiness per hectare" (Kucharek, 2006): in fact, as several recent innovative studies underline (e.g.: Sampson, 2003; Haybron, 2011; Layard, 1980; 2006, etc.), an innovative parameter for measuring the quality of life can be found in happiness, whereas the latter is referred to the social and environmental context (Helliwell & Putnam, 2004) rather than to individuals, and differs from a product-based well-being (it is rather closer to an access-based concept).

Anyway, such approaches move from the idea that sustainability can be really achievable if referred to the local dimension, in which a greater accessibility to informations implies an effective control on both production and exclusion processes. In fact, the autonomy of the economic system from the social and political sphere clearly leads to the question of the concrete possibilities of democratic control, as the latter tends to decrease with the growth of the financial, technical and bureaucratic apparatus (and with a larger and low-cost supply of goods).

Thus, the transition from the concept of inter-dependence, which is at the basis of the network metaphor, to the idea of autonomy is connected to the need of enlarging participation in decision-making (especially as regards the management of resources), and of awarenessly rescaling down. In fact, the myth that the market would define, through self-regulating dynamics, the optimal scale for developing economic and productive processes is quite misleading, as it only happens in the short term in response to price changes, while in the long-run it rather tends to support its self-expansion, with the predominance of trends towards aggregation. On the contrary, shifting the centre of gravity of economic processes closer to the level of political participation could mean an increased responsibility on how and what can be produced in a certain territory, e.g.: with the possible establishment of environmentally and socially sustainable agricultural or self-managed energy systems (Scoppetta, 2009).

Interesting suggestions come from the interpretation of certain Italian marginal territories as „slow territories" (Lancerini, 2005; Lanzani, 2007), whereas slowness is not synonimous with backwardness, but indicates a different and slower trajectory towards sustainable development, which requires time in order to allow collective learning processes. In this sense, autonomy and slowness mean assigning centrality to marginality, as the latter can be intended as a sort of "litmus test" for sustainable development policies, and it can effectively play a specific role in the construction/reformulation of European territorial scenarios.

4.3 Measuring the re-territorialising potential of slow territories

An interesting research field is highlighted here, and it concerns the search for new analytical and interpretative categories that could offer useful insights into such innovative concept of marginality. Moving from a definition of "territory" as the result of long-standing evolutionary processes between human settlements as local milieaus and the environment, such more complex and dynamic parameters to be defined have to refer to the concept of social capital, even if it is not an unambiguous notion, as it include a „dark side" (Cremaschi, 2007), i.e.: when it is not intended as pure public good, whose individual consumption does not reduce the use by the others, but rather, being the result of utilitarian strategies, is „capitalised for rent seeking by particularistic social networks „ (id.), so that complexity (of social relations, but also institutional) ends becoming a factor of „disorder" (Donolo, 2001).

In this sense, Putnam (1993) distinguishes between „horizontal" and „vertical social capital": the latter concerning „inequal agents in asymmetric relations of hierarchy and dependence", while the former is able to generate trust and cooperation, strenghthening reciprocity rules, and facilitating the flow of informations about the credibility of the involved actors. A further distinction concerns „bridging" and „bonding" social capital (Putnam, 2000): the latter characterised by a tendency to reinforce exclusive identities and homogeneous groups and based on „strong ties" (Granowetter, 1983) – in the case of marginality and marginalisation, a tactical response to hostile conditions, as „strong networks seem to be linked to both economic insecurity and lack of social services" (id.) – by both contributing to the fragmentation of communities, and perpetuating the condition of marginality itself. Therefore, one could talk about social capital as „social support" and not as „social leverage" (De Souza Briggs, 1998), being the former intended as an aid in addressing the needs of everyday life (which are particularly acute under economic deprivation), while the latter is aimed at supporting subjects in the broadest sense, by facilitating access and changes of opportunity structures. Finally, the distinction between social capital as „embeddedness" or „autonomy" (Woolcock, 1998) stresses the importance of building links with the outside, and seems to be particularly interesting as it does not refer to an idea of "assimilation" of marginal territories to hegemonic visions and values, but rather to the construction of a critical relationship between "slow" (with their specificities) and "speed" territories, i.e.: to the construction of an innovative more pluralistic way of thinking the concept of "development".

Therefore, the search for innovative categories for measuring the re-territorialising potential of the proposed slow territories can only move from a concept of social capital which, unlike other forms of capital, is understood as a constantly used public good, i.e.: whose possible decay does not depend on its excessive use, but rather on its non-use, as its iteration, and the progressive expansion of social relations, constitute the key-factor for its accumulation. Such iteration is ensured and facilitated by trust, as the latter „lubrificates cooperation" (Putnam, 1993).

The capacity of a territory in terms of planning, cooperation, and networking can then be identified as a parameter in order to measure its re-territorialising potential as well as the ability in self-constructing from below alternative ideas of development. A further parameter may be the way in which power is given to weak actors, and how this is used to support a shared place-based spatial strategy. In this sense, a relevant reference is the transposition of the concept of „capacitation", introduced by Sen (1999), from the individual to the collective dimension of territories, whereas theit are conceived as being able to acquire an autonomous capacity to express different development models, in which not only economic but also social, environmental, historical and institutional factors are included. Anyway, autonomy seems to be a key-category, and it does not simply means decentralised power, but rather self-regulation of territories, i.e.: the ability in developing individual and collective preferences towards sustainability through non-paternalistic strategies (i.e.: making sustainable development concretely desirable).

Activism of marginal territories – i.e.: the greater or lesser recurrence with which they construct (or participate to) spatial strategies – constitutes a further element, and such criterion can be also used in negative, in order to evaluate the level of weakness in planning. But it is worth noting that planning cannot be a criterion in itself: in fact, it cannot be seen as the only parameter of self-sustainable local development, but rather as a necessary condition. What is more important is the way in which marginal territories are able to (re)define their own identity around a project through the construction of a shared territorial imaginary that allows the persistence of ties and the establishment of interiorised values and methods beyond the project itself. In this sense, the evaluation of results and outcomes of such projects is to be intended in

immaterial terms of process, rather than of material achievements (an infrastructure, a building, etc.). In this sense, slowness alludes to an evolutionary process, where a longer time – although short-term indirect and unexpected outcomes, however, are not to be excluded – is required by the cognitive dimension of the collective cultural construction aimed at the co-evolution of people and places. Thus, the spatial strategy may be understand as a construct rather than as a product, and it consists of the re-production of common goods, which constitute the basis and the most qualitative element of development, by giving a stronger sense to the concept of "social cohesion", and allowing a non-contradictory approach to the notion of "development".

4.4 Networking slowness

On the background of territorial and political rescaling occurring in the European space, a relevant issues for slow territories concerns their ability in constructing larger networks. In this sense, what becomes crucial is the inter-municipal dimension, which may not correspond to any existing administrative entity, as it can be conceived as a result of sharing actions over time. Such spontaneous forms of inter-municipality define an intermediate level at which projects, strategies and agreements towards local sustainable development can be effectively and fruitfully established and implemented.

In this sense, an example is given by the French experiences of the so-called "Pays" (Santangelo, 2003): in fact, the Law LOADDT (1999) enable the inhabitants of a cluster of municipalities to form a legally recognised "Pays", based on mutual consent and defined in terms of territorial identity. For historical reasons, Italy appears as one of the countries which has more largely exploited the potential of inter-municipal cooperation, and public spending "cuts", and proposals for reorganising local government (both due to the current economic crisis) are currently highlighting the emerging phenomenon of the "Unioni di Comuni" ("Union of Municipalities") due to legislative changes initiated from the Law n.142/1990. Such territorial clusters have become a relevant reality (313 Unions), which includes 1.500 municipalities and a total population of about 6 million people, i.e.: 9,5 % of national population, which corresponds to that of all the metropolitan cities with the exception of Rome (ANCI, 2011). A wide range of clustering and cooperative instruments is used, and their variety is likely to have few equals in the European context. (Hulst & Van Montfort 2007). Furthermore, it is worth noting that the phenomenon cannot simply be pushed in the conceptual framework concerning very small municipalities, which are forced to join for purely financial reasons. Although there is a strong trend towards clustering by "dust municipalities", the "small only" is not the unique pattern, as we also have a "satellite" (a number of little municipalities around one or two larger centres), a "big only" (two or three larger centres), and a "couple" model (and, obviously, mixed forms). And, even if such new aggregations often move from the need of answering the growing demand for public services, once cooperation has been established in certain policy areas, there may be a positive spill-over effect towards further sectors.

Therefore, the proposed innovative categories can be fruitfully used for measuring the potentials of such territorial re-organisation that emerge from below, by drawing alternative geographies of development.

(Univ.-Prof. Dr. rer. nat. Sascha Henninger, University of Kaiserslautern, Dept. of Physical Geography, Pfaffenbergstr. 95, 67663 Kaiserslautern, sascha.henninger@ru.uni-kl.de)

1 ABSTRACT

The atmosphere is a crucial ecological factor which could strongly influence the human being, the community, and nature by local weather conditions. One part of this ecosystem is the city in which anthropogenic factors (traffic, industry, housing complexes) and natural factors (water, soil, air) interact in a tight space. The interconnection of the various factors creates a highly complex urban ecosystem. One of the most important reasons for the intensive research in the field of urban ecosystem is the realization that physical and meteorological processes are at work within the climate of these agglomerations and the local climate, which influences the human being. However, humans are also unconsciously influencing this climate. Urban design and other artificial changes in the terrain also create anthropogenic climate modifications. This can have positive as well as negative consequences. Since the climatology is ever more developing from a descriptive science toa global, interdisciplinary system science which has an increasing social position, because of energetic processes of transformation that can be displayed more and more accurately. Especially, the anthropogenic influenced climate and its ecological systems and processes are in the focus of numerous disciplines. Some of these disciplines are geography, urban design, architecture, environmental design, medicine, and agriculture. This paper wants to show how micro scale climate measuring could be performed in habitats nowadays in a new way. The most important climatological measurement units will be introduced. Furthermore, it will be described how currently manual measurements are performed by the use of individual devices. Subsequently, it will be explained why these classical measurement units are not adequate to describe an urban ecosystem. The question should be answered, which indicators must be gathered, in order to optimize the analysis of the influence of the urban climate on the human well-being and how adequate data and information infrastructure could look like? It will be discussed which additional data and methods of climate monitoring are necessary to describe the urban ecosystem more accurately. Finally, new concepts will be introduced how the urban ecosystem can be explored by a new innovative combination of psychological, physical, and climate data. In the process, bio-vital functions, crowd sourcing as well as emotional data will be gathered additionally to climatological data.

2 INTRODUCTION

The atmosphere extents up to a height of 1000 km. Especially, in its lower sections it is an factor for the environment. The climate and the weather are important for the nature and the society. The climate describes the condition of the atmosphere at a certain location over a long period of time.The weather, on the opposite, describes the perceivable short term conditions of the atmosphere at a certain location [cf. KUTTLER, 2006:1]. Meteorology has its roots in the Greek language and means the science of the celestrial phenomenons, and is therefore a part of geoscience. It deals with the physical and chemical phenomenons and processes of the atmosphere as well as reactions with solar radiation and the surface of the earth. In a time-space relation, its interest includes everything between microturbolences and climatology, for instance the local weather. The research field of climatology is, because of its interdisciplinarity, than the one of the meteorology [cf. Brockhaus, 2009:218FF]. Meteorology can be seperated into the dynamic or theoretical meteorology, synoptic metrology, and the experimental metrology (physics of the atmosphere) [cf. Brockhaus, 2009:218FF]. One basis of the observation of the weather is a constant recording of it. By using current data and taking the condition of the atmosphere into account, a weather forecast can be created. Amongst others, the measureable data consists of the air temperature, air pressure, and precipitation. Furthermore, parameters like wind direction, cloudiness, layer of snow, hours of sunshine, special weather phenomenons (e.g. hail, thunderstorms, fog), the behavior of animals, and the phases of the vegetation is being analyzed [cf. Brockhaus, 2009:40FF]. Climatology is the science of the climate, the change of climate and its consequences. Climatology is a part of meteorology as well as of geography. It has connections to biology, chemistry, physics, glaciology and geology. Climatology can contentwise be subdivided into climatological aquisation of information, climate diagnostics, climate modelling, and the research of climate

effects. Because of the complex and manifold processes of the climate system, a special, physical climatology arises, which primarily uses physical climate modelling. It is regarded as impossible to understand climatological processes completely in the foreseebale future. Additionally, applied climatology is important for the engery industry (usage of wind, water, and solar energy), agriculture (bioclimatology), the public health sector (humanbiometeorology), and water economy (hydrometeorology) [cf. Brockhaus, 2009:183].

As a result, it can be concluded that climate effects are cumulative and have consequences on human beings. These consequences occur spatially very in different ways. Resarch to increase our understanding of the connection between the global climate change and health is strongly needed [cf. Kappas, 2009:223].

Nowadays, the applied urban climatology has gained importance beyond the controversy of the global climate change. Most scenarios for developments of the climate in the next decades point towards an increasing global temperature. Extrem weather conditions will increase, especially in urban areas will be an intensification because of local climatological and air quality factors. The applied urban climatology deals with climate and air quality modifications. There is not only observating and analysing the climate and air quality, but also the analysis of the consequences for the biotic and abiotic factors of the urban ecosystem. The applied urban climatology can be considered as a link between climatology and urban design. Knowledge, gained out of urban climatological analysis, is transcribed by analytical climate maps and planning reference maps respectively. By now, humanbiometeorology is a constant part of urban climate. Human biometeorology analyzes, amongst others, the effect of the urban climate on the well-being of humans [cf. HENNINGER, 2011:89F].

Various micro, meso, and macro factors are shaping the urban climate. For instance, latitude, landscape, height above sea level, the distance to major oceans or sees, the size of the city, the population, the type of rural and urban land use, the topographical, rural and urban structures, the rate of sealed areas, source of emission and the perceivable and latent rejected heat of technical processes [cf. KUTTLER, 2006:372F].

3 MEASUREMENT PROCESSES

3.1 General Measurement Processes

Different measurement processes are suited differently well for various situations. Therefore, it is regarded as reasonable to formulate definitions and declarations of the measured area. Afterwards, the measurement precision, the scale, and the measurement duration have to be determined. Depending on the stage of development and the standartization of the measurement methodology, these preconditions can vary. It has to be differenciated between stationary measurement, remote sensing methods, additional methods and mobile measurement.

3.2 Stationary Measurements

The stationary measurement is often executed in measurement networks. Established networks in Germany are the synoptic-climatologic measurement and observation network, and the extraofficial climate and precipitation measurement network of the German Weather Service (DWD). However, these measurement networks were not meant for the data aquiring in an urban climatological context. These networks are for the weather forecast. The major problem is that the spatial density of the individual measurement stations is too wide for an analysis of the urban climate. Nevertheless, measurement stations near an urban area can be used as reference. Stationary measurement processes are well suited for observations over a long period of time [cf. OTTE, 1999:289FF]. Professional measurements are conducted in a Stevenson screen, what means that a box is attached at the top of a two meter high frame. The relevant measuring instruments are inside the box. The box protects the sensible instruments from damage as well as outside influences which could distort the measurements. Blinds secure an undisturbed air circulation. Another type of measurement stations are the various small and semi professional private stations. The basis for a private measurement station is a thermometer, a hygrometer, and a barometer. Additionally, one can add a rain gauge and an anemometer. All these instruments can be found seperatly or as a single measurement instrument. Private stations can be distortet because of inaccurate measurement technique and frequently wrong locations.

3.3 Remote Sensing Methods

Remote sensing methods like, for instance, RADAR, LIDAR, and SODAR are mostly ground based methods, but an exploration via airplane and satellite is also possible. Thereby, the atmosphere is explored by radio, light and sonic waves. The development of drones ("anmanned air vehicle" (UAV) or "unmanned air system" (UAS)) has increased in the past few years. Nowadays, drones are mainly used by the military. However, a civil or private usage is possible. Drones would offer new possibilities for the climate observation and landscape monitoring. Due to low costs for aquisation and maintance, a multitude of data can be gathered with these unmanned helpers. Unlike ballons and airplanes, drones would allow to monitor the climate and the weather in street canyons and close above buildings. This could be done at a fixed position as well as over a distinct transect. A more precise horizontal observation of the urban boundary layer would be possible. Also a theoretical determination of the urban canopy layer and urban turbulent layer respectively is possible. Another idea could be to follow individual persons in the city from a "birds eye view". The person could be observed with an infared camera to gain new insights into the reaction between the human organism and the urban structure (if it is not against the law).

3.4 Additional Methods

Phenological obervations are part of the additional methods. The vegetation offers information related to the climatological advantages and disadvantages. However, often various different factors are playing a role, for instance soil quality [cf. OTTE, 1999:299]. One example of additional methods would be the project "Klimabiene" (www.klimabiene.de). By spreading out researchers over a wide area, questions about correlations between weather, the development of the vegetation, and flock events could be answered.

3.5 Mobile Measurement

Another possibility detecting the inhomogeneous urban structure is using mobile measurements. The advantage of this type of methodology is the high density of measurements, which could be mapped spatially. Although, especially in the applied urban climatology, the methodology of mobile measurements to detect data of air temperature and air humidity has been practiced for a long time, mobile air quality measurements do not have quite a long tradition. Already in the 1920´s, mobile air temperature measurements were made by Schmidt and Peppler. The first ones were semi-mobile, but in the course of the time the technological development allowed to measure continuously from the beginning to the end of the transect [cf. Henninger, 2011]. At the department of Physical Geography at the University of Kaiserslautern, such measurements are carried out by the students regularly. The climate data are gathered by individual portable measuring instruments and e.g. the results are written down manually. Exemplarily, the measurement devices record air temperature, air humidity, surface temperature, lighting conditions, and the wind speed. Later on, the gathered data can be copied into a Geographic Information System (GIS) and can be analyzed. The GIS makes it possible to show the relation between the different types of soil-coverage and air temperature. For example, the air above the natural surface is colder than the one above the asphalt (Fig. 1).

Fig. 1: Mobile measurement – Map of the air temperature – Group project – GSP&Stadtklimatologie 2009

However, it is easier if the data could automatically be determined and recorded. Hence, another method of climate monitoring is an electronic and mobile field book.

It is desireable to include smartphones as mobile measurement devices. Beside localization via GPS, smartphones have various sensors which can be used to collect environmental data. Furthermore, smartphones allow data transfer (e.g. UMTS, LTE) and the possibility to store, amongst others, digital documents, pictures, and audio recordings in a database.These functions enable smartphones to be used as electronical field books.
Fig. 2: App: „Baumkataster" – Recording position & data of a tree

The self-developed (ALLBACH, GERMANN) mobile tree app ("Baumkataster") is an example for an electronic field book (Fig.2). It is possible to store the location of a tree as well as to determine it according to its classification. Some meta data, such as the height and the circumference of the tree, can also be stored. Afterwards, the data can easily be edited on the computer.

Another way of mobile measurement of the climate is done by car. A monitoring car can continually gather stationary, as well as mobile meteorological and air quality data. In Essen it was possible to show the connection between an average CO_2 emission and various types of land use [cf. HENNINGER, 2005, 2011]. Tracer and drift smoke experiments are also mobile measurement techniques. They are especially suited for the phenomenological and visual proof of air movement near the ground. They can be used to measure nightly cold air flow under autochthonous weather conditions. Tracer experiments use easily managable chemical tracers such as sulfurhexafluoride (SF_6). This gas can be measured short after it was emitted in the investigation area. By this, it is possible to gain knowledge about the penetration depth and the volumetric flow rate [cf. KUTTLER, 1996] [cf. OTTE, 1999:289].

3.6 Urban Sensing

A new type of measurement could be the so-called 'urban sensing.' The individual human being or his or her carried equipment can be used as a measurement instrument for 'urban sensing.' A combination of stationary

and mobile sensors is possible [cf. Campell 2006]. Urban sensing in combination with the 'Web 2.0/ Web 3.0' is a new possibility to gather and analyze data. These data, which can be gathered actively as well as passively, have a yet unpredictable value for urban design and climatology. It might be necessary to develop new algorithms and programs, which are able to do more than simply process physical input, in order to make this new data source complete accessable. The possible usage could be separated into three fields: personal scenarios, social scenarios, and public scenarios. A personal scenario could be the monitoring and analysis of one's own vital functions. In a social scenario data of a fixed group of people could be gathered and handled by social networks like Flickr. In a public scenario there would not be any limit and the whole population could take part in it [cf. Srivastava; et al., 2006:1F]. One advantage of this kind of data collection is the possibility of monitoring huge areas over a long period of time [cf. Hof, 2007:1]. Out of financial reasons, this is mostly not possible with the classic methods like couting and measuring. Also the already existing ubiquiority of mobile devices is important for the accuracy of the data [cf. Goldman; et al., 2009:4FF]. There are already projects which try to use urban sensing. Noisetube (http://noisetube.net) is a system for the monitoring of noise. Waze (www.waze.com) is a mixture of crowdsourcing, geotagging, traffic information system, and real time map. Users are able to inform each other about traffic jams, accidents, and other problems. They can even use it for mapping a city on their own. Because data could be collected in real time and it is also possible to send the data directly to the system, this program is interesting for planners. Another aspect which might be interesting for planners is the possibility to monitor areas like nature protection areas or new development sites. A combination with an augmented reality technique might even increase the popularity of urban sensing [cf. Allbach, 2010]. A simple use of urban sensing was the project tracking people of CPE at the TU Kaiserslautern. During this project the movement, activities, way of locomotion, and various other metadata of students was manually gathered and analyzed around-the-clock over a longer period of time. Additionally to the aspects of covered distance and way of transportation, it is also possible to analyze the availability of parking spots at certain locations, the demand for public transportation and the availability of electronic vehicle networks. Furthermore, it is possible to gather climatological data directly and indirectly. The metadata can also be used to draw even more conclusions. The average movement speed, the rate of emission of each person or in a specific area can be calculated. It is possible to compare the influence of the development of the temperature in a certain time frame. Which ways of transportation are selected during a specific season or temperature? How long does a certain group of people expose themselves to the weather? These are questions which could be answered through urban sensing.

Fig. 3: Tracking People 2.0: – Presentation oft the routes and frequency taken by car – [Allbach, Fabisch 2009]

This, of course, very simple system could be automated and expanded with state of the art technology. Updated and expanded information content could lead to the development of new theories which could base upon new statistical facts and new combinations of data.

The data could be used to identify the monitored area and select the required measurement techniques as described in the introduction about measuring methods. In figure 3 the transects of the students taken by car can be seen, sorted by frequency. At the red marked main routes it might be possible to measure extreme

magnitudes of e.g. emissions. These data can also be helpful to select and postion suitable measurement instruments. Connections between the way of usage and climatological and medical metrologcal data could be discovered. Additionally, it is possible to create special subgroups through the metadata, e.g. male, female, student, pupil, senior citizen, allergic subject, etc..

Another type of urban sensing is called tagging. Thereby, information is connected to a geographical position, e.g. uploading pictures to google maps. In the field of urban design, tagging is used in the two dimensional space in the study "A New Urban Sensing and Monitoring Approach: Tagging the City with the RADAR SENSING App" (Zeile, Memmel, Exner 2012), the "Sensing the City" project (Bergner, Exner, Zeile, Rumberg 2012), and "Mobile Digitalisierung von Baulücken – Baulückenerfassung mit GIS, iPad und Geoweb" (Biwer, Broschart, Höffken). Especially the plattforms ALOE and RADAR, which were developed by Martin Memmel at the German Research Center for Artificial Intelligence (DFKI), offer various possibilities how urban sensing scenarios could be realized.

Fig. 4: Tagging with augmented reality – Emotinal Maps & Partizipation – Allbach 2010

New technologies like augemented reality (AR) can be used for urban sensing. The diploma thesis "Augmented City Kaiserslautern" (ALLBACH 2010) explains how virtual tags, as an information carrier, can be blended into the real world. For planners, the active tagging of objects in the real world offers an comprehensive database. How a project is accepted by the puplic can be analyzed. Nuisances like noice, dirt, problems with a typ of ground covering, or insufficient accessability could be identified in a new way and through the uploading of pictures and voice recordings be further documented [cf. ALLBACH 2010, 2011].

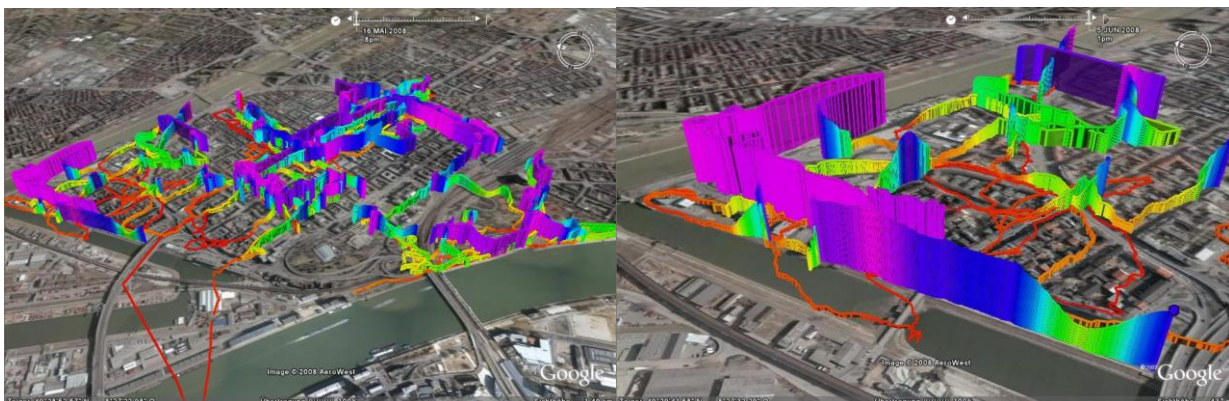
The project „Emomap" of CPE of the TU Kaiserslautern tries to discover in how far it is possible to gather and analyze georeferent emotions with the prototype of a 'smartband' (developed by Dr. Papastefanou at the GESIS – Leibniz-Institute for the Social Sciences) and a GPS logger. Another similar and interesting project was called "Biomapping". It is a puplic project which is analysing the perception of puplic areas.


Fig. 5: Emomap: Analysis of the results of all groups – Allbach et al. 2008

Figure 5 shows the different routes which were used in the urban area of Mannheim. The "emotions" are depicted by the height of the graphs. It is striking that in some areas of the city higher amplitudes can be seen. Already during the experimentit could be realized that the emotional mapping of a city is hardy possible out of various reasons. It was not possible to explain definitly what caused the emotions or the psychophysiological processes. However, they supposed that climatolocigal or bioclimatological aspects could have been the reason for the reactions, for instance a shadily park as seen in figure 6. A certain statistically conection between temperature, stress and emotions could be proven. It has to be noted that the prototypical test procedure as well as the insturments are error-prone.

Fig.5: Emomap: Possible interconnection of climate & "emotions" – Allbach et al. 2008
Fig. 7: Embedded Urban Sensing – Example for the measured data

4 DEVELOPMENT OF A WEB BASED SYSTEM TO STORE CLIMATE DATA

A multitude of biovital functions could be recorded by the sensors. For instance, heart rate, airflow, temperature, level of blood oxygen and skin resistance will be recorded, but much more is possible. The climate indicators depicted in figure 6 shall be linked with the biovital functions. Unfortunately, it is not possible to measure all biovital functions at present. It would be revealing to measure blood counts of various probands. This has already been tested by companies such as Medisana, Withings, and Sanofi-Aventis, but it is not possible to combine all existing single sensing instruments into an all-in-one gadget. Also, most instruments do not offer the possibility to access the data since most producers favour closed systems. However, it is detectable that the publication of various crowdsourcing applications, which monitor the biovital functions, in the context of social media plattforms, are appealing to the users. For instance, the sharing of covered distance, energy consumption, time needed, and covered difference in altitude with friends in Facebook. This might pressure the producers of E-Health-plattforms to create an open system.

The various sensors gather a multitude of different data. They have a highly differentiated quality and conformity. A method must be found to connect and blend them which one another, since this is an important aspect. It has to be considered that data is available in various different formats and that it has to be brought into a compliant format later on. Especially time and geopraphical position are critical values and can lead to severe misinterpretations, if they are imprecisely measured. If the data is to be saved in a system, standards have to be defined in order to make the data compareable. Measurement units, names, spelling, and units have to be defined, too.

Since as much as possible data should be gathered, it seems to be reasonable to keep the maximum amount of attributes of the data unlimited. At the same time, the collected data has to offer a certain amount of information content. This content has to be at least date, value, unit, and the precise geopraphical position of the measurement.

The processing of the data will be done by a centralized system. A GIS seems to be the most suitable way to gather, analyze, and publish the "Complex-Urban-Sensing-Daten." Questing, whether it makes sense to intermingle the data, and if they are in some way connected, is also an important aspect of the work. The project requires not only knowledge of the subject, but also creativity. Especially this creative process can at the moment hardly be done by machines or an artificial intelligence (AI). At this point it must be alluded to Pachube, which continuously developed further in the past years. Meanwhile, the Pachube project has be sold and renamed to Cosm. Many of the described functions can partly be achieved by Cosm. However, the dewwelopment, availability, and the interests of a company can not be predicted [cf. MACMANUS 2011].

This short description illustraits it and a complex system is needed in order to gather the complete data. Out of this reason we want to define a minimum of the essential requirements.
Fig. 8: Structure of the System (KUSS – CUSS) – various measurements in the city

Requirements

-       Availability
-       Connectivity
-       Handling of heterogenic data
-       Stability and performance
-       Storage capacity

- Capability to analyze
- Open source and expandability
- User profiles and scenario instances
- Usability
- Additional values for the user

There are various requirements for an all-encompasing sensing plattform. Ideally, it should be accessable world wide. However, this will not be possible in the early stages because of language differences and lacking accessability of data connections.The system has to have a high connectivity, which means the ability to connect as many as possible sensor devices of various sorts as well as to spread the gathered data to other plattforms. Furthermore, it must be able to export and import the gathered data. This allows the processing of specialized local data as offered by GOSOL and ENVI-met and the uploading of additional information about the urban and natural structure, for instance urban ground composition. Another linkage could be a connection to a social media network.

The system has to be able to store various heterogenic data. But this is problematic. An example could be the temperature at a certain place, but also the information about the height of a tree. The potential data and its information content are wide spread. The "Semantic Web" technique might be helpful to achieve this goal. Another requiement is the stability and perforemance of the system. The system has to be able to handle the amount of quickly succeeding measured data, which can consist of large mounds of data, e.g. pictures, and which can be used by various users simultaneously in real time. The system has to be failsafe and independent of any company which might shut it down or sell it. It has to offer enough storage capacity, secure the data, and guarantee that data are unmodified. Furthermore, it has to be possible to import data directly and manually. The system should have at least a rudimentary ability to analyze the data. Expandability and being open source are important features of the platform. In order to impliment new functions and develop it further, it would be helpful if the system was built up in a modular way. User profils and scenario instances will help to order and filter the data in the system. It could be possible to create spezialized user groups like allergic subjects or pupils which are effected more by certain factors. Usability is important since users prefer a simple and easy system. Furthermore, it should not be ignored that older people and people without technical knowledge must be able to use the system. For the administrators it could be helpful if the system was easily manageable and developable. The plattform should offer something to the user. It would be possible to include an alarm function for special weather conditions, dangerous measurement results, and advices for the user.

5 CONCLUSION – AND FUTURE WORK

Climate and weather are complicated and complex. Likewise is the heterogenuous structure of an urban area. Research is required in order to gain a better understanding of the connections between an urban area, climate, human beings and their health. Out of the single topics and fields a new system science will arise. The presented methods and techniques will allow it to observe and analyze climatological data and data which are relevant for urban desgin. A multitude of individual measurements try to establish a connection between the climate, the city and human beings. The use of crowdsourcing and urban sensing will allow to gather novel and specific data. Even scenarios which include the complete population could be realizeable. New techniques like smartphones, mobile internet, embedded systems, and AR offer a new potential for the monitoring. The gathered data can be digitalized and further processed, for instance in a GIS and new kinds of maps could be created. Climate data are often defined by thresholds and guidelines which are based on long term basic and empirical research. A direct and complex research within the urban ecosystem would be remarkable. The presented standard climate measurement methods are mostly directed at special fields of climate research. Manual measurements are often required. Missing or inconsitant measurement results are mathematically calculated. The presented possibilities of crowdsourcing, urban sensing, and Web 2.0 plattforms should be used in climate research. A new form of climate monitoring is coming into existance, one which not only supplies the planner with pure measurements result, but also with human biovital functions and other metadata of the urban population. This should be done by a centralized system ("Complex-Urban-Sensing-System" CUSS) (Fig. 8). The recording of immitiate bodily reactions could lead to new insights into the complex urban ecosystem which might change the planning process and offer a new

way of monitoring. These new observations should be done by daily carried gadgets and stationary measurement stations as well as a new developed sensing instruments. Out of this reason, the authors want to point to their other paper "Mobile Embedded Climate Sensing 2.0" in which, amongst others, this instrument will be introduced in detail.

A basis for the system could be geographic information system, which in connection with a database can be used for analytical purposes. Also the WEB 2.0 / Web 3.0 can be used for the realization of an urban sensing system. It is our intention to develop a system which is qualified for the storage of climate data. Our expanded measurements of the climate will start with the first autochthonous weather situation of 2013. At present we are also analysing climate accessibility (www.klimabarrierefreiheit.de) and we hope to present our results in 2014.

New Public Open Spaces and Old Prejudices: Public Space Uses in the Centre of Medellín

Eva Schwab

(DI Eva Schwab, University of Natural Resources and Life Sciences Vienna, Institute of Landscape Architecture, Peter-Jordan-Straße 82, 1190 Vienna, Austria, eva.schwab@boku.ac.at)

1 ABSTRACT

Since the beginning of the 2000s, Medellín/Colombia has undergone a well-publicised urban transformation, both in the city centre and in the peripheral informal settlements, turning the city from one of the most dangerous hotspots of a drug-related armed conflict into a showcase for inclusive urban upgrading. This change has not only benefitted the city's inhabitants but also improved Medellín position as tourist attraction and target for international investment. Successive mayors and their administrations have invested in the iconic design and upgrading of public spaces, mobility infrastructure as well as educational facilities. Combining participatory practices, trans-institutional collaboration and transparency with high-quality design has been an emphasis in the upgrading strategy. The "recuperation" and "reinterpretation" of public space as a "safe space for all" have been another focal point in the transformation process. Educational performances, celebrations and events in the newly establishes public spaces are used to promote and anchor these goals, to establish use in formerly neglected areas and to define "apropriate" behaviour in public space.

The Feria de las Flores, Medellín's most important traditional festival dating back to the 1950s, has started to play a central role in the municipal government's strategy to transform public space not only through material interventions but also through a process of re-signification.

Comparing the everyday use of the spaces where the Feria de las Flores takes places with the official promotion of the festival and the uses in these spaces during the events, this paper describes how the Feria de las Flores is used to define and publicise desired practices of public space use, and how it – despite a portrayal to the contrary – adds to an exclusionary experience for the most vulnerable inhabitants of the city, who depend on public spaces and the informal economy for their livelyhoods.

2 MEDELLÍN'S PUBLIC SPACE IN THE CONTEXT OF SOCIAL INEQUALITY

Medellin, the capital of the department of Antioquia is located at about 1500 m in the central Andes, and is Colombia's second largest city after Bogotá, the capital of the country. It covers a surface of 380,64 km². The average population density is at about 6000 persons/km², with only 60 p/km² in the rich southern districts (comunas) and more than 20.000 p/km² in the poor northern neighbourhoods.

Urbanization for a long time followed the Spanish rectangular pattern (and legislation) and progressed without any bigger changes or adaptations until the 1930 – 1940, when processes of rapid industrialization and population growth changed the city's face (Schnitter 2006, Romero 3rd edition 2007).

In the year 1938 168.000 people lived in the city, in 2011 there are almost 2.4 million (Alcaldía de Medellín 2011: 19). This population growth has been driven not only by industrialization and the impoverishment of the rural population, but also by the armed conflict between guerrillas, paramilitary, military and drug traffickers in the country[1] which has lasted for over 60 years and has caused massive forced displacement. In 2010, for example 30,099 desplazados[2] came to Medellin (Personería de Medellin 2010: 21) to start a new life.

Neither the modernist urban development plans of 1948, 1970 and 1985, which contributed to the social segregation of the city and to the impoverishment of public space (Avendaño Vasquez 1998: 89pp) nor social housing initiatives were able to cope with this increase in population and so from the 1950s on (Betancur 2007), but increasingly since the the 1970s (Schnitter 2005) self-build settlements formed on the slopes surrounding the city centre. For the city, a degree of informality of 22 % has been diagnosed (Werthmann 2011), meaning that 22 % of all residential buildings have been erected informally by self-build

---

[1] This conflict is one of the longest running armed conflicts in the world. The beginning of the conflict between guerrillas and military is usually specified with the mid-1940s. From the late 1970s on, criminal gangs contribute heavily to the increase in urban violence in the poor neighbourhoods of the city (Canos, Gallo, Zuluaga (ed.) (2008): Dinámicas de guerra y construcción de paz. 17 et seqq.).

[2] This is the highest number of newly arriving refugees for 10 years, most of them settled in Comuna 13 in the northwest of the city.

---

initiatives. Furthermore, for the job sector, the informality rate is at about 50 %.[3] 50 % of the city's population is living[4] in housing considered informal – a clear physical sign for the pronounced inequality of society, which influences all aspects of human well-being, like education, income, health and security issues.

For long, violence has characterized Medellín's image (Torrejon 2009) and life and since the end-1980s the government has invested massively in a fight again crime. Due to major military interventions and a policy of disarmament and re-integration of former gang members, Medellín's death toll has taken a significant and much applauded dip until 2006. More recently, the vacuum that was left after the destruction of the major drug cartels in the early 1990s has resulted in increased fights for territory and power in the drug business, especially in the poor peripheral comunas and the death toll has encountered a new peak. While robberies and kidnappings can happen all over the city, the numbers of deaths and injuries as a result of armed conflicts in the peripheral districts are exceptionally high (Medellín, cómo vamos 2010: 31 pp).
Fig. 1: Annual rate of homicides, per 100.000 inhabitants. Source: Medellín Cómo vamos (2011): 30

This situation of constant threat had and still has a massive impact on the lives of people in the city: public space has been perceived as a threat and was therefore rejected;[5] the city was experienced segmented by invisible borders. Since the mid-1990s, politicians and administration alike recognized that improving Medellín's security situation was the basis for improving the quality of life of all residents and for a successful redefinition of the city, which they based to a large extent on a reinterpretation of public space and an increased focus on social equality.

This was in accordance with the new Colombian Constitution from 1991, which the Colombian government drafted to overcome its crisis of legitimacy of the late 1980s. The 1991 Constitution emphasises citizens' participation and grants their co-governance in legislative, judicial, electoral and fiscal initiatives while at the same time making place for strict neo-liberal policies and decentralisation (Hunt 2009: 333). Public space became central is this context as the "privileged space of citizen communication" and "the necessity of offering spaces of coexistence and the democratic exercise of citizenship" was recognized (PMEP 2005: 2; POT 2000: 13 cited in Hunt 2009: 333).

This combination of neo-liberal politics and governance through spatial interventions is occurring in various countries around the world (Anjaria 2013, Schwab/Garcia 2012) and the practice has entailed criticism: Some take issue with urban policy and state that "(…) because cities are under increasing pressure to be competitive in the global economy, they have turned away from democratic governance, which is seen to be inefficient and uncompetitive" (Purcell 2003: 12), while others try to raise awareness of the potentially exclusionary power of urban space production (Zukin: 1996).

On a different note, many publications stress the importance of public space in projects of urban transformation in countries with high levels of inequality. Enrique Peñalosa, former Mayor of Bogotá, sees in public space an important equalizing factor towards a more inclusive society and stresses its role for the

---

[3] http://www.inura.org/NMM_Posters_PDF/INURA11_Medellin.pdf

[4] The residential areas of the city are divided into 6 estratos; the classification is based on a survey of the quality of infrastructure and provision of municipal services, the building and the public spaces. Depending on the assignment, the tax burden of an apartment or a house is calculated. 50 % of residents are living in the 2 lower estratos in informal settlements, which are mainly concentrated in the northeast and northwest of the city on the slopes. Another 30 % live in estrato 3 (bajo medio) in districts that often arose from consolidated informal settlements (Departamento Administrativo de Planeación 2010).

[5] The city's poor public space ratio per inhabitant at 4 m² is a physical indicator for that process.

development of civil society (Peñalosa: 2007), and Gouverneur and Grauer argue that "public spaces working as urban connectors can play a key role in achieving integration, minimizing inequality, and fighting violence and resentment" (Gouveneur/Grauer 2008: 30). The unquestioned celebration of the all-transformative power of (good) design (Roy 2004: 308) may have given way to the more realistic evaluation that public spaces are important actors in the shift towards a more equal society, but that they are of little help if socioeconomic progress for marginalized groups is absent (Gouveneur/Grauer 2008: 29).

3 METHODOLOGYCAL CONSIDERATIONS

This article presents work from my PhD Thesis on the role of public space and socio-spatial justice in the upgrading of self-build settlements in Latin America and comprises research undertaken in Medellín between July 2011 and January 2012. The work is set within the tradition of Qualitative Research. For this paper, primary data extracted from user analysis through participant observation as well as from document analysis through qualitative analysis of content is presented in a case study of the Feria de las Flores festival and one of its venues, the Parque de los Pies Descalzos. A Literatur Review provides the context for the findings obtained during fieldwork. As will become apparent in this article, the city government avoids putting its urban transformation process into the context of critical deliberation. It is my intent to offer a reflective context by discussing my findings in the light of the two major points of criticism and screening them for structural similarities.

Participant Observation was carried out to analyse the use of six selected spaces, three in the centre of town, three in the poor comunas on the periphery. The sites were observed on 7 occasions throughout the week and at different times during the day (weekday mid-morning, midday, afternoon and evening; weekend mid-morning, afternoon and evening), lasting for 30 minutes each. These 7 observational moments were distributed throughout a timespan of about a month. Through colour and sign codes, activity and users were categorized into three categories of activity (pedestrian traffic, activity, observation) and eight user groups (male/female kids from 1 – 12 years of age, male/female teenagers from 13 – 20 years, male/female adults from 21 – 65 years of age as well as male/female elders above 65). In a later step, the results of these observations were transferred into digital maps and also collated in tables.

Document Analysis was conducted on diverse print and video documents, such as the Municipality's Urban Development Plans (2004 – 2007 and 2008 – 2011), official communication by the mayor's office on issues surrounding the urban transformation process, municipal reports on quality of life aspects in Medellín (Medellín, cómo vamos), plans and planning documents as provided by the Planning Department and the architects. Special importance was put on assessing the document's author, the context and purpose of the document's creation, the intended audience and the document's significance in the context of the on-going transformation process. It was my aim to capture hidden meaning and ambiguity and to discern the ways in which realities were socially constructed with a political agenda.

4 FINDINGS: MEDELLÍN'S RECENT URBAN TRANSFORMATION

4.1 First Steps towards a redefinition of the city

In 1993 first projects for the upgrading of peripheral informal settlements started under the PRIMED programme[6] (Programa Integral de Mejoramiento de Barrios Informales – Integral program for the upgrading of informal settlements), which followed a new logic and methodology: instead of erasing whole neighbourhoods with bulldozers and relocating the inhabitants in social housing, the project invested in the physical and social improvement of the barrios with the aim to keep social structures intact[7] (Betancur 2007). Around the same time, after nearly 15-years of planning and construction, the first metro-line was inaugurated in 1995. It provided efficient public transport from the city's poor north to the rich south and made getting to work for many inhabitants of the northern comunas considerably easier and cheaper.

---

[6] Funded by the German government through the German Federal Ministry for Economic Cooperation and Development (BMZ) and the bank KfW (Reconstruction Loan Corporation).

[7] PRIMED objectives: establishment of appropriate planning and implementation mechanisms, expansion of civic participation, physical improvement of neighbourhoods, physical improvement of houses (resettlement, faute de mieux); awarding tenure; mitigation of geological risks in the areas of Pan de Azucar, Picacho and Nuevos Conquistadores.

Long before the Metro began operations, an educational campaign called "Cultura Metro" was launched. Lectures, artistic interventions, street festivals and social work were used to instil understanding and pride for the new means of transport. Cleanliness, social control, non-violence and tolerance were key themes of the campaign. For many, the metro was the beginning of a discourse about public space. The Cultura Metro campaign can also be understood as the beginning of a new kind of political and administrational communication which combines educational and regulatory measures with fun and entertainment to define and enforce desired behaviour.

4.2 Medellín presents itself as exemplary laboratory for urban transformation

In accordance with the Urban Development Plan 2004 – 2007 which was geared towards new governance, social inclusion and the creation of new jobs as well as positioning Medellín globally,[8] in 2004 the Urbanismo Social programme was established by the then-mayor Sergio Fajardo with the aim to reduce the long-lasting social inequality.[9] Good design, public participation and communication, as well as inter-institutional cooperation and transparency were defined as main means to reach this goal. Through this programme, the "historic debt" against the poor should be paid and a city with "public spaces for all" should be created. Other much-used, albeit ambiguous terms in the discourse are the "recovery of public space for the encounter of citizens" and "the establishment of an adequate use of public space" (Alcaldía de Medellín 2011). The programme focused on a comprehensive approach to upgrade the whole city and invested in the upgrading of peripheral settlements through infrastructure improvement and the construction of stunning educational facilities and the upgrading of the rundown and depleted city centre through emblematic (public space) projects. In these projects, iconic architecture is used to create attractions of city-wide significance (ibid.: 137 et seqq.) to help reinterpret public space positively and to demonstrate Fajardo's slogan "The most beautiful for the most humble"[10]. The Parque de los Deseos and Parque Explora, the Parque de los Pies Descalzos, the Parque de las Luces are some of the public spaces, which are presented as successful urban interventions of high quality design and as central space for all user groups (Martignoni 2008).

4.3 Points of Criticism

While the methodology of the Urbanismo Social has established a break with the municipality's decades-long neglect of the peripheral poor neighbourhoods, and the city government and the Urban Development Department have been awarded international recognition and accolade,[11] a growing group of academic critics is gaining attention. Two main points of criticism can be distinguished:

4.3.1 Questionable Reduction of Poverty and Inequality

Recent research suggests that despite the highly visible political communication of the successes of urban transformation efforts in Medellín, it remains unclear if sustainable economic improvement for the inhabitants of the poor comunas could be fostered through the interventions. In the immediate vicinity of the new project, increased small scale economic activity (much of it informal) can be observed and housing prices and rents show some stimulation, outside these small areas however, the benefit is a lot less evident

---

[11] Both the mentioned spaces as well as the interventions in the barrios populares have won many international architecture prizes and recognitions by the UN (amongst others) (Alcaldía de Medellín 2011: 224) and serve the city as advertising for their improvement strategy (ibid.:13f). It is the government's goal to establish its methodology as best practice and to pass on the knowledge to other cities around the world and especially delegations of other Latin American governments have been known to pilgrimage to Medellin.

(Brand, Dávila 2011: 655). Furthermore, the same authors estimate that less than 10 % of the inhabitants of the poor comunas use the newly built infrastructure, public buildings and open spaces and point out that "the social impact of specific projects remains somewhat unclear". Additionally, both the quality of life index and the human development index have increased along the same percentage as the whole city (MacNamara, 2009; Blanco and Kobayashi, 2009; Cañón, 2010; Quinchía, 2011 cited in Brand, Dávila 2011: 656 – 658). What is more, the poor estratos suffered proportionally more from the negative effects of macroeconomic developments, pointing to the fact that inequality is higher among poor estratos (Departemento Administrativo de Planeación 2011). Brand and Dávila also point to the fact that participatory practices have diminished and/or been turned into token participation and that the architecture of the projects has been criticised for "ostentation" and "lack of originality". Other urbanists in Medellín describe the projects as imitations of Barcelona ignoring Colombian tradition and reality (Schwab 2011: 15). They conclude that "[A]gainst all prima facie visual evidence, a quick-fix approach motivated by short-term political impact and publicity-conscious gain are unlikely to be successful (Brand, Dávila 2011: 659). Along the same line, Leibler and Musset determine that the biggest impact of the transformation process has been a change of self-esteem and national and international representation, which "result from massive promotion of the ideals of social justice in the project through intensive political communication" (Leibler, Musset 2010; my own translation)

4.3.2   Continuing Depreciation and Exclusion of People in the Informal Labour Market

Hunt draws attention to the fact that it is a widespread phenomenon in the recuperation and recovery of public space that the informal sector is blamed for its invasion and derelict state, and that street vendors are demonised through ascribing them a "culture of informality" and portraying them as violent, filthy, illegal tax evaders who live an easy live. Despite this common assumption, mainly illegally parked cars, private constructions and formal businesses can be made responsible for their self-serving appropriation of public space, while informal street vendors occupy less than 10 % of public space through their selling activity. Even so, as the same author demonstrates for the case of Bogotá, in political communication and public perception, street vendors are made culpable for bringing chaos to public space and should be removed in order to recuperate it for the use of all citizens, thus creating a dual logic of legitimate and illegitimate citizens or noncitizens (Hunt 2009: 334). The increase of work in the informal sector in Medellín[12] sheds an ambiguous light on the effects of the recent governmental and economic restructuring, because "the reality of the invasion of public space by ambulant vendors is linked to processes of economic restructuring that have generated severe unemployment, aggravated by the agrarian crisis and the internal conflict in the country with the resulting displacement of the rural population" (FVP 2005: 2 in Hunt 2009: 336f).

Furthermore, and quite contrary to the idea of the street vendors' easy life, statistics "reveal vendors' severe poverty, as well as the gruelling hours they must endure to eke out a living. Some 81 % of street vendors work every day of the week, and 60 % work more than 40 hours per week, with the average workday consisting of 10 hours. Despite labouring more hours per day and more days per week than any other working group, the state reports that the vast majority of street vendors (76.2 %) earn at most the minimum wage, while 40.1 % earn less than half the minimum wage. Of these workers 95 % don't have pensions to care for them in old age" (Hunt 2009: 336f). Given the widespread interventions against street vendors in the new policies to reinterpret public space, it results especially interesting to know that "Constitutional Court decision T-772 of 2003 established that anyone whose basic needs are not met by the state has the right to utilize public space for income-generating activities" (Hunt 2009: 338). This not only questions the social and moral aspects of the interventions against street vendors, it also puts them into a negative light juridically.

4.4 The role of Animación Urbana in the reinterpretation of the city

As was already the case with the „Cultura Metro" campaign, the government's official communication and education strategy play an essential role in the transformation process. „Animación Urbana" alludes to all those activities by the mayor's office, the planning departments or municipal social services in public spaces which are meant to provide entertainment for the population and simultaneously perform an educational task by encouraging a new vision and use of public space. The official goal of Animación Urbana activities is to

---

[12] http://www.inura.org/NMM_Posters_PDF/INURA11_Medellin.pdf

contribute to the reinterpretation of public space in order to promote a new urban identity, which is based on a new understanding of communal live and social justice.[13] Animación Urbana activities often take place in the above mentioned new central open spaces and try to use established formats like festivals and celebrations to transport their message.

The "Feria de las Flores" is one of Medellín's most traditional festivals. It was created in 1957 to uphold the traditional customs of flower growing and arranging and to serve as a folkloristic tourist attraction. In the five decades of its existence, the Feria de las Flores has become a major cultural reference point for Medellín and Antioquia, and today offers a complete spectacle with about 150 different events over a 10 day period. During this time, the tourism sector boasts a hotel occupancy rate of over 80 % (Radio Caracol 2011: 15). Throughout the Feria the city vibrates with live, more people than usually are walking in the streets after dark, and also the presence of the police and the military is more obvious than throughout normal times. In addition to the parks and squares of the city, especially the shopping malls act as venues for the various events. It allows a deeper understanding of the idea of public space in Medellín, which is influenced by concerns for security, order and social distinction, to know that half of the events take place in shopping malls and to read the mayor's introduction to the Feria, where he describes the importance of the festival for public space, as during the Feria "the citizens, united as a family, flock to the streets" (ibid.: 5).

Nowadays, the Feria is not only a tourist attraction but plays an important role in terms of the above mentioned Animación Urbana and the construction of identity: as a collective celebration as well as staging of the (apparently) peaceful coexistence it receives huge media coverage already weeks before the starting date. The theme song and the accompanying video play an essential role in this. In 2011, two different groups were selected to interpret the song: the rappers laberinto elc, who describe life in the poor neighbourhoods of the city with critical songs and the boy's band Piso 21, well known for smooth faces and catchy pop rhythms perform "Feria en mi casa" and conjure up the idea of everybody being part of the Feria. The accompanying video[14] shows the boys singing in the streets of the barrios populares on the periphery of the city, in the newly created public open space, at the market and on the construction site. This official presentation of the city shows the major projects of the urban transformation process and presents Medellín as a place of happy, proud, working class people who willingly accept informality, who make the best of their situation by celebrating and singing together. Seen from the perspective of the city's development plans, one can state that the video accomplishes two tasks: it helps to improve Medellín's image and to position the city globally as the exemplary laboratory of urban change, but more than that it takes effect as internal representation and mobilization in the sense of Animación Urbana, and as a marketing tool for the transformation processes in the city,[15] and thus serves a political purpose. Also during the various events of the Feria, self-representation and Animación Urbana take a prominent position in the event.

4.5 The role of the new public spaces in the reinterpretation of the city

The newly created public spaces not only serve the community through new equipment and new spatial offers, they are also used for the representation of the city' positive change. They serve as stage for local TV shows, backdrop for business commercials and as venues for open air concerts. I will focus on one space here, the Parque de los Pies Descalzos, which is exemplary for the new public space developments in the centre of Medellín.

4.5.1 Parque de los Pies Descalzos

Parque de los Pies Descalzos (Barefoot Park) is situated in the administrative centre of the city, with the town hall and the district government of Antioquia, the convention centre and the Teatro Metropolitano just a short walk away and is surrounded by administrative and representative buildings of Empresas Públicas de Medellín (EPM).[16] The park lies on a little urban island formed by the busy multi-lane main roads of the city,

---

[13] http://urbanismosocialmedellin.universia.net.co/galerias/familia1c2.jsp

[14] http://www.youtube.com/watch?v=CCic0YTgBb4

[15] Some of the comments on youtube indicate how striking it is that almost all of the video was shot in poor districts.

[16] EPM is a public utility service company, providing water, sanitation, energy, gas and telecommunications. It was founded in 1955 and initially served only the city of Medellín and its inhabitants. Nowadays, it is one of the biggest companies of Colombia, providing 1/5 of Colombia's inhabitants with energy and one of the biggest energy providers in whole Latin America. The Municipality of Medellín is its 100 % owner. Since the year 2000, EPM (90 % sponsor)

San Juan (calle 44), carrera 57 and 63 and the motorway called La Regional. These roads on the one hand create important barriers towards the park and make approach difficult for those who walk. On the other hand, the mentioned roads are frequented by almost every public transport bus that connects to the town centre and therefore makes the park readily accessible for those using public transport. Apart from the buses, Metro stops Alpujarra and Cisneros are within a 15 minutes walking distance and supervised car parking is available just next to the park.

Parque de los Pies Descalzos was opened for the public on the 7th December 1999. When EPM approached LAUR (Laboratorío de Arquitectura y Urbanismo de la Universidad Pontificia Bolivariana) for an integrated design of their parking spaces, LAUR came up with the idea to counter the negative influences of the modernist urban plans from the earlier years on the administrative centre of town by upgrading public space. A central quality of the area was to be a public park that would represent EPM but equally bring them to show "social commitment" and "give back to the community" (personal interview with the architects), while all their initial requirements for parking and accessibility would be met. The park was to offer a central public space that would express EPM's role as provider of hydroelectric energy and offer a ludic yet educational space for the inhabitants of Medellín to create awareness for natural resources. The park was constructed on a plot of land that belonges to EPM, and paid for by EPM. It was then turned over to the municipality after its completion. Obras Públicas[17] is now responsible for general maintenance issues in the park, but EPM provide maintenance to all the water and sand surfaces and they employ park "rangers" who are responsible of the educational programmes and contact with the users. They also contract the private security firm that surveys the park 24 hours a day, 7 days a week. This fact has entailed critique from within Medellín's academe and some practicing urbanists, as it endangers the space's publicness (personal interviews).

The park's name has symbolic and evocative qualities alike: It makes reference to the many children of the city living in poverty who have to walk barefoot and who are invited to enjoy the park's attractions. On the other hand, it invites visitors to take off their shoes and use the water and sand areas to contemplate and stimulate their senses. Some of the zones are only accessible without shoes.

Before the construction of the park and the surrounding EPM facilities, the area was taken up by former industrial storage space and waste land. The centric part of the city suffered from neglect and showed all the known problems of depleted inner cities. The park was the first big public space development after years of neglect of the topic, so it marks a turning point in peoples' consciousness and the city's public space politics (personal interview with the architects).

4.5.2 Analysis of use in Parque de los Pies Descalzos

On working days, it is a diverse space mainly for people who are connected to EPM in one way or the other, as customers or employees. People are crossing the square to and from EPM. During lunch break, the employees divide into two groups and occupy different spaces. While the executives go and have lunch in one of the nearby restaurants, the common employees like the cleaning ladies and secretaries sit in the park and eat their packed lunch. Sometimes, kids and their parents are using the water attractions. Through the observation, it has become obvious that the park has been awarded the status of an important tourist attraction as various groups of Colombian and foreign tourists take guided tours through the park. During the week, slightly more men use the park than women, especially at times when there is a lot of pedestrian traffic by EPM executives. On workdays, the number of users varies between 101 and 132.

In difference to results from participant observation in other central spaces in Medellín, street vendors are significantly underrepresented and consumption is reserved to the cafés and restaurants in the adjacent building. This is striking, especially during lunch time;[18] only 2 or 3 vendors are to be found on the streets

and recognised educational institutions in Medellín formed the Fundación EPM, which performs educational activities in the public spaces of the city and offers an important number of student grants to disadvantaged young people.

[17] Secretaría de Obras Públicas is a municipal entity responsible for the design, construction and maintenance of public infrastructure, as well as the city's buildings and installations.

[18] If there is such a thing as culture of informality, it is that of buying from street vendors.

surrounding the park. It can be assumed that this is in consequence of the security guards controlling the space.

The picture presented above changes drastically during the weekends, when families use the park with their children and the site turns into a major recreational facility in the city centre. Around 250 people can be observed during a Sunday afternoon. As during the week, the better-off frequent the restaurants, while the others enjoy their picnic on one of the wooden platforms or the benches. Working class people from the barrios populares are clearly overrepresented. The kids mingle at the water features and the park rangers are busy explaining the different attractions. During the evening, the space is frequented by young couples, both homo- and heterosexual. The few homosexual couples tend to sit in more secluded spaces, while the others freely show their affection to the world. There are a few more ambulant vendors to be observed, they are trying to maintain a low profile while offering snacks and fruit or services like photo taking. In comparison to other spaces, their number is still relatively minor. But it shows a common logic, namely that ambulant vendors are to be found when there is a crowd and that they hope to find better working conditions with more people around. All in all, the park offers various subspaces that are used by a diverse clientele, so that the Parque de los Pies Descalzos can be described as a space that represents the diversity and multiplicity of urban life in Medellín. On the other hand, it is a more regulated space than other comparable spaces through the influence of private security guards and the park rangers, which are to upkeep EPM's clean image.

During the festival, the site was the venue for a series of events called Parque Cultural Nocturno (Nightly Cultural Park), which presented concerts in different musical styles from Acid Jazz to Vallenato. Between 2000 and 10,000 people attended the free performances by popular artists. Before the concert, between performances and after the show, the time was used by two presenters to create a positive vibe for the on-going urban transformation. New project were explained, the use of tax revenues was demonstrated, and interviews with sponsors were conducted. Special emphasis was put on presenting the good conviviality of all citizens through references to the events of the day, which portrayed success stories of inclusion and improved lives. Those present were commended on the one hand for their "adequate" behaviour, on the other hand urged to continue to show their "buena cultura" (= good education, sophistication), eg to not get drunk and to leave the venue in an ordered manner, to have "healthy" fun and to support the security guards in their important work of keeping order. Private security guards and the festival supervision ensured compliance with the standards of behaviour. In accordance with the types of music presented, the size and the composition of the crowd varied. Working class people were less represented than usually, and most people arrived in cars to the concerts.[19] It is interesting to note in this context that street vendors who were present during the normal times and who were so ubiquitous at the other festival venues, were prevented to enter the park in order to sell their goods and only stands by the festival's official sponsors were allowed to offer drinks and food (at a much higher price than the informal vendors who made it past the controls).

5 CONCLUSION

Structural similarities with the two main points of criticism can be detected in the results from the investigation of this case. The Feria de las Flores on the one hand can be seen as a traditionally important celebration of public space and diverse cultural practices that fulfils an essential function in a city like Medellin, where public space has been historically equated with danger. The use of the long-established Feria as a tool for the re-interpretation of public space shows the administration's intention to see urban transformation not only as a task of architects and planners, but to understand it as well as a process of production of space by the citizens. The objectives of the new policy are not only to physically improve but to reach a shift of meaning of public space and an increased self-confidence of the residents in the participation in and the use of public space. To achieve this, Animación Urbana increasingly uses mass media, places of consumption and spectacles to reach the population and transport its message.

On the other hand, the exclusion of informal vendors is not only contrary to the experience of daily life in the city where street vendors offer and sell merchandise from vegetables to snacks to single cigarettes, it is also contrary to the celebration of informality which is conveyed through the video. This ambiguity and contradiction raises awareness to the danger that informality is made into an image of "favela chic" devoid of

---

[19] Only 15 % of Medellín's inhabitants own cars or mopeds, so this is a clear indicator for the social composition of the group of visitors (Medellín, Cómo vamos 2010: 66).

the everyday problems people have to face and that the city capitalizes (culturally, socially and economically) from marketing a particular life situation while at the same time aggravating it. The use of the festival for political communication fits the prototypical description of spectacularization of neoliberal urban governance which is to develop both external and internal effects.

It is to be regarded as highly critical that the city administration postulates "adequate" behaviour in public space at an event which is stylized as "open for all" and through the video appears especially geared towards lower income groups, since the required "adequate" behaviour reproduces hegemonic perspectives on space and society, and denies them their use rights and thus their earning potential.

The use of the word "cultura" in this context makes it easy to overlook the structural imbalance in the demand for adequate behaviour, because it turns diverse ways of behaving into people's personal responsibility and choice and neglects inequalities. Despite the obvious good-humoured nature of these animación urbana activities, Hunt (2009: 332) emphasizes that "civic education [is] a noncoercive technology of governance that both empowers and subjugates". In the case of the street vendors, the latter is obvious. It is equally obvious that the urban transformation processes and the recuperation of public space in Medellín has led to a reallocation of resources, an intensification of the marginalization of certain populations and thus to "the exacerbation of inequality" (Hunt 2009: 345) for the poorest inhabitants.

Without wanting to downplay the far-reaching changes in the lives of the inhabitants that programmes like Urbanismo Social have accomplished, which have contributed to both structural improvements and a new sense of the public, one must not forget everyday life in Medellín which is affected by an continued social inequality in all its manifestations, such as unemployment, lack of education, and violence. The obvious danger is that in this attempt to turn Medellin into a formal city and a destination for international tourism and investment structural inequalities persist or are even intensified. Thus the fact that during the events of the Feria social hierarchies and exclusionary settings were reproduced casts severe doubt about "the city for all".

New Quality of Public Spaces as a Stimulant for Socio-Economic Development – the Specificity of Medium-Sized Towns

Anna Golędzinowska

(M Arch, Anna Golędzinowska, Faculty of Architecture, Gdansk University of Technology, ul. G. Narutowicza 11/12, 80-233 Gdansk, Poland, a_g@tlen.pl)

1 ABSTRACT[1]

Compared to Europe, Poland is a country with a relatively low rate of urbanization. The main pillars of economic development are in emerging metropolitan areas. However, the majority of the population live outside the largest cities.

Medium-sized towns have been affected by the adverse effects of political and economic transformation more drastically than large multifunctional centers. But even in the conditions of low budgets and limited interest from private investors, smaller municipal centers turned out to be much more determined than large cities in implementing projects aimed at improving the physical quality of their public spaces. First major projects were initiated in the 1990s, but a significant increase in this type of investment came along with availability of the EU Structural Funds.

We can distinguish several phases in the investment in public spaces. At the initial stage, the main motive for changes was to create a new town image, attractive for both tourists and investors. Later, as integrated revitalization programs were promoted and the municipalities themselves experienced first negative symptoms of gentrification, more attention was paid to the everyday needs of local communities. A change of attitude could be seen at the level of institutions in charge of defining the distribution of the Structural Funds as well as in the municipalities themselves.

The paper presents the evolution of strategies for small and medium-sized towns – including the expected impact of the new EU programming period.

2 INTRODUCTION

Beside the evident advantages, the democratic breakthrough of the early 90s in the region of Central Europe brought along also a series of transformation shocks related to the need to adapt quickly to the new rules of state organization and new economic conditions.

As the region's largest country and the first one to be subjected to the said transformations, Poland is an interesting example for observing these adaptation processes. After 45 years of a centrally planned economy, we could still see regional differences that were the effect of the partition of the country that lasted throughout the 19th century (the present territory of Poland was divided among Prussia, Russia and Austria) and migrations after World War II (differences between the parts inhabited by the original native populations and the so-called recovered territories). The differences were manifested in various aspects and scales: from the development of settlement networks, through economic standards to the residents' self-identity and approach to the heritage of the space around them (SAMSONOWICZ & TAZBIR 2002).

The administrative systems of the countries of the Eastern Block were strongly centralized, based on the principle of the primacy of ministry-level structures (HIRT & STANILOV 2009) This state of affairs virtually made it impossible to pursue social, economic or spatial policies in a rational way, taking into account the local specificity, which seemed crucial with regard to the above-mentioned regional differences. The inefficiency of that system of managing the country became particularly evident when juxtaposed with the system of developed Western countries, where the managerial revolution that had started in industries was transposed also to the public administration (KULESZA 2000).

In 1990, the first significant step was taken in Poland towards decentralizing the state management: the establishment of self-governing communes. The process of changes was launched in many institutions and areas of managing public affairs, such as education, welfare, public order protection. The chief tools for spatial planning were, too, given over into the communes' hands. This is how a state based on civil society

---

[1] For the purpose of the present paper, "medium-sized towns" are understood as those with populations between 10,000 and 100,000, in accordance with the term as it is defined in the National Spatial Development Plan of 2005. This rather broad term includes also, with regard to their functions, also smaller towns that are the capitals of poviat districts.

was to begin functioning (KULESZA, 2000). The giving over of the previously centrally supervised tasks to the communes was related to the need to provide to the local governments funds for running development programs – especially by establishing a participation in the tax revenues and by communalizing the estate resources. These mechanisms were being merely shaped in the first half of the 90s (REGULSKI 2000). Accordingly, the first full-fledged communal development strategies could appear only after the situation had stabilized.

The experience showed to us that those new entities did not yet possess a sufficient institutional capability to shoulder the new challenges in this respect. In fact, as the free-market principle started to replace the old order rather abruptly, the system of spatial planning found itself in a deep crisis (KOCHANOWSKI 2004, JĘDRASZKO 2005). The effects of that crisis exerted a strong impact on the quality of public spaces – that element of the urban tissue that did not generate any direct financial benefit. Owned by "nobody", the public spaces were often appropriated for parking or retail purposes.

One specific element of this complex settlement system was the medium-sized town. Despite the rapid urbanization taking place in the world, the majority of the country's population still live outsides the largest cities. Theoretically, medium-sized towns, as an intermediate link in this arrangement, should provide to their residents access to translocal services and innovations. Such was one of the assumptions of the second phase of the territorial reform (1999), which resulted in the establishment of poviats (ZWIĄZEK POWIATÓW POLSKICH 2013). Practically, strengthening the role of translocal centers turned out to be difficult because the poviats' capitals were on their own in coping with local problems and the fact that a given town was the poviat's capital was not a sufficient factor in attracting private capital.

Despite their limited funds, the development strategies of medium-sized towns show a stronger co-relation between implementing development strategies and improving the quality of public spaces than it is in the case of cities with a metropolitan potential.

3   MEDIUM-SIZED TOWNS IN THE NEW REALITY

In orderto better understand the situation of smaller urban centers at the threshold of democratic transformations, we should examine more closely the political and economic factors of the 20th century. In the time of rapid civilization changes, the original role of such centers – servicing the surrounding rural areas, turned out to be too modest an offer. The need to diversify the economic offer of small and medium-sized towns was understood already in the times of real socialism, but the ministerial rule was largely restricted to locating new state-owned industrial enterprises instead of promoting the urban development processes. Naturally, this way of development could not be successful everywhere (KOLIPINSKI 1973). What seemed to be a "lottery win" in the 60s and 70s turned out to be a curse at the threshold of the market economy. Sudden collapses of "breadwinning" enterprises deprived of state subsidies – enterprises providing both work and an educational-cultural-and-sport offer – led not only to unemployment but also to frustration of individuals and a crisis of the collective identity.

	Year			
	1995	**2000**	**2005**	**2010**
Population of Poland in total	38,609,399	38,253,955	38,157,055	38,200,037
Urban population	23,876,667	23,659,690	23,423,740	23,264,383
Ratio	61.84 %	61.85 %	61.39 %	60.90 %
Population of cities > 100.000	11,275,064	11,204,400	11,059.584	10,940.879
Ratio to population in total	29.20 %	29.29 %	28.98 %	28.64 %
Ratio to urban population	47.22 %	47.36 %	47.22 %	47.03 %
Population of medium-sized towns	10,662,853	10,432,343	10,350,202	10,270,558
Ratio to population in total	27.62 %	27.27 %	27.13 %	26.89 %
Ratio to urban population	44.66 %	44.09 %	44.19 %	44.15 %

Tab. 1. Share of urban population in the country's population. Source: Own summary based on Local Data Bank (2012)

The economic situation affected the demographic one. Medium-sized towns, considered in a strictly demographic context, are home to almost 27 % of Polish population counted in total, and more than 44 % of

urban population. Taking into account the statistical average from years 1995-2010, this group of towns was affected by population loss (Tab. 1). However, the ratio of population in comparison to general population of Poland or urban population in total remains stable. Basing on criteria of population change, medium-sized towns can be divided into three types of categories:

- towns affected by rapid loss – caused by unemployment and low quality of life or, on the contrary, gentrification

- stable towns – in which the falling industry was replaced by new business, usually small and medium-sized enterprises

- fast growing towns – located on the outskirts of large cities or connected to them with frequent rail connection (GOLĘDZINOWSKA 2012).

3.1 Specificity of public spaces in medium-sized towns

Describing the condition of the public space at the threshold of the Polish transition to democracy, we can claim that the Polish towns were affected by the effects of the solutions reducing their significance similar to those that could be seen in other countries of Europe. The phenomena such as the establishment of mono-functional districts stripped of public space, spatial expansion of towns, extensive use of new residential functions and primacy of road traffic were accompanied by a lack of sufficient care for the condition of shared spaces characteristic of the Eastern Bloc, and, which resulted from the political situation of the time, lack of positive connotations with regard to co-participation in the public space. In the mid 90s, competition emerged for the degraded public-access spaces: multifunctional retail-and-entertainment centers, which led nearly to extinction of historical market places and boulevards in many towns.

First discussions about the need for individualization of spatial solutions and return to the development of residential projects of a smaller scale conducive to the residents' association with the surrounding space arose in Poland most probably already in the 1980s, but the true renaissance of this way of thinking came took place only after the decentralization of the spatial planning system of the 90s – so as long as 30 years after the process had been completed in Western Europe. The irony of the situation is that large cities became the subject of intensive development by a new group of interest holders: private developers, who saw a business opportunity in addressing the problem of insufficient housing. They provided a range of housing options in smaller residential complexes but without providing any connection with the system of public spaces. Many of those residential complexes were fenced off the surrounding area, because such were the expectations of atomized society. Another factor contributing to the degradation of public spaces was the growing availability of the thus-far luxurious article: the car. In fact, many public spaces were converted to serve parking purposes.

The smaller towns stand out against this background. Here, the traditional places of the residents' everyday integration largely retained their social functions, despite their predominant wear and poor aesthetics. It is related to a smaller interest on the part of private investors in developing facilities that would be competitive to the public space and or in any investment whatsoever. Consequently, the public authorities remain here the creators of the socio-economic policy to a larger extent than it is in larger centers. We should observe also that in smaller towns and in more compact urban systems smaller distances to a large number of destinations made them more conveniently accessible on foot.

In the context of the contemporary tiredness with uniformity and the demand for uniqueness and authenticity of experience, the livability of the public spaces in medium-sized towns was certainly perceived as their advantage. It may become the foundation for creating a new image, especially in the degraded post-industrial towns, and a boost for the development of tourist and urban functions.

T. Markowski confirms that it is the physical attributes of smaller towns' public spaces that played a larger role in shaping their competitive image than such factors as innovations or a knowledge-based economy (2006). The phenomenon is confirmed by the observed consistency of the local authorities in such towns in applying for funds with a view to upgrading their public spaces. The purpose of the work carried out in medium-sized towns is usually to improve the technical condition and the functional features of the public space. Unfortunately, in the majority of cases little attention is paid to the architectural qualities of the work – the applied solutions are often average-quality, cheap or historicist.

Over the past 20 years we can distinguish certain trends concerning investment in public spaces, largely subject to the process of integration followed by functioning within the structures of the European Union. The matter concerns not only availability of external funds but rather the adoption of a certain culture in managing the urban development.

3.2 Formal conditions coming from the Polish law

To understand the role and context of the quality of public space in the development policies of Polish communes (towns), it is important to become familiar with the chief related formal-legal conditions.

The Constitution of the Republic of Poland (1997) provides that the state "shall ensure the freedoms and rights of persons and citizens, the security of the citizens, safeguard the national heritage and shall ensure the protection of the natural environment pursuant to the principles of sustainable growth," and it "shall provide conditions for the people's equal access to the products of culture which are the source of the Nation's identity, continuity and development," while the citizen's function is to care for "the common good", among other duties.

Despite the Constitution's emphasis on the values related to the functioning of public space, a definition of the "territory of public space" first appeared as late as in the Act of 23 March 2003 concerning spatial planning and development, where the term was defined as "a territory of special significance for the needs of the residents, improvement of their quality of life and conducive to establishing social contacts with regard to its location and functional-spatial features, determined in the study of conditions and spatial development objectives of the commune." The requirement to determine in a study of conditions and spatial development objectives territories of such great importance for the residents' quality of life seems justified but further provisions of the Act stipulate an immediate need to draw up a relevant local plan. This obligation causes that the matter of shaping a system of public space is often omitted in the communes' plans for fear of the need to provide for it financially. However, lack of such a declaration does not mean that public space does not exist in a given commune (town). Squares and streets are often presented as traffic space while parks and other similar places of leisure are referred to as green areas or places of the provision of services. Their proper function is quoted only at the moment of drawing up a local development plan or even later while applying for a specific construction permit. As much as a spatial policy pursued this way secures the existence of public spaces in the structure of the town, it does not guarantee that the venues' features determining their values will be preserved – values including the spatial continuity and cohesion as well as thought-out interactions with the area around it.

Nevertheless, activities aimed at developing good public spaces often occupy an important place among the provisions of other programming documents which are not related in any direct way to the Act on spatial planning and development. These documents include, above all, general strategies for the commune's (town's) development and local revitalization programs. Noteworthy, the inclusion of provisions on public spaces in these documents are a voluntary initiative of local governments assuming that an improved quality of public spaces can help in resolving diagnosed problems or achieving the adopted development objectives.

As it was already mentioned, the first such documents were drawn up in the mid 1990s, but they became more widespread at the beginning of the new century, as part of the preparations for the functioning in EU structures. Defining a development strategy and local revitalization programs, even if not required by the Polish law, was to create opportunities for the town of applying for external funding.

3.3 Financing the transitions in public spaces

Since the financial opportunities related to Poland's accession of the European Union were first made available, we have seen a steady growth in the number of projects aimed at creating new or renovating old public spaces. One of the factors that have led to the surge in the investments can be found in the access of Polish local governments to the resource of good practices from other European countries. However, the key factor for the decision-makers seems to be the fact that public space, as public good, improves the competitiveness of the whole region without favoring any particular entities, and so without violating the balance of competition.[2]

---

[2] "A company which receives government support obtains an advantage over its competitors. Therefore, the EC Treaty generally prohibits State aid unless it is justified by reasons of general economic development."

Considering the accessibility of the funds and principles of allocating them to Polish self-governments, we can distinguish three basic periods:

- pre-accession period,
- programming period 2004-2006,
- programming period 2007-2013.

Financial support in the pre-accession period was available from the year 2000. At this stage of support, with regard for the delay in the development of the basic infrastructure there was no question yet of financing integrated programs of renovating the urban space.

Taking into account the increasing competence of the relatively new, democratically elected local governments, we should mention also the assistance programs related to the transfer of good practices from the EU member states and from the United States (e.g. USAID, KnowHowFund), initiated already in the 1990s. On the wave of those projects, in the 90s first development strategies were being drawn up to revitalize degraded residential districts (MILCZYŃSKA-HAJDA 2007). Interestingly, the innovative solutions were first applied in smaller urban centers such as Sopot, with a population of 40 thousand at the time, or Dzierżoniów, with 35 thousand inhabitants.

Voivodeship	Differentiation of revitalization projects depending on the town's population or its administrative function
Dolnośląskie	Individual priorities: 1) up to 10,000, 2) above 10,000
Kujawsko-Pomorskie	Individual competitions within a single priority: 1) from 5,000 to 10,000, 2) towns from 10,000 to 15,000, 3) from 15,000 to 20,000, 4) above 20,000, 5) sub-regional towns, 6) nodal cities of the voivodeship's capital agglomerate area
Lubelskie	Not applicable – open to all urban districts meeting the criterion of degraded area
Lubuskie	Not applicable – open to all urban and rural areas meeting the criterion of degraded area
Łódzkie	Not applicable – open to all urban districts meeting the criterion of degraded area
Małopolskie	Not applicable – open to all urban districts meeting the criterion of degraded area
Mazowieckie	Scoring preference for town with populations above 5,000
Opolskie	Not applicable – open to all urban districts meeting the criterion of degraded area
Podkarpackie	Not applicable – open to all urban districts meeting the criterion of degraded area
Podlaskie	Not applicable – the program does not cover comprehensive revitalization of urban areas
Pomorskie	**Separate priorities: 1) Development of local basic infrastructure up to 35,000 inhabitants, 2) comprehensive revitalization programmes above 35,000 inhabitants (separate competitions for towns with a poviat role and others)**
Śląskie	Separate operations: 1) up to 50,000 inhabitants, 2) above 50,000 inhabitants
Świętokrzyskie	Separate operations: 1) growth centers: voivodeship's capital and capitals of poviats, 2) other urban centers
Warmińsko-Mazurskie	Not applicable – an indicative list of towns of various sizes
Wielkopolskie	Within the same priority: 1) comprehensive revitalization of urban areas (in town up to 50,000), 2) revitalization of degraded urban areas (integrated projects in town above 50,000 residents, combine with projects improving the housing infrastructure).
Zachodniopomorskie	Separate priorities: 1) up to 5,000, 2) Szczecin Metropolitan Area

Tab.2. Criteria of size and function of towns applied in Poland's 16 Regional Operating Programs. Source: Own study

The programming period of 2004-2006 was the first period in which Polish towns could benefit from the European Regional Development Fund. As a shortened period (for the old member states the period stretched from 2000 to 2006), it was largely the time of adaptation to the new conditions and the time of building institutional capabilities to develop policies of regional development. For all the Polish voivodeships, a common Integrated Operating Program of Regional Development was adopted.

source: http://ec.europa.eu/competition/state_aid/overview/what_is_state_aid.html

Financial assistance for the renovation and shaping new public spaces was directed first of all within the operation "Degraded urban, post-industrial and post-military spaces". In order to qualify for financing within this program, towns had to first adopt the said local revitalization programs, which required analyzing the purposefulness and objectives of the planned projects. Moreover, support was available only in what were believed to be the so-called degraded areas – delimited on the basis of criteria modeled after those adopted for the Joint Programming Initiative URBAN.

Support for the modernization of local road infrastructure and local cultural and tourist facilities was possible in turn within the operation entitled "Areas qualified for restructuring" – here, the supported territory was delimited in the poviat scale, and much simpler criteria were applied. In practice, it meant a possibility of supporting public space renovation projects in most territories outside the largest urban centers.

In the programming period of 2007-2013, the integrated program was replaced with 16 Regional Operating Programs (ROP). All these documents provide for the possibility to support projects related to renovating public space, but in different ways, as determined by the voivodeship's authorities on the basis of the region's specific features. In 15 out of 16 voivodeships, there was a possibility to co-finance the implementation of comprehensive revitalizing projects, but in as many as 8 voivodeships separate provisions were incorporated depending on the size of the particular center and its role in the settlement structure. 5 voivodeships provided for the possibility to extend repayable assistance for urban revitalization within the JESSICA Initiative,[3] but no project relating to public space has been carried out through this program so far.

In the case of the Pomorskie Voivodeship, which will be examined in detail further in the present article, "Comprehensive Revitalization Projects" were reserved for towns with populations above 35,000. Smaller towns could obtain co-financing for simpler projects concerning the development of "Local Basic Infrastructure". In the latter case, simpler procedures were used; the applicants were not required to have an Local Revitalization Program or to delimit a degraded area on the basis of predefined criteria. However, preference was given to the so-called structurally weak areas. In the Pomorskie Voivodeship also smaller projects improving the quality of degraded historical downtown districts could receive support within the priority axis "Tourism and Cultural Heritage".

4 PUBLIC SPACES IN DEVELOPMENT POLICY – A CASE STYDY BASED ON THE EXAMPLE OF THE POMORSKIE VOIVODESHIP

The Pomorskie Voivodeship has been selected for the purpose of an in-depth analysis. The region is characterized by a very diversified settlement pattern. The group of towns meet the "medium-sized" criterion includes 22 places, 16 of which are capitals of poviats or towns with poviat rights. The population of the biggest town in this group in 2011 amounted to 9676 inhabitants (Sztum). Population changes in years 1995-2011 varied from 27.78 % growth rate (Reda) to 14.25 % decrease (Sopot). What is interesting, both of the extreme examples are situated within so called Tricity Metropolitan Area (Tab. 3).

The area is characterized by historic Polish (i.e. Tczew) or Kashubian[4] towns (i.e. Kartuzy, Kościerzyna, Wejherowo) as well as towns dominated by settlers moved there after the Second World War (i.e. Pruszcz Gdański, Nowy Dwór Gdański, Słupsk). Considering the economic base and its changes, the division may be more detailed, towns afflicted by a bankruptcy of a significant production company (for instance Tczew, Starogard Gdański, Ustka), service providers which try to adapt their offer to current needs and towns within so called Tricity Metropolitan Area, which want to ensure competitive conditions for a housing market rivalling with the central parts of the metropolis. When it comes to public space development as a part of urban composition, the most interesting examples are new towns deprived of historical centres, located in the Metropolitan Area: Rumia, Reda and Pruszcz Gdański.

Several spectacular examples of transformation of public space from the pre-accession period may be found in the Pomorskie Voivodeship. They are often highlighted in literature of the subject as examples of good practices. A forerunner of restoration of the cityscape was Sopot. This historic health resort, which is located in the very centre of the Tricity Metropolitan Area, had its local revitalisation program designed in cooperation with local inhabitants. From 1997, renovation of consecutive historic quarters is being supported. Projects are executed mostly thanks to subsidies offered by town authorities to tenants'

[4] Slavic autochtonic group in Pomorskie region

Anna Golędzinowska

associations, but a central fragment of the town, which had been devastated during the war, was redeveloped thanks to one of the first examples of public-private partnership in Poland. Another example is renovation of the Old Market Square in Chojnice. Here, town authorities developed the market square and provided support to owners of the tenement houses located nearby, providing financial support as well as executing elevation restoration works. Thanks to its new and attractive image, this historic center reported significant development of services and the town became a major centre in the south-western part of this voivodeship. During this time, works on the new centre in rapidly developing Pruszcz Gdański were initiated. The majority of works was completed only in 2006 but it was the crowning of the process initiated by an architectural contest from 1996. In this case, again, the project was conducted with use of no external means.

Town	Population		Spatial features		Change of development strategy		Most important project in public spaces		
	In 2011	Change 1995-2011 (%)	Part of larger agglomeration	Historic centre	Economic base before 1989 (state driven)	Current strategy	Pre-accesio	2004-2006	2007-2013

Tab. 3. Characteristics of medium-sized towns in the Pomorskie Voivodeship. Source: Own study on the basis of Local Data Bank, local strategic documents and intervievs (2012).

As it was already mentioned, during the period 2004-2006, it was possible to finance integrated revitalization projects in degraded areas, selected within the URBAN Initiative methodology. Within the probed group of towns, only Chojnice managed to execute the project of transformation of a hospital, located in the town centre, into a culture-and-social complex. Ustka managed to execute the first stage of its revitalization program within 'restructuring areas' action. Tczew currently faces the consequences of restructuring railway infrastructure. It managed to create Exhibition and Regional Centre for lower Vistula river and created recreational space along the river banks. Thus a gap of lost identity of this railway town was filled with the new clear image of a river town.

In the years 2007-2013 the biggest urban space renovation projects were to be financed through 'comprehensive revitalisation projects'section of the Pomorskie ROP – combining infrastructural, social and economic objectives for towns exceeding 35 thousand inhabitants. Contrary to the URBAN Initiative, a high culture value was not among the priorities of this program. However, beneficiaries residing in the territories meeting the criteria of "degraded areas" opted for those projects which played a key role for the town's identity. An important element of almost all the projects submitted to financing within this program was to elevate public spaces located in historic centers (Słupsk, Tczew, Starogard Gdański, Wejherowo, Lębork). An example was Rumia, which planned to create a completely new town centre based on few remaining historic relics of an old Kashubian village.[5] Interestingly, the regional leader, Sopot, did not decide to take part in this contest. It does not mean that it stopped procuring means for its revitalization program; numerous smaller projects were successfully implemented from the means dedicated to improving tourism attractiveness. A similar procedure took place in Malbork and Chojnice. Smaller towns from this group were willing to take advantage of the simplified procedures on shaping so-called "local basic infrastructure". Thanks to this kind of support, public spaces in Kościerzyna, Bytów, Puck and Nowy Dwór Gdański were renovated and upgraded. All those projects are to elevate the tourism features of those places. Nowy Dwór Gdański also adapted the 19th century dairy into Żuławski Historic Park,[6] a transformation that was not only to increase the general attractiveness of the place but also to shape common identity in the town dominated by immigrants. Miastko had its historic park renovated and Reda created a new park in the central part of the town, with a plan to create a green center for the town which it never had in the past. Ustka has been investing in its spa image for years. Sztum and Człuchów, which have Teutonic castles located in the centers, carried out projects on public space, within a tourism propagation section.

Several different models of support have been available for medium-sized towns in the Pomorskie Voivodeship so far. During the last period of the program, there were two models divided by the demarcation line of population size (complex revitalization and basic infrastructure development) and one optional model available to all communes (tourism propagation). Despite the fact that the EU policy shows increased expectations concerning public space renovation in the context of social problems solution, town authorities in medium-sized towns in Pomorskie region seem to combine those processes with the strengthening of their competitive position, attracting more tourists and new inhabitants. This is confirmed by the majority of projects financed from their own means as well as certain moderation when it comes to procuring funds for comprehensive revitalization programs.

5   CONCLUSION AND OUTLOOK

Assessing the significance of the quality of public space in medium-sized towns from the European perspective, we should emphasize that the current strategy Europe 2020 promotes inclusive growth and sustainable growth, as opposed to the Lisbon Agenda that promoted improving competitiveness of the European economy in relation to the largest economies of the world. Therefore, we may assume that the role of translocal centers providing access to services and social integration opportunities will continue to grow.

The policy of the Polish state as it has been expressed recently – to a large extent an adaptation of the European policy to the Polish conditions – lets us expect another seven more active years of investing in the space of small and medium-sized towns. In the present economic situation the government is departing from the previously promoted policy of focusing on development through metropolises, as the largest urban centers can more easily depend on private capital. The National Development Strategy 2020 adopted in September 2012 emphasizes among its objectives "creating conditions for the development of regional, sub-regional and local centers and for strengthening the potential of rural areas".

The EU policy for the future programming period, too, seems conducive to the development of a "local Poland". By the decision of the European Council of February 2013, Poland is to remain the largest beneficiary of the cohesion policy in the 2014-2020 period – despite the overall cuts – receiving EUR 72.9 billion for the purpose, up 6 per cent from the budgetary period of 2007-2013. In the time of the crisis and falling prices for construction services, it indicates an opportunity of a larger number of viable projects.

---

[5] This project did not obtain financing as it was decided that the proposed solutions do not significantly contribute to social and economic problems issues.
[6] Żuławy is a cultural micro region located in the Vistula delta.

What is more, the concentration principle was introduced saying that a minimum of 5 per cent of funds in the Europea Regional Development Fund is to be used for sustainable growth of urban areas. In the context of the above-mentioned plans of Poland we may expect that the small and medium-sized towns will participate generously in this amount.

However, the open question is whether or not the quality of the public space remains an attractive instrument for achieving development objectives defined this way. The inclination to invest in public-access spaces – by nature not generating any profit – may be largely subject to the following issues: difficulty in providing own contribution to particular projects, communal debt[7] and availability of non-repayable grants related to the predicted larger contribution of repayable assistance (JESSICA, above all) in the cohesion policy. In effect of the change in the paradigms of development we should expect departure from supporting projects related to tourism or other "leisure industries" to the benefit of community-building projects. However, in this case we should expect a growing importance of the so-called "soft projects".

The experience of the Pomorskie Voivodeship shows that the most spectacular projects of transforming the existing or shaping new public spaces were carried out without assistance from EU funds. The cause of this situation lies in the wide time span of the investment and its character reaching beyond the framework of support defined in seven-year programming periods. And so the optimal way for development may be to keep the quality of the public space infrastructure in the hands of self-governments as own tasks, shifting efforts to supporting social functions that make it possible to take the best advantage of the transformed landscape.

Nuove strategie sociali, economiche, urbane e architettoniche per il social housing

Flavio Mangione

(Arch. Flavio Mangione, Comitato Tecnico Scientifico Casa dell'Architettura di Roma, Via Santa Croce in Gerusalemme 75, 00185 Roma, flaviomangione@libero.it)

1 ABSTRACT

La questione dell'alloggio popolare diventa particolarmente complessa quando è costretta ad occuparsi sia di fascie sociali con gravi disagi, sia di famiglie con un reddito leggermente superiore a quello stabilito per avere diritto all'alloggio, ma nello stesso momento non sufficiente per confrontarsi con gli affitti dettati dal libero mercato. Un nuovo approccio alla questione del Social Housing riparte da una rilettura critica della questione esistenziale di una fascia di popolazione che non ha lavoro, lo ha perso e non riesce a reimpiegarsi, non riesce a socializzare o quanto meno non riesce a sentirsi parte di una comunità dove sia possibile crescere e migliorare la propria condizione economica, culturale e umana. Si tratta in pratica di lavorare sull'idea di trasformare il 'tempo lavoro' in 'valore denaro' utilizzabile per il reinserimento sociale. Il futuro del Social Housing dovrà attuarsi attraverso l'occupazione lavorativa che in ambito commerciale si chiama 'ripresa dei lavori effettuati'. Se una cittadinanza risana, con una opportuna e necessaria manutenzione, i propri alloggi e il verde in cui vive, migliorando la qualità della vita e dello spazio urbano "questo deve essere riconosciuto". La questione estetica e formale dell'architettura dovrà essere rifondata, quindi, su nuovi parametri di ordine sociale. Una delle esperienze più interessanti in tal senso è il lavoro di Patrick Bouchain in Francia. Altre realtà in Italia si stanno adeguendo, con fatica, a questa nuova strategia insediativa che sembra l'unica seriamente perseguibile per scardinare un sistema sclerotizzato e speculativo.

2 NUOVE STRATEGIE SOCIALI, ECONOMICHE, URBANE E ARCHITETTONICHE PER IL SOCIAL HOUSING

In Italia, come in molti altri Paesi europei, la questione dell'alloggio popolare diventa particolarmente complessa quando è costretta a interessarsi di una fascia sociale veramente povera, o posta ai margini della società, che arriva a non essere categorizzabile perché non possiede documenti o i requisiti minimi per rientrare in liste di attesa normate dallo Stato.

Paradossalmente esiste un'altra fascia sociale che ha dei punti in comune con la precedente. Esistono delle famiglie con un reddito leggermente superiore a quello stabilito per avere diritto all'alloggio sociale ma nello stesso momento non sufficiente per confrontarsi con gli affitti dettati dal libero mercato. Nonostante la situazione francese non sia grave come quella italiana esiste un serio problema nel soddisfare le richieste di queste due classi sociali che sembrano diventare sempre più numerose. Patrick Bouchain in Francia, occupandosi principalmente di chi ha una condizione estremamente disagiata, parte da una rilettura critica della società contemporanea per proporre un nuovo approccio alla questione dell'alloggio popolare. Non si tratta di realizzare fisicamente quattro mura per dare protezione a chi ne ha bisogno ma risolvere un problema più ampio che ha a che fare con la questione esistenziale di una fascia di popolazione che non ha lavoro, lo ha perso e non riesce a reimpiegarsi, non riesce a socializzare o quanto meno non riesce a sentirsi parte di una comunità dove sia possibile crescere e migliorare la propria condizione economica, culturale e umana. Sostanzialmente si ripropone l'idea di una 'autocostruzione' che non sia nostalgica della situazione postbellica o di quella utopica degli anni '70 ma che tenga conto di una realtà sociale che non troverà mai il pieno impiego. Non solo, in alcune aree la disoccupazione raggiunge livelli di allarme sociale, ma sono sempre di più quelle persone che perdono il posto di lavoro e non riescono a trovare una nuova occupazione. Oltre a questo punto di osservazione ve n'è un altro che si occupa del recupero dei materiale generati dalle discariche e di realizzare dei componenti costruttivi che siano trasformabili e reimpiegabili ciclicamente.

Inoltre si ha anche l'idea di trasformare il 'tempo lavoro' in 'valore denaro' utilizzabile per il reinserimento sociale. Tutte le esperienza nate da questo programma, sia in Francia, sia in altre parti del mondo, sono state ideate e realizzate senza l'intervento della politica, proprio alla quale vogliono dimostrare che questa non può risolvere tutto.

La prima tappa per questi alloggi sociali 'un po' differenti' risiede nell'accordo con il sindaco nel considerare che questa operazione sia indispensabile. A oggi sono stati realizzati quattro insediamenti nelle città di Tourcoing (2009-2011 Le Grand Ensemble à Tourcoing : Réhabilitations et habitations neuves – Zac

de l'Union), Boulogne (Le Grand Ensemble à Boulogne: Réhabilitations de 60 maisons locative avec les habitants), Beaumont en Ardèche (2010-2011 Le Grand Ensemble à Beaumont en Ardèche : Etude pour la Construction de 8 maisons en accession) e Marsiglia (Le Grand Ensemble à Marseille : Etude pour la réalisation de Logements collectifs – Friche de la belle de mai).

Si tratta di tre contesti completamente differenti con particolari situazioni da adattare ai vari siti. Inoltre si sottolinea che questi lavori devono essere svolti nella tranquillità e nell'urgenza. Si deve avere il tempo di collaborare con più ambiti disciplinari. Nell'università che potrebbe attivarsi e contribuire in ogni luogo dove è presente una facoltà e dove s'istituisce un nuovo centro di autocostruzione. Negli istituti tecnici di formazione professionale e di reinserimento. Gli studenti di architettura potrebbero partecipare sotto forma di specializzazione o formazione durante il corso degli studi, ma anche come stage per l'esame di Stato. Insomma, una collaborazione su più fronti che possa innescare un circolo virtuoso utile a tutti i soggetti che intendono partecipare. Si collabora con dei piccoli uffici HLM secondo i casi, o dei promotori filantropici che vogliono condurre questa esperienza di costruzione a costo ridotto nella speranza di trovare il modo di creare degli affitti sempre più bassi. Per il terreno di Marsiglia è stata realizzata una società cooperativa di produzione (SCOP) con l'intento di creare una società di interesse collettivo (SCIC) di cui Patrick Bouchain è il presidente e il direttore generale.

Nella Friche (terreno abbandonato – zona industriale dismessa) La belle de Mai a Marsiglia, ottenuto con 45 anni di battaglie, gli abitanti possiedono un terreno due volte più grande rispetto alle loro necessità. Patrick Bouchain gli ha proposto allora di diventare azionisti della SCIC e anche agenti culturali aprendo il loro terreno alla realizzazione di alloggi sociali, favorendo la mixité sociale, economica e culturale. Ogni inserimento di alloggi sociali dovrà essere un intervento di natura contestuale e non globalizzante. Infine uno dei punti chiave prevede cha ogni persona che ha vissuto in uno di questi alloggi apportando delle migliorie sia nell'abitazione che nell'urbano di pertinenza gli debba essere riconosciuta la possibilità di alloggiare i propri cari anziani. In un affitto commerciale questo si chiama la 'ripresa dei lavori effettuati'. Se una cittadinanza migliora i propri alloggi con manutenzione all'occorrenza, con una migliore qualità della vita e dello spazio urbano, con una migliore organizzazione questo deve essere riconosciuto. In pratica l'architettura e la sua costruzione devono passare attraverso l'occupazione lavorativa. L'architetto sarà una figura professionale altamente qualificata che affiancherà il cittadino nei sistemi di co-generazione della città. Un crescente e libero accesso ai sistemi informativi globalizzati, ai nuovi sistemi crossmediali, aiuterà a raggiungere una più equa compensazione economica, fiscale, legislativa e tecnica; aiuterà la formazione di una coscienza abitativa più efficiente, una coscienza urbana che porterà alla realizzazione di nuove smart cities dal basso, dal fondo di una condizione umana e sociale non più sostenibile.

3 CONCLUSION

Argomento incontestabile di speculazione, e unico affare per gli specialisti, l'atto di costruire la città non implica mai i primi soggetti: i suoi abitanti. Quelli a cui l'habitat è destinato sono esclusi dal processo che lo genera. Passivi, subiscono il loro alloggio come una fatalità. Partendo da questa constatazione allarmante sono in atto diversi studi per reinventare la produzione e la gestione dell'habitat sociale, una nuova riflessione sull'azzeramento di una gran parte delle norme e delle abitudini che frenano oggi una crescita sostenibile della città. Riattualizzare le norme e i metodi per renderle compatibili con la società e con l'ambiente è diventato ormai un obiettivo prioritario. Coinvolgere l'abitante nella realizzazione e nella gestione del suo luogo di vita significa ridefinire lo spazio abitativo e nello stesso tempo reinventare lo spazio pubblico. L'habitat e la sua costruzione possono ridiventare la matrice di un nuovo civismo, di un nuovo esercizio della democrazia. Si tratta di reinventare la responsabilità collettiva grazie alla costruzione dell'habitat e di riconsiderare una maniera superata e improduttica di generale gli spazi in cui l'uomo vive.

1 ABSTRACT

Der Beitrag beschäftigt sich mit der Erstellung von Landbedeckungsklassifikationen aus sehr hochauflösenden, digitalen ULTRACAM Luftbilddaten aus den Jahren 2007 und 2011 für das Stadtgebiet von Graz (Österreich). Am Beginn dieser Arbeit steht ein Überblick über die in der Literatur dokumentierten Forschungsarbeiten, welche sich mit thematisch ähnlichen Fragstellungen, oder ähnlichem Datenmaterial beschäftigen. Danach werden die verwendeten Datengrundlagen, die Datenvorverarbeitung, sowie das Untersuchungsgebiet kurz beschrieben. Der zentrale Teil der Arbeit dokumentiert die praktische Umsetzung der Landbedeckungsklassifikation von Graz in unterschiedlichen Ausarbeitungsstufen und zu zwei unterschiedlichen Befliegungsterminen (2007 und 2011). Zentraler Teil der vorgestellten Projektarbeit ist die Erstellung der Regelsätze der objektbasierten Klassifikation und der Umgang mit datenbezogenen Problemen wie etwa der abgeschatteten Bildareale in den Bilddaten von 2007. Die Legende bzw. die Landbedeckungsklassen wurden in Zusammenarbeit mit der Abteilung für Grünraum und Gewässer der Stadt Graz und dem Referat für Photogrammetrie des Vermessungsamtes Graz erarbeitet. Ziel war es hier, Planungsgrundlagen für die Stadtplanung und Stadtentwicklung bzw. für die Abteilung für Grünraum und Gewässer der Stadtverwaltung Graz zu generieren. Anhand von Testgebieten, die die unterschiedlichen Stadtstrukturen repräsentieren, wurden die Regelwerke entwickelt und getestet. Ferner wurden die Klassifikationsergebnisse unter Einbindung der jeweiligen Höhenmodelle (LiDAR und Photogrammetrie) miteinander verglichen. Das Ziel dieses Arbeitsschrittes war es, ein möglichst repräsentatives Regelwerk für die gesamte Stadt Graz zu entwickeln. Die generierten Regelwerke wurden in einem weiteren Schritt für das gesamte Stadtgebiet von Graz an den Luftbilddaten von 2007 umgesetzt und anschließend evaluiert. Es zeigte sich, dass für eine flächenhafte Umsetzung nur geringe Adaptierungen notwendig waren. Durch die in dieser Arbeit untersuchte Möglichkeit der Höhenabstufung der Vegetation allgemein und im Speziellen der Waldklasse wird u.a. eine neue Betrachtungsweise der Waldgebiete der Stadt Graz ermöglicht. Besonders durch die Repräsentation von annähernden Einzelbaumsegmenten ist diese Darstellung als sehr realitätsnahe zu bezeichnen. Dieser Themenbereich wurde im Rahmen dieser Arbeit auch mit separaten Einzelkarten dargestellt, um die Interpretierbarkeit zu erhöhen. Im letzten Teil der Arbeiten wurde das Gesamtregelwerk auf die Luftbilddaten 2011 angewandt. Durch den unterschiedlichen Aufnahmezeitpunkt (September und Juni) bzw. durch die unterschiedliche geometrische und radiometrische Auflösung der Daten ergaben sich neue Herausforderungen für die Klassifikation. Schließlich zielt das Gesamtprojekt auf die Entwicklung einer allgemein gültigen Auswertemethodik für zukünftige Befliegungsprojekte der Stadtvermessung Graz hin, um den Auswerteaufwand (Adaptierung der Regelwerke) möglichst niedrig zu halten und zu automatisieren. Den Abschluss der Arbeit bilden eine generelle Ergebnisdiskussion der erhaltenen Resultate, sowie ein Ausblick über weitere Analyse- und Verwendungsmöglichkeiten der gesammelten Erkenntnisse und eine Beschreibung der zur Anwendung gebrachten „best of" Methode.

2 EINLEITUNG UND PROBLEMSTELLUNG

Für unterschiedlichste Aufgabenszenarien der Stadtplanung im Bereich der fernerkundungsgestützten Analyse stehen eine Vielzahl an Sensoren und Aufnahmeplattformen zur Verfügung. Die stetige Entwicklung von neuen Sensoren und der damit verbundenen Steigerung der geometrischen, spektralen, radiometrischen und multitemporalen Auflösungsqualität erfordern im Laufe der Zeit auch die Entwicklung neuer Analysemethoden (WENG 2012, PATINO and DUQUE 2013). Die kombinierte Nutzung von Höheninformation und optischen Daten stellt auch bei der Generierung von Landbedeckungsklassifikationen eine praktikable Herangehensweise dar. Durch die fortschreitende Steigerung der Verfügbarkeit von sehr hochauflösenden und multispektralen Daten, wie auch von LiDAR Daten, ist ein Trend in Richtung dieser Kombination durchaus feststellbar.

Die Fragestellung dieser Arbeit lautet, in wie weit die Integration von Höheninformation in den Vorgang der objektbasierten Klassifizierung zu einer Verbesserung der Genauigkeit führt und ob durch diese zusätzliche Informationsquelle auch weitere neue Klassen über s.g. Höhenfeatures stabil abgeleitet werden können. Die Hypothese besteht darin, hochauflösende ULTRACAM Bilder mit zweierlei Höheninformation zu fusionieren, um so neue Informationen und Klassen zu generieren. Erreicht werden sollen hochgenaue Klassifikationsergebnisse bzw. Klassen unter Einbindung der Höheninformation. Außerdem soll die Auswirkung der Einbindung verschiedener Höheninformationsquellen auf die Klassifikation qualitativ beschrieben werden. Ebenfalls ein Ziel dieser Arbeit ist die Erstellung von Regelsätzen an nur drei Testgebieten innerhalb der Stadt Graz, die dann für das gesamte Stadtgebiet angewandt werden sollen. Darauf aufbauend zielt das Projekt auf eine umfassende, wiederholbare „Best of" Methodik für eine Landbedeckungsklassifikation des Grazer Stadtgebietes ab. Die Ergebnisse werden von verschiedenen Ämtern des Magistrats Graz in ihre Planungsprozesse eingebunden.

Die hier vorgestellten Arbeiten sind Teil eines langfristigen Kooperationsprojektes (seit 2004) mit der Stadt Graz bzw. dem Amt der Steiermärkischen Landesregierung, bei dem Fragen des Stadtklimas bzw. der Stadtentwicklung laufend behandelt werden (LAZAR und PODESSER 2009, SULZER und KERN 2008 und 2009, SULZER et.al 2009).

3   DIE KOMBINATION VON LIDAR DATEN MIT OPTISCHEN FERNERKUNDUNGSBILD-DATEN

Die Erfassung von flächendeckenden LiDAR Daten wird von vielen regionalen und überregionalen Verwaltungsorganen durchgeführt. Die so erstellten hochauflösenden Höhenmodelle der LiDAR Befliegungen werden mit optischen Fernerkundungsbilddaten (flugzeug- und satellitengestützt) kombiniert und für unterschiedlichste Fragestellungen analysiert.

Eine in der Literatur sehr häufig dokumentierte Kombination von LiDAR mit optischen Daten ist jene der Ableitung von forstlichen Parametern. Besondere Beachtung wird dabei auf die Klassifizierung von verschiedenen Baumspezies auf Einzelbaumniveau geschenkt. Diese Anwendungen basieren häufig auf der Nutzung von hochauflösenden Luftbildkameras oder Zeilenscanner in Verbindung mit Digitalen Oberflächenmodellen (DOM's) (HIRSCHMUGL et al. 2007, WASER et al. 2010, CHEN et al. 2008, HALL et. al 2011). Die Verbindung von optischen Bilddaten mit 3D Daten erzielt in der Regel bessere Ergebnisse, als Anwendungen, welche eine solitäre Datenquelle verwenden (WASER et al. 2010, RAFIEYAN et al. 2009). Die Detektion von Einzelbäumen ist ein sehr komplexer Sachverhalt. Die Klassifikation verschiedener Spezies kann auf der Basis der Intensität der LiDAR Punkte (ORKA et al. 2007), mit Hilfe von Trainingsgebieten (RAFIEYAN et al. 2009) oder mit der statistischen Analyse der LiDAR Punktwolke (HOLLAUS et. al 2009, HÖFLE et al. 2012) selbst durchgeführt werden.

Ein weiteres Themenfeld, welches durch die Kombination von optischen Bilddaten mit 3D Daten bearbeitet werden kann, ist die Charakterisierung von Dachflächen. Diese, zur urbanen Fernerkundung zählende Anwendung, nutzt meist Hyperspektraldaten, um einen möglichst großen Teil des elektromagnetischen Spektrums zu nutzen. Unterschiedliche Dachmaterialien besitzen charakteristische Reflexionseigenschaften in bestimmten Bereichen des Spektrums und benötigen daher für derartige Analysen, Systeme mit einer enorm hohen spektralen Auflösung. Die LiDAR Daten ermöglichen in erster Linie eine geometrische Einteilung in unterschiedliche Dachtypen (LEMP und WEIDNER 2005). Eine der Hauptaufgaben liegt in der Auswahl der entsprechenden Kanäle, welche das zu klassifizierende Material bestmöglich charakterisieren. Am Beispiel des AVIRIS (Airborne Visible/Infrared Imaging Spektrometer) Systems, welches über 224 Kanäle verfügt (AVIRIS Homepage 2011), wird klar, dass das Vorhandensein von spektralen Kurven der Materialien für eine detaillierte Analyse notwendig ist. Aufgrund der hohen Veränderungsrate in urbanen Gebieten sind zudem Informationen über die Gebäudestruktur von zunehmendem Interesse (ALEXANDER et al. 2009, HEIDENA et al. 2012). Anwendungen, die solche Datengrundlagen benötigen, sind unter anderem Städteplanung und Städtedesign, Niederschlagsabflussmodellierungen, Telekommunikationsuntersuchungen, Lärmsimulationen, Mikro-klimauntersuchungen (ZHOU et al. 2009). Für die Durchführung solcher Analysen gehören die Derivate von Digitalen Oberflächenmodellen (DOM's), wie zum Beispiel die Gebäudehöhe, die Dachneigung sowie die Ausrichtung des Gebäudes (ALEXANDER et al. 2009, ZHOU and NEUMANN 2012). In diesem Zusammenhang muss auch die Erstellung von Solarkataster angeführt werden, bei der aus LiDAR bzw. aus

photogrammetrischen Oberflächenmodellen die Neigung sowie die Ausrichtungen der Dächer berechnet werden. Kombiniert mit der Modellierung des Sonnenverlaufes können so Klassen erstellt werden, welche die Effizienz von Dachflächen hinsichtlich ihrer Nutzung für Solarkollektoren beschreiben. Das Magistrat Graz hat in den letzten Jahren einen solchen Kataster erstellt (http://www.geoportal.graz.at/cms/ziel/4515589/DE/).

Auf eine korrekte Trennung und richtige Verwendung der Begriffe Landbedeckung und Landnutzung sollte vor allem bei der Zusammenarbeit mit Kunden und Projektpartner geachtet werden. Bei Projektpartnern, die in die Thematik der Fernerkundung und Geoinformatik nicht tief eingearbeitet sind, kann es oft und leicht zu Verwechslungen kommen. Dass diese Trennung innerhalb von Projekten nicht so leicht realisierbar ist, zeigt das Beispiel von Ackerflächen bzw. landwirtschaftlich genutzten Flächen. Denn stringent betrachtet dürfte diese Klasse eigentlich nicht existieren, da im Sinne einer Landbedeckungsklassifikation die potenziellen Flächen normalerweise entweder der Klasse „Grünfläche" oder der Klasse „Offener Boden" zugeordnet werden müsste. Trotzdem erscheinen Klassen wie zum Beispiel „Äcker" oder „landwirtschaftlich genutzte Flächen", in vielen Projekten bzw. in Forschungsberichten. Allgemein können Landbedeckungs-klassifikationen auf verschiedene Art und Weise erstellt werden:

- Pixelbasierte, solitäre Sensornutzung: Pixelbasierte Klassifikation des Datenbestandes, welche nur aus einem Fernerkundungssensor z.B. LANDSAT TM besteht.

- Pixelbasierte, integrative Datennutzung: Pixelbasierte Klassifikation des Datenbestandes, welche neben dem Primärsensor noch weitere Informationen wie z.B. die Exposition, die Hangneigung, oder die Geländehöhe nutzt.

- Objektbasierte, solitäre Sensornutzung: Objektbasierte Klassifikation des Datenbestandes, welche nur aus einem Fernerkundungssensor z.B. LANDSAT TM besteht.

- Objektbasierte, integrative Datennutzung: Objektbasierte Klassifikation des Datenbestandes, welche neben dem Primärsensor noch weitere Informationen wie z.B. die Exposition, die Hangneigung, oder die Geländehöhe nutzt (MUICK 2011).

In Anbetracht des thematischen Hintergrundes dieser Arbeit wird der Fokus nur auf die objektbasierte, integrative Datennutzung gerichtet. Ähnlich wie in den zuvor beschriebenen Ansätzen ist die kombinierte Nutzung von Höheninformation und optischen Bilddaten auch bei der Generierung von Landbedeckungsklassifikationen eine praktikable Herangehensweise.

Im Besonderen ist die Kombination von LiDAR Datensätzen mit QUICKBIRD oder IKONOS Daten ein in der Literatur weit verbreiteter Ansatz (ARROYO et al. 2009, CHEN et al. 2008, WUEST and ZHANG 2008, KE et. al 2010). Durch die fortschreitende Steigerung der Verfügbarkeit von sehr hochauflösenden multispektralen Daten, wie auch von LiDAR Daten, ist ein Trend in Richtung dieser Kombination durchaus feststellbar. Eine Vielzahl von jüngeren Anwendungen wurde mit einer objektbasierten Methode umgesetzt. Zum einen haben Vergleiche bewiesen, dass objektorientierte Ansätze besser geeignet sind, sehr hochauflösende Daten zu verarbeiten (ZHOU and TROY 2008), zum anderen ist die Integration von zusätzlichen Datenquellen und dem Expertenwissen des Bearbeiters deutlich einfacher.

4 DAS FALLBEISPIEL GRAZ

4.1 Das Untersuchungsgebiet

Das Untersuchungsgebiet der vorliegenden Arbeit ist im Wesentlichen begrenzt durch die Stadt Graz (ca. 128km2). Die steirische Landeshauptstadt Graz ist mit rund 270.000 Einwohnern die zweitgrößte Stadt von Österreich und liegt im nördlichen Teil des Grazer Feldes auf einer Seehöhe von 351m (Grazer Hauptplatz) und wird im Norden und Westen der Stadt vom Steirischen Randgebirge umschlossen (Fig. 1). Die höchste Erhebung der Stadt befindet sich hier mit 763m im Westen der Stadt auf dem Plabutsch mit steil abfallenden Hängen. Der Osten ist geprägt von hügeligen Ausläufern des Oststeirischen Riedellandes mit seinen lang gezogenen, sanften Hügeln und Rücken und zerschnittenen Tälern. Ein weiteres charakteristisches Merkmal ist das markante Durchbruchstal der Mur bei Weinzödl im Nordwesten der Stadt. Im Zentrum der Stadt bildet der Schlossberg mit 474m Seehöhe eine wichtige Landmarke, in Richtung Süden weitet sich das Grazer Feld.

Die Testgebiete sind räumlich so verteilt, dass alle Landnutzungsklassen der Stadt Graz bestmöglich erfasst werden bzw. repräsentative Regelsätze erstellt werden können. Im Bezirk Innere Stadt liegt Testgebiet (1), welches den urbanen, innerstädtischen Charakter repräsentiert. Testgebiet (2) liegt im Bezirk Mariatrost und stellt die Übergangszone zwischen der dicht verbauten Innenstadt zum lockerer verbauten Gebiet (hoher Grünflächenanteil mit geschlossenen Waldflächen) dar. Testgebiet (3), das sich den Bezirken Liebenau und Puntigam befindet, spiegelt den locker verbauten Typus wider, jedoch im Gegensatz zu Testgebiet (2) in Mariatrost, sind hier auch großflächige landwirtschaftliche Flächen eingestreut.
Fig. 1: Die Lage des Untersuchungsgebietes innerhalb der Steiermark (Österreich), die Bezirke der Stadt Graz und die Lage der Testgebiete (MUICK 2011)

4.2 Datengrundlagen

Die zentrale Datenbasis für die Landbedeckungsklassifikation besteht aus zwei ULTRACAM-X (SCHNEIDER und GRUBER 2008, GRUBER et. al 2009) Befliegungen (B, G, R und NIR) vom September 2007 (8 Bit) und Juni 2011 (16 Bit) mit einer (heruntergerechneten) geometrischen Auflösung von 25cm (die Originalbilddaten von 2011 besitzen 7cm Auflösung). Aus diesen Befliegungen wurden True Orthofotos sowie Digitale Oberflächenmodelle erstellt (BISCHOF 2011) und vom Magistrat Graz (Referat für Photogrammetrie des Vermessungsamtes) bereitgestellt. Ebenso kamen LiDAR Daten von 2009 im originalen „las Format" zum Einsatz. Die LiDAR Daten wurden vom Amt der Steiermärkischen Landesregierung in einer Auflösung von 0,25 Metern zur Verfügung gestellt.

Bei der Datenvorverarbeitung für die drei Testgebiete wurden aus den LAS Files die Layer Intensität, Returnnumber und ein DOM abgeleitet. Ferner wurde der NDVI aus den ULTRACAM Daten berechnet und auch NDSM's (LiDAR und ULTRACAM) wurden berechnet. Für die Anwendung auf das gesamte Stadtgebiet von Graz war es auf Grund der softwareseitigen Einschränkungen notwendig, einzelne Teilblöcke für die Klassifikationsberechnung zu erstellen.
Fig. 2: Die Datengrundlagen: INTENSITÄTSBILD (LiDAR) – ULTRACAM – DGM – NDSM (von links nach rechts).

4.3 Methodik

Für die Umsetzung der Landbedeckungsklassifikation wurde ein objektbasierter Klassifikationsansatz gewählt. Wie im vorigen Kapitel erwähnt, sind gerade objektbasierte Ansätze bei sehr hochauflösenden Daten und der Integration komplexen Datenstrukturen im Vorteil (ZHOU et al. 2008, BLASCHKE et. al 2008, BLASCHKE 2010). Die Erstellung der Legende (Fig. 3) erfolgte in enger Zusammenarbeit mit der Abteilung für Grünraum und Gewässer der Stadt Graz und dem Referat für Photogrammetrie des Vermessungsamtes Graz, um so eine optimale Folgenutzung der Ergebnisse zu gewährleisten.

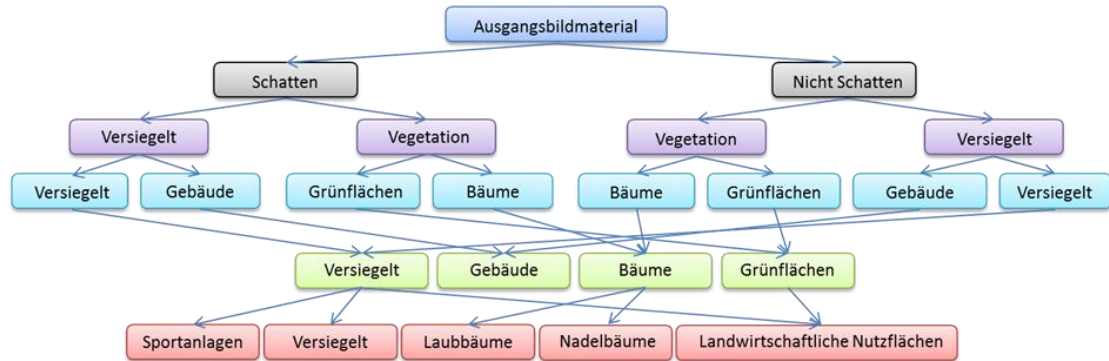
Legende: Grünflächen, versiegelte Flächen, Laub- und Nadelbäume, Strauchschicht, Gebäude, Gewässer, Sportanlagen und landwirtschaftliche Nutzflächen. Die Erstellung der Regelsätze basierte auf drei repräsentativen Testgebieten, welche über sämtliche städtische Nutzungscharakteristika verfügten. Für die erste Segmentierung kam eine Multiresolution Segmentierung zum Einsatz. An dieser Stelle sei erwähnt, dass die durch direkte Einbindung des NDVI bereits in der Segmentierungsphase zusammen mit der spektralen Information und dem photogrammetrischen ULTRACAM NDSM gute Ergebnisse erzielt werden konnten.


Fig. 3: Prozessierungskette für die Klassifizierung der ULTRACAM Daten (MUICK 2011).

Ein großes Problemfeld stellen abgeschattete Flächen in urbanen Gebieten dar. Gerade in Altstadtkernen mit sehr engen Gassen und Innenhöfen sind Schatten meist durch Gebäude induziert. In den Übergangszonen vom städtischen zum ländlichen Verbauungstyp ist anteilig auch der Schattenwurf von mittlerer bis hoher Vegetation nicht zu unterschätzen. Eine besondere Herausforderung stellen aber die Innenhöfe dar, welche in einigen Fällen sogar komplett abgeschattet sind. Diese totale Abschattung kann auch durch moderne Verfahren der digitalen Bildverarbeitung und durch den Einsatz von höher radiometrisch auflösenden ULTRACAM Daten (2011 mit 16bit, reel mit 12bit) nicht zur Gänze kompensiert werden. Natürlich lassen sich Schattenbereiche aufhellen oder anpassen. Der Grad dieser Anpassung ist aber sehr stark vom Datenmaterial selbst abhängig. In den ULTRACAM Daten von 2007 (8bit) nehmen Schattenflächen einen Flächenanteil von ca. 30 % ein. Bei der Klassifikation von abgeschatteten Bereichen kommt es verstärkt zu Fehlzuweisungen. Die ausgewählte Methodik zielt darauf ab, zuerst die Schattenflächen anhand ihrer „Brightness" innerhalb eines hierarchischen Algorithmus zu klassifizieren. Durch diese Vorgangsweise eröffnet sich die Möglichkeit, differenzierte Klassifikationsalgorithmen einzusetzen. Im Anschluss wurden die jeweiligen Schatten- und Nichtschattenklassen wieder zusammengeführt, um die klassifizierten Features wie z.B. Gebäude anhand ihrer Proportionen (aera, lenght to with, rel. border usw.) noch besser zuweisen zu können. Diese Methodik wurde bereits von ZHOU et al. (2009) im Vergleich mit zwei weiters angeführten Schattenkorrekturmethoden erprobt und lieferte sehr gute Ergebnisse.

Bei der Erstellung der Regelsätze wurden auch auf die sensorgeometrischen Eigenschaften des Datensatzes Rücksicht genommen. Die LiDAR Daten waren insbesonders in stark abgeschatteten Bereichen eingebunden, in denen eine Klassenzuweisung nur basierend auf 8bit ULTRACAM Daten (2007) zu große Fehler produziert hatte. Hier bot der Einsatz der „Intensität" eine wertvolle zusätzliche Entscheidungshilfe. Die Detektion von Einzelbäumen stellt eine komplexe Herausforderung bei der Klassifikation dar. Die Lösung zielt darauf ab, zuerst potenzielle Baumspitzen (seeds) zu finden, aus welchen dann Segmente wachsen sollen (CHEN et al. 2008, HIRSCHMUGL et al. 2007). Für das Auffinden der seeds werden meist „lokale Maximum Filterverfahren" verwendet. Die Erfolgsquote hängt zum einen von den Filterparametern ab und zum anderen auch von der Kronendachstruktur, dem Abstand der Bäume und vom Datenmaterial. Diese Herangehensweise wurde im Rahmen dieser Arbeit leicht adaptiert durchgeführt. Der erste Schritt lag in der Detektion von Schattenflächen innerhalb der Waldklasse. So konnte für die abgeschatteten Bereiche das LiDAR NDSM zum Einsatz kommen. Das Auffinden der lokalen Maxima wurde zweistufig durchgeführt. Nach einer Reihe von verschiedenen Parametertests des Maximum Filters wurden nun die Basis seeds klassifiziert. Darauf aufbauend erfolgte eine Plausibilitätsprüfung der Maxima anhand ihrer Distanz zueinander und zu anderen Klassen. Dadurch konnte die Qualität der seeds weiter verbessert werden. Grundsätzlich ist an dieser Stelle festzuhalten, dass besonders geschlossene Kronendächer in Laubwäldern, aufgrund ihrer im Vergleich zu Nadelwäldern eher ebenmäßiger Oberflächenbeschaffenheit, Probleme beim

Auffinden der lokalen Maxima bereiten. Da eine Ableitung forstlicher Parameter von Einzelbäumen nicht das Ziel dieser Arbeit darstellte, sondern eine möglichst realitätsnahe Darstellung von Laub- und Nadelwäldern sowie eine Einteilung der Waldklasse in Höhenstufen, ist der verwendete Ansatz als äußerst erfolgreich zu bewerten. Die Aufteilung der Waldklasse erfolgte mehrstufig. Dabei kamen Werte des NIR, der Intensität und Formparameter zum Einsatz. Lediglich für sehr stark abgeschattete Waldgebiete konnte auf Grund der fehlenden spektralen Informationen keine weitere Aufteilung der Waldklasse erfolgen.

Die Kombination der spektralen Informationen mit Ratiobildungen wie dem NDVI sowie der Einsatz von Höheninformation und Intensitätswerten ermöglichte eine Entwicklung dreier sehr gut angepasster Regelsätze. Für die Anwendung auf das gesamte Stadtgebiet ist natürlich eine Fusionierung und Adaption der Regelsätze notwendig. Im Rahmen dieser Fusionierung wurde deutlich, dass der Regelsatz des urbanen Testgebiets den mit Abstand geringsten Einfluss auf das resultierende Regelwerk hatte. Auf dieser Basis wurden sämtliche Bildblöcke prozessiert, einer minimalen manuellen Korrektur unterzogen und im Anschluss mosaikiert.

Fig. 4: Das unterschiedliche Auftreten von Schatten 2007 (links) und 2011 (rechts).

Für die Erstellung der Landbedeckungsklassifikation 2011 konnten bereits einige Erfahrungswerte der Klassifizierung der 2007er Daten in der Datenaufnahme umgesetzt werden. So wurden die ULTRACAM Daten mit 16 bit an das Referat für Photogrammetrie des Vermessungsamtes Graz geliefert, und auch der Befliegungszeitpunkt wurde auf Juni verschoben. Daraus resultierten im Besonderen zwei Vorteile: Die nun kleineren Schattenflächen (Fig. 4) konnten ohne die zusätzlich Nutzung der Intensitätswerte sehr gut klassifiziert werden und auch die spektralen Unterschiede innerhalb der Waldklassen wurden so deutlich gesteigert, sodass hier auf die Einbindung von Zusatzinformation verzichtet werden konnte. Auf Grund der Steigerung der radiometrischen Auflösung auf 16 bit und der damit einhergehende Verzicht auf die Nutzung der Intensität und des LiDAR NDSM's mussten einige Teilbereiche des Regelwerkes abgeändert werden. Von diesen Änderungen waren vorrangig sämtliche Schwellwerte der Schatten- und die Baumklassifikation betroffen.

5 ERGEBNISDISKUSSION UND AUSBLICK

Die Ergebnisse der vorliegenden Arbeit zeigen deutlich, dass die Erstellung von Regelsätzen für die Klassifikation des gesamten Stadtgebietes (Fig. 5) anhand repräsentativer Testgebiete möglich ist (Fig. 6 und Fig. 7). Diese Einschätzung basiert auf den Ergebnissen von qualitativen und quantitativen Genauigkeitsuntersuchungen. Für die quantitative Abschätzung der Ergebnisse kam für beide Zeitpunkte eine Fehlermatrix zum Einsatz. Diese ergaben eine Gesamtgenauigkeit von 92,3 % für das Klassifikationsergebnis 2007 und 94,0 % für 2011. Die höchste Fehleranfälligkeit wiesen die Klassen Nadelbäume und Laubbäume auf, welche bei beiden Zeitpunkten eine Genauigkeit um 84 – 87 % erreichten. Damit liegt das Ergebnis quantitativ im Vergleich mit CHEN et al. 2008 oder ARROYO et al. 2009 auf einem sehr ähnlichen Niveau. Dennoch ist ein quantitativer Vergleich auf Grund der unterschiedlichen Datengrundlagen als wenig sinnvoll zu bezeichnen. Ein qualitatives Indiz, welches sich auch auf der quantitativen Ebene wiederspiegelt, ist der geringere Anteil der Schattenflächen in den Daten von 2011. Durch den vier Monate früheren Befliegungszeitpunkt konnte der Anteil der Schattenflächen in etwa halbiert werden (ca. 15 % statt 30 %, Fig.4). Aufgrund der Reduktion der Anzahl der Inputlayer und die Weiterentwicklung der verwendeten Software war es darüber hinaus möglich, die Schattenflächen 2011 noch feiner zu segmentieren als dies 2007 möglich war. Diese Methodik der separaten, feineren Segmentierung von Problemstellen wurde ebenfalls für die Klasse der Gebäude verwendet. Diese Herangehensweise ermöglichte eine nochmalige Verbesserung des Klassifikationsergebnisses. Im Vergleich der NDSM's,

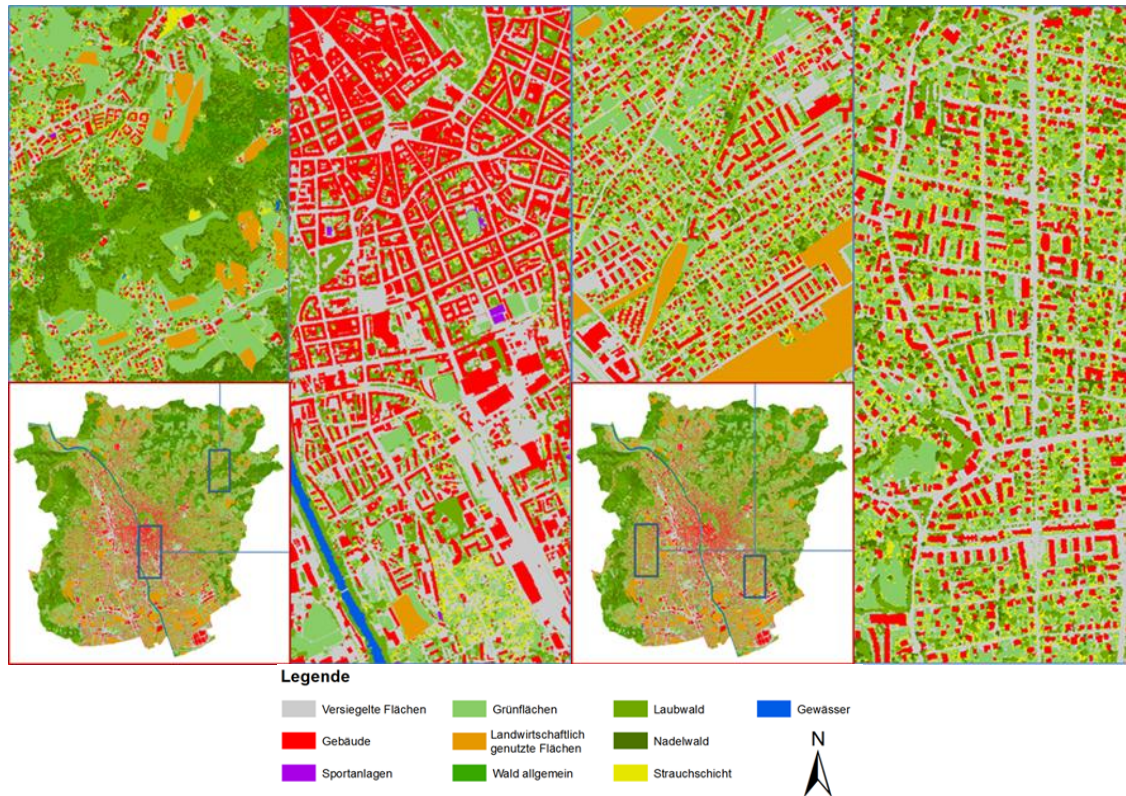
welche aus LiDAR Daten bzw. photogrammetrisch abgeleitet wurden, lässt sich festhalten, dass der Einsatz von photogrammetrischen NDSM's deutlich bessere Ergebnisse liefert. Dies lässt sich durch die unterschiedliche geometrische Auflösung der LiDAR Höheninformation zu den ULTRACAM Daten erklären. Denn im Besonderen die Lagerichtigkeit der Höheninformation hat entscheidenden Einfluss auf die Güte eines auf objektbasiertem Wege erstellten Klassifikationsergebnisses. Speziell bei der Klassifikation von Gebäuden tritt diese Bedingung zu Tage. Dies liegt vor allem in den Formparametern der Gebäude begründet, welche sich in urbaner Umgebung durch lange scharf abgegrenzte Kannten äußern.


Fig.5: Die Ergebnisse der Landnutzungsklassifikation für das Stadtgebiet von Graz 2007 (links) und 2011 (rechts).

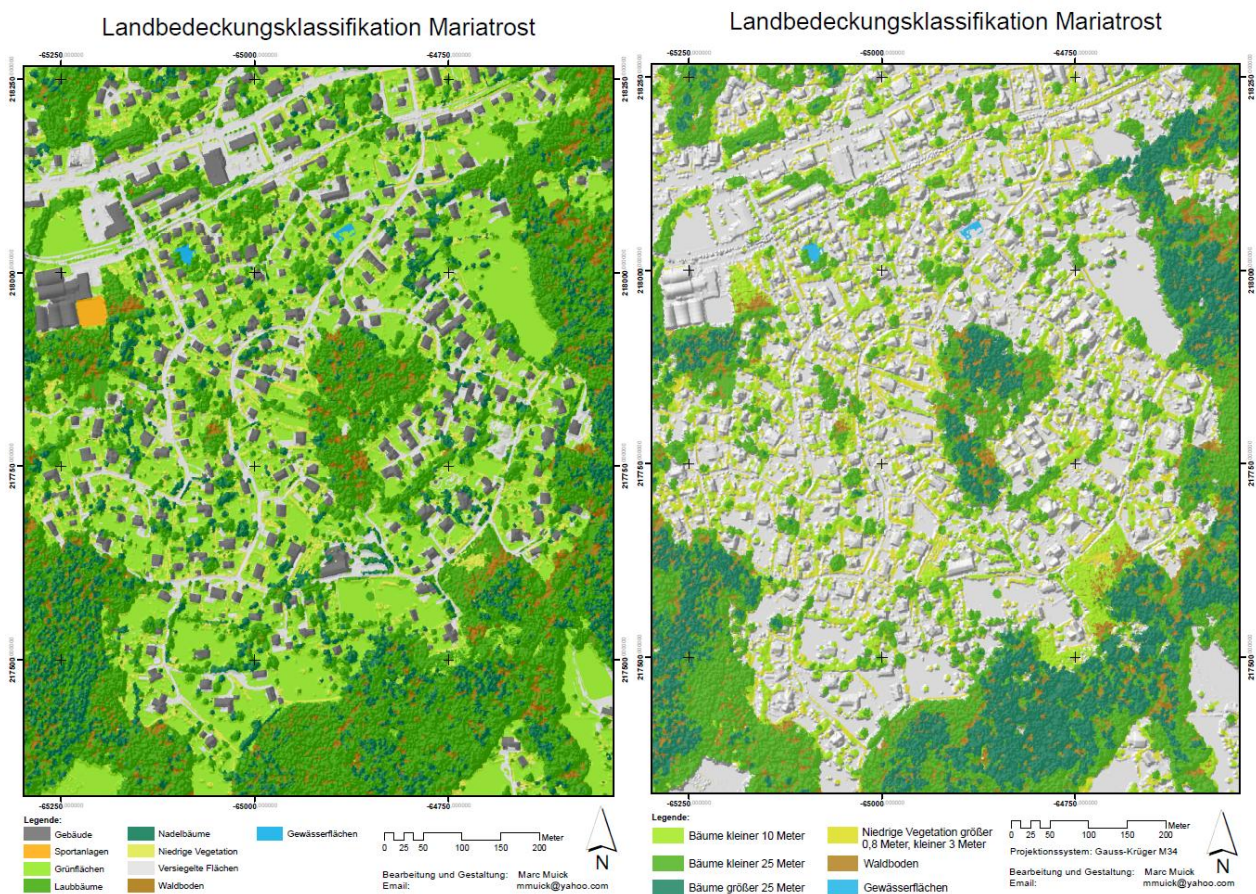
Die Ergebnisse dieser Arbeit verdeutlichen, dass durch die Integration von Oberflächenmodellen in den objektbasierten Klassifikationsvorgang eine Fülle von neuen Möglichkeiten entstehen. Zum einen können aufgrund der Höheninformation neue Klassen abgeleitet werden, die ohne diese zusätzliche Information nur sehr schwer oder gar nicht klassifizierbar wären. Weiters können aber auch Klassen, welche im Rahmen der Erstellung von Landbedeckungsklassifikationen bereits als Standard zu bezeichnen sind, schneller und genauer erfasst werden. Als Beispiel sei hier die Trennung von Wald- und Grünflächen angeführt. Diese werden im Normalfall über spektrale Merkmale oder Texturen klassifiziert. Mit der Nutzung der Oberflächenmodelle können diese Klassen einfach, schnell und korrekt klassifiziert werden. Die Zeitersparnis bei der Erstellung der Regelsätze durch die integrative Datennutzung ist deutlich feststellbar. Auch die Länge der Regelsätze lässt sich auf gleiche Weise reduzieren. Aber auch die Kombination der unterschiedlichen Oberflächenmodelle steigert die Qualität des Ergebnisses. Auf Grund der differenzierten Entstehungsweise der genutzten Oberflächenmodelle wurde versucht, die jeweiligen Stärken bestmöglich in den Klassifikationsvorgang einzubinden. Die größte Stärke des photogrammetrisch erzeugten Oberflächenmodelles liegt in seiner sehr guten geometrischen Übereinstimmung mit den ULTRACAM Daten, was besonders für den Vorgang der Segmentierung von Nutzen ist. Die Stärken der LiDAR Daten liegen zum einen im aktiven Aufnahmeprinzip, was sich besonders bei abgeschatteten Bildbereichen bemerkbar macht, und zum anderen in den vielen zusätzlichen Informationen, welche sich im LAS File verbergen. Dennoch ergeben sich nicht nur neue Möglichkeiten und Verbesserungen, sondern es treten bei der Nutzung der Oberflächenmodelle auch neue Schwierigkeiten bzw. Fehlerquellen auf. Die meisten Probleme resultierten aus Lagefehlern der Oberflächenmodelle.


Fig.6: Die Landnutzungsklassifikation (links) und Höhenabstufung der Vegetationsstruktur (rechts) im Testgebiet Mariatrost (MUICK 2011).
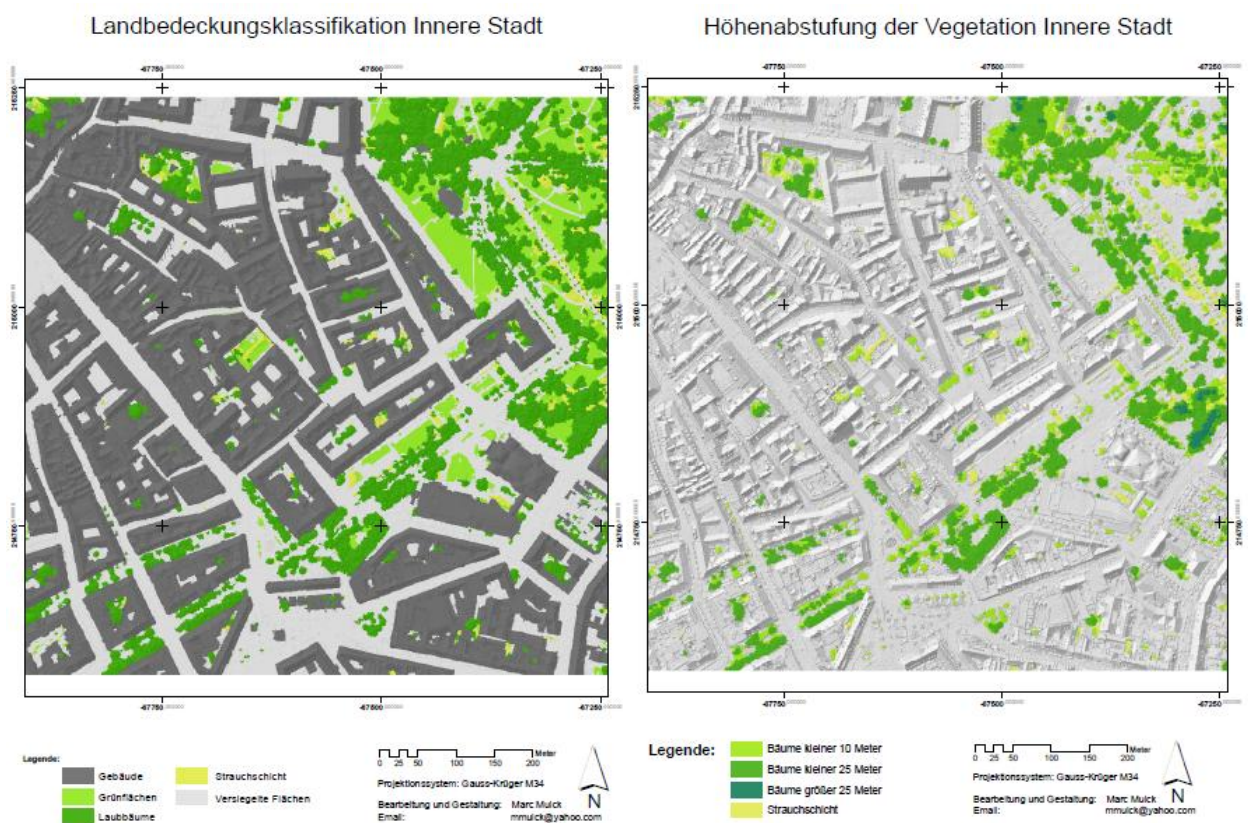

Fig.7: Die Landnutzungsklassifikation (links) und Höhenabstufung der Vegetationsstruktur (rechts) im Testgebiet Innere Stadt (MUICK 2011).

Für das Projekt LISA (Landinformationssystem für Österreich) spielen die geometrischen Vorgaben für die jeweiligen Klassen eine entscheidende Rolle. Während die MVU (minimum validation unit) jene Mindestobjektgröße spezifiziert, ab welcher die Qualitätskontrolle durchgeführt wird, wird durch die MMU (minimum mapping unit, Mindestkartiergröße) definiert, ab welcher Größe Objekte erfasst werden dürfen (WEICHSELBAUM et al. 2009; GRILLMAYER et al. 2010; STEINNOCHER et al. 2011). Da die Mindestkartierungsgröße für das LISA Projekt allgemein bei 25-50m2 liegt, ist die bei LISA angewandte Analysemethodik mit der hier vorgestellten Methodik nicht unmittelbar vergleichbar. Auch wenn für sämtliche Klassen in LISA Attributinformationen aufgenommen werden, wie zum Beispiel die Gebäudehöhe oder die durchschnittliche Höhe verholzter Flächen, so wird für Graz ein höhere räumliche Auflösung von 20-25cm angestrebt bzw. die Höheninformationen aus den photogrammetrischen Höhenmodellen bzw. aus den LiDAR Daten direkt eingebunden.

Fig. 8: Ergebnisausschnitt 2007 (links) und 2011 (rechts); grau: Landwirtschaftliche und versiegelte Flächen.

In einem Folgeprojekt werden die Datensätze der ULTRACAM Befliegungen von 2007 und 2011 mit Change Detection Verfahren für das Stadtgebiet von Graz analysiert (SALENTINIG 2012). Ziel ist es hier einerseits, verschiedene Verfahren auf ihre Güte und Anwendbarkeit zu untersuchen bzw. andererseits konkrete Bearbeitungsabläufe zu generieren, die bei zukünftigen Befliegungen angewandt werden können. Ein Ansatz bietet sich mit einem „Postklassifikationsansatz", bei dem die Ergebnisse zweier getrennt durchgeführter Klassifikationen auf Basis getrennt durchgeführter Klassifikationen der ULTRACAM Daten verglichen werden (Fig. 8). Der zweite Ansatz fokussiert alleinig auf die Erkennung von Änderungen in Ausdehnung, Nutzung und Höhe von Landnutzungsklassen.

(Mag. Doris Bistricky, OPK – Open planning collective for landscape, the arts, culture and pedagogy, Vienna)

1 ABSTRACT

The liberal reorientation of the Vienna governance structure in the 1990s also brought about a fundamental change in urban planning (cf. Novy et al., 2001) and in the housing policy. The involvement of private sector stakeholders caused a shift towards market considerations in the housing sector. Exploitation logics took precedence.

Ever since the 1920s, decent, affordable housing was provided in the tradition of public-funded, municipal housing schemes, owned by the city. At the outset, these traditional municipal residential buildings boasted of generous open spaces that played important social functions and were part of the supply and maintenance facilities in the buildings.

Upon reorganisation of the housing sector in Vienna, execution and planning processes were confronted with new challenges that are at the fault line between market and exploitation needs of private commercial stakeholders and quality requirements imposed by the public sector as the provider of funding. The research project 'freiWERT'[1] examined the role which open spaces play in the marketing and exploitation process of housing complexes and how a high quality of open spaces could be ensured in new housing developments.

The interdisciplinary team of landscape architecture of the Vienna University of Natural Resources and Life Sciences and urban sociology of the Vienna University of Technology analysed and evaluated the actual open space qualities of selected Viennese case studies from a design and socio-spatial perspective. These results were juxtaposed with the image generated in the course of the marketing process. Having regard to the decision-making processes in the planning and construction phases, it was possible to show the reasons for deviations and discrepancies.

The results permit us to draw the conclusion that the quality and the provision of open spaces as part of housing complexes are essential elements in the marketing of subsidised housing. However, in the further course of the process, this standing is significantly reduced by inadequate quality assurance and lacking prioritisation. The fact that open spaces in housing complexes only indirectly generate revenue is a relevant factor in the decision-making processes. Hence, measures for ensuring social and open-space related quality despite its limited ability to generate revenue have to be taken into account when carrying out construction projects and must be raised in the strategic-political debate and anchored in governance structures.

2 OPEN SPACES IN SOCIAL HOUSING PROJECTS IN VIENNA

2.1 Historical review

The exemplary social housing developments in Vienna are mostly associated with the achievements of the housing policies during the interwar period. 'Red Vienna' laid the foundations for the provision of social housing by means of a large-scale housing programme for the construction of 64,000 apartments in the period from 1919 to 1934. At that time, these major construction projects commissioned by the City also served to counteract the crisis in the construction industry (cf. Eigner, page 74 et seq.). The architecture department of the City of Vienna, the municipal construction authority, was soon not able to handle the ambitious construction programme by itself, and resorted to freelance architects (cf. Blau 1999, 147). One quarter of the buildings were planned by the city's own architects in the municipal construction authority; leading external architects were commissioned to design the remaining three quarters of the buildings (cf. Bernard 1999, 21). Numerous architects of these residential buildings were students of Otto Wagner (cf.

---

[1] Licka, L., Dlabaja, C., Grimm-Pretner, D, Papst, S., Rode, P., Witthöft, G. Wück, R.: FreiWERT – Examination of the quality and value of open spaces in inner-city new building projects and presentation of innovative solutions, financed as part of the House of the Future of the Federal Ministry for Transport, Innovation and Technology, Vienna 2012.

Krippner 2004), such as Karl Ehn, the author of the most famous example, the 'Karl-Marx-Hof". They were also responsible creating the open spaces of the complexes. In many cases, green courtyards were provided. In the 'New Vienna Building Regulations', which entered into force in 1930, a minimum light incidence was prescribed for the first time for living areas; this in turn required larger open spaces (cf. Weihsmann 2004, 128 et seqq.). In the professional debate about the proper concept and structure of the housing programme, ranging from proposals for residential settlements inspired by the English garden city movement and urban multi-storey flats, priority was eventually given to so-called "superblocks", in other words, large compact urban residential structures. Frequent urban residential solutions consisted of more or less closed perimeter blocks with garden courtyards. Their design was often fairly simple, functional and made do with limited resources. Open spaces served as playgrounds, for recreational purposes and as symbols of social progress (ibid.). The execution of the construction works, and most likely the landscaping of the open spaces in particular, was carried out by the municipal garden authority (cf. Kratochwjle 1931).

The construction density was generally lower than with contemporary residential developments. The built up area of the Karl Marx Hof, for example, accounts for 31 %. 'The total surface of the garden space as such amounts to 24,187 m².' (Kratochwjle 1931, 52). The floor space ratio was 1.35 (Kleindienst 1989, 10 et seq.). According to Viennese municipal policy, the green spaces and open spaces were generally an important aspect of the infrastructure provided for inhabitants (cf. Kratochwijle 1925). Hence, also in the case of 'The establishment of municipal housing complexes [...] consideration was given to hygienic living conditions and gardening requirements or requirements of urban landscaping. In the case of new buildings, as a rule only 50 % of the site surface was built on, and the remainder was earmarked for garden spaces in courtyard form.' (Weihsmann 2002, 39). The gardens were established on naturally developed soil, without subterranean constructions.

With a few exceptions, the architects were also responsible for the basic design of the open spaces as part of the housing complex. In annual programmes, the construction programme including social infrastructure and the supply facility were drafted in cooperation with various municipal departments and politically adopted by the city council before the planning was undertaken in the various individual construction projects. The municipal planning authority was closely involved in the realisation of the projects, during the planning stage as well as a supervising authority, even though the actual planning was done by freelance architects (cf. Blau 1999, 147). Compliance with the requirements for the structure and organisation of open spaces to ensure light, air and multiple usability was monitored by the municipal construction department during the entire development process, from the first drawing through to the detailed plans (1999 Blau ibid.). Drawings including perspectives (1:200) and execution plans (1:100 to 1:1) had to be submitted with a detailed description of the design of the façades and all external and inside architectural details as well as a model (in wood or cardboard 1:360) and plans and detailed drawings of the landscape design of the entire complex (Blau 1999). The architects were also commissioned to carry out the artistic supervision of works. Much of the construction materials came from municipal businesses, and the construction companies were commissioned by the municipal planning authority as well (Blau 1999).

The gardens in the courtyards enhanced the value of the apartments overlooking the courtyards and improved conditions for supervising children from the apartment. 'Enhancing the quality of apartments overlooking the courtyard which previously were feared [due to the bad light conditions and lack of social contact — Authors' note] resulted mainly from the garden design and the creation of playgrounds for children and rest and relaxation areas for adults.' (Weihsmann 2002, 39).

A balance between the public green spaces as recreational areas and the gardens of the municipal housing complex was created in two directions: Landscape architect Fritz Kratochwjle, head of the municipal landscape authority, wrote in 1931: "No major municipal housing complex now lacks a garden, playgrounds or a paddling pool. These facilities naturally provide significant relief for public facilities, since the children of the families who live there do not need to make use of such facilities or even play on the street." (Kratochwjle 1931, 58). On the other hand, the 'large garden areas' of, e.g. the Karl Marx Hofwere accessible to the inhabitants of the surrounding settlements as well and [offered] sufficient space for rest and recreation for everyone. In addition to planting trees, flowerbeds were created as well, for perennials and summer flowers, lending the complex colour and movement.' (Kratochwjle 1931, 52).

REAL CORP

In the time when social housing was established in Vienna, the responsibility for planning, programme, execution and supervision were thus concentrated at the municipality itself and very closely linked with the socio-political programme. Furthermore, a direct interaction was established between public policy regarding green spaces and providing open spaces for housing complexes.

2.2 Reorientation of the housing policy

The housing policy of the City of Vienna underwent structural and strategic reorientation since the 1980s. The reason for this lies in a crisis of the fordist economic model, which manifested itself in Vienna in the form of an internal market-oriented system with corporatist and clientelist networks. The reorientation started already in 1982 on a national level with a deregulation of tenancy law, which led, in conjunction with other measures, to recommodification of housing. As of the 1990s, the increased presence of private-sector developers and housing companies is apparent. (cf. Novy et al: 2001, 136).

At the same time, these trends also became evident in the market for small-scale rehabilitation and new construction: As of the 1980s, a significantly increased presence of private-sector stakeholders has emerged, whose activities concentrated primarily on development projects with a strong emphasis on structural infill and rehabilitation activities. The result of these activities is apparent in the concentration of the owner structure and in the proliferation of condominium. In the case of the actually realised projects, the focus was on increasing the usable space and on increasing the rent and sales prices by creating high-quality residential and office space. In the open space, the privately used share was pushed — e.g. terraces, balconies or private gardens — as these were directly value-enhancing features (cf. Grimm-Pretner / Rode 2002).

The urban development project 'Donau City' may serve as a model for large-scale new construction projects. This example illustrates a change or reorientation of the corporatist network: The municipality no longer acted as an active stakeholder, but transferred instead the operative component to the development company, WED (Vienna development corporation for the Donau area), whose owners have clear links to the social democratic movement. The ensuing public-private partnership could be directly or indirectly controlled by the municipality and was bale operate for profit at the same time (cf. Novy et al 2001: 133). This change in paradigms — the retreat of the municipality as an active stakeholder from the construction sector (the last municipal housing complex was constructed in 2004) while strengthening at the same time private-sector institutions and networks connected to the municipality or its funds through ownership structures — seems to have taken place in the subsidised housing sector as well. The corporatist elements of the previous regime were thus developed and adapted under the auspices of a municipality acting as an entrepreneur — a process of outsourcing and privatisation while maintaining direct or indirect control through the ownership structure.

These changes in the structure of stakeholders also required changes in the urban planning department as a formalised regulatory authority. Up to that time, the public or semi-public stakeholders were the main recipients of urban development measures as well as of land destination plans and land use plans as far as the social housing sector was concerned. New governance forms had to be established in order to regulate the interaction between private and public stakeholders. The institutional setting comprises the Expert Advisory Board (reorganised in 1987 as part of the amendment of the building regulation code and endowed with new areas of responsibility), the Land Advisory Board (Grundstücksbeirat — established in 1989) as well as of the two decentralised planning institutions, the Vienna Business Agency (Wirtschaftsagentur — established in 1982 as the Vienna Business Promotion Fund, WWFF) and the Housing Fund (Wohnfonds: established in 1984 as the Vienna Land Procurement and Urban Renewal Fund — Wiener Bodenbereitstellungs- und Stadterneuerungsfonds). Its objectives are to manage the real estate assets and to organise the cooperation between the urban planning department and the private-sector real estate developers (cf. Novy et al: 2001, 138). The Land Advisory Board as well as developer competitions (since 1995 — cf. Knolll 2009) were established for quality assurance. Until 2008, regard was laid to the three columns (architecture, ecology and economy) for the purpose of evaluating the submitted projects, in which cases the open spaces as part of the housing complex mainly served ecological purposes or, in matters of maintenance, formed part of the economic considerations.In 2009, the fourth column of social sustainability introduced an open list of criteria, where barrier-free and anxiety-free design, everyday practicality, multiple use and integration options are being discussed especially in regard to open spaces as part of the housing complex. Once the Land Advisory Board or the jury of a developer competition has granted approval of a project or acknowledged its eligibility for funding, the submission to the building inspection department during the

design or submission planning (M 1:200 – M 1:100) represents the next supervisory level. In this stage, the focus is primarily on technical issues; in regard to open spaces, this means compliance with the provisions stipulated in the Building Regulations (site topography, guardrails, subterranean structures, playgrounds for small children, sealed surfaces, etc.). A final verification step only takes place after completion of the construction works, following acceptance by the building inspection department or review by the Housing Fund. At this stage, open spaces play a subordinate role.

In a study undertaken on behalf of the Housing Fund, Knoll / Moser (2009) reviewed if the plans for the open spaces of housing development projects submitted to the Land Advisory Board and acknowledged by that body as basis for funding have been implemented in fact. For 60 projects, the descriptions submitted to the Land Advisory Council were compared to the actually implemented project. 12 projects (amounting to roughly 20 %) were found to have a very high level of open space quality (cf. Knoll / Moser 2009). These projects were published on the homepage of the Housing Fund, while the assessment of the remaining 48 projects does not appear. In these cases, the requirements of the Land Advisory Board were not completely met. This may require significant action in terms of quality assurance and quality control.

In summary it can be said that the Viennese public housing policy has been a field for interaction between public and private stakeholders since the 1980s. In this period, a retreat of the public sector as an active stakeholder can be observed in the production process as well as in municipal real estate policy. This structural change is in line with the overall approach of an entrepreneurial city, which regulates the process of creating subsidised housing by means of decentralised and external institutions. This occurred against the backdrop of the interplay between exploitation-oriented interests of private sector developers and quality demands of the public sector. In this situation, the realisation of high structural density is in conflict with an adequate supply of open space. In the development of quality assurance instruments, increased attention to differentiated qualities and functions of the open space is apparent. Private sector stakeholders have also recognised the value of open spaces (for private use) in marketing their projects.

However, it remains unclear how the conflict of the built density and adequate supply of open space is to be dealt with, to which extent also open spaces for common use are to be taken into consideration in the housing projects and how open space as part of a housing complex is to take the role of a social space. The question to which extent the realised open spaces correlate to the marketing images and resident satisfaction was examined in this research project.

3   EMPIRICAL EXAMINATION OF THE ROLE OF OPEN SPACES

The selected case studies reflect the types of residential buildings currently constructed in Vienna. The integrated design and social space analysis reveals the correlations between structural and functional conditions on the one hand, and social conditions on the other. These analysis results are included in the Post Occupancy Evaluation (POE). The production processes of open spaces are illustrated in a process and policy analysis, evaluating the strategic positioning of the construction projects within the company as well as the effective public presentation of the company and the construction project. As primary data, landscape architectural surveys of the open spaces in the settlement, planning documents and meeting minutes from different phases of the planning and execution process, interviews with the commissioned landscape architects and the developer´s project managers, marketing documents of the housing developers as well as questionnaires, discussions and documented inspection visits with the residents of the apartment buildings were used.

The results of the research dimensions are brought together by representing the design-analytical and use-related evaluation of the POE as the result of the process of creating the open spaces.

4   RESULTS

In the following section, the evaluation results of two case studies examined as part of the FreiWERT project will be presented. They reflect tendencies of the contemporary practice of creating and quality of housing-related open spaces in subsidised housing in Vienna.

4.1 Housing complex on Breitenfurter Straße, 1230 Vienna

4.1.1 Brief description

The housing complex located in the southern Viennese district of Liesing was built by MIGRA GmbH,[2] Gemeinnützige Bau- und Siedlungsgesellschaft (non-profit construction and housing company) and Wiener Heim Wohnbau GmbH in the period from 2003 to 2005. The decision to purchase was taken on the basis of a schematic urban development analysis as well as a first calculation of the expected floor space by the developer, which presented binding parameters for the planners and project developers in the course of the entire project. The construction of the residential complex was funded in part through the housing subsidy WWFSG 89,[3] in part with funding obtained on the open market in cooperation between the two developers without a tender procedure.

For overall planning, a hand-drawn sketch from the acquisition phase served as a guideline, defining the built form, the achievable floor space, the integration of existing trees and the requirement for noise protection. Planning and construction meetings organised by the developer were a key element ensuring cost and quality control. In doing so, general quality and furnishing standards were defined for the open space. 45 % of the land area of 10,451 m² were built up with multi-storey buildings comprising 158 apartments and a floor space ratio of 1.5. The complex consists of four-storey buildings on the street that are integrated in the perimeter block construction style of the Breitenfurter Straße, two recessed central-core high-rise blocks with six storeys each as well as three detached rows of buildings with six storeys each at the core of the block. The rear buildings follow the concept of a 'stacked rowhouse complex' and are designed in such a way that each residential unit has its own open space for private use and the site is used optimally.

The open space is zoned into private spaces, common spaces and transitional spaces as well as with two playgrounds for children. 70 % of the open space is earmarked for common use, which are separated from the terrace gardens for private use between the rows of houses by hornbeam hedges. Prohibition signs prevent walking or playing on most parts of the lawns. The design makes do with few elements and materials. Land development facilities and the legally required infant playgrounds are functionally arranged, yet not integrated in form, position and dimension into the spatial concept. The simple landscaping concept consists of existing trees, shrubs, lawns and hedges.

Fig. 1: Function and zoning of the residential complex on Breitenfurter Straße

---

[2] The Fund for the Advice and Support of Immigrants was founded by the City of Vienna and the social partners, and holds a 45 % stake in MIGRA GmbH. 25 % are held by ARWAG Holding AG, which is in this way, as well as through personal connections, closely linked to MIGRA GmbH.

[3] The Act promoting the construction of new residential buildings and rehabilitating resid̄ential buildings as well as granting residential subsidies (Vienna Residential Building Promotion and Residential Building Rehabilitation Act — WWFSG 89) governs the funding of housing and requires that the overall construction costs be reasonable, the development costs be economically feasible and that the prices for rental apartments or condominiums are reasonable (cf. WWFSG 89 in the applicable version).

4.1.2 Results of multilevel analysis

The analysis of the open spaces and social environment comes to a similar conclusion: With the exception of spaces reserved for private use, the quality of the open spaces is rated mediocre to poor. The process and policy analysis reflects a contradictory consideration of the open space in the course of the construction process.

Design of open spaces In the perception of the residents, the aesthetic composition recedes into the background, and an analysis of the design shows that not much attention was paid to it and that the design focused primarily on urban planning considerations regulated in the building code. In the planning process, the landscape design of the area played a subordinate role: No professional landscape architectural planning was commissioned, instead, this service was provided by the architect. As a result of delayed decisions in the planning process (i.a. in order to expand the built-up area in the ground floor), lack of planning content (e.g. topographic planning, insufficient information in the site foreman's plan) and lacking technical expertise, the open spaces were not developed in a clear and consistent manner. Certain decisions were not discussed and agreed in the proper planning and execution meetings, but instead directly on site with the executing contractors (e.g. layout pattern of tile flagging, detailed topographic planning). The process analysis reveals a certain disregard for the professional contribution of landscape architects, expressed in part directly in the decisions, but also by simply not dealing with specific issues. Thus the project ended up with merely a minimum standard of open spaces.

For marketing purposes, open spaces play a significant role in the presentation of the project. The slogan of 'stacked rowhouse complex' evokes the image of owning a home with a garden. Since the built-up volume (three to five storeys) and the construction type (rows of buildings) do not correspond to the image evoked, the open spaces play a key role in creating and transporting the image. Though the limited landscape architectural design and lack of prioritisation of open space contradict the part these spaces play in the marketing and exploitation process, they reflect the current market approach and need to recoup expenses, thus requiring a maximum of floor space and a reduction of costs that are not directly recoverable such as expenses for qualitative open spaces..

Open spaces for private use: The open spaces for private use are considered by residents to be of particular importance and are used for recreational purposes. In the 'stacked rowhouse complex', the private open spaces have been conceived from the outset for peaceful relaxation and recreation and are presented as such for marketing purposes.

The images generated as part of the marketing process correspond to the 'urban village' concept, furnished with various types of open spaces for private use (own gardens, loggias, roof terraces) and promising a combination of secluded private dwelling in suburbia with urban quality of life. The illustration of functional borders (chain link fencing) in the renderings give an impression of a privately-owned home with a garden. This emphasis on private open spaces as part of the marketing strategy is reflected in the project concept, but was lost during the planning and execution process and reduced in size and furnishing as part of decisions to cut costs.

Common open spaces: The quality of the open spaces for common use is rated as low by the design analysis. Undifferentiated design, a lack of meeting points and retreats, recreational facilities limited to standardized infant playgrounds as well as restrictions of use by prohibitions characterise the open spaces earmarked for common use. Most residents consider these open spaces to be mere visual effects, and active use mainly concentrates on the public recreational areas in the vicinity — Wienerberg and the Liesing brook — while use of the courtyards is very limited. The overall recreational offer in the vicinity was an important aspect already in the early stages of the project and for establishing the image for marketing purposes. Residents appreciate the existing trees on the property. The existing trees were already taken into account during the acquisition phase and integrated from the start into the project planning. In the project management, the design, furnishing and use of the open spaces for common use were inadequately reflected. Quality standards for the open spaces were rather vague. To prevent conflict, the use of common spaces has been actively reduced. In the planning phases, the decision was taken to erect a fence to separate the construction sites; the maintenance phase is characterised by prohibition signs and a lack of means of residents to participate in the decision¬making process or to make changes. Some attempts to appropriate the gardens are still visible in scarce plantings. However, they were merely tolerated if not restricted by the housing adminsitration.

The low use and acceptance rate is in conflict with the marketing strategy, which focuses on widespread use in particular of the common spaces. The renderings for marketing purposes highlight the common areas in a very prominent fashion and show many people using these facilities.

4.2 Housing complex on Troststraße, 1100 Vienna

4.2.1   Brief description

The housing complex in the Viennese municipal district of Favoriten was planned in 2002 to 2004 by a consortium of architects in collaboration with a landscape architect as part of a property developer competition on behalf of a non-profit housing and construction company, GESIBA Gemeinnützige Siedlungs- und Bau AG.[4] Entitled a 'multigenerational residence', the project focused on assisted living facilities for senior citizens, which was the topic of the competition together with the theme of 'planning housing for everyday life and gender neutral'. GESIBA acquired the property from the Vienna Land Procurement and Urban Renewal Fund. The housing complex was built with funding from the housing subsidy WWFSG 89 (see supra).

The competition brief defined the key strategic decisions for the course of the project: Visual and audio contact between the apartments and the open spaces, the creation of private outdoor areas and terraces for common use, as much sunlit areas in the courtyard as possible, a varied range of offers for the different needs and ecological quality. The assessment of the jury highlighted the concept for developing the property and the design of the open spaces and established specific parameters for the construction and furnishing of the open spaces (for example, a furnishable design of the private spaces was required). Continuity in the construction process was to be ensured by a smooth transition from the project manager to the construction manager and by regular consultations between the landscape architect and the architects. Nevertheless, the expert planners had to respond repeatedly to changes that occurred partly even in the execution phase.

Covering an area of 4,655 m2, with 64 % of the property was built-up with five to nine-storey buildings, which resulted in a total of 140 apartments and 42 senior citizen apartments at a floor space ratio of 2.59. In line with the urban structure of the surrounding area, the buildings were constructed as a perimeter block development and includes a central open space at the inside of the block.

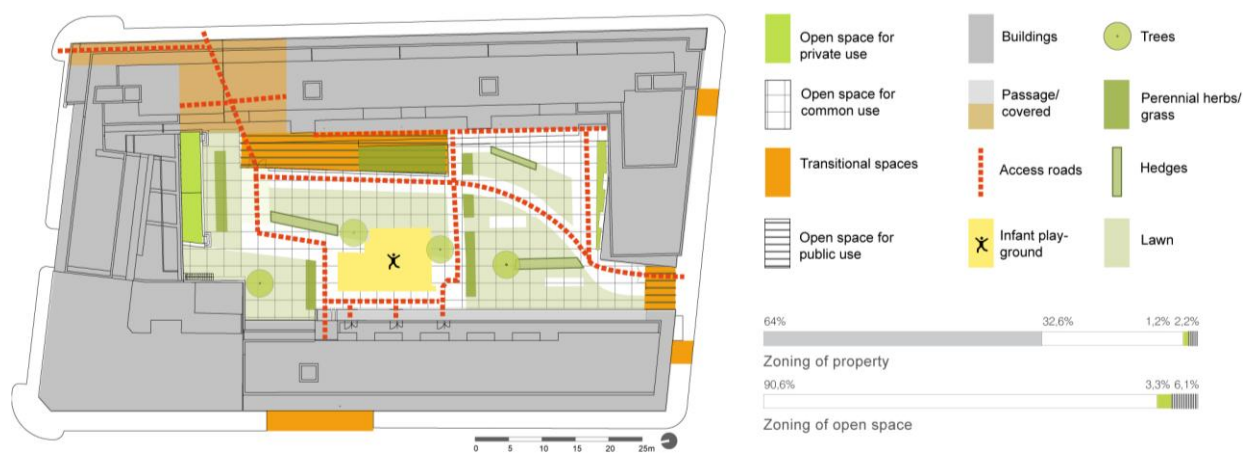
The open space is divided into areas for private use, for common use, transitional areas, an infant playground and recreational areas. Approximately 90,6 % of the open spaces are classified as areas for common uses and spans across nearly the entire inner courtyard. Two apartments have a private terrace garden in the inner courtyard, the other private open spaces are balconies. The spatial structure is provided using the topography. The courtyard is clearly visible and divided into different segments. The shapes and materials create a discrete and consistent overall appearance. The landscaping design underlines the functional and spatial sequence of the segments.


Fig. 2: Function and zoning of the housing complex on Troststraße

---

[4] GESIBA Gemeinnützige Siedlungs- u Bau AG is managed on behalf of the City of Vienna by Wien Holding GmbH, which holds 99.97 % of the shares in GESIBA AG.

4.2.2   Results of multilevel analysis

The open space and social evironment analysis for this housing complex arrives at a similar conclusion: The quality of the open spaces — with the exception of areas for private use —- is rated mediocre to poor despite the ambitious open sapce design. The conclusions are very much related to the lack of space, to the walls needed for the sloping terrain and to conflicts of usesThe process and policy analysis shows that open spaces played a subordinate role during the construction process.

Design of open spaces The open space in the housing complex is characterised by a high density of buildings and is classified as mediocre. The courtyard situation on the narrow construction site is dominated, but at the same time protected, by the high buildings. The design analysis assesses the spatial structure overall as positive. Many residents consider the design of the open spaces to be aesthetically attractive, even though the parents of small children tend to feel that the topography and concrete borders pose a risk and do not consider the open spaces to be inviting. In the planning process, the open space concept submitted to the competition was adapted, according to the landscape architect, to the actual conditions on site and to reduced quality demands. Especially the subordinate role of the common area and poor execution and maintenance weakened the result.

For marketing purposes, the emphasis was especially on reducing floor space in favour for a sun-filled courtyard. This strategic decision has contributed significantly to winning the competition. In the early stages of marketing, the dovetailing of the ground floor uses with the open spaces was emphasised; yet in the course of the project, this aspect was lost due to changes in the use of those areas and related access.

Open spaces for private use: The open spaces for private use are considered to be positive, both from a design and a socio-spatial perspective. The balconies are adequately dimensioned and overlook the courtyard. For many residents, these private step-out facilities are an important feature. Parents can communicate with their children from this vantage point, and especially elderly residents are able to avoid conflicts in the common areas. At the same time, the use of these private areas is restricted by the soundscape in the courtyard.

In marketing materials, the open spaces for private use were mentioned in addition to the common outdoor areas, but were not emphasised.

Common open spaces: The open space for common use is too small for the large number of residents and is overall deemed to be mediocre. Though an orderly spatial structure and a variety of use options are offered on the limited area available, there are only few opportunities inviting an extended stay. At the same time, a high level of social control and acoustic incidence restrict the usability of the courtyard. 30 % of the residents — mostly children and their parents — use the common area on a regular basis. In general, the courtyard is not perceived by residents to be an intergeneration communication area. During the construction process unforeseen expenses in civil engineering imposed pressure to reduce costs in the landscape architectural features and necessitated changes in the post-tender stages. This had an impact especially on the quality of the materials and the design.

In marketing the housing complex, special focus was on the open space intended for common use. A clear structure, social control, variety of usages, peace and tranquillity, were emphasised in the project descriptions as well as illustrations. The intention was to provide as many different options for using the open space as possible to appeal to different user groups. The social character of the shared housing concept was emphasised and suggested conflict-free coexistence between the residents. The marketing materials used the verbal image of 'peaceful coexistence' in the 'tranquil recreational and leisure area' of the courtyard. This image contrasts with the assessment of residents who note the conflict potentials of using the common spaces in particular.

5   DETERMINATION OF FIELDS OF ACTION

By capitalising the Viennese real estate sector, the activities of the private sector stakeholders have increased. Since the 1980s, a new regime of regulation in the form of an 'entrepreneurial city' was created through the establishment of funding institutions and the setting up of advisory boards and quality assurance instruments. In the reorientation process, corporatist elements were incorporated and transformed into the new regime. For example, the structural and political proximity of some non-profit property developers with the City of Vienna is striking. The entrepreneurial city is manifested in the area of subsidised housing by

outsourcing the operative business to stakeholders acting as private sector companies while establishing at the same time a control system through shareholdings and means to participate indirectly in the decision-making processes.

Due to the outsourcing of the construction process, the aspect of exploitation and marketing has become more important, resulting in a stronger emphasis on cost and pricing aspects. These arguments give rise to a greater structural density, which significantly restricts the spatial configuration and even further the usability of the open spaces earmarked for residential purposes. Furthermore, the consideration given to open spaces in the projects continues to be inadequate, which is manifested i.a. in the shifting and reallocation of costs in the overall project. This considerably curtails the work performed on the open spaces, being the last in line, even though a good quality of design and materials is important especially in the case of high density.

The functional interaction between superordinate and housing-related open spaces continues to exist, yet an imbalance is discernible. While the concept of public superordinate open spaces are used by the property developers as appealing location factors for marketing purposes, the housing-related open spaces do not offer the corresponding value due to poor quality or lack of quantitative features. Usage and usability reflect this imbalance. From a professional perspective, a matching compensation (quality-wise, quantity-wise or financial) is required.

Open spaces are used to a considerable extent for marketing on all levels, in other words as superordinate public open areas, as common areas of housing complexes and in particular open spaces for private use, the latter are seen to be directly and financially realisable marketing factors. The results of the case studies show that there are significant deficits from an urban development, design and use-related perspective especially in regard to commonly used open areas. Open spaces as a marketing argument are only treated consistently as far as privately used open spaces are concerned. For the common areas, the short-term profit orientation and the compliance of construction costs seem to have a quality reducing impact, causing a discrepancy between the marketing image and reality of usage. Positive knock-on effects are not taken into account in the operational cost-benefit calculations or in quality assurance considerations.

While certain standards have been introduced and expanded by the regulations and quality assurance instruments of property developer competitions, the role of landscape architecture in the overall planning and construction process has remained weak. A strengthening of this position may be achieved by means of continuous professional support through all phases of the process and by taking the characteristics of landscape architectural design in to account, e.g. the dependence of the usability on the available space and spatial configuration, interactivity of design and usage at the ground floor levels, a procedural development in general as well as implementation subsequent to the overground construction works. Yet the case studies reveal standardised procedures and a moderate interest in creating high-quality open spaces. The perception of an independent professional quality should be reflected in the structure of the construction budget as well in the quality assessment and monitoring for the purposes of housing subsidies.

It is apparent, moreover, that the property developers have a rather limited interest in small-scale care, maintenance and adaptation of commonly used open spaces. It appears that the input required for care and adaptation is too uneconomical and difficult to calculate. Yet this fact too shows how important it is to strengthen the focus on open spaces and their function as social areas in the process. The professional support of development, use and appropriation processes is urgently needed if social sustainability is understood to be more than the installation of prohibition signs in the Viennese tradition of preventing conflict.

This raises the question of whether new stakeholders and instruments should be engaged in this field. Just like 'Red Vienna' formulated specific strategies and supported them in their implementation, it appears to be also necessary in regard to open spaces earmarked for common use to support and develop a clear programme in all stages of the planning and construction process. The reorientation of the governance structure offers the possibility of liberalisation while professionalising the planning and construction process at the same time. But also the inclusion of civil society elements such as participation and self organised processes is necessary to entrench the dimension of responsible behaviour, co-determination and the concept of social space in the final instance.

1 ABSTRACT

Nowadays modern, geospatial information system (GIS) based, integrated property data systems (infrastructures) are used for increasing the performance of the public sector and decreasing the administrative burden on society with regard to real estate, spatial planning, also in property tax administration and property mass appraisal. [2]

The real property tax is a strong source of local incomes and essentially demands highly effective administration and functioning of the property tax system and enhances public confidence in local governments. [18]

The recent fiscal crisis has stimulated interest in new revenue sources of local governments, including capturing immovable property price increments [3]. This challenge in 2008 led the responsible authorities to revise the current property tax and mass appraisal systems in the Republic of Latvia (Latvia) with the purpose of developing and implementing a new strategy for fair real estate tax policy. One of the purposes was also to make more efficient the functioning and use of property related data information systems on for better real estate tax administration and use in mass valuation.

Within implementation of the Communities action plan for setting environmental policy (Directive 2007/2/EC of the European Parliament and of the Council of 14 March 2007, establishing the Infrastructure for Spatial Information in the European Community – the INSPIRE directive), since 2009 the implementation of several important large scale projects for the development of GIS have also been started in Latvia with the purpose of improving the property related spatial and descriptive data and statistics spatial data processing, maintenance and sharing.[7]

The benefit from the three planned large scale information systems: "Development of the State Land Service's Geospatial Data Geospatial Information System" (SLS GIS), "Information System for Administration and Supervision of Territorial Development Planning of Local Governments, Infrastructure and Immovable Properties", which is more widely known as Territorial Development Planning Information System (TDPIS) and Building Data Information System (BIS), also will contribute to improve the functioning of the property taxation system and property mass valuation in Latvia.

This paper will describe suggested possible proposals for the improvement of real property tax administration and mass valuation system, because new implementations are only on the development phases now: there are no completed and functioning solutions yet regarding of new approach of property related data registration and sharing, as well as use in the property taxation administration and mass valuation.

Key words: real property tax, property mass valuation, spatial planning, GIS, INSPIRE directive

2 GENERAL FACTS ABOUT LATVIA

Latvia is the central of the three Baltic States and renewed its independence in 1991 after collapse of the Soviet Union.

The area of the country is 64,589 sq. km: the length of the border – 1,862 km. In accordance with the 2011 Census, 2 067 887 people lived in Latvia in 2011. [17]

The Administrative Territorial Reform of 2009 has improved administrative capacity of local governments, moving from almost 600 administrative units with 28 regions to 119 counties (local governments), 9 republican cities and 5 planning regions. [17]

Latvia's political, economic and culture centre is the capital city of Riga, where almost one third part of Latvia's population (707 thousand) lives and works. [16] Latvia is a member of the United Nations (1991), the World Trade Organization (1998), NATO (2004) and EU (2004).

Latvia's national currency is "the lats" (LVL). 1 LVL is equivalent 0,702804 Euros. In 2014 Latvia will be presiding over the EU, as well as plans to join European Monetary Union.

The dominant sectors of Latvia's economy are trade (16.9 % of GDP), production (19.1 % of GDP), financial services (3.8 % of GDP), construction (6.1 % of GDP), real property operations (7.6 % of GDP), and agriculture and forestry (4.5 % of GDP). GDP increased most rapidly immediately after Latvia's accession to the EU, reaching its highest growth in comparative prices in 2007: 12.14 billion Euros, but at the same time the budget deficit reached 22 % of GDP. [6]

During past two decades Latvia gradually established its property right and data registration system (Unified Computerized Land Register), developed the modern digital National Cadastre Information System (Cadastre IS) with integrated market value based property mass valuation as well as developed property taxation system.

Latvian land reform is almost completed: 64.6 % of all of Latvia's territory belongs to private and legal entities, 4.7 % – to municipalities, 30.7 % – to the state (including public waters and state forest land). There were about 5.7 million objects registered in Cadastre IS, which is maintained by the State Land Service (SLS), on 01.01.2012: of them 1 million were land parcels (with territory coverage of 100 %) and 1.4 million buildings (with the territory coverage 96 %). [15] Almost 96 % of real properties are secured in the Unified Computerized Land Register (2013). [16] The State Address Register contains 1,346,139 addresses (2011). The total stock of assessed property values on 01.01.2013 was 25.9 billion Euros. [16]

Latvia has a traditional three level spatial planning system with 100 % area coverage ofthe entire country. All municipalities have local territorial plans, which is the basic document for stated current and planned land use within their area of jurisdiction.

The global economic crisis hit Latvia in early 2008. In order to overcome the impact of the economic crisis on the national budget, Latvia was granted a 7.5 billion Euro loan from the International Monetary Fund (IMF) and European Commission (EC) at the end of 2008, bearing a lender's oversight on urged reforms within three years period. [6]

The real GDP contracted by18 % and the unemployment rate reached almost 20 % in 2009. Positive GDP growth returned only in the last quarter of 2010, and then followed by an increase in average of 5 % or 10.15 billion Euros in 2011. [6]

3   THE CONTEXT OF THE SINGLE EUROPEAN INFORMATION SPACE

The Establishment of The Single European Information Space of European Community is the one of three pillars defined by the European Commission (EC) i2010 strategy (2005), whose objectives are to offer high, bandwidth communication, rich content and digital services with a market oriented regulatory framework for all users in European Community with regard to spatial information, including property related information. [7]

The concept includes geodesy and cartography as the essence and mutual connection of geospatial infrastructure elements (see Fig.1). [5]

In 2007 the INSPIRE directive laid down general rules for establishing an infrastructure for spatial information in the entire Community that is the basis of support for the Community's policies and for the fulfillment of the requirements of environmental issues around Europe. [7]

To ensure that the spatial data infrastructures of the Member States are compatible and usable in a Community and trans boundary context, the INSPIRE directive requires that common Implementation Rules are adopted in a number of specific areas: metadata, data specifications, network services, network services and technologies; licenses on sharing, access and use; and coordination and monitoring mechanisms, processes and procedures, established, operated or made available in accordance with the INSPIRE directive requirements. [7]
Fig. 1: Geospatial information elements. [5]

The INSPIRE directive should be based on the developed infrastructure for spatial information of Member States and does not require new data collection system. The Member States must ensure that this infrastructure is compatible, interoperable and usable on the national level, as well as in the Community trans-boundary context. The Member States' duty is also to develop and launch national Geo-portals which will be integrated in the European Geo-portal and via that the data and services required by the INSPIRE directive will be available in the national and trans-boundary context. [7]

The three annexes of the INSPIRE directive list 34 spatial data themes [subjects?], including land use, land cover, addresses, cadastral parcels and buildings, administrative borders, etc. maintained by public sector for what Member States must provide specified set of spatial data storing, maintenance, availability and share in the most appropriate level with the possibility to combine spatial data from different sources across the Community. The INSPIRE directive's common Implementing Rules require each Member State to implement INSPIRE directive's requirements into their own legislative systems. The Member States are also therefore engaged in implementing the appropriate technologies, policies and institutional arrangements that will form the basis for their INSPIRE compliant systems. [7]

The development and implementation of the INSPIRE directive will follow a work schedule consisting of three phases: the Preparatory Phase (2005-2006), the Transposition Phase (2007-2009) and the Implementation Phase (2009-2019). [7]

In order to quicken the implementation of its digitally based and customer oriented strategies, the EC lunched several programs (such as e-Content and e-Content Plus programs) on behalf of Community's Member States to develop GIS related infrastructure, testing and launching new e-services and sharing related national experiences and best practices. It is well known that GIS as a computer system will be capable of creating, storing, managing, analyzing, and displaying geographically referenced information. GIS will allow one to understand, question, interpret and visualize data in many ways that reveal relationships, patterns, and trends in the form of maps, globes, reports, and charts. [13]

4 THE INSPIRE DIRECTIVE IMPLEMENTATION INITIATIVE IN LATVIA

The INSPIRE Directive has been adapted in Latvia's legislation by the adoption of the Spatial Planning System Development Concept (2009) and the passage of the Geospatial Information Act in 2009. [8]

The concept included geodesy and cartography at its essence and the mutual connection of geospatial infrastructure elements intended to eliminate the overlapping of spatial planning documents, creating a new legal framework to enable the new administrative and territorial reform by local governments (counties), the effectiveness and quality of the planning of its development, the definition of the appropriate planning documents, expertise, provision a number of new laws and regulations for its development. Geospatial Information Act set the role of the institution, the degree of responsibility in information maintenance and information exchange among institutions regarding annexes of the INSPIRE directive. [8]

The implementation of the INSPIRE directive with regard its data themes is split among the number of Latvian authorities emphasizing common cooperation, actions and data sharing with regard to the progress of the implementation of directive. The Ministry of Defence has granted supervision of overall processes and

reporting duty about the progress of implementation of INSPIRE. Latvia's Regional Development Agency (LRDA) is the responsible authority for development of Latvia's National Geo-portal where information (metadata) requested by the INSPIRE directive will be accessible by everyone. [8]

From 2009 several of Latvia's public authorities have started to develop their GIS systems (such as TDPIS, BIS, SLS GIS, etc.) using funding from the European Regional Development Fund for the purpose of complying with the requirements of the INSPIRE directive and to solve problems that have emerged in the public sector, such as insufficient development of information systems and their interoperability and lack of integration; undeveloped technical basis for the introduction of e-services and the decrease of administrative burden for entrepreneurs and citizens.

5 THE PROPERTY TAX AND ITS ADMINISTRATION SYSTEM

The real property tax is a so-called "ad-valorem tax" or "unit based tax" and is directly connected with geographic location. Land and other immovable features (human made improvements on land, such as buildings and structures) are usually visible, immovable, have geographic location and coordinates, specific use, physical parameters, the owner or user, and the value, so it is difficult to taxpayer to escape the tax as easily they can avoid other levies. [2]

In almost all countries around the world, also in Latvia property tax administration is a duty of local governments. Income from real property tax is a strong and considerable source for local governments, and all revenue from real property taxation goes to the budget of the local government where the specific real property is located. [18] For example in 2011 Latvia's local governments were collected 165 million euros (15 % from local tax revenues) from real property tax. [12] The revenue basis from property tax usually dependent on three politically sensitive variables: tax base (the taxable objects), tax rate (how much taxpayers will pay) and estimated revenue from taxes (requested income). The property tax collection is a complicated duty for local governments because of necessity to manage a large number of different taxation objects (real estates), as well as subjects (property owners and users). Setting of property tax requires use of special knowledge and capacity to work with variable data and data basis which very often is a challenge for small in size municipalities. Failure to establish a creditable tax base usually erodes taxpayer confidence; dampers compliance rates, and limits revenue performance [2]

The Law on Immovable Property Tax in Latvia was adopted in 1997, setting the basic principles of property taxation, taxable objects, tax relief, valuation, and information to be used, etc. [9]

In 2006 with adoption of Law on Cadastre valuation, issues were separated from general taxation legislation. Currently The Law On Immovable Property Tax also assigns local governments limited power for setting taxation policy within their jurisdiction with regard to taxation rate (from 2013) and objects of taxation (for imposing tax on auxiliary buildings of residential real estates), as well as allows the granting of relief for separate categories of taxpayers based on regulations issued by each municipality (such as for pensioners, the poor, repressed persons). The real property tax examines management capacity of local administrations and requires strong cooperation between involved partners, maintenance of the relevant tax (taxpayers) administration system and an appropriate data basis containing property related information. There are no unified property tax administration principles in Latvia. Local governments manage property taxation issues in accordance with their administrative capacity.

There are four main partners involved in the implementation of property tax in Latvia:

- The Ministry of Finance sets general principles and proposes appropriate legislative initiatives with respect to taxation);
- Ministry of Justice sets general principles and proposes appropriate legislative initiatives with respect to property valuation, property cadastre, as well as ownership registration (maintenance of the Unified Computerized Land Register);
- The SLS – Cadastre IS is responsible for the maintenance and performance of real estate mass valuation.

Local governments are responsible for the administration of property tax and revenue collection in their jurisdiction, development of local spatial planning documents and issuing building permits. It is also the duty of the local governments to determine land uses (land uses types) for taxation purposes. The determination of

land use types is based on permitted current land use in a relevant local territorial (spatial) plan or legally permitted use of the property. There is no unified developed classification of land uses for spatial planning in Latvia; otherwise the SLS uses their own classification code system (unified approach) for managing of land use types with regard of mass assessment in the Cadastre IS.

Due to crucial effect of spatial planning on real estate development, cooperation with the spatial planning policy setting authority in the Ministry of Environment and Regional Development and the construction process supervision authority in the Ministry of Economy also is required.

6 THE CURRENT PROPERTY MASS VALUATION SYSTEM AND PROPERTY RELATED DATA REGISTRATION SYSTEM; ITS CONNECTION WITH PROPERTY TAXATION

In Latvia property valuation was established along with the restoration of property rights and the development of a property data recording system. Market value based real estate valuation was gradually introduced from 1998 with the passage of the Law on Immovable Property Tax. Mass valuation is one of the responsibilities of the SLS along with the maintenance of Cadastre IS.

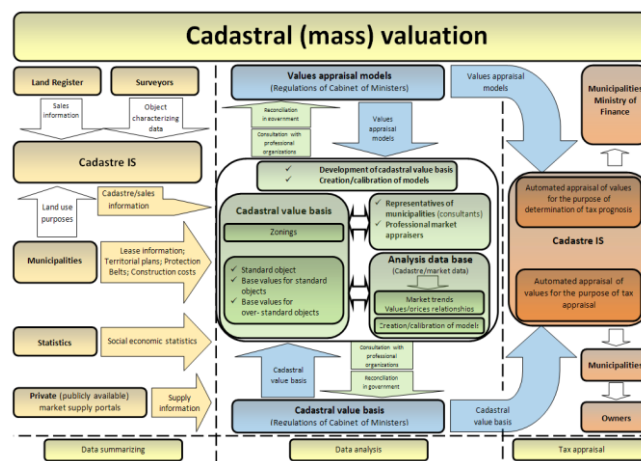
The basis for the setting of property tax is assessed values of real estate entered in official real estate data recording system – cadastre. The basis of value assessment is real property sales data. The establishing of property value for taxation also requires appropriate administrative resources; management, cooperation and an effective property related data system (see Fig.2). [2]


Fig. 2: Mass valuation performance in Latvia. [17]

The development of the mass valuation system demands continual improvements to achieve maximum quality with an efficient use of available resources.

The quality of the property assessment system is also determined by term accuracy, uniformity, equity, reliability, and a "low per-parcel cost system". [2] [4] Incomplete or obsolete property data in the registers is the main obstacle for accurate valuation performance or the introduction of improvements in mass valuation models. The three basic functions of a mass valuation system are revaluation, data maintenance, and value updates. [2]

Nowadays the functioning of the mass valuation system depends on the degree of automatization of the three interdependent subsystems:

- an administrative system;
- data management and system;
- data analysis and valuation system. [2]

The Computer Assisted Mass Appraisal (CAMA) system is commonly used for real estate valuation for tax estimation purposes in many countries around the world, since the use of computers and IT technologies became ordinary for performance of duties in large scale planning and data evaluation. CAMA is a generic term of any software package used by property assessment authority with regard to establishing real estate valuation for tax estimation purpose. The use of CAMA allows for the application of a systemic (automatic)

approach of appraisal to groups of properties at a given date using standardized procedures and statistical testing and analysis methods. [13]

CAMA approach is the most effective tool to perform mass valuation in the most efficient way in the complete sense of the term „efficiency". The use of CAMA ensures the performance of annual mass valuation and the update of properties values at the same tame on large number of the objects (usually on properties registered in the data base – cadastre) using common evaluation approaches (models), ensuring values accuracy, as well as "low per parcel" costs.

The Mass valuation system consists of mass appraisal applications of valuation models to real estate value. The spatial model and automated sales analysis are part of the modern property valuation system. The integration of GIS and CAMA enables the mass assessment function to be concurrent with relevant updated spatial data and supports the creation and maintenance of an accurate single property data repository with respect to each land parcel's geometry and descriptive data supporting workflow, updates, and mass appraisal input. GIS adds value to CAMA systems, such as an appraisal model, which can place added value on property that has, for example, a building located on coastline. If the parcel's description and spatial data are maintained in a geodatabase, location impact calculation is simple and easy using the spatial intelligence of GIS. [13]

CAMA or automatic (mass) valuation modules have been integrated into the Cadastre IS since 2001: mass assessment applies to all cadastral objects (land, buildings, engineering structures, premises) using accumulated cadastral information on specific property annually or whether data update takes place in the Cadastre IS. The source of cadastral information is land and building surveying cases.

The SLS for mass valuation purposes develops and updates the value (zoning) maps, determines value models for land and buildings, value bands (levels), and model parameters. GIS applications for value zonings are not developed yet, although GIS is the basis for the cadastral map in matters of property information.

Accurate valuation requires the SLS to keep strong cooperation with local governments, appropriate actual social economic statistics, reliable market data base, accurate data on encumbrances and property use, etc. The catalogue system is used in the Cadastre IS for the classification of land and building use types and encumbrances. The cadastre is often used by local tax administration authorities for setting of property tax, responses on complain, determination of land use for taxation purpose (land use type). Local building boards are use cadastre information as a basis for the development of local territorial plans and detail plans.

Since 1998 improvements in Latvia's valuation system have occurred several times. The most important changes to affect accuracy and low per-parcel costs have been connected with the development of appropriate software for valuation. In order to improve assessment accuracy and integrity, the valuation model has been improved several times taking into account the accumulated data in the Cadastre IS.
Fig. 3: Cadastre IS and its data exchange partners. [17]

In Latvia the Cadastre IS and the ownership register (the Unified Computerized Land Register) is maintained separately by different authorities – the SLS and the Latvian Court Administration. All real estate shall be

entered into the Cadastre IS – it is mandatory due to the fiscal function of the Cadastre IS. Securing of ownership can take place only after completion of cadastral activities in the Cadastre IS. Electronic information exchange takes place daily between the Cadastre IS and the Unified Computerized Land Register in regard to delivering actual sales prices for the maintenance of The Real Estate Market Data Information System. This system is the property market information (sales data) source for setting of mass value basis [10]

The assessment of values used for tax estimation and the cadastral surveying of buildings is the function of the SLS which maintains the largest state information system – Cadastre IS. Almost all Latvian registries are linked with the Cadatre IS [see Fig. 3].

The maintenance of an effective property tax administration and mass valuation system requires the efficient acquisition of information from several large-scale state maintained information systems, which contain property related technical and legal data such as:

- The Cadastre IS – land parcel and building spatial and descriptive data, surveying information, building valuation files, land and building use types, land value zonings, base values, the Real Estate Market Data Information System, encumbrances, etc.;

- The Unified Computerized Land Register – ownership and real estate market information;

- The State Address Register of the SLS – addresses, administrative units, administrative boarders;

- The State Forest Service Data Base – forest surveying data;

- The Rural Support Service Data Base – cultivated areas of arable land, etc.

Property mass assessment also requires local, regional and national social-economic statistics maintained by local governments and the Central Statistical Board of Latvia. Mass valuation system requires actual (permitted) land uses from local territorial plans maintained by local governments. Permitted land use types shall be entered in the Cadastre IS. The type of use has a decisive effect on the assessed value: base values used in assessment differ among different property uses within one valuation zone and can be considerable. Local governments also are responsible for assigning of adresses (names of administrative units, streets and estates) and the numeration of buildings. Address information shall be entered in State Address Register of the SLS.

The local municipal tax authority uses almost all information from Cadastre IS and from its cooperation partners for setting of property tax. These systems operate separately and require extra resources (time and work) from local municipalities for the purpose of obtaining necessary data and use this information for the input in tax administration. For example:

- the estimation of the volume of tax for each taxable real estate, local tax authorities use current mass assessment in the Cadastre IS;

- the list of taxpayers is maintained using actual residence data from the State Address Register and the Population Register with regard to the names of taxpayers and the addresses of legal entities from the Enterprise Register. Tax notices have been sent to the residences or entrepreneurship addresses of all relevant taxpayers at the beginning of each taxation year;

- tax reliefs request additional information about taxpayers that might be stored by other entities (such as the State Revenue Service), etc.

In order to better determine municipal administrative capacity, the Joint Municipal Information System has been developed, but this system is not in complete use yet.

In current the information exchange and circulation among registers is slow: technical information overlapped and registers very often contained similar records and inaccurate data. The Law on Cadastre obliges property owners to update information in the cadastre when changes to property take place (for example, building renovation impact on building cadastral information), but due to the complexity and costs of the process, this responsibility has not been completely completed.

The applied system requires an efficient system for taxpayers to receive actual information about properties and their values. Required cadastral data as well as assessed mass values are available for costumers in the data distribution portal of the SLS www.kadastrs.lv for a small fee. Several fee-free e-services, like "My data

in Cadastre", are available in the Latvian national portal www.latvia.lv. The information for clients also is provided at the regional offices of the SLS. [17]

7 THE PROPERTY RELATED DATA SYSTEM AND ITS CONNECTION TO PROPERTY TAXATION AND MASS VALUATION

The recent fiscal crisis has stimulated interest in new sources of revenue, including capturing immovable property price increments, and the improvements of property taxation in connection with mass valuation and cadastral information update were among highly recommended reforms of international lenders for the purpose to set better, fair taxation policy and to increase of municipal incomes in the recent economic crises context. [3]

With the implementation of common GIS solutions, many countries around the world have successfully performed integration of specific functions in information systems with real property registration and management to ensure efficient data use in various economic sectors and to reduce costs for data acquisition and maintenance. GIS solutions will focus on the exploration of new sources of information that would provide property data actuality and completeness, security, as well as to not increase registry maintenance costs. GIS applications implementation has shown a rapid increase in the use of spatial data in many countries (Denmark, Finland).

It is suggested that the INSPIRE directive implementation activities also be used in order to better property taxation and mass valuation performance.

In accordance with the INSPIRE directive, 34 data themes shall be covered and integrated into a new GIS system: almost all economic branches, professionals, entrepreneurs, researchers, tax authorities, property developers and managers, property owners and citizens will benefit from these new developments and will make spatial data more accessible for all users.

In Latvia two separate strategies were developed for the improvement of property tax policy and mass assessment, emphasizing better data accumulation, integrity and exchange among registers. The newly developed concept of mass valuation (2012) plans massive reforms in property related data management system for the purpose of improvement of valuation models and better performance of real property tax in near years. The new principles (directions) shall be implemented for the future development of mass valuation system and solving problems which disturbs the current system for full functioning; for example new solutions for:

- building information collection and update – the use of registration of building (structures) data from project (design) documents for new constructions and reconstructions in BIS and the use of self-assessment (owners declarations);

- determination of land use for property taxation purpose – the use combination information of TAPIS with Cadastre IS graphical (spatial) part for each land unit (indicating permitted land use, building intensity and density); use of building code (building classification) for determination of land use for built-up land units from the Cadastre IS textual (descriptive) data; connection of descriptive and spatial information for determination of multiple land use of land parcel;

- new data collection for the purpose of perfection of valuation of commercial properties – rental information collection in the market data base of Cadastre IS.

Consequently all of mentioned above solutions, the concept will require also strong cooperation among involved parties and early informing of society about coming improvements and their obligations with regards of data update in the registers. [1]

The three large-scale planned information systems will contribute to better the performance of mass valuation, resulting in better taxation policy, transparency of the system and cooperation among partners:

- The TDPIS will focus on requested standardized land use information from local territorial plans for mass valuation;

- The BIS will ensure the accumulation and updating of building data;

- SLS GIS will concentrate on cadastral data accuracy and interoperability with other information systems, integrated valuation models; appropriate analysis tools (local, national statistics, market data, etc.) for mass valuation performance, etc.

8 THE DEVELOPMENT OF THE STATE LAND SERVICE'S GEOSPATIAL DATA GEOSPATIAL INFORMATION SYSTEM

The aim of "The Development of the State Land Service's Geospatial Data Geospatial Information System" (SLS GIS) is:

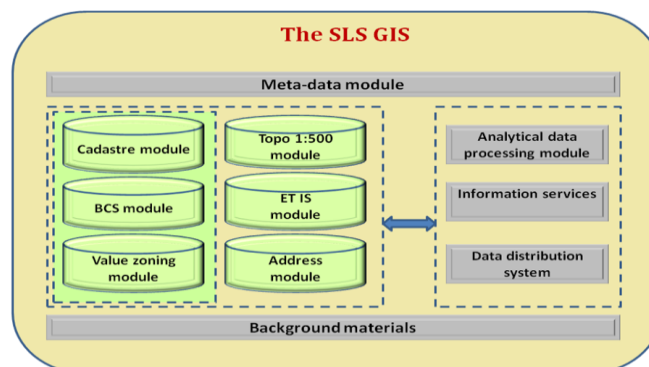
to develop a joint system for the entry, storage and processing of SLS's geospatial information, by ensuring migration of geospatial information already stored in the SLS into the new system;

- to modernize SLS data distribution system;

- to ensure e-services to the society related with SLS geospatial data;

- to ensure information services to other organizations for the transfer of SLS geospatial data needed in order to fulfill their functions. [17]

With the development of the SLS GIS, the requirements of INSPIRE directive in the sphere of cadastral information, addresses, boundaries and buildings has been also implemented. [15]

It is planned within the frameworks of SLS GIS to develop new, centralized object oriented information system for SLS geospatial data, in which a joint spatial data base owned by the SLS will be logically integrated and stored: spatial data of the cadastre (including, the land value zonings, building cadastral surveying data); spatial data of the State Address Register; spatial data of administrative borders; topographical data on the scale of 1:500; data on protection zones from documents regarding the planning of territory; other data available for SLS. It is planned to integrate 6 data modules; to develop their meta-data module within SLS GIS. (see Fig.4)


Topo 500 module – Topographic information in scale 1:500 module BCS module – Building cadastral surveing module ET IS module – Encumbred Territories IS module Fig.4: SLS GIS structure. [17]

The background materials for maps will be ortho-photo maps; topographical data in scale of 1:2000 and 1:10 000; satellite maps and thematic maps owned by the SLS.

Data integration will be ensured by mutual linkage and integration in both the descriptive and spatial data of the SLS.

The two modules: the Value zoning module and the Building cadastral surveying module will be very important for better mass valuation performance and for improvement of CAMA. Other modules will also be important in matters of cadastral data and its quality (data used for mass valuation of real estates).

The Value zoning module will ensure connection of base value information with value zoning maps; the tool for correction of zoning maps using cadastral map elements; analysis features and development of thematic maps.

All land uses for valuation purposes will be obtained from TDPIS. For this and spatial planning purpose the unified classification of land uses will be developed and integrated within the system.

The building cadastral surveying module will allow:

- for the mutual exchange of building data with the future BIS;

- automatic creation of a building data file in the Cadastre IS and its storage within future digital archive system

- drawing of building layouts in connection with coordinate system and use of standardized modules, data control and correction and the automatic obtaining of cadastral descriptive data, etc. [17]

It is planned to launch SLS GIS in 2015. All customers of the SLS will receive benefits from this integrated approach, like a availability to new spatial data sets, a centralized high resolution topographic data base, information about encumbrances, single customers derived services (e-services and information services) and a data distribution system, analysis features, information services, availability of cadastral information in the national portal www.latvija.lv , e-services for cadastral surveying professionals with regard to the updating of thematic maps and the electronic ordering of services and information.

9   THE TERRITORIAL DEVELOPMENT PLANNING INFORMATION SYSTEM

The aim of future TDPIS is to create modern, GIS based systems for transparent spatial planning information storage, processing and sharing, territorial development and real estate and infrastructure management for the entire territory of Latvia in lieu of the current, autonomous, unconnected with actual property information planning systems of local municipalities. [14]

Within TDPIS the framework of the infrastructure system has been created that will include a spatial development module for the purpose of local territorial planning of local municipalities, where local land use graphic and descriptive data (information on current and planned land use, including development restrictions and encumbrances) will be stored.

TDPIS will contribute also to cover all territories of local municipalities and all property related information in the performance of municipalities' duties.

TDPIS will contain all of Latvia's planning system (national, regional, municipal plans, also detail plans and local plans), functional zonings, and all documentation on planning initiatives, activities and normative regulation.

There will be two stages to the implementation of the TDPIS:

(1) The first stage will cover a survey of the current situation and the development of requirements for future systems, development of the basic functionality of TDPIS module and the implementation of it as a pilot project in 5 municipalities to test TDPIS integration with other information systems, development of security and test requirements and the testing of the newly developed e-service „Information about legal land use of the real estate in accordance of local territorial plan". Currently, this stage is in its completion phase;

(2) The second stage will include TDPIS technical development, introduction, integration, software purchasing and users training; introduction of the module of monitoring and evaluation of regional development indicators and e-services on current land use, a land use plan browser, electronic certificates on the permitted use of land parcels, detail planning and use restrictions of properties as well as digitization of information resources.

Within TDPIS the unified land use classification will be developed and introduced for both spatial planning and property mass valuation purposes and will be used from the catalogue in both systems – TDPIS and SLS GIS. The Module of Indicators of Regional Development will be developed and integrated with TDPIS for the providing of actual statistics concerning selected territory and will be very usable for the SLS in evaluation of territories within determination of mass value basis (evaluation of social economic factors for mutual comparison of the territories). It is planned to lunch TDPIS in 2015 with other systems: SLS GIS and BIS. [14]

10 THE BUILDING INFORMATION SYSTEM

The BIS is among those Latvian GIS projects which will be implemented in close cooperation with SLS GIS, TDPIS and SRDA (the responsible institution for developing Latvia's national geo-portal) and local building authorities (such as Riga City Building Board). The purpose of the future BIS is to provide future electronic circulation, standardized collection and use spatial and descriptive information about constructions, it's planning and documentation, which in present is collected, maintained and used separately by different public and local authorities.

Through BIS access will be provided to information on professional organizations: the Construction Merchant Register, Builders and Architect Practice Certificate Registry, Register of Energy Auditors, Building Energy Efficiency Performance Certificates Register, Residential Housing Manager Registry, Building Inspectors registry, etc.

The BIS will provide the following significant interfaces to The National Information System Integrator, Geospatial Data Integrator, Population Register, Business Register, Cadastre IS of the SLS, State Address Register of the SLS, TDPIS, Unified Computerized Land Register and Joint Municipal Information System. Four new e-services will be developed and launched:

(1) Construction project (initiative) review;

(2) Issuing of building permission;

(3) Reconciliation of simplified reconstruction or renovation and Construction commissioning.

The development of construction monitoring functionality is also planned, including mobile application, reporting module, use of e-signature, use of branch statistics and normative documents, e-service features and on-line payment options, as well as the performance of industrial research – BIS implementation and testing of at least 30 local construction boards before the launching of its operation. [11]

It is planned to lunch the BIS also until 2015 with the TDPIS and SLS GIS. The introduction of BIS will be step forward to make access to the building process and its documentation transparent for all parties involved: public and municipal authorities; process supervisors; entrepreneurs and costumers. All documents and communication among clients and data exchange partners will be provided only in electronic form with the purpose of decreasing the existing administrative burden in dealing with building information from the issuing of planning permission to the registration of a newly developed building.

11 CONCLUTIONS

The implementation of qualitatively new national spatial data system is a great challenge for the enforcement of the design of Latvia's national spatial data infrastructure (national GIS), as well as for planned massive reforms in property taxation administration, mass valuation and the fast updating and registration of data in the Cadastre IS, which will lead to improvement in the quality of valuation and taxation of property. The enforced reforms in the development of Latvia's national spatial data infrastructure are in the early stage and will be completed only in the next few years.

In practice GIS creates new opportunities for updating spatial and descriptive data and for making the system transparent (clear) and interoperable. GIS solutions will focus on the exploration of new sources of information that will provide property data actuality, completeness and security without increasing registry maintenance costs.

In order to improve the situation and to prevent an unsatisfactory and inadequate state of the modern technology that provides opportunities in the sphere of geospatial information, it is necessary to work out the binding normative acts for all involved institutions, to standardize the acquisition, treatment and exchange processes of geospatial data, as well as to ensure distribution of geospatial data and to improve legislation. [5]

The implementation of INSPIRE is a great opportunity for Latvia to develop its large interoperable information GIS in accordance of required data structures of the directive, as well as to provide this systems interoperable in cross-border context through Europe.

The impact of the new GIS developments on the property tax administration system and property mass valuation can be estimated as:

(1) improved property data structure and determination of the land use (SLS GIS and TDPIS);

(2) better property valuation models using GIS modeling capabilities (SLS GIS, TDPIS, BIS);

(3) better transparency and public information (the property values, and its characteristic data in the Cadastre IS will be easy accessible online: valuations zones with attributed spatial and descriptive data, market information and statistics etc.).

The data accuracy and complete coverage in the registers will provide better performance of property taxation: accurate real estate values and faire taxes; more accurate taxable object data base (more accurate taxable building data); better informing of taxpayers, etc.

At the same time main contributions in the improvement of the SLS GIS will also contribute to the development of the largest IS based data base covering property spatial and descriptive data in the entire country; TDPIS will contribute to the storage of authorized information concerning planned and current land uses in each municipality, but BIS will provide a complete overview of every building construction process from project application to the construction operation, even includingfurther building improvements and other changes.

It is planned to provide within SLS GIS also cleavage (section) of different graphical data: cadastral maps with topographic information; remote sensing data – LIDAR and ortho-photo maps with the purpose to observe changes in land use structure. Recent tests have shown that the first (pilot) section cadastral map with topographic information allowed to determine almost 80 000 new building objects which had not previously been recorded in the Cadastre IS and might be earlier unidentified objects of taxation.

Optimizing Public Participation through ICT and Social Networks: Questions and Challenges

Chiara Garau

(Chiara Garau, Research Fellow, University of Cagliari, Faculty of Architecture, DICAAR – Dep. of Civil and Environmental Engineering and Architecture, Via Santa Croce, 67, Cagliari, 09124, Italy, cgarau@unica.it)

1 ABSTRACT

Since the 90's, urban planning education, integrated with information communication technologies (ICT), has attributed great importance to training using communicative approaches, producing great enthusiasm which has been manifested in many experiences (Mitchell 1998; Talen 2000; Batty et al. 2003; Steinman et al. 2005). For the supporters of this experimentation (Kwan 2002; Sieber 2004) and increasingly strong scepticism (Angotti 2011; Craig et al. 2002; Esnard et al. 2004; Harris et al., 1998; Pickles 1995; Warren 2004), the issue of citizens e-participation in decision-making still remains topical. While the participatory dimension can be banalized or seen as "supporting" one-way communication aimed exclusively at the capture of consensus, on the other hand it can be consolidated by going beyond the web, thus developing the first virtual interactions, and only then belonging to the local communities, thus activating potentially virtuous dynamics. Starting from this position, the paper highlights (1) the importance of how the net is used, (2) how the transfer of online communication in local civic action can occur also with social networking, (3) how this can be evaluated, creating a prototype to quantify participation in social networks. The objective of this work is to identify opportunities and problems of participatory planning through new technologies offering possible solutions through a "discussed" use of ICT and the drafting of guidelines to enhance the sharing of knowledge between the different actors in the planning process.

2 INTRODUCTION

In today's society, civic participation in its various forms, has become not only more sought after in regulations, but increasingly necessary in order to find the promised certainties in the resolution of common problems (D'Ambrosi, 2011). In literature such resolutions are synthesised in two main ways: either they are conflitual or collaborative. In the first case, the community provides the impetus for the involvement in public decision making with the decision makers. These decision makers may be more or less receptive in carrying out their role, but in general the participative dynamic goes from the outside to the inside: the policy makers must demand a role in the decision making process (Arnstein 1969; Friedmann 1987; Reardon 1998; Beard 2003). Another aspect of this same model describes experts who, within the government, act on behlf of the citizens. Among the most important are the advocacy planners (Davidoff 1965), the equity planners (Altschuler 1965; Krumholz et al. 1990; Krumholz et al. 1994), and also the progressive planners (Clavel 2010, Angotti 2011). They use their professional expertise to deal with the problems of marginalized groups.

The second case, which since the 90s has been pushed more and more, sees the relationship between policy makers, citizens and public opinion as a process with great collaborative potential to develop. Within this process, on the one hand there is strong individuality, but on the other hand cooperation becomes fundamental both to sharing the responsibility and to trying out new ways of planning more suited to globalisation.

These reflections allow consideration of the concept of planning and participation, which, while maintaining the social and civic characteristics have led to a broader meaning: today we talk about interactive planning thanks to collaborative governance which allows for the creation and implementation of inclusive policies on an urban or regional scale (Innes 1995; Healey 1997; Forester 1999; Abers 2000; Fung, Wright 2003, Innes et al. 2003; Delli Carpini, Cook, Jacobs 2004, Crosby et al. 2005; O'Leary et al. 2009; Feldman, Khademian 2007; Briggs 2008).

On the one hand the concept of "interactive planning" is evocative of a flow of information which increases the knowledge of the various equal users spread accross the web's "Magnum sea", on the other hand, its combination with ICT results in the invention of political strategies based on reticular rather than homogenous logic. Recent researchers have underlined collaboration inside the network which includes both public and private actors (Kettl 2002; Booher et al. 2002; Hajer et al. 2003, Goldsmith et al. 2004; Agranoff 2007; Sandfort et al. 2008).

The drive towards paradigms imprinted on new cultural models has tried to construct a path that would integrate the classic path with the new theoretical models not only in local contexts.

However, if today there is consensus in recognising the importance of participatory processes, often there is obvious discontent in the absence of agreement or the adamant position taken on the issues in question or even in the degree of effectiveness perceived or measured in the inclusive process.

Based on these considerations, the collective process in which the content and forms of democracy are reconsidered is evident, giving particular significance to community participation. It is a process that today affects not only scholars and the institutional forms of government, but also groups, movements that express themselves in unconventional forms, thanks to web 2.0. However, the literature agrees that participatory processes must be structured and permanent (continuous not occasional); hence the need to construct contexts where the comparison of points of view might be the same for all matters of collective interest. The network can do much in this direction. In fact, it allows interation which, in various forms – for istance: Participatory Planning GIS (Garau, 2012); 3D models (Hudson-Smith, 2005); platforms and computer games; integrated portals with augmented reality, etc. (Hanzl, 2007) – also lets young people propose and share ideas, but also atypical forms of association.

3 THE IMPORTANCE OF THE NETWORK IN URBAN PARTICIPATORY PLANNING

The web is an interface for information about and the promotion of planning in progress. This is often a necessary tool for the sharing of experiences, coordination and organisation of actvities and events. There is a vast amount of literature about citizen participation through the internet. Weber believes, for example that the inclusive actions on the web exert positive influences on participation policies, independent of the civic participation (Weber et al., 2003). Conroy and Gordon found that technological approaches in public meetings increased the level of satisfaction compared to traditional public meetings (Conroy et al. 2004). But there are also those who argue the opposite: it becomes a problem accepting the validity of the interface technology which the citizen might not know how to manage. To this point the citizen may feel manipulated (Innes 2005).

Today, an active participatory environment that uses internet has great potential to engage the public. Just consider how the latest generation technology allows you to raise the public debate even to young people through new participatory forms and practices. This occurs, for example, with virtual communities and social networks which, more and more, interact asynchronously with each other, creating a multitude of interactive environments in which people socialise (Facebook, Twitter), share content (Flickr, YouTube, Stumbleupon, Digg, blogs) and skills (Wikipedia, Linkedin).

The use of these tools allows integrated forms of communication, encouraging the expressive dynamics of mobilisation; individual and collective spheres converge transforming the lack of transparancy of individual relationships, making them transparent, potentially able to activate civic actions in different public areas (Boccia Artieri, 2011).

Furthermore, it is important to note that also on the web, the instruments used in an inclusive process depend largely on the level of participation that wants to be attained. The International Association for Public Participation (IAP2), relying on the scale of participation proposed by Arnstein (1969), has articulated five levels of public participation (inform, consult, involve, collaborate, empower) each successive level allows a greater impact on the overall process. Low levels of participation (inform, consult) involve the use of information tools such as interactive websites, public meetings or focus groups. Higher levels of participation (involve, collaborate, empower) allow feedback and the consequent practical implementation of community projects, through tools which go beyond a mere expression of willingness by those involved.

In order to understand which participatory process might be more suitable, Schlossberg and Shuford, suggested a matrix with various types of "users" along one axis and various levels of "participation" along the other. According to the authors, the understanding of the place in which the participation occurs is essential for its greater credibility and effectiveness. In their model, for example, the web pages are only sufficient to inform and consult the netizens. Consequently, the choice of tools to facilitate effective participation should be dictated also by the constraints of the web and by the characteristics of the actors involved in the participatory process (Schlossberg et al. 2003).

The new online communications and in particular social networks allow three main actions that enable participation: educational or informative action; relational action and finally organised action.

It starts from an initial approach in which the actors involved use the virtual spaces to create and disseminate information about the phenomena in question (the interaction in this phase is conversational and the degree of participation is emphasised by, for example, the "likes" on facebook or on blogs and by the sharing of this information with other parties involved), and then use the technology as an active part in the creation of connections between many individuals, developing a sense of gathering and community (the interaction in this phase is marked by the individual will to express their opinions, inputting skills, experience and personal opinions). It can also arrive at a level in which the virtual space can influence forms of participation for collective mobilisation (the interaction in this phase reaches the most advanced levels and is designed to eliminate digital boarders, i.e. the dynamics constructed on the web become real, through heterogenous participatory actions which can be carried out in practice because they are put into the daily life of the city).

4 E-PARTICIPATION AS A SOCIAL ACTIVATOR IN LOCAL CIVIC ACTION

Virtual-real interaction is so powerful, above all for young people, that some researchers have underlined how for example social networks have assumed a relational role that has a direct impact on their lives (Leyts 2011, Valtat 2011).

However these relational forms have major problems: many virtual movements, drivers of local civic action, do not have any continuity. In fact, more often than not they reach a "relational" peak which coincides with certain events of public interest and only last as long as is required for that activity. Online exchanges between contacts and updates end as soon as the event or action is no longer a priority for public discussion.

Therefore, if on the one hand the online tools help to organise civic action in a decentralised way, on the other hand, they are not able to guarantee stability and continuity, if not near specific emerging events (Kavada 2010, p. 117). The power of the web appears evident and it would be desirable to be able to exploit the initial enthusiasm in order to succeed in creating live and permanent relational processes (continuous not occasional) taking care to maintain the communicative architecture of the web, assuming common long-term projects.

One way to do this, could be a "quantitative and qualitative assessment" of the results which measure the contribution citizens want to give to ensure that decision-makers work better. It is possible, for example, to create indicators to monitor the cultural, social, intellectual and political growth of the participants during and after participatory processes. This could be published from time to time online, monitoring and updating the data, creating a greater sense of civic belonging to those who are part of that movement.

In this way, estimates could be produced of the perception that the drivers of the group "support" not only their interests but also the online community's. The increased desire in wanting to participate in decision-making could be analysed because it gives confidence and credibility to the participatory process.

Public awareness on the issues and policies in the long term can allow an effective assessment of the results of the initiative. In fact, the effectiveness of a participatory process is associated with the coherence of objectives and instruments adopted. Often this fails because it is given at an early stage when expectations are not consistent with the objectives or the time set (Laino 2012).

In the whirl of discussions regarding this debate it is fundamental to focus on the original objectives and resulting criteria that have led to inclusive planning practice (these criteria can include, for example: data and information circulating, respecting the schedule and working to short, medium and long-term deadlines, effects and assessments of the participatory process, etc.). However, over the course of time it is not easy to keep up the commitment to building cooperation and adapting such practices into society.

5 THE CONSTRUCTION OF A MATRIX TO MONITOR THE DEGREE OF PARTICIPATION

When thinking about the preparation of a methodology to monitor the users' degree of participation, it has been suggested that an interpretation matrix is set up which, on the basis of indicators related to the concept of participation in social networks, allows the evaluation of forms, activation and effects. The analysis is inspired by the ladder of citizen participation introduced by Arnstein (1969), then developed by Schlossberg et al. (2003) and by Bailey et al. (2011) to then put it into the world of social networks.

Once the blogs, forums and generic pages have been chosen to monitor, it is necessary to evaluate two important criteria in the first phase: the level of interaction (ranging from simple dissemination of information to the interaction itself) and the level of interest (which goes from involvement to the autonomous participation of other users), both structured by the same parameters but following different logic. In particular for the first (interaction):

- activities – how often they are updated;
- intensity – intensity of the conversations, tone of voice, etc.;
- credibility – level of dissemination among "influencers" in the various reference areas
- impact – willingness to change an idea, propensities etc., in relation to the objectives set

For the second (interest):

- activities – number of comments (total and average) in each post; number of daily comments etc..
- intensity – speed of dissemination: once a new post is written, the time it takes for the other users to read it is evaluated;
- credibility – level of confidence in the drivers of the movement
- impact – conversations, actions, directly measurable, in relation to the objectives.

In this way for each blog or forum selected, a first approximation can be made with a methodological grid to assess the current situation of the level of influence (1 = low, 2 = medium, 3 = high) based on the interaction and interest taken (Table 1 and Table 2).

Example A	LEVEL OF INTERACTION		LEVEL OF INTEREST	
	Information	Interaction	Involvement	Autonomy
ACTIVITY		3		2
INTENSITY		3	2	
CREDIBILITY		3		3
IMPACT		3		1

Table 1. Example of evaluation of degree of participation in a generic blog in social networks

Example B	LEVEL OF INTERACTION		LEVEL OF INTEREST	
	Information	Interaction	Involvement	Autonomy
ACTIVITY		2	3	
INTENSITY	3		2	
CREDIBILITY	2		2	
IMPACT		1	1	

Table 2. Example of evaluation of the degree of participation in a generic blog in social networks

In order to allow comparison between more movements, the average of the sub-parameters is taken (activity – intensity – credibility – impact) so that there is a single numerical value for the level of interaction and interest. This numeric parameter will measure the degree of participation (Figure 1).
Fig. 1. Comparison of level of participation of generic blogs in social networks

The two axes (formed by the level of interaction and interest respectively) identify four areas where, in each one the partipatory valence changes: the first is the so called civic education, equipped with a low level of interaction (one way comunication) and a low level of interest among participants. The second, partnership connects a low level of interest with a significant level of participant interaction. In the third area, activism combines a high level of interaction with a high level of participant interest in terms of autonomy of the other users interacting in the blog. The last area, independence, links a high level of interest with a low level of of interaction.

It has been noted that the success or failure of a blog depends on a set of merits, causes and indiscretions in which roles, competences, duties and responsibilities are monitored continuously. With this in mind, this tool is anticipated as a prototype to help measure participation in online environments which are difficult to quantify.

6 CONCLUSION

Public participation has been a constant of the planning process, especially since the nineties. Every generation has made its unique contribution in an attempt to bring improvements to interactivity between citizens, government and policy makers. And while it woud seem that planning might not have an apparent need for the support of the social media, in some way, it has to seize its great potential. On this subject Christ (2005) was a pioneer, anticipating the concept that the social media would have led to a rethinking in the way to deal with the communicative and relational approach with the people involved.

Today one cannot underestimate the fact that on the one hand there is great technological progress which improves the quality of life of the individual, but on the other hand the model of development inevitably produces a social polarization in which users at different levels with the city "have to adapt in a constant and flexible way" (Castells et al. 2002, p. 82). This strong compromission of the city with the digital technology is evident in relation to globalisation (Sassen 2003); cities are in fact the result of a process of the redefinition of their structure, in which two complementary tendencies play a key role: on the one hand there is the push towards decentralization and territorial dispersion by the new information and communication technology (Barbieri 2010); on the other hand there is the tendency towards "global cities" acting as nodes in a network. It is important not to exasperate the research in seeking to engage the user in an almost surreal way, until it gets to a point in which it wants to make as real as possible what, in fact, is not real.

Planning in Fragile Sites in Turkey: in Case of Hasankeyf

Hale Mamunlu Kocabas

(Asst. Prof. Dr. Hale Mamunlu Kocabas, Mimar Sinan Fine Arts University, City and Regional Planning Department, mamunluh@gmail.com, hale@msgsu.edu.tr)

1 ABSTRACT

Hasankeyf is a small town in the Batman Province in southeastern part of Turkey, and located along the Tigris River. Hasankeyf is an ancient city and is rich in history. It hosted many different cultures like Byzantine Empire, Atudiks, Ayyubids, Ottoman Empire and contains more than 300 important archeological monuments like The Old Tigris Brige, The Citadel, Small Palace, Ulu Mosque, Süleymaniye Mosque etc., also thousands of caves exist in the cliffs in the city. Along these, it has a very sensitive and unique ecosystem. It has been declared a natural and cultural conservation area the Turkish government in 1978. Specialists and scientific researchers claim that Hasankeyf meets the criteria defined by the UNESCO-World Heritage Center and should be added to the World Heritage List.

However, the Ilısu Dam Project seriously threatens Hasankeyf, the potential World Heritage Site. This project was prepared many years ago without the evaluation of Environment Impact Assessment Report and without consideration of the unique heritage qualities of Hasankeyf. Ilısu Dam Project was designed to be the second biggest dam and the 4th highest power and energy production plant in Turkey and planned as one of the most important investments in GAP-Southeastern Anatolia Project, which is the primary element of the long-run regional development plans of the southeast of Turkey. There were even international supporters at the beginning such as Austria, Germany and Switzerland. Even though there were so many objections and protests by Non-governmental organizations, the project has not been canceled yet. This site will be inundated, and the identity and memory of the Hasankeyf will be lost if the construction of hydroelectric Ilısu Dam Project comes to an end. As a solution, they plan to transfer all the settlements lay on that area to another place in the same region.

This paper aims to discuss the critical situation of planning in fragile sites in Turkey with regards to the case of Hasankeyf in context defined by the following question: How to plan for a 'unique' potential World Heritage Site (WHS) whilst taking into account, both past history and future development possibilities? In this context of the paper, suggestions are made in relation to the planning regulations and organizational structure for the sustainability of conservation areas.

2 GENERAL CHARACTERISTICS OF HASANKEYF SITE

Hasankeyf is a historical place located near the Tigris River in the southeastern Turkey, north to the Mesopotamia (see figure 1). With the advantages of Tigris River, which is rich in water resources, the region had hosted more than twenty civilizations including Rome, Byzantine and Seljuk, and survived until today. Due to the water resources, it had been strategically important in every period of history as well as an economically active site due to being on the historical Silk Road and accordingly with its traditional architectural buildings, such as inns, caravanserai etc. in the course of history. It is a well-known fact that this historical city and its surrounding attract a great number of local and foreign tourist each year.

The exact date of the establishment of Hasankeyf has remained in dark so far; due to the insufficient data and information in hand, the opinions on its establishment have been nothing but a possibility. The geopolitical location of the city, its importance as well as many caverns occupied for settlement purposes indicate that Hasankeyf is a very old settlement. The history of the Hasankeyf dates back to the ancient age. The name of the city which is Hısnkeyfa is translated as 'Kayahisarı'. It had been stated that these words mean a place 'which is easy to defend' in the old history and by tribes. Since the fortress is massive stone, Hasankeyf means 'Stone Fortress' in various languages (Hasankeyf Town Governorship). Unique quality of buildings in the site and ruins embodying the basic settlement characteristics of a Middle Age Islam city as well as its unique landscaping make Hasankeyf a WHS which must be protected with care. The genuine Middle Age city texture of the site, worth-to-see artifacts and the co-existence of nature and history dramatically spellbound the visitors. With its natural elements, cultural landscape, high quality work of arts, first-class architectural buildings and engineering structures, Hasankeyf is not only important for its region but also for the world (Ahunbay & Özge, 2010, p:1).

Figure1. Location of Hasankeyf, the WHS in Turkey. Source: http://maps.google.com/

This unique and sensitive historical place is declared as first degree Conservation Area (CA) by the Republic of Turkey Ministry of Culture in 1978. Since then the 2005 United Nations Education, Science and Cultural Organization (UNESCO) Operation Guidelines set out the generic key qualities of the unique World Heritage Sites which are also valid for the Hasankeyf CA. The function of UNESCO is to protect and preserve the cultural and natural heritage properties which were developed by different cultures and civilizations through the human history and enlighten the different phases, stages, richness and differences of this common past, by drawing attention on the fact that these properties are increasingly in danger due to not only conventional destruction but also the changing social and economic conditions.

Figure 2: Settlements of Hasankeyf. Source: http://www.dogadernegi.org.

UNESCO evaluates the natural and cultural heritages in the world according to 10 criteria. Hasankeyf fulfills the 9 of these criteria which are set out below as follows:

1. To represent a masterpiece of human creative genius.

Hasankey is an outstandingly valuable site with its masterpieces such as the tomb of Zeynel Bey, Sultan Süleyman Mosque and Bridge and Citadel towering above the waters of Tigris River. In particular, the doors of the fortress and bridge design are unique artifacts.

2. To display an important exchange of human values, over a certain period of history or cultural area, on developments in architecture or technology, monumental arts, town planning or landscape design.

With several examples, Hasankeyf was a source of inspiration to its visitors and persons who had an influence on their own culture by carrying their experience with them. Hasankeyf had hosted many persons through the centuries and had been the melting pot of many rich and interesting experiences. For instance, Iranian architect of the tomb of Zeynel Bey was the person who introduced the glazed brick to this city which has a very solid background in stonemasonry. The architectural structure of the tomb is also new for the site; a style which born in Samarkand, the capital of Greater Timur Empire, and crossed beyond the Iran reaching up to this city. A trip towards east or west to the Hasankeyf reveals that such kinds of structures also reach up to Istanbul. As another example, Hasankeyf Bridge is famous with its 40 meters central arch. The remnants of the bridge give an idea about the exquisite details of its design. The tradition of building bridges with single span on the great rivers is repeated around the 16th century by Architect Hayreddin who constructed the Mastar Bridge, which is today inscribed on the World Heritage List.

3. To bear a unique or exceptional testimony to a cultural tradition, living or disappeared civilization.

The attributes which make Hasankeyf unique are its exceptional location on the Tigris River and urban elements survived until today. In the recent excavations, interesting findings which belong to Roman age and previous ages are brought to the light, which gives us the hint on the deep-rooted history of the city. Site is geographically under the influence of Syria and Iran architecture. Also the modernization waves of 19th and 20th centuries has not destroyed city, which makes the site more important as a rare ruin.

4. To be an outstanding example of a type of building, architectural or technological ensemble or landscape which illustrates (a) significant stage(s) in human history.

Hasankeyf is a host which welcomes very rare architectural types of Anatolian-Turkish architecture. The building called as Kızlar Mosque is an interesting example of the tomb architecture. With its cylindirical walls ornamented with the glazed bricks and double-wall dome, Tomb of Zeynel Bey is the only mausoleum under the influence of Timur period. Göreme, located in the Cappadocia and one of the World Heritage sites is a World Heritage protected area with its churches carved into the rocks and underground cities. Also in Hasankeyf, many house, religious and business buildings are carved into the rocks. These traditions provide us important historical and aesthetic data on the civilizations existed near the Tigris River for very long years.

5. To be an outstanding example of an human settlement, land use or sea use, in particular, this example should have not lost its durability under the impact of irreversible change.

Taking its special position and uniqueness, this historical settlement which conserved the traditional living spaces carved into the rocks is an extraordinary protected area with its reputable Middle Age buildings. The city water supply system, caverns, stone houses and the store complex carved into the rocks on the road rising above the Fortress illustrate a thousand years of art and mastership as well as skills and cultural tradition of the residents. In the recent period, traditional lifestyles of the residents have changed dramatically; in 20th century, they moved from the caverns to the Down Town. Today, the dam project, pressures of change due to the contemporary lifestyles as well as tourism expectations are the risks with which this Middle Age town faces.

6. To contain superlative natural phenomena or areas of exceptional natural beauty and aesthetic importance.

Hasankeyf is located in the north to the Tigris River, one of the two great rivers making up the Mesopotamia. The river is the most basic potable water resource and for hundred thousands of years everything in the site has been shaped according to the river flow. This also includes the human settlements dating back around 10.000 years. The riverbed is alone a unprecedented natural miracle, since in its flow direction from Turkey to the Persian Gulf, it created a unique system of geological formations and a wide range of riverbank systems. This system of geological formations includes deep canyons, moist gallery forests, sandy places just a few meter to the half-deserted sites and calcareous steps occupying a very wide area. Also human history which developed monumental civilizations contributes in the natural geography of the Tigris River.

7. To be outstanding examples representing major stages of earth's history, including the record of life, significant on-going geological processes in the development of landforms, or significant geomorphic or physiographic features.

The section of Tigris River in the territory of Turkey is in the south to the collision zone of the Arabia and Anatolia continental planes. It deeply digs the bed of the Tigris River especially around Hasankeyf and continues to flow towards the south. It seems that most of the Valley of Botan Creek (Uluçay) springing from Siirt and emptying into Tigris will remain under the water after the launch of Ilısu Dam. This valley which is shaped as a result of massive tectonic elevations is a sort of Great Canyon of Turkey. The slopes of the Tigris Valley are full of with the limestone which is easy to dissolve when contacted with the water. This attribute allows for the formation of natural caverns which had been used as a house by the residents in the past.

8. To be outstanding examples representing significant on-going ecological and biological processes in the evolution and development of terrestrial, fresh water, coastal and marine ecosystems and communities of plants and animals.

Following the rapid destruction of the river and canyon ecosystems in the Euphrates basin, Tigris Valley remains the sole and last example which has these attributes in the southeastern Turkey. The uniqueness and irreplaceable of the site can also be understood from the number of types of migratory birds sensitive and in danger and the sizes of the biological diversity specific to this basin (Welch 2004; Eken et al. 2006). Eken et al (2006) identified five Important Natural Sites (INS; globally significant sites in order to protect the biodiversity) in relation with the section of Tigris River in the territory of Turkey. In addition to these INSs, Welch talks about five 'Priority Sites' which compose of one single and complete ecosystem along the Tigris Valley (Ahunbay & Özge, 2010, p:2-8). All the freshwater aquatic species in the area are the species irreplaceably specific to that region. The section of Tigris in the territory of Turkey is still a river part which is protected and untouched.

9. To contain the most important and significant natural habitats for in-situ conservation of biological diversity, including those containing threatened species of outstanding universal value from the point of view of science or conservation.

As it will be conceived by the existence of five difference INSs within the territory, this stream system is very important in terms of natural habitats and threatened species. 1. INSs of the Tigris River can be listed as Bismil lowland, Tigris Valley, Küpeli Mount, Eruh Mountains and Cizre Silopi NSI. Under the influence of Mediterranean, step and desert climates, Tigris Valley is a very wide biodiversity area for many endemic species which are extremely in danger and have the priority of protection such as Cicer Echinosperium. The cliffs dominating the Site are the habitat of species such as Hiertus Fasciatus, Falco Naumanni, Nephron Percnopterus and Gyps Fulvus, which are globally in danger. Steep and arid sandy hills are important reproduction habitat for rare bird species such as Apus Affinis, Emberiza Cineracea and Ceryle Rudis. Rafetus Euphraticus is endemic specie living in the Tigris and Euphrates stream systems. This turtle specie lays their eggs in the sands around the riverbank of Tigris. Capra Aegarus uses the rocky cliffs and steep canyons of the Tigris Valley. Hyaena Hyaena living in the caves and caverns of the Site is one of the priority mammal species in INSs (Ahunbay & Özge, 2010, p:2-8). However, the CA universally is a 'World Heritage Site' due to housing natural and cultural remnants of various ages.

In order to protect Hasankeyf and Tigris Valley, which is under the large urban development pressures in the context of current changing social and economic conditions and which must absolutely be protected as a WHS, the Turkish Government must apply UNESCO to enlist the Site as an official World Heritage Site.

3 ILISU DAM PROJECT AND ITS IMPACT ON THE HASANKEYF CONSERVATİON AREA

Designed in 1950s and approved in1980s, Ilısu Dam Project is currently being constructed on the Tigris River as a part of Southeastern Anatolia Project (GAP). It is a multi-sector, integrated regional development project launched in the region of Southeastern Anatolia, one of the relatively less developed regions in the country, comprising 9 administrative provinces (Adiyaman, Batman, Diyarbakir, Gaziantep, Kilis, Mardin, Siirt, Sanliurfa and Sirnak) in the basins of the Euphrates and Tigris and in Upper Mesopotamia. The GAP had been planned in the 70s consisting of projects for irrigation and hydraulic energy production on the Euphrates and Tigris, but transformed into a multi-sector social and economic development program for the region in the 80s. Social processes have become important for environmentally resilient planning and resource management. The basic strategies of the project include fairness in development, participation, environmental protection, employment generation, spatial planning and infrastructure development.

Its basic objectives include the improvement of living standards and income levels of people so as to eliminate regional development disparities and contributing to such national goals as social stability and economic growth by enhancing productivity and employment opportunities in the rural sector. As an integrated project, it goes beyond physical investments in such facilities as dams, power plants and irrigation schemes and encompasses activities and investments, in a coordinated manner, in many diverse fields including agricultural development, industry, rural and urban infrastructure, communication, education, health, culture, tourism and other social services.

State Water Authority which operates the project on behalf of the ex-Ministry of Environment and Forest describes the purpose of Ilısu Project as follows; 'Ilısu Dam Project will contribute to the development of Southeastern Anatolia Region, notably of provinces of Diyarbakır, Batman, Mardin, Siirt and Şırnak. When completed, it will provide an annual added value of 400 million US Dollar in our economy with the annual average energy generation of 3,833 billion kWh. Ilısu Dam and Hydroelectric Power Plant (HPP) is the Second Largest dam and HPP in terms of water volume and the Second Largest in terms of installed power and the largest dam and HPP on the Tigris River and when completed, it will provide an annual added value of 400 million US Dollar just in terms of electricity generation. It impacts 144 settlements, including 1 town, 101 villages and 42 arable fields and a total of 37100 citizens living on the project boundaries. A new settlement area is created named ' New Ilısu Village' as an alternative to the citizens living in these settlements under impact of Project. Tigris River is the last river of which ecosystem has not been intervened by such as dam etc. on the Southeastern Anatolia. However, with the construction of the Ilısu Dam, Tigris River will lose this attribute and the historical Hasankeyf settlement will remain under the water.

On the grounds of Dam construction which began before 1993, it is legally exempted from requirement of issuing Environmental Impact Assessment. Pursuant to the Environmental Impact Assessment Regulation published in Official Journal No 26939 dated July 17, 2008, Environmental Impact Assessment (EIA): defined as the identification of positive or adverse impacts of the projects planned on the environment; of the measurements which will be taken in order to minimize or eliminate the adverse impacts on the environment, of the works which will be executed in the monitoring and control of the project implementations as well as of the evaluation of the alternatives to the project sites and technologies to be adopted. However, pursuant to the provisional article of this regulation; provisions of the Environmental Impact Assessment Regulation are not applicable on the exempted projects which are started before publication of the Regulation in Official Journal No 21489 dated February 7, 1993.

It is certain that the impacts of the Ilısu Dam will cause the irreparable consequences. Ilısu Dam, at the same time, does not fulfill the Environmental Impact Assessment, Water Framework Directive, Habitat and Bird Directives, Strategic Environmental Analysis Directive of the European Union, EU Human Rights standards and World Bank standards Bern Convention, World Bank Committee principles, which are undersigned by Turkey. The Environmental Report issued by three European companies in 2005 was very poor and insufficient work and adopted the approach which ignores the consequent fact of Hasankeyf remaining under the water and resulting damages on the ecosystem.

As indicated in the working report 'Evaluation of the Ilısu Dam Environmental Impact Assessment Report' published in 2006 for the Ilısu Dam and Hydroelectric Power Plant (Ilısu Project) by Doğa Association;

(1) Ilısu Project will cause a great environmental impact since it will change and deteriorate irrecoverably the critical natural habitats.

(2) The impacts which will be caused by the project are not explicitly stated in the Evaluation of the Ilısu Dam Environmental Impact Assessment Report, the measurements required for alleviating the impacts of the project and World Bank's OP 4.01 Environmental Assessment and OP 4.04 Natural Habitats Implementation Policies, which are among the international conditions Environmental Action Plan (EAP) of the project are not fulfilled. Thus, the measurements for minimizing the adverse impacts of the project suggested by the project are not capable of offsetting the biological diversity to be lost due to the project.

(3) Evaluation of the Ilısu Dam Environmental Impact Assessment Report does not suggest other alternatives of the project at a sufficient level.

(4) The activities which must be performed for the public participation and public opinion pooling at the start and during the Evaluation of the Ilısu Dam Environmental Impact Assessment process were not fulfilled comprehensively at the level required by OP 4.01.

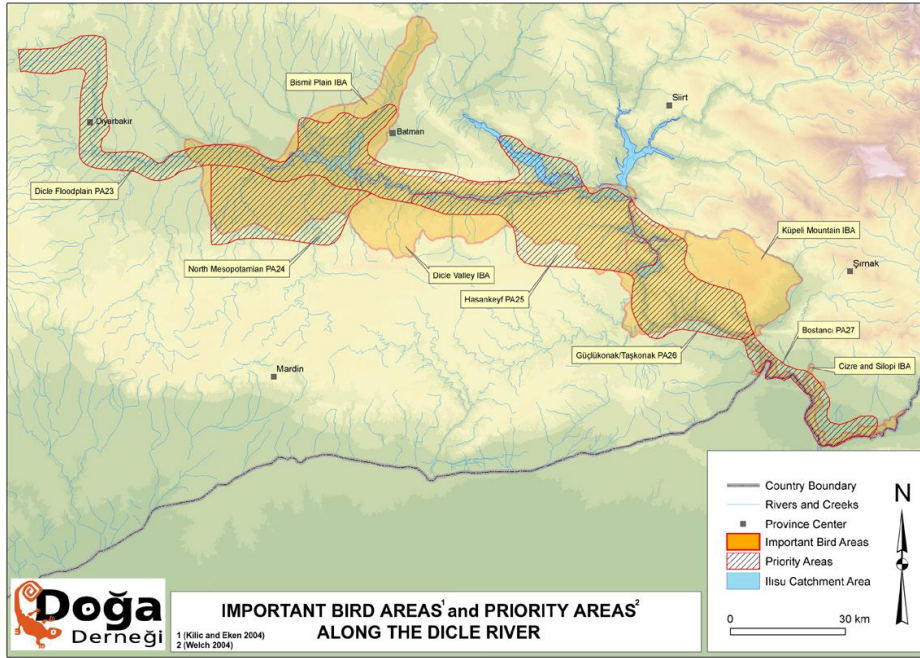
In addition, Evaluation of the Ilısu Dam Environmental Impact Assessment Report is intended to fulfill the standards of Work Bank, it shortly mentioned on the publication 'World Bank Environmental Resource Book' (1999). Particularly 8th and 10th sections of this resource book provide suggestions on the 'Dams and reservoirs' and 'Hydroelectric projects'. Although the 2nd Section of the 'World Bank Resource Book and Environmental Assessment Resource Book Version No. 12 (October 1997) and the book Biological Diversity and Environmental Assessment Tools (March 2000) are relevant to the issue, surprisingly enough even their names are not mentioned in the Evaluation of the Ilısu Dam Environmental Impact Assessment Report (Doğa Association, 2006, p: 14).


Figure 3: Important Bird Habitats and Priority Sites along the Tigris River. Source: Doğa Association, 2006, p:10.

Notably of Doğa Association, many non-governmental agencies, academicians, intelligentsia and public take initiatives for many times to inscribe the Hasankeyf on the World Heritage List and brought the issue to the world agenda and found supports from the international arena. Nevertheless, Turkish Government has not given up this project and has not applied UNESCO for inscription of the Hasankeyf on World Heritage List.

Despite of worldwide protests, Germany, Austria and Switzerland agreed on the project with Turkey in 2007. As a result, European companies are incorporated in the Ilısu Project. However, three European countries demanded the fulfillment of the 153 criteria for the development of the project. The Project was required to meet to the World Bank Standards. However, during the time, Turkish Government did not perform the demands in order to fulfill the standards, Germany, Austria and Switzerland cancelled the agreement they made with Turkey in 2009 and withdrew their loans (Doğa Association Publications, 2010). Nevertheless, Ministry of Environment and Forest which insisted on the implementation of the project, procures financing from two local banks. When the Ilısu Dam Projects is brought into life, it will have irrecoverable damages on the natural and cultural values of Tigris Valley and Hasankeyf as well as tourism industry, which is important for the region as well as the country.

4   EVALUATION OF THE PLANNING PROCESS OF THE SITE

While the resolutions concerning the preservation of the natural, historical and cultural structure of the region are incorporated in the Report on the 'Environmental Plan (Scale: 1/100.000) for the Region encompassing Mardin, Batman, Siirt and Hakkari Provinces' (uncorfimed) issued by the Ministry of Environment and Urban Development, the Ilısu Dam is accepted as a postulate under the title of projects and investments which govern the plan decisions, which is in contrary to these resolutions adopted. In the Report: it is stated that there are dam, HPS, Airport, Railroad and Industrial investments which will support the development of the Region. The transportation projects increase the accessibility of the plan region and open the gate for new suggestions. By benefiting from the water potentials in the region, the launch of Dam and HPS projects will play an important role in the meeting the irrigation and electricity need. The

evaluation process of the HPS projects of which applications made by the private sector should be facilitated and pave the way for the investments and 23 HPS Projects are estimated. Among them, Ilısu Dam which will be one of the largest dams of Turkey is legally exempted from the requirement of preparation of Environmental Impact Assessment due to the fact that its construction began before 1993. This is very mistaken attitude. In the recent years, the establishment of the HPSs of which adverse impacts on the natural cycles and ecosystem are very well-known has become widespread under the privatization scopes, the number of which has been increasing in an uncontrolled manner.

Again in the same Report of Environmental Plan; although it is said that concerning the protected areas 'this areas shall be subjected to the Law on Protection of Culture and Natural Properties No 2863 and relevant regulations as well as relevant resolutions of the boards', and without considering the 'protected area' attribute of Hasankeyf and most probably without consulting the Protection Board, new plan resolutions are brought about the settlement. Since the Hasankeyf will remain under the water as a result of Ilısu Dam Project, it is intended to change the settlement site. In the Report it is stated that 'Especially, Ilısu Dam will have important effects on the region. The dam which will cause the historical values to remain under the water will contribute in the region in terms of agricultural and electricity generation..... By resolving on the Sub-Zone Development plan of Ilısu Dam Lake Surrounding; Hasankeyf has an important historical and cultural potential at the intersection of the civilizations. However, since the settlement will remain under the waters of Ilısu Dam of which construction started in 2006, it will be moved to the area which is proposed by the Mass Housing Administration to the north of Kuru Neighborhood across the Tigris River".

The public who was still living in the rock caverns according to the climatic characteristics which is generally hot and arid and warm in the winter, are expelled from the caverns without pooling the public opinion and compelled to live in reinforced concrete houses planned new under the name of modern settlement area during the 1970s. Again with this project, despite of all protests, relocation is planned without pooling the public opinion and participation.
Figure 4: Current Settlement of Hasankeyf &New Settlement of Hasankeyf in Ilısu Dam Project Plan. Source: DSI.

Under the resettlement works to be carried out in New Hasankeyf Town, the 1st Phase infrastructure tender is completed in 2010 under the Development Plan works with the budget transferred by DSI General Directorate to TOKİ Administration. It is claimed that the new settlement will be a modern town with its 58 houses, technical infrastructure, school, government office, municipality service building and green areas etc. and an attraction for water sports and tourism. According to the Ilısu Dam project plan, certain monuments of the cultural and historical importance will be demounted and rebuilt in an 'Archeological Park' in a new zone to be constructed near the dam reservoir. New area which is 10 km to the current Hasankeyf is at the hills of Raman Mount. Although feasibility and archeological diggings has not been completed in the Hasankeyf, specialists emphasize that demounting of these monuments from their places is technically impossible. Furthermore, the genuine texture of the Hasankeyf, the nested togetherness of the natural and cultural values, rock caverns, tumulus etc. will be destroyed irrecoverably. Council of State adjudicated on

the imposition of the EIA requirement on the Ilısu Dam Project and suspension of the execution thereof in the course of action filed by TMMOB Chamber of Architectures and Chamber of Landscape Architectures in relation with the Project which will submerge Hasankeyf town in the waters and has adverse impacts on the ecosystem of Tigris Valley on7th Januar 2013.

Area Status	New Hasankeyf	Current Hasankeyf	Increase
Settlement Area (Hectare)	294.86	50.82	6 times
Green area (Hectare)	78.7	0.87	90 times
Green Area (Ratio)	27 %	2 %	14 times

5 CONCLUSIONS

Each town/region in Turkey houses very unique and rich history, cultural and natural values. However, due to the lack of awareness both of these values as well as of protection of them, very sensitive, fragile and important CAs are adversely affected. Despite of the increasing awareness on the values attached to the historic areas and their protection in the recent years, actions taken are insufficient. Tigris Valley which houses Hasankeyf is the home of both natural and historical and cultural values which must be preserved. The settlement which has the attributes of the World Heritage is threatened to be remained under water once the Ilısu Dam Project is completed. When Hasankeyf case is considered in terms of planning, two issues are apparent: firstly, preservation of the Tigris River is essential and secondly protection of the natural and historical cultural structure of the Hasankeyf is essential. Ti6gris River is one of the most important rivers and the most sensitive ecosystems of the world in terms of water resources. In this respect, regional strategic planning approach is required to protect this exclusive structure of the Tigris River and valley to ensure its sustainable development.

Today, urban developments pressures on natural environment present problems. Planning ad management perception that is sensitive to 'water' resources respecting nature and taking sensitive ecological thresholds in to consideration intended for providing sustainability and also resiliency is gain importance. This approach, which is based on the ecologically centered planning, is directed beyond the planning of the water sources towards the integrated planning and management, which evaluates the natural systems and the social, economic and cultural systems all together. Basins become important as a strategic planning unit in ensuring the balance between protection-utilization and protection from the natural disasters/risks. In this context, innovative basin planning and administration approaches needed to ensure sustainable development in CAs. Today, in Turkey the function of planning and administration of the water resources is mainly delegated to the State Water Authority the moreover, uncoordinated and conflicting decisions between authorities may results in fayour of development in CAs; (such as in the Hasankeyf example, development of the Ilısu Dam Project of DSI despite of the protected area decision of the Ministry of Culture and Tourism).

Development of an integrated planning and coordinated administration approach at the Basin-scale would enable various actors both at central and local levels to work as a team. In addition such a transparent and innovative organizational structure would enable participation of the local actors who will consider the sensitive ecosystem of the basin. This restructuring will pave the way for the creation of the inventory of genuine ecosystems of the basin, analyses of the environmental impact assessment of the plans and projects designed and an integrated assessment of them. Moreover, all the residents, workers etc in the basin would receive awareness trainings whilst contributing the planning processes. In this context, legislation must be amended to include the establishment of the 'Basin Agencies' as well as issuance of the 'Basin Management Plans'. Basin Management Plans which would provide a roadmap at the regional scale must also be in compliance with the decisions on sub-scale areas of protection inside the basin (natural, historical and archeological protected areas etc). The natural, historical and cultural values of region should be protected and its tourism potential should be improved.

Although Hasankeyf is declared as a protected area, it does not have a Conservation Plan. The protection plans must be prepared for the area for the immovable cultural properties and artifacts in the CA. As stated by Article 20 of Law on Protection of Culture and Natural Properties No 2863 'The in-situ protection of the immovable cultural properties and artifacts is an essential principle'.

Moreover, with the 1992 Valetta/Malta European Treaty on Protection of Archeological Heritage to which Turkey is a party, Parties to the Treaty have to take necessary measurements to protect the archeological heritage, to take archeological research activities under the scientific assurance, to ensure preferably in-situ protection and care of the archeological heritage. Turkish Government must apply to the UNESCO for inscription of the Hasankeyf on the World Cultural Heritage List by preparing CA Plans.

Turkey inscribed 2 mixed (cultural/natural) and 35 cultural, a total of 37 properties on the UNESCO World Heritage List since 1994, its first inscription. The requirements on 'Area Administration' and preparation of 'Area Management Plan' which are defined by UNESCO as the indispensable elements for the protection of the Heritage Sites/ Conservation Areas just began appearing in our national legislation. Site administration is a unit which brings the authorities and agencies together and enables all the works to be performed with collaborative and participative processes by identifying goal-oriented protection policies under the main principles. There are number of Area Management Plans prepared for relevant sites in example Edirne, Istanbul, Çatalhöyük. In this respect, 'Area Management Plans' can be prepared for Hasankeyf under the current legislative framework.

The main Regulation governing the protection of CAs is on the 'Law on Protection of Cultural and Natural Properties' No 2863. Article 2 of the legislation state that; 'The scope of this regulation is the procedures and principles concerning the identification of the functions, authorities and responsibilities of the advisory board, site president, coordination and audit board which will take charge in the identification of the administration sites of the protected areas, archeological ruins and interchange field and junctions, the preparation, approval, implementation and audit of the administration plans as well as execution of the site administration'. In the Regulation, the targets of the site administration are to ensure following;

a) the accurate identification of the site borders, its interaction zones in an integrated historical, social, cultural, geographical, natural, artistic perspective and the junction points with which it is related due to the historical, cultural, social, geographical and artistic reasons in terms of protection, development and assessment of the site,

b) indication in the administration plan of the ways to create an appropriate balance between protection, accessibility, sustainable economic development needs and local community,

c) the development of the general strategies, methods and tools to raise the value of the site up to the international level, determination and creation of the financial resources for such purposes,

d) The establishment of an activity network which will create an international collaboration and exchange in order to develop the cultural tourism,

e) the development of implementation plans in order to improve the regional cultural systems in the protected areas having the potential to create an industry by associating them with each other within a certain region,

f) the cooperation between local community and public authorities and agencies, non-governmental organizations, persons with ownership rights in the site, voluntary legal or real persons in protection and evaluation of the administration sites,

g) Care, repair, restoration, restitutions of protected areas and archeological ruins as well as interaction fields. The identification of the utilization and development principles and limits as well as keeping it alive by preservation under the international protection principles and provisions of treaty in line with the site administration goals together with the display, organization and landscaping,

h) Adoption of high standards in the administration of the cultural properties, conservation area, design and implementation, professions and equipments.

Given the current legislative framework, it is possible to prepare an 'Area Management Plan" for Hasankeyf would have a paramount importance in order to ensure balance between protection in the region with a view to sustainable overall development complying with the upper scale plan decisions.

Planning Times of the City: an Overview on Urban Time Policies

Marco Mareggi

(Marco Mareggi , Adjunct professor, Politecnico di Milano, DAStU, via Scalabrini 76, 29121 Piacenza, marco.mareggi@polimi.it)

1 ABSTRACT

Urban and social time emerged as a theme of public policy and in Italy it has been translated into public actions at the end of the 1980s. Its significant focus was centred on the coordination of urban timetables, particularly those of public and private services, in order to make daily life easier. In Italy, hundreds of municipalities, few metropolitan cities and networks of small and medium towns are involved to promote these kinds of policies. The time-space approach has been disseminated also in other countries of the European Union and recently the Congress of Local and Regional Authorities of the Council of Europe has adopted a recommendation in order to foster local time policies.

This paper analyzes the development of urban time policies in Italy after the implementation of the national law (Act 53/2000) and, in particular, its relation with the regional legislation. From this point of view, it is possible to appreciate the "trespassing" of these policies on gender's equal opportunities, social welfare policies and urban planning (for this one with not constant and difficult interactions). Secondly, the paper reviews what happened about the implementation of urban time policies at regional level, both in Northern and Southern Italy, where the increase of local time policies is also a consequence of the allocation of regional and national funds. In conclusion, the paper proposes a classification of the towns' experiences in their specific relation with urban planning (urban time policies, time oriented urbanism and a spillover of planning tools at different territorial levels) and represents an opportunity to discuss weakness and opportunity (specific field of public policies and toolbox to enrich other policies) of the "trespassing" of these policies.

2 INTRODUCTION

Time is a fundamental component of social interaction. Every single behaviour takes place in time and in space. The urban and metropolitan life has made the relationships more complex and the management and coordination of social time and programs, in particular in the urban contexts, became a planning and design issue. After the crisis of the modern city these themes have been periodically take into consideration in Europe. In the Seventies, in France, the radical experiments of social time's re-organization (Chiesi, 1989: 15) were not adequately implemented and they quickly failed (Échange et projets, 1980). At the end of the 1980s, in Italy, were launched the urban time policies. Their significant focus was centred on the coordination of urban timetables, particularly those of public and private services, in order to make daily life easier. "It soon became clear that working on the time schedules of public services means influencing individual relationships, mobility of people and the real possibility to enjoy the city as a collective property and common good" (Italian Environment Ministry, 1999: 50).

In this way, urban and social time emerged as a theme of public policy and it has been translated into public actions. On the basis of previous spontaneous and ground-breaking experiences, local time policies, with the implementation of the national law (Act 53/2000), have become a "duty" for the Italian municipalities.[1] This law concerns family care and parental leaves and makes definition and implementation of the "Territorial Timetable Plan" or TTP (Piano territoriale degli orari) compulsory for the municipalities with more than 30.000 inhabitants. This legislative tool, highlights the importance of time in public actions, and it is even more important today, in the context of the global crisis, because of the increasing flexibility and precariousness of the labour market.

In 2000, it was affirmed that 170 municipalities had been involved in time-oriented projects, in timetable plans, or in studies concerning urban social time. After the implementation of the national law, the dissemination of these projects started to be more connected to the role played by the regions and the municipalities. At the moment, hundreds of municipalities, few metropolitan cities and networks of municipalities of small and medium towns are involved to promote these kinds of policies.

---

[1] Disposizioni per il sostegno della maternità e della paternità, per il diritto alla cura e alla formazione e per il coordinamento dei tempi della città, Act 53/2000 (Dispositions to support motherhood and fatherhood, for the right for care and education and for the co-ordination of the times of the city).

The time-space approach, that has a clear Italian origin (Mückenberger, 2011: 241), has been disseminated in other countries of the European Union (Boulin & Mückenberger, 1999; Mareggi & Bonfiglioli, 2004). Nowadays, it has been experimented by French cities (companies and territories) and by few German and Spanish cities. In France, a long process of social animation produced national non-legislative initiatives and local interventions in municipalities that, after, decided to set up a national association.[2] Some cities, like Lyon, Paris, Belfort and Poitiers, implemented specific time policies; some other cities (Dijon) introduced some aspects of these specific policies in the urban planning and design practices (Boulin, 2008; Rochman &Tremblay, 2011). In Germany, the planning of the town schedules is mainly an opportunity to trigger a buttom-up approach to new projects and to develop specific initiatives in few cities, like Bremen, that copied the Italian idea of setting up a specific office in the municipalities to develop projects and ideas for social animation (Mückenberger, 1998; Eberling & Henckel, 1998). In Spain only few cities, like Barcelona, promote communication campaigns and local policies to reduce the problems of life-work balance in the family context. On the contrary, in the Netherlands, from 1998 to 2002, the State has been promoting an important program about "Daily routine (Dagindeling)" organizing a big national communication campaign and 140 projects about town schedules and life-work balance (Dijst, Karsten & Breedveld, 2002; Tummers 2007). Unfortunately, this successful initiative suddenly ended. It was all about a limited dissemination of explicit time policies, and a big production of implicit time policies dealing with work-family life's reconciliation (labor, welfare, gender and family policies) widespread all over the European member states. Recently, the Congress of Local and Regional Authorities of the Council of Europe adopted a recommendation (Rec 295/2010) and a resolution (Res 313/2010) – named "Social time, leisure time: which local time planning policy?" – addressed to the 47 member states in order to foster local time policies.

This paper analyzes the development of urban time policies in Italy after the implementation of the national law (Act 53/2000) and, in particular, its relation with the regional legislation and the allocation of grants to the municipalities that, in Italy, are the main institutions that play a real role in the management of the urban and social schedules. Secondly, the paper reviews what happened about the implementation of urban time policies at regional level, both in Northern (Lombardy, Veneto, Emilia-Romagna and Piedmont) and Southern (Apulia and Abruzzi) Italy, where the increase of local time policies is also a consequence of the allocation of regional and national funds. In conclusion, the paper proposes a classification of the towns' experiences in their specific relation with urban planning (Italian middle-size cities with a long experience in planning and implementing time policies, network of towns and European metropolitan cities ongoing experiences) and represents an opportunity to discuss weakness and opportunity of the "trespassing" of urban time policies in other public policies.

3 TWO GENERATIONS OF REGIONAL ACTS

The national law Act 53/2000 entrusts the municipalities with the task of implementing the policies of harmonization and coordination of the times of the city, recognizing the promotion role they played in the previous decade. The same law entrusts the regions with the task of issuing laws in this sector in order to allocate grants. This role is getting more and more important because the regions can support and spur the action of the local institutions. The regions, moreover, ensure the continuity of the Municipal Time Offices, especially now that the global crisis is extremely strong.

According to a survey carried out in 2008 (Mareggi 2010), the number of regions that have regulations about urban time policies is quite high. Only 4 regions in the Centre-South of Italy and one region in the North of Italy cannot count on specific regulations in this sector (Fig. 1).

The survey identifies two different generations of regulations concerning the cities' Territorial Time Plan. These two kinds of regulations have both proposed ideas and allocated grants.

The first generation of regional laws, in the Nineties, involved the North and the Centre of Italy. Only 9 regions issued laws to implement the guidelines contained in the national law that reformed the local institutions and entrusted the mayor with the task of coordinating the urban schedules (art. 36, Act 142/1990). These laws:

---

[2] The network "Tempo Territorial" (http://tempoterritorial.free.fr/) was funded in 2004 and now, in 2011, it is made up of the Municipal Time Offices (and similar offices) of more or less twenty cities/provinces/regions.

Fig. 1: Italian Regions that have regulations and bills about time policies (Mareggi, 2010: 38). Some regions present different normative tools indicated with over-lapped symbols.

- fostered social and time policies concerning public and private offices, social services, public transportation and commercial/tourist/leisure/cultural services;

- proposed criteria for the organization (and sometimes even the regulation) of the opening hours of the public and private services, to improve accessibility and usability (intended as the possibility to combine personal needs with the fixed opening hours of the services);

- contributed to renew the government's agenda, increasing the importance of the public action and answering the citizens' daily problems;

- supported preliminary surveys to write down the Territorial Timetable Plan (this practice was often not efficient enough).

These laws aim at coordinating and regulating the time schedules. They propose a clear definition of the intervention' sectors. But, sometimes, the local actions implemented on the basis of these laws are not organic and not suitable for the territorial contexts and their local actors (Mareggi & Bonfiglioli 1997).

These different laws – in their chronological sequence – express an evolution of the sector, able to create and offer visibility to a political, social and scientific united community considered as an issue network that becomes policy community (Heclo, 1978; Balducci, 1991: 102).

At the end of the Nineties, only the Tuscany Region felt the necessity to propose a second law about these topics (l.r. 38/1998). This was a ground-breaking action that represented a change and an interesting example for the government of the cities, also intended in the physical sense. Moreover, this law supports the implementation of new interventions and it recognized that only mixing knowledge and practices you can support policies and make them more meaningful, as local policies have demonstrated. Then, it proposes the approval at the same time of the TTP and of the Land Use Plan, fostering the inclusion of the time policies in the urban planning (exactly through the regional laws). Last but not least, it makes clear that people (subjects of different age, gender, origin and culture) are the mirrors of the changes that take place in the space and time of daily life.

The second generation of regional laws implement the content of the Act 53/2000. It involves the entire national territory and even the South of Italy. Some regions prepared specific laws or updated the previous ones while, in the second half of the first decade of the century, other regions included these contents in some laws concerning equal opportunities and social policies or urban planning policies (with ambiguous value). These laws:

- allocate the state grants of the Fund for the Harmonization of the Times of the City that was opened with the Act 53/2000 and distributed through calls for proposals according to the European model;

- support the implementation of actions (but also surveys and feasibility studies) carried out by the municipalities or by networks of municipalities;

- support actions to improve the quality of daily life and harmonize the work/life balance, the personal relationships, the training opportunities and the personal time of all the people who live, even temporarily, on a territory; and also actions to ensure equal opportunities for men and women;

- taking into consideration the experiences of the municipalities and of the universities that have studied these topics, the laws propose new goals and guidelines;

- foster integrated policies to reconcile life/work, flexibility of the working hours, revitalization of the urban, economic and social life, provision of services and sustainable mobility (coordination of the transportation hours, alternative mobility reducing the use of cars and the emissions of polluting gases in the sector of transportation).

In this way, urban time policies enlarge their fields of interventions, over their traditional sectors. The practices seem to exploit the new possibilities offered (with uncertain results) by the new laws. However, some experts underline that the constant attention to side-results, like for example the reduction of pollution and of the car traffic, has weakened the main goals of the Act 53/2000 that was designed to foster the harmonization of the working, care, training and social time. In this way, the reasons which are at the basis of the production of the TTP are searched in other sectors, far from the original motivations that produced the temporal policies as a tool to work on the town and increase the liberated time in the society.

This search of justifications "somewhere else" demonstrates a will (or a weakness) that seems to anticipate the loss of a specific sector. The laws for the TTPs changed the focus about urban planning (in Tuscany differently than in Basilicata), or are used for the development of policies in favour of gender's equal opportunities (in Apulia and Liguria); somewhere else, they are included in the social or family policies (in Piedmont and Friuli Venezia Giulia, while in Abruzzi and Emilia Romagna also offer support to the companies), or they become a tool to implement the "Zone Social Plans" (Piano sociale di zona) for a better social welfare (in Campania and Apulia). The fact that the Fund for the Harmonization of the Times of the City became a part of the National Fund for the Social Policies contributed to the creation of the general framework explained here above.

It is possible to divide the trends for the definition of the public action in this sector in three different categories, starting from the regional laws. In the first category are included the specific policies (Lombardy and Abruzzi); in the second are included those time policies which are considered side-policies of other public policies considered priorities in the agendas of the regional governments (Apulia, Liguria and Campania); in the third are included the policies that are not well-defined and do not have specific aspects.

This variety of laws underlines a wider characterization of the centers for the development of the time policies and, in contrast with the previous decade, it reveals the lack of a united and recognizable political and scientific community. The general framework is twofold: on one side, the regional laws introduce in the government agendas a social necessity and they give it the same importance of a public policy; on the other side, the variety of the local interventions seem to produce a great variety of disharmonious practices.

4 A REVIEW OF URBAN TIME POLICIES IN THE DIFFERENT REGIONS

It is interesting, at this point, to change the perspective and focus on local practices. In this paragraph they are still considered from the point of view of the different regional watchdogs that tried to analyze from the quantity point of view if the municipalities have accepted the (economic) proposals of the laws and the directions of their interventions. This is an overview of the synthetic outcomes produced in some regions of the North and South of Italy. This analysis is the result of an original research about the regional documents (that cannot boast a specific literature) carried out by the writer of this paper.

From 1997 to 2009 in Piedmont 174 municipalities (out of 1.206) approved a coordination plan of urban times (17 of them have a population of more than 30.000 inhabitants and, for this reason, they are obliged to do it by the law), but only 14 of them have implemented a project. The money allocated are more or less 1,8 billions of Euros distributed through 12 calls for proposals. Few municipalities, from 1997 and 2001, demonstrated their interest. Then there was a peak in 2002 and the trend was kept constant till 2007 (Bocco,

2012: 158). Turin, on the contrary, has recently (2008-2011) carried out some integrated space-time interventions in the districts, winning a public-private foundation's grants.

The Region Emilia Romagna, thanks to the first generation of laws, promoted TTPs integrated with the urban tools in order to improve the services' network, the public facilities, the commercial services and the mobility infrastructures. After the national law, on the other side, it has oriented the local action towards the services for children and the flexibility of the working hours. Through specific regional calls for proposals, from 1995 to 2000, have been allocated some regional grants: the interest of the municipalities has not been constant and it has decreased. According to some managers of the public administration, this situation was provoked by the small amount of money available for the single institutions (less than 50.000 Euros for the projects' implementation). On the other hand, this situation was probably related to the high quality of the region welfare that ensures a high level of women employment. Only in 2004 the Region decided to open a new call for proposals to foster future actions concerning the TTPs or agreements between the companies and the trade unions about new flexible working hours (projects for childhood, adolescence and family). 14 interventions were carried out and they produced a great variety of results. Recently, because of the reduction of the amount of money transferred by the State to the territorial institutions, the Region has decided to allocate the resources of the national fund in a different way.[3]

In Veneto, after the approval of the national law, only two regional calls for proposals were opened for the definition of the TTPs. 1,1 billions of Euros were totally allocated, equally distributed between the first call for proposals in 2004 that gave money to 6 municipalities with more than 30.000 inhabitants, and the second (2011-2012) that gave money to 24 small and medium municipalities (from 5.000 to 40.000 inhabitants) for projects concerning local plans for the reconciliation of life and work. The first call for proposals was financed by the National Fund for the Harmonization of the Times of the City, the second used the resources allocated by the Department of Equal Opportunities of the Italian Government for interventions to improve the reconciliation of private and working life. It was implemented a new set of public policies in several sectors to support families, the inclusion of women in the labor market and to ensure a work for them. In these two calls for proposals, the focus of the actions is the support to families and their time organization with services destined to parents who work and have children (easy access to services and helpdesks) creating a friendly social context.[4]

From 2003 to 2011, Region Abruzzi has opened 4 calls for proposals investing 340.000 Euros and allocating money, in some cases even a small amount (less than 10.000 Euros) to each institution. Totally were involved 3 capital cities and 5 networks of municipalities who cooperate in the social sector, for a total of 52 (out of 305) municipalities that have presented the TTPs. Only 2 municipalities and a network of municipalities implemented the planned projects. The main issues of the plans were: harmonization of the timetables of public and private services with the working hours; accessibility of the information helpdesks and of the services of public administration (helpdesks, cultural services and quality of the social services); work on mobility that can contribute to reduce the emissions of polluting gases in the sector of public transportation. As the mountains characterize the territory's inner part, the actions were mainly destined to answer the necessities of young families/tourists of small villages. The theme of the equal opportunities was not adequately analyzed. Especially the first experiences were mainly focused on co-design and participation and not on implementation.[5]

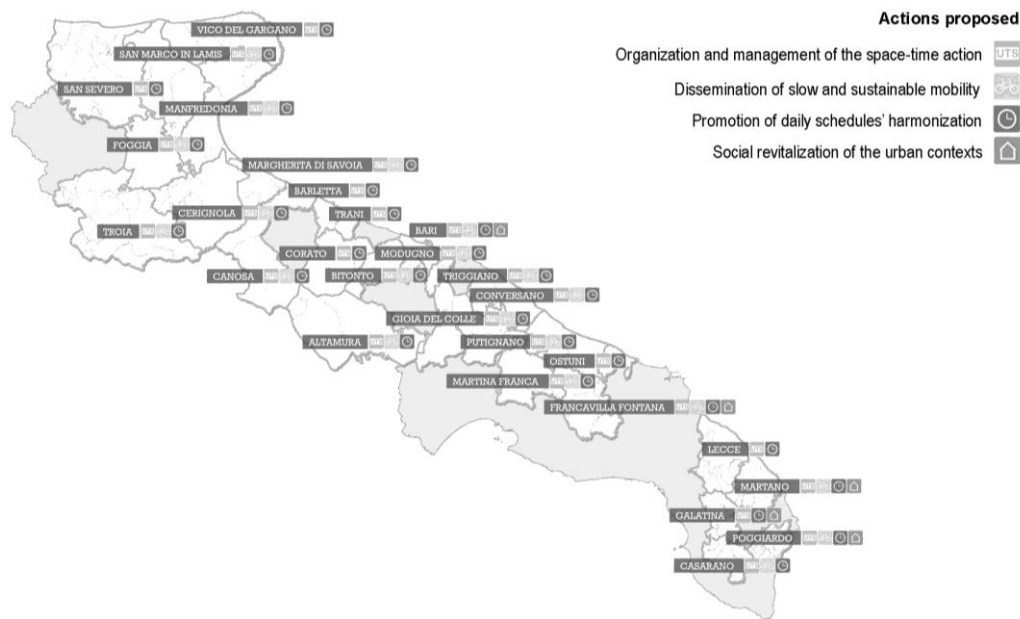
[5] REGIONE ABRUZZO: Attuazione delle politiche regionali dei tempi (l.r. 40/2005, art. 8, comma 3). Relazione informativa. March 2009.


Fig. 2: Territorial areas of Apulia Region that have participated to a call for proposal 2009-2011 in order to carry out a feasibility study for the Territorial Timetable Plan (Source: Region Puglia, 2012).

In 2007, the Region Apulia started to implement urban time policies. The law for equal opportunities (Regional Act 7/2007), in fact, introduced rules for the coordination of the hours, timetables and places of the town. The general intervention's criteria and the different kinds of projects present original and characteristic aspects of the territorial context but also, in general, of the policies concerning social life and equal opportunities: new services for depopulating areas and a new organization of the school timetables to fight drop-out and prevent social unease; promotion of participation and renovation works in suburban areas by children, seniors and families; creation of "work/life balance centres". Moreover, with a significant change in comparison with the most important Italian experiences, Apulia law is characterized by a strong connection between TTP and the "Zone Social Plan". With the call for proposals 2009-2011 were approved 26 feasibility studies for the TTPs of municipalities associated in territorial areas[6] that proposed the goals of their actions (Fig. 2). The total amount of money allocated was 3 millions of Euros. Then, the region decided to allocate a grant of 35.000 Euros for each of the 17 territorial districts that, in February 2013, start experimental actions for the implementation of the TTP and will set up an Inter-Municipal Time Office. The feasibility studies aim at improving the social welfare: the harmonization services for the families who have children (school extra curricular activities, school-house transportation also with public means of transport), services for seniors who live in rural areas (home care, increase of shops in the neighborhoods, transportation to daily centres for seniors, slow mobility), on-line services that make easier the access to institutions. In some experimentations are planned even some actions to change the calendar of the school-weeks (5 days per week) in primary and secondary schools (experimentation in Lecce for some weeks).[7]

The Region Lombardy approved a law about these issues only in 2004, even if, in the previous years, several social actors (university, trade unions, chamber of commerce and other organizations) and some other municipalities had implemented concrete actions concerning the urban time policies and had decided to set up Time Offices dedicated to these issues. Five cities had already approved the TTP. The law (Regional Act 28/2004) introduced the key themes and questions that mark the second generation of laws described above. In implementing this law, the region reaffirmed some necessities that characterize this public policy: a specific municipal department/office dedicated to these themes; the joint implementation of experimental actions and the definition of the TTP. In nine years, Region Lombardy has launched 4 calls for proposals (one is ongoing) and 10 cooperation agreements with the municipalities with more than 30.000 inhabitants

---

[6] These municipalities associated in territorial areas are similar to the inter-municipal management of some health-social services organized in Italy through Social Zone Plans.

[7] REGIONE PUGLIA, PRESIDENZA DEL CONSIGLIO DEI MINISTRI-DIPARTIMENTO PER LE PARI OPPORTUNITÀ: Studi di piani di fattibilità per i Piani dei Tempi e degli Spazi. Bari, Foggia, Lecce, 2011. that in 2008 still did not have a TTP. The total amount of money allocated by the Region was 10 million of Euros. The municipalities that received a grant were totally 129 (out of 1.544) and 46 of them received money from different calls for proposals for the implementation of the initiatives (Fig. 3). In this way, 49 cities and 11 networks of municipalities approved a Territorial Timetable Plan and carried out specific policies/actions. The actions focused on several themes:

- synchronization/de-synchronization of school timetables (extra school activities, harmonization of school calendars, family care during holidays);

- coordination of the shops' opening hours (night/Sundays opening with festivals in the public space, changes in the opening hours);

- cooperation with the Zone Social Plans and with the urban tools for the definition of the services' system;

- telecommuting;

- urban renewal also through participation planning with the inhabitants of the areas;

- harmonization of the events' calendar;

- coordination of the services destined to tourists and visitors (environmental-friendly means of transport for tourists, tourist services);

- sustainable mobility for the reduction of pollution provoked by means of transport (collective cabs, environmental-friendly shuttle buses, on-demand transportation, pedibus and bicibus, night transportation to discos, bike sharing, house-school transportation);

- accessibility and hours' usability of the services mainly of the public offices (changes in the opening hours, night opening, helpdesks in the commercial centers, temporary helpdesks, "one-stop services", "Citizen's Day") also on-line (certificates' service, booking and payment).

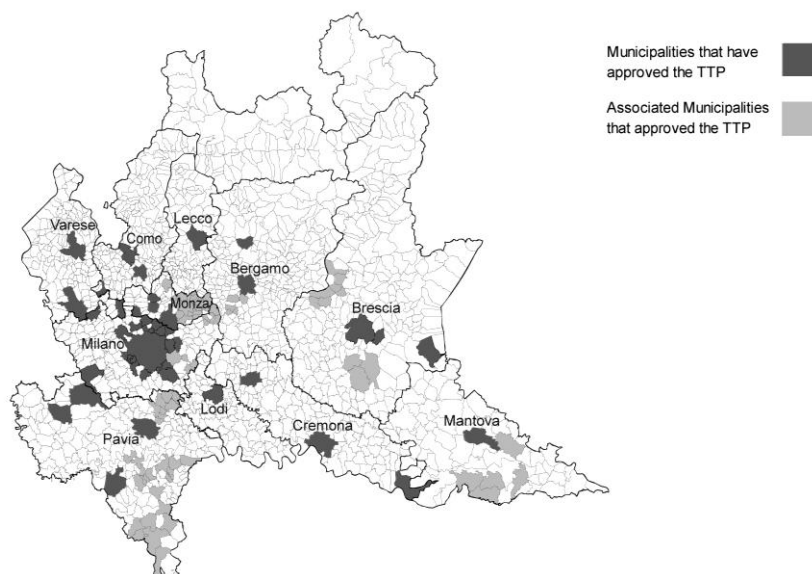
The on-going call for proposal fosters the implementation of actions in the last two sectors.


Fig. 3: Municipalities of Lombardy Region that have approved the Territorial Timetable Plan of the City (Data Source: Region Lombardy, 2012).

Lombardy Region has decided to take actions involving the municipalities as they are the institutions destined to the implementation of urban time policies. The Region, however, has also decided to foster inter-sectoriality and to include explicit references to this public policy in tools and laws concerning the services' planning, the quality of the environment, the opening hours of the shops, the sustainable mobility, the local transportation, the Zone Social Plan and the tools for companies' competitiveness.[8]

[8] REGIONE LOMBARDIA: Tempi delle città in Lombardia. Politiche regionali per il coordinamento e l'amministrazione dei tempi delle città. Attuazione e risultati della legge n. 28/2004 risposta alla clausola valutativa. Milano, May 2011. REGIONE LOMBARDIA: Politiche temporali urbane in Lombardia. Le pratiche dei comuni.

On the other hand, it is necessary to underline the will of the Lombardy municipalities to act in this sector even independently from the regional support. This is demonstrated by the work of some municipal Time Offices or by the independent interest to revitalize Milan's Time Office in the last year.

In this overview are not analyzed some regions in which were promoted urban time policies before and after the approval of the Act 53/2000 like Tuscany, Liguria and Marche (for these regions were not carried out researches).

According to the results of this analysis, the regional institutions are promoting and demonstrating an interest (even if it is not constant) for these themes. There are big differences in the economic resources invested by the regions and in the grants available for the municipalities, with a decrease in the amount of money allocated in the last years. It is important to underline that in 2002 the Fund for the Harmonization of the Time of the City (art. 28, Act. 53/2000) was included in the National Fund for the Social Policies that does not specify the distribution of the money destined to urban time policies. The decision about the amount of money to be destined to the TTPs is a task of the regional government (done only by some of them). It is possible, however, to collect more money through other national grants. In 2011, for example, Region Veneto has decided to include the time policies in the framework of some projects designed to improve women's employment.

Even if the recent laws have fostered the institutionalization of the management tools and the concrete implementation of the actions, in several regions it's still quite evident the trend to spur the design projects, plans and feasibility studies without particular attention to the set up of the Time Office or to the actions carried out and their results. Lombardy Region is an exception in this context.

From the point of view of the definition of the projects' main issues, the implementation of the regional calls for proposals confirmed an increase in the number of themes treated and in the arguments to justify them, but also a strong connection with the tradition of previous practices. These initiatives are not well-integrated with the urban context and do not involve some subjects, even if the actions – when they are implemented – seem to face specific problems and time needs and timetables (finding proper and feasible solutions).

5 CITIES' EXPERIENCES

At this point, the paper focuses on the actions implemented by the towns to plan their urban timetables. This is the main point of view that has been used for years for the surveys in this policies and research sector.

Starting from the city means recognizing that the projects are not only related to state and regional calls for proposals, as it demonstrated by Bozen with its 20 years-experience in this sector, or by Turin in the last years or by Milan (more recently). The cities and the social actors that promote time policies in Italy act not for a "duty" or for a strong legislative reasons. The decision of implementing urban time policies is generally a political choice of some administrations that decide to promote innovative projects, setting up Time Offices and managing social arenas.

For the classification of these policies have been considered: the dimensions of the cities involved, the main issues of the projects (Bonfiglioli, 1997; Belloni, 1997; Paolucci, 1998), the methodologic organization of the Territorial Timetable Plan (Chiesi, 1997) and the characteristics of the public action (Mareggi 2002). In this paper I want to propose a different analysis, mainly focusing on the relation with urban planning. During the last twenty-five years, in Italy, the analysis of the "times of the city" and the "reflections on actions" have developed in three fields of intervention.

The first field of intervention – that is the biggest one – is urban time policies produced by municipalities with private/public partners. These policies are widespread in Italy, as it is demonstrated also at legislative level. Urban time policies are public policies that intervene in the time schedules and time organization that regulate human relationships at urban level. These local policies become a specific field of intervention of the public actions/policies and they are implemented with a variety of approaches. The actions are carried out with the involvement of local partners and in a cross-sectorial way involving different departments of the municipality that is, generally, the promoter. The policies produced have different relevance regarding services (school, commerce, transport, tourism, public administrations, safety, public spaces), an urban area

or the entire city and have different impacts on citizens and the organization of services. The brief analysis presented for Region Lombardy presents an overview of the experiences. Several Italian municipalities have approved a Timetable Territorial Plan, as it was said in the previous paragraph. It is not clear the continuity over time of this sector of public policies, because it is characterized by strong contradictions: above all in the public administration these urban time policies are managed as sectorial actions, but the nature of time schedules and of social times is intrinsically transversal.

The second field of intervention is time oriented urbanism. At the beginning the promoters have the ambition to create a new approach of land use planning. Few experimental cases are promoted by the university world and municipalities, as in Bergamo where the TTP is part of the town planning and the municipal Time Office develops integrated actions for the space-time management and provides a set of new ideas for the Land Use Plan and for the planning of the services (Zambianchi 2010). Other experiences that use time as a component of the urban plan are detected in Tuscany, where it has been compulsory till 2005. The few cases in the literature do not testify particular characterization and performing skills. Limited experiences are implemented in France, for example in Dijon, but also in this case they are not related to a specific public policy or a set of specific projects. Time is recognized as a resource (exactly as space, water and energy) necessary to make the town more attractive and pleasant. (Trouwborst 2012).

The third field of intervention is a spillover of planning tools at different territorial levels, implemented by public administrations in Italy (and Europe). Introducing in this way time oriented variables in preliminary studies and analysis, and tools to define strategies and renewal policies and projects. There are several examples. The new TTP of Rozzano (2012), a municipality near Milan, collaborates with the Land Use Planning of Services to test usability and accessibility of open spaces, both for the description and for the potentialities after the implementation of the new Land Use Plan (Mareggi 2013). Some urban projects are focused on daily time intended as slow mobility (for example Ancona) or as quality of the urban space and housing (for example San Donato Milanese) or, to improve the "habitability" profile of the city (like in Bologna). The life in different seasons in the territories is the topic of several analysis, like for example the Adriatic Coast (with dynamic or traditional techniques of analysis or studying the mobile telephones' data) and in excellent cases of Land Use Plan like in Urbino in 1990-94 or to design strategic pictures of the territorial regional plan of Emilia-Romagna. The temporary uses are a fundamental element of the strategic document for Berlin 2020 and of experimental geographical studies in Gorizia and Nova Gorica. Stable and moving populations (and their calendars) renew the traditional studies for mobility in some large scale planning tools (Mareggi 2011).

Defining these three fields of interventions is a way to recognize that, also starting from the city, the planning possibilities of the urban times changed from a public specific and characteristic action (that remains the main field, urban time policies) towards interventions in other sectors, in this case analyzed in relation with urban planning. In this movement toward other sectors, in the best practices, the urban times become opportunities to change the focus of the projects and move it towards contexts. On the other sides, methodological tools, that have been developed and tested in the urban time policies, are implemented and often enriched.

6 CONCLUSION

The path presented in the paper starting form the regions offers an original point of view about the researches concerning these topics that are generally analyzed taking into consideration the action carried out by the cities. Moreover, it underlines a specific characteristic of the Italian approach to this public policy that mixes top-down behaviors of the central and regional governments with the bottom-up action of local institutions and actors. Their mixture has probably ensured a quite constant presence of these themes in the agendas of the government, even if they still have a second-level position.

The three points of view presented in the paper (the regional rules, the implementation in the regions, the experiences of the cities) recognize a specific thematic field of public policies (Drewe 2005) even if this theme is considered in a wider way in comparison with the original goal of "setting the time free for everybody". At legislative level, the trend is towards gender's equal opportunities, social welfare policies and family policies and towards urban planning (for this one with not constant and difficult interactions). For the implementation in the regions, it is reaffirmed the will of increasing the number of topics that are at the basis of the interventions, while the panel of actions are traditional. The actions tend to face time problems

and needs finding proper and feasible solutions. The cities' experiences seem to have detected (or oriented?) the increase in the fields of intervention that the new laws allow and support and, moreover, they use in different sectors the methodological and operative toolbox offered by the space-time oriented approach.

This "trespassing" represents a weakness and an opportunity.

The search somewhere else for strong motivations and the lack of a specific characterization are a weakness of a sectorial public action because it reduces its appeal and its capacity to attract economic and human resources. Perhaps it has also been reduced the social interest that was at the basis of these policies but it has not been reduced the complexity of the urban and metropolitan life that the global crisis has worsened for families and single subjects. Moreover, a competition among the sectors of the public action, for example among the equal opportunities policies (that work on the subjects and mainly with the companies) and the urban time policies (that work on the city and mainly starting from the municipalities), can reduce the strength of them both. In the same way, the relationship with the urban planning policies is even weaker and less important.

The "trespassing", however, could be an opportunity as they could open two scenarios (not in mutual contrast and not in competition) that can trigger on one side urban time policies intended as a specific public policy (with the specific weakness of the sector that become part of the action), and on the other side the use of methodological and operating space-time oriented tools to enrich other social and urban policies (that use technical and methodological expertise as a significant and collaborative contribution but not exclusive or dominant). Perhaps this work in specific and respected fences (both in political and research sector) can improve knowledge and savoir faire about the city's and citizens' time.

1   ABSTRACT

The last two decades in Poland has been a period of expansive growth of small businesses, and dynamic transformations of the space around the city. The development of these two phenomena occurred in a period of economic transformation after year 1989. Dynamic changes of the spaces surrounding the cities based on movement of people and enterprises from the central city into the suburbs are nowadays the main field of interdisciplinary scientific research on the topic of the city. It seems that the characteristic element of the Polish suburban landscape is a large number of SME sector businesses located there.

The research team expresses the opinion the reason for locating SME businesses in the suburban areas is not only the lower cost of conducting business compared to the city centers. Decision about location are dependant on many various factors of spatial and social character.

The main aim of the article is to examine the level of interaction between the process of suburbanization and the development of the SME sector in selected suburban areas on the example of the Tricity Metropolitan Area (TMA).

2   THE BACKGROUND OF DEVELOPMENT OF THE TWO PHENOMENA

2.1 The genesis of the polish suburbanization

The American term urban sprawl is strongly associated with the lack of consistency in terms of morphology. It is characterized by the fact that the location of objects is spatially dispersed and unrelated . In addition, this form begins to take over the functions of the central city as more and more come here shopping centers, new public spaces and so-called business parks . There is lack of traditional compact building area and relationships between the different parts are quite random and also appear inefficient transport network and system of media technical infrastructure. However, the scale of suburbanization is different in different countries (Fig. 1). Disciution abut the problem of the suburbanization shoud also add the issue of the scale and than investigate if the proceess are the same and differ only about the sacle.

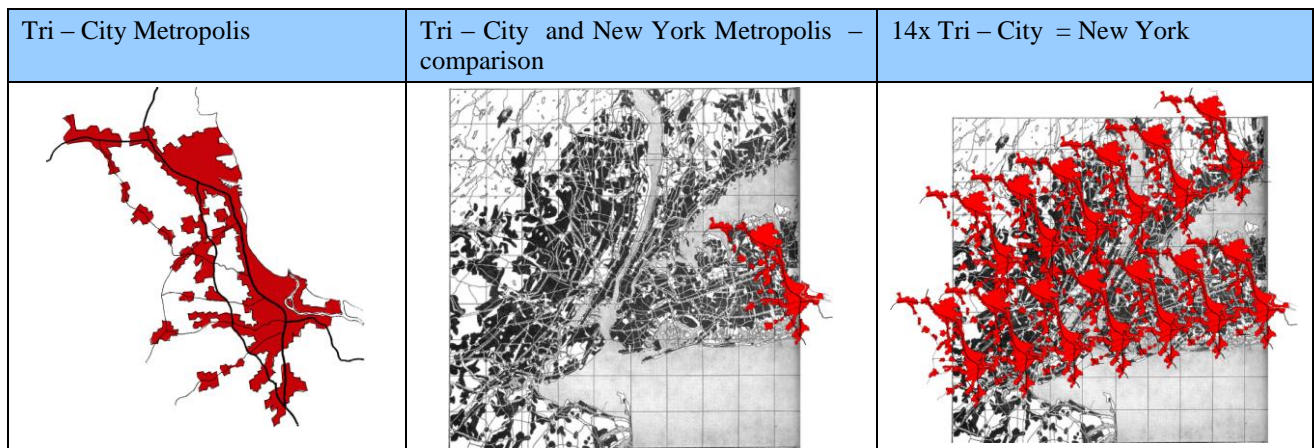
Tri – City Metropolis	Tri – City and New York Metropolis – comparison	14x Tri – City = New York


Fig. 1 : Suburbanization in the metropolitan area of Tri-City and New York – a comparison. Source: own study based on J. Martyniuk-Peczek, American Dream and Polish matter: Polish and American context of urbanization, P. Lorenz (Eds.) The problem of urbanization. Warsaw: Urbanista, pp. 103-112

However in polish landscape not only the scale differs. The genesis is also a bit differed. The polish process of suburbanization is linked strongly with the change of the political system after 1989. Completely different than it have been in the Western Europe or the U.S., where the processes has began with ideas healing of industrial city and new movement of garden city. When after the the Second World War the processes of suburbanization have been particularly strongly developed in the United States, Poland was at that time in a completely different model of planning – central planning. In 1945 decree "of the planned spatial

development of the country" was introduced.[1] This decree, including the next decrees, like "the state investment plan" of 1946 and "a planned national economy" in 1947 established the general rule, introduced after the Second World War, the so-called. "Socialist planned economy system." An important element of the system created the Polish People's Republic (PRL), was taken over by the state of basic means of production, and as a consequence – take control of the central principles of development. The consequence of such treatment was short-term economic planning, and the planning was in isolation from the economic condition of the country. Social planning turned out to be an illusion. Any attempt to bring the private sector to extensive urban development is typically ended takeover of private owners of significant field surfaces. The legal bases for expropriation were local zoning plans. In this respect they were primarily used as a tool for limiting the private sector of the economy. The owners used the various legal and illegal ways to build over their lands. (for example, sold for "supposed relatives"). The consequence was the practice of the various methods of private investment, which departed from the principles of planning time spatial order logic. As a result of the abolition of ground rent, reducing the functioning of the real estate market and the expulsion of private property in the PRL has been to deform the structure of spatial planning, the devastation of the visual landscape, as well as the formation of a typical "urban fallow land," or undeveloped areas in attractive locations. At the same time, however, PRL has left millions of newly built apartments, all modern in concept districts and numerous public buildings (schools, hospitals, offices, etc.).

The reform of the political system in1898, resulted in the introduction of the Land Use Act, but only after 1994. Until then apply Starna detailed plans yet. Spatial Development Act of 1994 abolished the central and hierarchical system of spatial planning, equipping municipalities' ultimately decisive power largely on land use throughout the country. It was a change in the system consisting of the departure of creative and comprehensive planning, supported by legislative and planning the transition to a regulatory nature, which is to take into account, inter alia, the right to property. From that moment there was a very intense and expansive process of urban sprawl. The community determined the rules and allocation of the land. Municipalities want to grow try to attract new taxpayers. The flexible development policy was introduced. In practice, it looked that the former agricultural lands were chaotically transformed the development areas. The process is relatively young – only two decades but very strongly growth.

The consequence of this process is nowadays suburban polish landspe made of the amorphous structure of the urban periphery, where relics of agricultural activities and focus of intense economic activity penetrate the frail structures extensivei housing and wasteland areas. There are no strict regulations allowing space in the initial phase of intensive economic development of the suburban zone which later formed the basis of conflicts and barriers to development, determining the functional capacity of the weakening economy in the mature stage of development. In metropolitan areas, where the observed trend of increased sprawl and suburban sprawl often comes to the creation of "a new form of in-between-city" , the city distributed network of the city, the fuzzy, functionally strongly connected, but devoid of the spatial compactness of traditional and non-traditional canons spatial order.

2.2 The rise of SME sector in Poland

Entrepreneurship, as a social phenomenon, is a very complicated process causing many problems regarding the analysis of its nature. It is known that entrepreneurship creates economic growth and social development, but it is unclear how it happens. People establishing business activities have various motives – from economic and social to the will of accomplishment. However, it is unknown what configuration of motives has the greatest influence on the success of an undertaking. Finally, it is obvious that enterprising employees are valuable to their employers. However, methods of making the most of their potential are still searched for .According to the GEM Report, the countries are divided into:

- factor-driven economies,
- efficiency-driven economies
- innovation-driven economies.

The GEM survey classified Poland in the second group .

---

[1] Tölle A., Wdowicka M., 2012

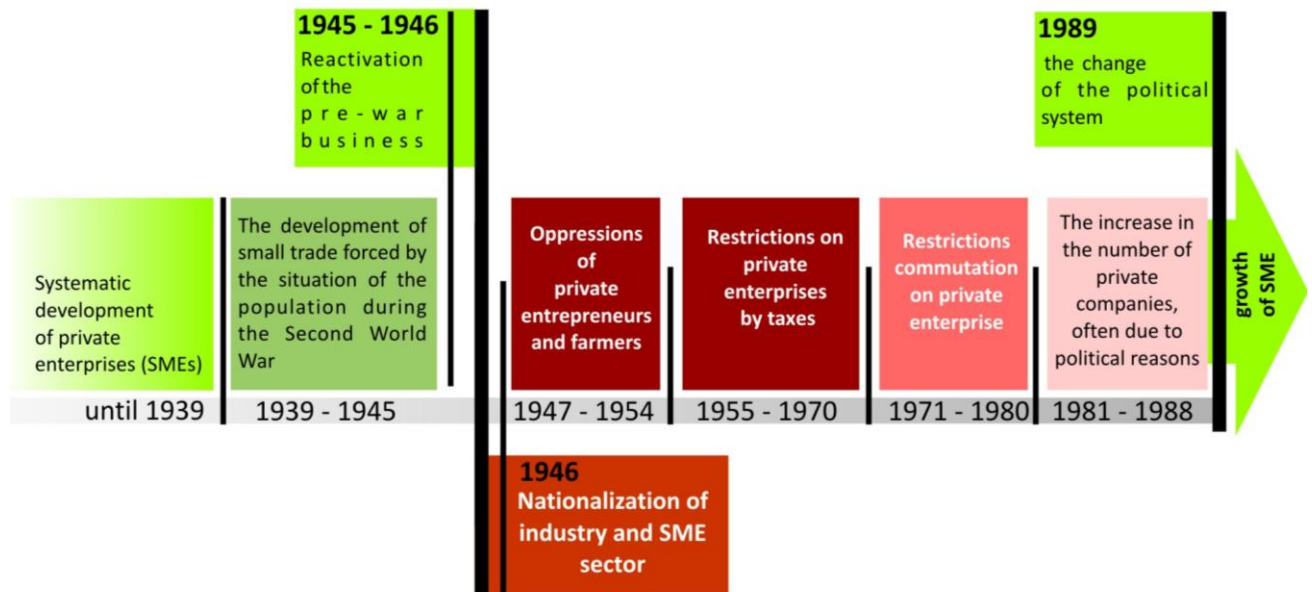
Although the SME sector is stimulating the development of the national economy, the Polish entrepreneurs in the years 1947 – 1989, the period of the planned economy dominated by the state sector, faced many difficulties in running their own businesses. However, the problems were not a result of reduced demand for the products and services, but the reason were actions of the state to discourage SME's economic activity (Figure 1).


Fig. 2 The development of the SME sector in Poland in the years 1939 – 1988. Source: J.Martyniuk-Pęczek, O.Martyniuk, XXX

On 23 December 1988, the Sejm (Lower House) of the People's Republic of Poland passes the law on business activity. This time, the changes are revolutionary – the law, in fact, breaks away with the entire previous economic order, making private enterprise equal in legal terms with the activity of the state.

That act along with the later ones (unification of the tax system, admitting free trade in foreign currencies) results in the starting up of many SMEs. To learn how to run a company at that time, it was enough to read a few acts: the Commercial Code, Tax Law, Customs Law, and Labour Code .

There were tens of thousands of people in Poland at that time who set up a small business, and let's get down to work. Work and mental powers were the only things which counted. It was the time of Polish economy transformation, from the centrally planned one to a free market economy. There are three phases of SME sector development in Poland druing this period.

First phase had began before the market economy was introduced and was named the preliminary phase of business development. The second phase is the period from 1989 to 1994. It is characterized by a rapid increase in the number of SME businesses. In recent years there has been a more than twofold increase in the number of small entities, which in large part was due to the economic recession. The SME sector has become a place to work for people who have lost their jobs in large state-owned enterprises. In the phase of market self-regulation, after 1995 the number of SME continues to grow, but the growth rate began to stabilize. This was due to the elimination of the weakest economic enterprises that have failed because of an increasingly mature and competitive market. Other causes of SME establishment in Poland were the need for self-realization, liberation or the desire to scratch the entrepreneurial independence.
Fig 3 – The development of the SME sector in Poland in the years 1995 – 2010, Source: own study based on data from PARP

At present, when the free market is already mature, there are other reasons why people start their own businesses. As the GEM Report shows, Poland belongs to the countries with the most disadvantageous structure of entrepreneurial motivation. The number of businesses established due to will to seize an opportunity is only slightly higher than the number of enterprises started up out of necessity. It might be evidence of a low development potential of Polish enterprises. A more disadvantageous ratio of the opportunity-driven entrepreneurship to the necessity-driven entrepreneurship can be found only in Bosnia and Herzegovina, Iran and Pakistan.[2] Unfortunately, value of the indicator of people perceiving business opportunities for Poland is low.[3] In Poland, slightly more than one-third (33.1 %) of people perceive business opportunities.[4] Fear of failure is an important factor that limits the level of entrepreneurship at the national level. Despite an identified opportunity and the will to use it, and despite of positively perceived capabilities, some entrepreneurs give up the establishment of a business as a result of fear of failure. In Poland, the fear of failure is much higher than in the comparable countries and it might be an essential factor that hinders the entrepreneurship. Over 56 % of Poles think that fear of failure can prevent them from starting up a business.[5] The above demonstrates a high level of uncertainty about the pursuing a business.[6] However, at present, SME companies are up 99.9 % of all companies in Poland. In 2010 number of people working in this sector in total amounted 60,3 %. Additionally the SME sector in 2010 produced 47,6 % of Polish GDP, including micro enterprises (29.6 %), small (7.7 %) and medium (10.4 %).[7]

In Poland, in contrast to the global trend, small businesses have a very low share in the industries belonging to high-tech industries. In most developed countries, small firms dominate the industry of IT, automation, specialized chemistry. In Poland, however, these companies dominate in the repair, manufacture and construction.

The SME sector has a full range of functions, not only economic, but also an important social ones. The primary social function performed by the SME sector in Poland is the formation of an economically independent middle class. It is commonly believed that the prosperity of the state and the smooth functioning of the market mechanism depend on the degree of development of the middle class in the society. Additionally, efficient business processes are created because of the propensity of SMEs to the use of local

[2] P.Zbierowski, D.Węcławska, A.Tarnawa, P.Zadura – Lichota, M.Bratnicki, Global Entrepreneurship Monitor – Poland, PARP, Warszawa 2012, s.27

[3] It is measured by the percentage of persons who claim that there are good conditions for business start-up in their neighbourhood within the next six months. That rate also falls as the economic development decreases – the average for factor-driven economies amounts to 53.6 %, in the case of efficiency-driven economies it is 40.3 %, and in the case of innovation-driven economies it is 34.9 %.

[4] P.Zbierowski, D.Węcławska, A.Tarnawa, P.Zadura – Lichota, M.Bratnicki, Global Entrepreneurship Monitor – Poland, PARP, Warszawa 2012, s.17

[5] This indicator is higher only in three countries (Thailand – 60.5 %, Bangladesh – 63.1 % and Greece 67.6 %).

[6] P.Zbierowski, D.Węcławska, A.Tarnawa, P.Zadura – Lichota, M.Bratnicki, Global Entrepreneurship Monitor – Poland, PARP, Warszawa 2012, s.18

resources and the ease with which these resources are able to use, increasing affluence in the region, changing lifestyles owners and employees based on the free market choices, economic freedom and effective enterprise. The social function of Polish SME is also reducing social costs and to alleviate social tensions associated with economic transformation.

3 THE INTERACTIONS OF THE TWO PROCESSES

However we could find in polish suburbans landscape the characteristic element which is a large number of SME sector businesses located there. The analysis of the literature describing the process of suburbanization in Poland, the authors characterize it often cite examples of European or American [Radziejowski 2006], except for Polish economic conditions – social. Analyzing the causes of the process of suburbanization shows include: Polish-specific phenomenon:

- "lack of tradition" efficient "use of land;
- Lack of tradition, local practices and standards for use of space;
- weakness of planning, mainly in the local scale, manifesting itself arbitrariness spatial development plans and easy alterations "[Fogel, 2012].

It seems that the specificity of Polish suburban areas is also high economic activity, boost in the last 20 years. As evident from the observations and preliminary research statistics on selected suburban areas of Gdansk, the number of inhabitants per one registered company in suburban areas (Chwaszczyno, Straszyn) and Gdansk is much lower. This means that residents of higher economic activity in some areas compared to suburban residents of Danzig [Martyniuk-Pęczek, Martyniuk 2012]. You can think about the reason for this significant difference in activity in the central city system – suburban areas and diagnose the cause of entrepreneurship residents of suburban areas. In Poland 64, 7 % of new businesses to the project of choice (opportunity enterpreneurship) and 35, 3 % of the projects undertaken by necessity (necessity enterpreneurship).

3.1 Characteristics of selected central city and its suburban areas

Tri-City Metropolitan Area (TOM) is an important part of the functional and spatial Pomeranian, and the most important economic and social center of the Southern Baltic Sea. Gdańsk, Gdynia and Sopot are an urban center. Functional area of TOM are – Pruszcz Gdanski, Rumia, Reda, Wejherowo, Tczew, urban-rural and rural communities Żukowo – Pruszcz Gdansk, Kolbudy, Szemud, Wejherowo, Kosakowo.

Selected for survey suburban areas are:

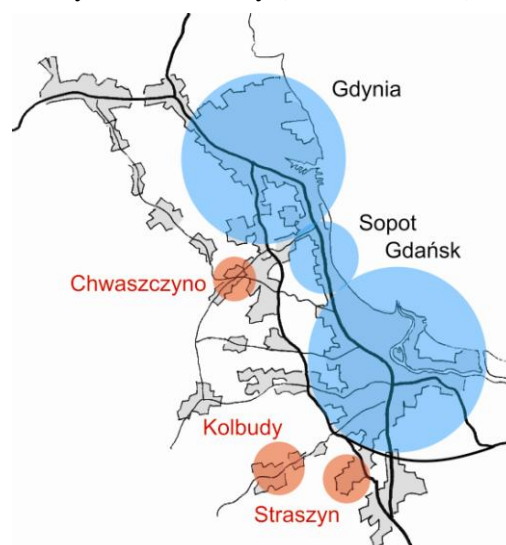
- Chwaszczyno – the part of urban – rural community Żukowo (district Kartuzy),
- Straszyn – the part of Pruszcz Gdanski – the rural municipality of Gdansk (Gdansk district)
- Kolbudy – the part of Kolbudy rural comunity (Gdansk district)


Fig 4 – Gdańsk, Chwaszczyno, Straszyn, Kolbudy – a system of spatial relations; Source: own study

As can be seen from the Pomorskie Development Plan, urban center (Gdańsk, Gdynia, Sopot) is the area include: the highest concentration of population in the labor market. It does not provide an affordable and attractive offer of investment areas and new housing stock. These cities, including Gdańsk, exhibit diverse growth of population and housing, but as a whole Tri-City loses population. The population of Gdansk amounts now 460.5 thousand.,

(in 2000 and 1990 the number of people amounted to 463 000, 465.100). Decline in population does not inhibit the development of new housing on large areas (Gdańsk South). Gdańsk reduces the number of people, often losing the wealthiest and most active group of people who search of a higher standard of resident, move to suburban communities.

On the contrary, the functional urban area (ring municipalities) shows both the demographic and investment dynamics. Migration rate in 2010 amounted :

- the county Kartuzy, where Chwaszczyno is located + 1017, (population of Chwaszczyno – 2678)
- the district of Gdansk, where Straszyn is located + 1873, (population of Straszyn – 1782),
    - The commune Kolbudy, where Kolbudy is located + 330 (population of Kolbudy – 3557)
    - The commune Szemud, where Koleczkowo is located +388 (population of Koleczkowo – 1261)
- the city of Gdańsk – 112 (population of Gdańsk – 460 517).

There is a growing area of land invested in both residential as well as commercial for services and manufacturing. Improving the quality of residence is parallel to the process of spontaneous development of new housing stock. Dynamic processes of urbanization are mostly "spontaneous" or even "chaotic", not full-fledged shaping the spatial structure . This is due to:

- transport accessibility and the price of land;
- the supply of building land in response to the demand – the owners are trying to sell all the land area that can find potential buyers.

Spatial development is very little efforts of the local authorities activities which do not prepare ahead of time investment areas (there is no urban and infrastructure plans).

Urban tissue sterilization is the reason of shifting economic activity outside urban areas or on the periphery, manufactures and service companies with their headquarters are moved to suburban areas and do not appear new companies offering higher order services.

In order to describe the economic activity in the studied areas, authors use following criteria of SME classification:

- the number of employees,
- the year of company establishment,
- the type of business.

All surveyed areas are dominated by micro and small enterprises (nearly 100 % of all businesses).(Table 2).

Enterprise size/ Number of employees	Gdańsk (%)	Kolbudy (%)	Chwaszczyno (%)	Straszyn (%)	Koleczkowo (%)
micro (2 – 9)	55	55	49	46	52
small (10-49)	35	35	40	41	36
medium (50-249)	8	11	10	9	12
large (powyżej 250)	2	0	1	3	0

Tab. 2 – The structure of the SME sector in selected areas, Source: own study based on statistical data

The period of development of the SME sector in the studied areas is presented in Table 3. The data indicate a rapid development of SMEs in the years 1989 – 1995 and 2002 – 2007 in Gdansk, Chwaszczyno, Kolbudy and Koleczkowo. In Straszyn, the number of start-ups increased throughout the period from 1989 to 2007. It is associated with the development of the southern districts of Gdańsk (Gdańsk South), which is in the near of Straszyn. The other reason is an intensive development of road infrastructure there.

Established	before 1989 (%)	1989- 1995 (%)	1996-2001 (%)	2002-2007 (%)	after 2008 (%)
Gdańsk	6	31	25	28	10
Kolbudy	6	36	22	19	17
Chwaszczyno	7	38	15	27	13
Straszyn	6	22	25	35	13
Koleczkowo	0	34	24	24	18

Tab.3 – The year of campany establishment in Gdańsk, Kolbudy, Chwaszczyno, Straszyn, Koleczkowo in (%); Source: own study

After 2008 the number of newly established enterprises significantly decreased. It is a period in which there was a sharp increase in single companies (so-called self-employment).

In the suburban areas we can also observe the great increase in the number of single activity raised, in comparison to the years 2002 – 2007, respectively:

- in Kolbudy + 40 %[8]
- in Chwaszczyno + 500 %,
- in Straszyn + 700 %
- in Koleczkowo +80 %.[9]

This could mean that the migration of people from Gdansk concerned in large part more active people, more likely to take risks. They are probably in large part freelancers, managers or specialists because such people often turned a contract of employment to self-employment.

By analyzing the type of business carried out by operators in Gdansk, Kolbudy, Chwaszczyno, Straszyn and Koleczkowo should be noted that most companies operate in the construction industry. In suburban areas other group companies are dominant actors in industry and manufacturing. These are often activities that require the production area. In the case of higher-order service (medicine and health, law, education, and education) companies in Gdansk, these industries account for 20 % of the total, while in the case of suburban areas it amounts about 10 %. Often these services are perceived as higher quality if they are provided in the city center due to the proximity of universities, public health specialists, the courts. This opinion is supported by the lack of firms that provide legal services in suburbs.

3.2 The economic activity of residents in suburban areas and the city center

In this part of article will be made a comparison of statistics on population and the number of registered businesses in the central city (Gdansk) and suburban areas (Chwaszczyno, Straszyn, Kolbudy, Koleczkowo) in order to determine the economic activity of residents. The results of the analysis are presented in Table 4.

Place	Population (persons)	The number of SMEs[10]	Activitie	
			population (person per SME)	families[11] (family per SME)
Gdańsk	460 517	8 019	57	14
Kolbudy	3 557	133	27	7
Chwaszczyno	2 678	149	18	4
Straszyn	1 782	206	9	2
Koleczkowo	1 261	50	25	6

Tab. 4 The economic activity of residents of Gdansk, Kolbudy, Chwaszczyno, Straszyn, Koleczkowo. Source: own study

---

[8] The greatest incerase in this enterprises category was in 1989 -1995 + 1 000 %

[9] The greatest incerase in this enterprises category was in 1996 – 2001 + 300 %.

[10] Without sole proprietorships.

[11] Average is four persons.

The presented data shows a much more higher population economic activity in suburban areas compared to residents of the central city. One company is conducted by:

- Every 57 citizen of Gdansk,
- Every 27 citizen of Kolbudy,
- Every 18 citizen of Chwaszczyno,
- Every 9 citizen of Straszyn,
- Every 25 citizen of Koleczkowo.

Assuming that the average family is four people, we can say that:

- in Kolbudy every 7 family conducts business
- in Straszyn every 2 family conducts business,
- in Chwaszczyno every 4 family conduct business,
- in Koleczkowo every 6 family conduct business.

In the case of residents of Gdansk, one company falls on every 14 families.

Updating statistics with data indicating companies in reality existed in suburban areas, economic activity is even higher compared to the city center. This is due to the fact that some people are still domiciled in the city center, but in practice both lives and business conduct in suburban areas. This can be described as a "hidden suburbanization." Much higher economic activity is not only determined by economic factors. It shows the analysis of land prices pointing out that the price of investment land in chosen suburban areas are higher than the prices of land in some districts of Gdańsk (Gdańsk East). The reason of such a situation is surely communication infrastructure, but also the social conditions that result from the characteristics of inhabitants of suburban areas.

The natives, the former owners of the land involved in agriculture in the past, after the sale of part of the land acquired funds to invest in a new company set up personally or by children. Another motivator setting up a company in suburban areas are family reasons (reducing the time and costs of traveling to the city), and the new needs of the population. It can therefore be concluded that the well-educated, active and creative residents of suburban areas conducive to the development of local entrepreneurship.

4 CONCLUSION

In Poland and especially in the TOM the economic activity is intense in suburban areas. This intensity is counted by the number of citizens and the firms established there. The experience of developed countries shows that decides about their economic power the SME sector. Polish model of "Edge City" based on the development of micro and small enterprises is somehow created. There could be a new way of the spatial development of this areas created on the basis of SME potential. Local authorities should change their passive attitude and look for the new opportunities. However there is quite a large number of SMEs operating in suburban areas, but officially registered in the city center. It results in taxes being paid not to the local communities, but to the Gdansk budget, giving rise to the so-called "tax gap." The challenge then is to encourage companies to register in the suburbs. Moreover – change to create something in kind of "local patriotism" based on the corporate social responsibility for the arounding space.

Apart from this, the development of SME is an opportunity for suburban areas in terms of joint activities in the framework of public law. Their strong links with the local community and the environment mean that their owners often personally solicit local infrastructure, knowing that it will be used not only by the company, but also the family. So they are more willing to participate in the cost of its development and actively participate in the planning process of establishment. This means that the development of the SME sector results in the development of suburban areas and can contribute to the financing of measures to improve the spatial order, eliminate the negative effects of suburbanization.

In summary, the Polish suburban areas are business incubators and it should be taken into account while planning and creating land use policy.

Polycentric Structures and Mobility in Agglomerations – an Analysis of the Vorarlberg Rhine Valley in Austria

Oliver Roider, Roman Klementschitz

(Dipl.-Ing. Dr. Oliver Roider, Institute for Transport Studies, University of Natural Resources and Life Sciences, Peter-Jordan-Straße 82, 1190 Vienna, oliver.roider@boku.ac.at)
(Dipl.-Ing. Dr. Roman Klementschitz, Institute for Transport Studies, University of Natural Resources and Life Sciences, Peter-Jordan-Straße 82, 1190 Vienna, roman.klementschitz@boku.ac.at)

1 ABSTRACT

Sustainable urban mobility always stands between conflicting priorities of different stakeholder groups and is even more difficult to achieve in a region with several municipalities with a similar number of inhabitants. The Vorarlberger Rhine Valley (Vorarlberger Rheintal) consists of 29 municipalities including the capital city of the Province, Bregenz, and the even bigger cities Dornbirn and Feldkirch. In the last 50 years the number of inhabitants almost doubled up to 250 000 inhabitants (reference year: 2011). The built up area has increased even more forming a single area of settlements with a widely polycentric structure. In 2003 a co-operation among the 29 municipalities has been established following the aim of a common vision of the Rhine Valley ("Vision Rheintal") including a balanced distribution of economic, cultural, educational, retail, recreational and administrational institutions across different locations.

The Rhine Valley has been selected as demonstration site of the Poly-SUMP project commissioned by the European Commission in 2012. The idea of the project is to understand elements of a successful implementation of a polycentric co-operation, to analyse to which extent polycentric structures are able to support sustainable mobility and to exchange experiences with other regions on a European level.

20 Stakeholders have been interviewed in the Rhine Valley covering a variety of stakeholder groups (local and provincial government, transport planner, cyclist group, economic sector etc.). It turned out that almost all experts ranked the collaboration among different stakeholder groups as well-established. Regular conferences and meetings as well as transparent transport planning processes are an ideal platform for exchanging interests and for finding common solutions.

Polycentric structures have an influence on the daily mobility of the inhabitants, e.g. the average trip distance is shorter than a region with just one major city, as people find appropriate destinations more likely nearby. Data of a mobility survey launched in 2008 show that the average trip length in the Rhine Valley is 8.6 kilometres, which is about 1/3 shorter compared to the rest of Vorarlberg. In order to be able to compare the degree of polycentrism and its effect in mobility among different regions a set of indicators has been developed including not only spatial data (e.g. population density) but mobility data as well (average distance travelled to work).

2 INTRODUCTION

Depending on local circumstances, the historical growth of population led to different settlement patterns, caused by the increasing number of centres and/or an increasing concentration of the population within one dominant centre (Figure 1). These effects create different settlement patterns (Bus et al. 2012):

(1) Monocentric regions are characterised by a high density central city which attracts and directs daily commuting flows from and to the surrounding regions, often leading to a high amount of mileage driven. Centripetal mobility patterns are aggregated on radial road or rail axes penetrating the major city core. Most of the inhabitants of a region live in the major city, almost all facilities of the daily live (work places, education, shopping …) are concentrated in this city.

(2) Disperse settlements are characterised by the equal distribution of the population all over the region without clear defined centres.

(3) Polycentric regions are characterised by a number of centres forming a network of cities of equal size with a balanced distribution of economic, cultural, educational, retail, recreational and administrational institutions across different locations.
Figure 1: Settlement patterns (Source: Bus et al. 2012)

The Poly-SUMP project commissioned by the European Commission within the Intelligent Energy Europe programme in October 2012 is dealing with the special needs of polycentric regions in terms of spatial and transport planning, as this is an even more difficult undertaken in a region with several municipalities of almost equal status and with a similar number of inhabitants. The idea of the project is to understand elements of a successful implementation of a polycentric co-operation, to analyse how polycentric structures support sustainable mobility, and to exchange experiences and transfer knowledge within polycentric regions. Based on lessons learnt a common methodology for Polycentric Sustainable Urban Mobility Plans (Poly-SUMP) is developed by testing practical planning approaches in European regions of Europe. The Vorarlberger Rhine Valley in Austria (Vorarlberger Rheintal) has been selected as demonstration site in the Poly-SUMP project as it has a long tradition of polycentric co-operation among the municipalities of the Rhine Valley.

Figure 2 Location of the Province of Vorarlberg in Europe (Source: google maps)

REAL CORP

3 THE VORARLBERGER RHINE VALLEY

3.1 Characteristics of the region

The Province of Vorarlberg is the most western province of Austria and is mainly a mountainous area where more than 2/3 of the territory is 1000 m above sea level (Figure 2). Thus, only 25 % of the area can be used as built up area or for agricultural use. Due to this land use restrictions the provincial government developed a soil protection concept early in the 1990'ies already. This concept considers real estate transfers, spatial planning and agriculture polices as well as aspects of air pollution control, environmental, landscape and nature protection [Amt der Vorarlberger Landesregierung 1992]. The province of Vorarlberg has an over average flourishing economy at Austrian as well as European level. Only 3.6 % of the population (reference year 2011) are currently unemployed [Statistik Austria 2012].

In 2011 the Province of Vorarlberg had about 372.000 inhabitants [Amt der Vorarlberger Landesregierung 2012]. Almost 2/3 of the population lives in the Vorarlberger Rhine Valley, which consists of 29 municipalities including the capital city of Bregenz, and the even bigger cities Dornbirn and Feldkirch. This is caused by the fact, that this region is one of the rare plain areas in the province and at low altitude between 400m (Bregenz) and 450m (Feldkirch). The extent is about 40 km from North to South and about 10 km from West to East. The river Rhine, which is bordering the region in the west, represents the national border between Austria and Switzerland at the same time.

3.2 Establishing polycentric concepts in the Vorarlberger Rhine Valley

In the last 50 years the number of inhabitants in the region almost doubled, the amount of buildings and the area of settlements increased even more, so that several municipalities have grown together forming an almost single area of settlement. Therefore the administrative boarders do not always represent areas functionally belonging to each other (Figure 3). Although Austrian municipalities are responsible for the construction of the local road infrastructure in their area as well as for the local spatial planning the project "Vision Rheintal" has been founded more than 10 years ago with the aim to establish a discussion platform across all 29 municipalities of the region and to develop strategies for integrated spatial and transport planning, following the principles of polycentric developments. One of the key topics is mobility, enabling sustainable transport by fostering settlement structures, which decreases the traffic demand and supports environmental friendly modes. These can be achieved by a balanced distribution of economic, cultural, educational, retail, recreational and administrational institutions across all 29 municipalities.

Some examples of the functional division for the major settlements in the area of the Rhine Valley are:

- Bregenz as the capital of the Province of Vorarlberg, but only the third biggest city in the region, hosts the provincial government, provincial police, provincial library, provincial school administration and main cultural facilities (theatre, festivals) whereas

- Wolfurt hosts the logistic centre for goods distribution for the whole area and cross border transport;

- Dornbirn hosts the polytechnic college, provincial television, provincial health insurance organization, chamber of commerce including supporting funds for economic development;

- Feldkirch hosts provincial court of justice, chamber of labour, pedagogical college, unions headquarter, provincial hospital, provincial finance office and act as diocesan town of the province,

- Lustenau hosts the provincial chamber of industry and the central provincial storage facility for oil supply.

4 ASSESSMENT OF THE CURRENT SITUATION IN THE VORARLBERGER RHINE VALLEY

The analysis of the current situation is based on a desk research of information mainly provided by the project "Vision Rheintal" and in-depth interviews with 20 stakeholders representing different stakeholder groups.

4.1 Assessment of the current transport situation

The evaluation of the current transport situation is based on a ranking provided by stakeholders on a scale from 1 (best) to 5 (worst). The mean value is 2.7, however, with a strong polarisation between

representatives of the chamber of commerce and oppositional parties scoring "unsatisfying" and local government and transport planners scoring "satisfying" on the other.

Figure 3: The Vorarlberger Rhine Valley Region with 29 municipalities (Source: Assmann 2006, own modification)

The situation for pedestrians and public transport users are rated positive by almost all respondents, whereas the ranking of situation for cyclists and car users dependents on the group of stakeholder the respondent belongs to. In particular, too restrictive policy towards private car traffic or missing capacity extensions of the road network are mentioned by car-oriented persons. On the other hand, there are stakeholders criticizing the car friendly policy in the area.

The questions for measures to be implement in the near future in order to improve the traffic situation polarised as well. The majority of respondents argued to invest in new infrastructure measures, however the focus on the transport mode differs depending on the particular interests, e.g. car-oriented stakeholders mentioned the missing extensions of the road network (e. g. a new link to Switzerland, bypass road for city of Feldkirch and Lustenau). Only a few times organisational measures are mentioned, i.e. public transport at traffic signals, mobility management, pricing measures (parking pricing, reduced public transport ticket) or improved marketing.

4.2 Assessment of competences

Sustainable development requires the coordination of policies and services of many actors – transport and urban planners, local and regional policy makers, urban and interurban public transport providers etc. – within and across different urban and administrative boundaries. Therefore, regular conferences and meetings as well as common transparent transport planning processes are pre-requisites for exchanging interests and finding common solutions in the Vorarlberger Rhine Valley.

Identifying stakeholders and understanding their current and potential role are important conditions to map the actors to be involved in a polycentric planning process. In the Vorarlberger Rhine Valley seems to be a common sense that all relevant institutions (and therefore competences) are involved in the current planning processes. It seems that these activities do not comply with the transport strategy in the region. Institution and persons primarily mentioned by the respondents are politicians (most important), administration staff at local and regional level, public transport operators as well as public transport consortia, citizens and the energy agency. A bicycle-coordinator, transport user's lobby group and the industry dealing with electric supply was mentioned only a few times.

In addition, the provincial government commissioned a regional transport masterplan for the Vorarlberger Rhine Valley. In 2006 a collaborative, consensus-oriented planning process was initiated to solve the traffic problems of this particular region. A multi-modal package of measures should be developed through a mediation process led by an external team, i.e. departments of the provincial government, the highway agency (ASFINAG), representatives of all affected communities, interest groups, and representatives of lobbying organizations as well as the conservation organisation in order to ensure the widest possible consideration of all interests. The aim of the process was to find a consensus on comprehensive mobility solutions, most suited to reduce negative impacts of transportation significantly. Thus, not only new road infrastructure for private car traffic has been considered, but more a useful combination of improvement of cycling and public transport measures.

4.3 Assessment of the implementation of sustainable mobility

Stakeholders interviewed were asked to score the importance of considering sustainable mobility in transport plans. Nearly all respondents fully identify themselves with the concept of sustainability. Elements often mentioned to be included in sustainable mobility plans are the maximum freedom of mode choice, efficient use of resources, less use of private car and not to stress future generations.

The good planning culture and the communication established among the 29 municipalities are one of the most important drivers enabling the implementation of sustainable mobility plans. In particular, this includes the cooperation between the municipalities on an administrative level within the region. Additionally, the awareness of the citizens with regard to the importance of sustainable mobility is seen at high level, which increases the acceptance towards sustainable transport planning.

The dominance of private car use and corresponding infrastructure supply in the region is still seen as main barrier. In addition, economic pressure on enterprises offering mobility supply (public transport, car sharing, etc.) sometimes prevents sustainable developments. Moreover, it is often difficult to change habitual mobility behaviour of the transport users.

Stakeholders scored the importance of different planning elements on a scale from 1 (not important) to 4 (most important). Generally, all elements discussed are important or very important. However, as it can be seen in Figure 4 political support is of most importance, followed by measurable goals and awareness measures.

4.4 Pros and cons of polycentric structures in terms of sustainability

The term polycentrism is known by the majority of the stakeholders asked. A missing dominate city was mentioned as characteristic of a polycentric settlement area by almost all stakeholders asked. This leads to a cooperation of municipalities at an equal level in order to develop the region commonly and to share administrative or spatial functions. Consequences on the transport system are noticed by a more homogeneous distributed transport demand and the option to create axes which supports the rail based public transport system. Advantages of polycentric regions are shorter distances between origins and destinations of trips, the opportunity to find smart solution on a smaller scale, keeping smaller villages attractive as

investments are more even distributed, a bigger variety of land use and infrastructure within the region. Generally, the co-operation among the municipalities enables more sustainable solutions for the whole region.
Figure 4: Importance of planning elements

Arguments against polycentrism are the more effective possibilities to access a dominant city by high capacity modes and the need of goods transport to drive through settlements areas as a clear segregation between settlement areas and transport corridors is missing.

5 MOBILITY PATTERNS OF THE VORARLBERGER RHINE VALLEY

For the comparison of mobility patterns of polycentric areas with monocentric regions a matrix is built where the capital city of the region is fixed as central spatial reference point with four classes of distance. This is a residual of a monocentric vision with the capital city considered as the most prominent centre of a region, where the higher urban/regional authority functions are located. However, thanks to the matrix structure, it is possible to analyse and compare the degree of polycentricity vs monocentricity of the regions in two ways:

Along the diagonal cells key land use variables (resident population, workplaces, total area, and settlement area) are recorded for the capital city and for the other communities grouped by class of distance from the capital city. These data allow computing population and jobs density indicators that may typically show a marked density gradient (from high value in the central city to low values in the distant poles) in monocentric regions, and a less steep density gradient in polycentric regions, where population and jobs are more distributed across the region. The first row and column of the matrix include mobility flows within the capital city (first cell) and to/from the capital city to the other poles. These are monocentric (centripetal/centrifugal) mobility flows. They can be compared with the magnitude of the mobility flows within the other distance groups of poles (recorded in the diagonal cells) and within these groups, which represent polycentric/transversal mobility flows (i.e. not gravitating towards the capital city).

Following the concept as mentioned above 4 areas are defined:

(1) Capital city (Bregenz)

(2) First ring around the capital city (poles of Dornbirn, Hohenems. Lustenau), which is about 8 to 20 km away from Bregenz)

(3) Second ring around the capital city (poles of Feldkirch, Götzis, Rankweil), which is about 20 to 40 km away from Bregenz)

(4) Other areas (remaining parts in the Province of Vorarlberg, Switzerland, Germany etc.)

For the analysis of the mobility pattern data of a mobility survey launched in 2008 are used. In total in this survey 17 140 households of 96 municipalities were contacted by mail or phone, which is about 12 % of all households in Vorarlberg. As reference days Tuesday, Thursday and Sunday were defined. More than 4 000 households responded and gave information about their daily mobility on a weekday as well as on Sundays (Herry et al. 2009).

The number of inhabitants is almost the same in the different areas as defined above and ranges from 70 000 to 95 000 inhabitants. Although Bregenz is the capital city of Province of Vorarlberg and place of the provincial government, it is even the smallest agglomeration of the Vorarlberger Rhine Valley. Same applies to workplaces which are well distributed over the poles with a slightly domination of the second ring, as this comprises the largest area (210 km²) and includes the biggest city of Dornbirn (Table 1).

Based on the number of trips stated in Table 1 the share of trips has been calculated according to the given O-D matrix. In monocentric areas it can be assumed, that the dominant (capital) city is attracting more trips. The share of these trips having other destination than the capital gives an indication on the degree of polycentrism. The analysis of the mobility data of inhabitants of the Vorarlberger Rhine Valley shows that ¾ of all trips are internal trips. A predomination of the relation to/from the capital city of Bregenz cannot be identified, only 10 % of trips originated in the first ring have the destination in Bregenz, and this value is even lower for the second ring.

			Destination poles			
		Dist. from capital city	Capital city (Bregenz)	First ring around capital	Second ring around capital	Other areas
			approx. 0-8 km	approx. 8-20 km	approx. 20-40 km	-
Origin poles	Capital city (Bregenz)	approx. 0-8 km	70 477 inhabitants 28 715 workplaces 96,98 km² in total, 55,91 km² (58 %) settlement area **183 097** trips in tot. on the average, 75 % of all trips (working day)	**31 483** trips in total on the average, 13 % of all trips (working day)	**7 208** trips in total on the average, 3 % of all trips (working day)	**20 774** trips in total on the average, 9 % of all trips (working day)
	First ring around capital	approx. 8-20 km	**30 671** trips in total on the average, 10 % of all trips (working day)	96 225 inhabitants 38 634 workplaces 210,92 km² in total, 96,71 km² (46 %) settlement area **221 382** trips in total on the average, 75 % of all trips (working day)	**23 434** trips in total on the average, 8 % of all trips (working day)	**19 166** trips in total on the average, 7 % of all trips (working day)
	Second ring around capital	approx. 20-40 km	**7 446** trips in total on the average, 3 % of all trips (working day)	**24 850** trips in total on the average, 10 % of all trips (working day)	84 289 inhabitants 29 551 workplaces 158,77 km² in total, 85,45 km² (54 %) settlement area **194 552** trips in total on the average, 76 % of all trips (working day)	**29 605** trips in total on the average, 12 % of all trips (working day)
	Other areas		**20 797** trips in total on the average (working day)	**17 294** trips in total on the average (working day)	**30 580** trips in total on the average (working day)	Not available

Table 1: Key land use and mobility data

In monocentric areas people often have to commute to the capital city, as workplaces are concentrated there. Therefore, the share of trips with the purpose "to work place" gives an indication of the advantage of polycentric structures, as it can be assumed that the inhabitants are able to find a proper workplace in a city nearby. Between 65 % and 69 % of all trips to work are internal trips, i.e. as workplaces are available at site (long-distance) commuting is necessary at a lower share only, even in the light of attractive (and assumable well paid) workplaces across the border in Switzerland (Table 2).

| | Destination | | | | |
	capital city	ring #1	ring #2	other areas	*in total*
capital city	69 %	15 %	4 %	12 %	*100 %*
ring #1	14 %	65 %	11 %	10 %	*100 %*
ring #2	4 %	12 %	67 %	17 %	*100 %*

Table 2: Share of trips to work based on the origin of trips based on ring concept (working day)

People who have to commute to the capital city for work are often using these opportunity to go shopping at this destination as well, as shopping facilities are established in dominant cities. This leads to a serious reduction of shops in the city centres of the surrounding municipalities and reduces the attractiveness of the overall appearance of public spaces in these areas. So it is of major interest to offer appropriate shopping facilities in each municipality. Due to the polycentric structure, no particular need to buy goods preferable in the capital city is identified. Up to 88 % of shopping trips are internal trips (Table 3).

| | Destination | | | | |
	capital city	ring #1	ring #2	other areas	*in total*
capital city	86 %	9 %	0 %	5 %	*100 %*
ring #1	7 %	85 %	4 %	4 %	*100 %*
ring #2	0 %	5 %	88 %	6 %	*100 %*

Table 3: Share of trips to shopping destination based on the origin of trips (working day)

The share of public transport trips on an average working day is less than in the other regions, however the use of the bicycle and walking seems to be more attractive compared to other regions of Vorarlberg. More than 1/3 of the trips are made by bicycle or on foot. The share of non-motorised modes is even higher on Sundays (36 %). This values give an indication that people living in polycentric structures are able to find their desired destinations nearby, so that the use of public transport, e.g. for commuting longer distances, is not that necessary than in other regions. Even leisure activities on Sundays are preferable undertaken by bike or are situated within walking distance, as more than 37 % of trips are undertaken by these modes (30 % car-driver, 28 % car-passenger). The share of car use is almost the same all over the Province of Vorarlberg, e.g. the share of car-driver or car-passenger is about 55 % on an average working day (Figure 5).
Figure 5: Modal Split on an average working day

The analysis of the average trip length per person and day determine the hypothesis that establishing polycentric structures are a proper tool to contribute to a more environmental friendly mobility. On an average working day the car trips of a car-driver in the Vorarlberger Rhine Valley are about 22 % shorter compared to the other regions in Vorarlberg, public transport trips shows a reduction of almost 25 % (Table 4).

average trip length [km]	**Vorarlberger Rhine Valley**	All other regions of Vorarlberg	Vorarlberg in total
car-driver	**10,8**	13,9	11,8
car-passenger	**13,4**	12,7	13,1
public transport	**15,1**	20,7	17,2
all modes	**8,6**	**11,4**	**9,5**

Table 4: average trip length (working day) [km]

In monocentric regions people often have to commute long distances to reach their workplace or schoolyard. Moreover, leisure and shopping facilitates are concentrated to just one dominate city. The analysis of the trip length according to purposes shows the advantage of a polycentric region. Instead of commuting to the capital city of Bregenz only, the inhabitants of the Vorarlberger Rhine Valley find appropriate workplace or schoolyards in one of the poles nearby. The same applies for leisure activities. Almost all trips of all purposes are shorter compared to the other regions in Vorarlberg (Table 5).

average trip length [km]	Vorarlberger Rhine Valley	All other regions of Vorarlberg	Vorarlberg in total
workplace	**9,3**	11,8	10,1
business	**22,2**	21,4	21,9
education	**7,0**	9,8	7,9
service	**4,5**	6,5	5,1
shopping	**4,0**	6,3	4,7
private purpose	**6,6**	9,8	7,6
leisure	**9,4**	13,2	10,5

Table 5: average daily trip length according to purpose (working day) [km]

At the same time people spend less time in transportation. On the average the daily trip duration on a working day is 20 minutes in the Vorarlberger Rhine Valley and 23 minutes in all other regions of Vorarlberg.

6 CONCLUSIONS

The Vorarlberg Rhine Valley has a long tradition of polycentric structures. 29 municipalities have established a common platform for the consensual development of spatial and transport plans in the region. Based on the results of interviews with stakeholders of the region it turned out that the communication culture among different interest groups are a major key for the implementation of sustainable measures in the region. Polycentric structures are able to support sustainable goals, as it offers the possibilities of finding points of interests nearby, so that the daily mileage driven is less than compared to other regions, Moreover, environmental friendly modes like bike or walking can be used more often. This has been determined by the analysis of mobility data. The average trip in the Voraerlberger Rhine Valley is 8.6 km, which is 2.6 km less than in the other region of the Province of Vorarlberg.

1 ABSTRACT

This paper focuses on the design of a cooperative game for engaging children and youth in creating sustainable living environments. In cooperative games players achieve their goals acting together, collaborating with other players and helping each other. In addition to acquiring new knowledge, and expressing their own ideas and aspirations regarding their living environment, players acquire social competences essential for the coexistence and work in the community. In order to test the possibilities for designing a collaborative game for children we designed and implemented the Pop-up Pest game. It aims to support children in learning about their environment, understanding possible changes in urban spaces, and acquiring skills for active participation. The Pop-up Pest game was designed within a 25 m² large playing area which depicts Pest side downtown of the Hugarian capital Budapest. The players are divided into three groups striving to improve urban traffic, to establish more green spaces in the city, and to initiate a variety of cultural activities. The first version of the Pop-up Pest game was presented in September 2012. A total of 167 players from all age groups played the game. In addition, the game has been tested with 14 and 17 year old pupils as well as with a group of university students. This article presents the motivation for the game, the game story, design, concept and the first results of testing. We conclude the paper with a critical discussion and further research directions.

2 INTRODUCTION

The living environment greatly affects the child's development process, which should include the architectural design and space. This environment has an impact on the socialization processes, the formation of identity, as well as on the development of the child´s cognitive skills and competences. The research in the fields of psychology and social studies related to children's experiences of their living environment and the significance of built environment for their development and socialization (Muchow 1938/1978; Zinnecker 1979) reveals that their demands and needs and their involvement in urban planning processes need to be taken in account.

Current planning practices are characterized by an increasing demand for the qualitative integration of underpriviledged social groups. The limitations and shortcomings of established participative methods have emerged in the last decades, especially regarding the selective nature of the inhabitants participating (Fürst and Scholles 2008). For example, specific groups often participate because of their educational background, their ability to articulate or their availability at a particular time. Other social groups, such as children and adolescents, or the poor and under-represented, have little or no influence on local decision-making procedures. In the last few years we can observe the growing importance of children's participation in urban planning practices. New planning tools have been developed which strive to include children in planning. An example is the so called "Spielleitplannung" developed in Rhineland-Palatinate, Germany, which integrates child-friendly activities and children's participation in city planning. Several pilot projects took place in Germany in the last ten years and these experiences are described in several volumes and project documentations (e.g. Kultusministerium und Wirtschaftsministerium 2005; Reicher et al. 2006, Studio Urbane Landschaften 2009; Gaus-Hegner et al. 2009). Most of these projects concentrate on summarizing the participatory framework requirements and the results of the participatory processes from a planner's perspective. Applied participatory methods are rarely placed in a theoretical educational context and have not been studied from the perspective of the educational sciences. A substantial work still needs to be done related to age-appropiate methods for children and young people, how these practices can help to support learning, and whether educational processes are needed to accompany the participation process or not.

Developmental psychology focuses on the design of appropriate forms of participation in terms of skills and competencies of different age groups. Researchers have concentrated on the development of spatial perception of children (Piaget and Inhelder 1971), on the way children reproduce their everyday spatial experiences (Hart 1979), and on the development of their ability to participate in political, planning and

design issues (Oerter 1992). Richard Schröder's experiments (1995) with preschool and elementary school children showed that age-appropriate forms of participation have to be defined and developed in order to enable the children to participate. He based his research on the conclusions of developmental psychology, specifically addressing how preschool and primary school children are able to make decisions regarding their living environment, recognizing that their expressions and views differ greatly from those of adults. He investigated whether children are able to work with models to express their opinions and suggestions regarding their living environment. According to the results of his study, modeling is a suitable method for primary school children, as they have the ability to express ideas by means of spatial design, rather than verbalizing or visualizing them graphically. Their abilities and competencies to verbally or graphically express their ideas develop later. Schröder's research results also showed that in the case of older, 12-14 year old children, modeling seem to lose its appeal, especially for boys. His research clearly demonstrates that participation processes with children should be designed differently than those for adults, and they have to be differenciated even between different age-groups of children. The methods used in participatory processes should be adapted to the needs, interests and abilities of the children (and even of the particular age-group), in order to ensure the efficiency and sustainability of the participatory process.

In this paper we focus on the design and implementation of a collaborative game which aims to support learning about the environment and participion in planning for children. The Pop-up Pest collaborative game addresses 12-18 year olds. Its main goal is to stimulate them to formulate their needs and wants regarding public places in the city of Budapest, specifically in the Pest areas. The Pop-up Pest game enables the children/players to express their opinions concerning city development, and the game supports the development of a sense of responsibility for open spaces, and facilitates their ideas about further development of these places. The players can acquire skills for active participation in an engaged and playful way. We tested the Pop-up Pest game with 167 children and young people in Budapest during the European Mobility Week in 2012. In addition, the game has been tested with 14 and 17 year old pupils and a group of university students. The aim of the preliminary testing was to identify whether the game, as a method and as a concept of a collaborative game, is appropriate and successful in conveying the learning content. In the testing of Pop-up Pest we concentrated on the evaluation of the gameplay and the game experience. We present a short summary of the testing results and conclude the paper with a critical discussion and our further research directions.

3 GAMES FOR PARTICIPATION IN PLANNING

3.1 Design games for community planning

Sanoff in his work Design Games published in 1979 (Sanoff 1979; Sanoff 1990) introduced the idea of games for community participation in urban planning. These games are ideally suited for community workshops and aim to enable the involved parties to express their opinions and – often competing – interests. Since then researchers increasingly used maps as a representation of the focused or contested territory. Such games are intended to reconcile urban planning issues while playing out various scenarios (Sanoff 2000). Author Clark Abt (1970), in his book "Serious Games" described a serious game for urban planning. It was titled Simpolis, developed in 1967 and focused on major urban planning problems in New York City. The Simpolis game concentrated on some major urban problems such as education, housing, civil rights, poverty, crime, and pollution. The main goal was to educate the citizens about these issues and to suggest and communicate possible responses and consequences of different decisions. The game involved a controlled role-play in which the players received their profiles and specific constraints within which they had to operate. In contrast to that, free role-play enables the players to act and decide about their strategies and moves freely without any limitations. Since the 1970s the game concept has been often used in urban planning. A recent example is The Big Urban Game (2003) which was created by the Design Institute of the University of Minnesota with the goal of encouraging the residents of Minneapolis and St. Paul to think about the design of urban spaces. The Stadtspieler game Stadtspieler (2009), a recent German example, invites the players to discuss urban planning issues. The players can build the city according to their wishes and ideas and prepare a fictive urban plan. They use modeling clay and design their own city elements. In this way they also take on different roles in the city such as investor, citizen and neighbor, or an urban planner, and learn these perspectives related to the design of city environment.

3.2 Motivation for designing a participation game

Games have a potential to facilitate deep and sustained learning (Gee 2003) and cooperative problem-solving skills offering "several different levels of learning simultaneously to students of different abilities" (Abt 1970:23). Malone and Lepper (Malone 1981; Malone and Lepper 1987) developed a taxonomy of motivations in the context of educational/learning games for children, with four motivational categories: challenge, fantasy, curiosity, and control. Additionally, games enable learning through experimentation with alternative possible solutions and strategies played in a changing and sometimes also competitive environment. Within a safe, controlled realm, a player gets feedback from each experimental iteration, accumulating knowledge from the game system (Abt 1970; Cheng 1999). Games provide playful and engaging environments; they can motivate the players with the help of playful elements integrated in the concept of the game (Krek 2008; Poplin 2011; Poplin 2012). Games may stimulate "internal listening", which "acknowledges the importance of listening as a strategy for children to make sense of their world. Listening is, therefore, not just an avenue for other people receiving information but a reflective process for children to consider meanings, make discoveries and new connections and express understandings" (Clark 2005:17). Games may allow and even encourage taking on different roles; they enable the children to take on new roles, to lead and design the process, and to be in charge. They allow a shift in a relationship between the adults and children to the point of "accepting the place of the unexpected" (Clark 2005:25). "The advantages of accepting a shifting in power are a release from the need for adults to 'know all the answers'" (Clark 2005:25). Games also offer multisensory communication tools and means and are not limited to written and/or oral skills of the children; they offer new ways of learning and communicating.

3.3 Learning theory and pedagogical concepts

Cooperative learning greatly emphasizes the activity of learners and facilitates communicative processes between learners with different backgrounds. This pedagogical approach is based on structured divisions of positive interdependence, individual accountability, equal participation and parallel interactions (Kagan 2001). Positive interdependence refers to the positive relationship between the development of groups or individuals. In learning situations characterized by strong interdependence amongst learners, everyone is responsible for one's own work and for the performance of the whole group at the same time. Common aims promote individual responsibility and improve learning performance (Kagan 2001). Due to the equal sharing of responsibilities everyone has the responsibility for one part of the whole task. This not only strengthens the sense of responsibility but also promotes equal participation.

Accentuated learning aims to have an impact on the players' mindset. The learning process should be designed to procure new ideas and approaches regarding the overall theme that learners focus on; it aims to connect to their existing cognitive structures. The new knowledge needs to be embedded in the learners' real living environment and everyday situations. New information does not simply flow into the recipient, but the recipient has to construct it himself, or rather integrate the new material to his cognitive system. Ideally, a teacher or tutor has to be open and approach learning with constructive and encouraging attitudes, which allows the individual knowledge acquisition and an active role of the students in the learning process (Nahalka 1997).

Our work is influenced by the so called jigsaw method, developed by Elliot Aronson and his colleagues (Aronson, Patnoe 1997). Their aim was to reduce competition between pupils in the classroom. In their experiments, Aronson and his colleagues analyzed a fifth-grade class, which was studying the biography of Joseph Pulitzer. The researchers divided the Pulitzer biography into six equal parts, so that each of the important turning-points of his life was on a separate worksheet. Each child received a part of Pulitzer's life; just like in a jigsaw game, every child had a detail of the biography, but in order to be able to get acquainted with the whole learning matter, or the complete life, everybody needed the knowledge the others had. Results showed that when using the jigsaw method, children learned to pay attention to each other in the learning situation in which everyone's contribution is needed. Due to the mutual dependence, children became more acquainted with each other and accepted each other's point of view – independent from their social or ethnic background (Aronson 2004).

4   POP-UP PEST: A COOPERATIVE GAME FOR CHILDREN AND YOUTH

4.1 Background

The game Pop-up Pest was developed as part of a PhD project at HafenCity University Hamburg, Germany. The game is meant to be a preliminary study for the research project "Playful Children's Participation in Urban Planning." The game development took place in Budapest, Hungary, in the summer of 2012 and the first tests were conducted in the autumn of 2012. The development and the implementation of the Pop-up Pest game was accompanied and supported by the kultúrAktív Association, the first organization in Hungary dedicated to education about built environments. The project got financial support from the Hungarian Ministry of National Resources and the National Institute for Family and Social Affairs, as well as the Kunsthalle Budapest. The Pop-up Pest game was presented in September 2012 during the centenary celebrations of the Ernst Museum (the exhibition venue of the Kunsthalle Budapest), and also during the European Mobility Week. The tests with school groups and one university group took place at Balint Jewish Community Center in Budapest, Hungary.

4.2 Aims

The main goal was to design and implement a collaborative game for children and youth from downtown Budapest. The Pop-up Pest game aims to facilitate learning about their living environment and to support them to develop ideas for changes and improvements. Playing the game, children and young people explored the characteristics of the chosen districts from different perspectives and became aware of the current planning conditions and deficiencies. The game also aims to improve their orientation and to support the acquisition of competences regarding the use of urban space and the improvement of the quality of community life. The Pop-up Pest game primarily focuses on three areas in which local children and youth could proactively take part in shaping their living environment: the environment, transportation, and culture.

The long-term goal of the game is to promote an active children engagement in urban development. In addition, a further aim of the game is to enable the players to learn about contemporary urban concepts by presenting existing examples from their living environment such as guerilla gardening, community gardens, street art, public art, advocacy, etc. A great importance is given to social skills reinforced by players during the game such as positive attitudes and behaviors towards others, tolerance and "advanced communication". Advance communication means to be able to communicate within the group, to understand complex communicative processes and to have the ability to be consistent with others and to be able to understand and interpret different viewpoints.

4.3 Location

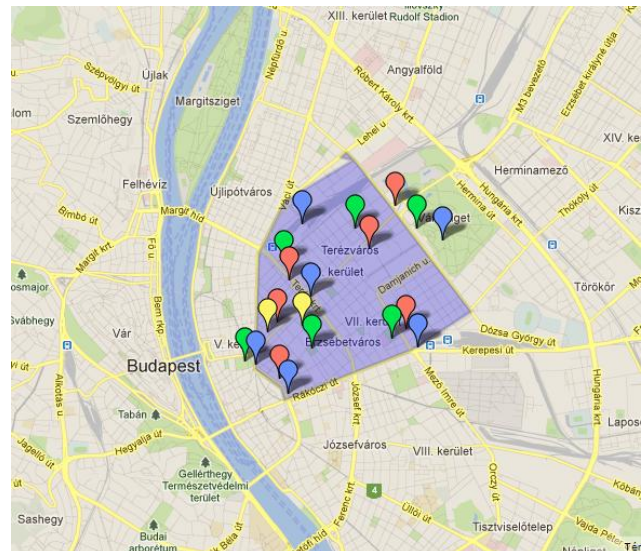
The game is located in the Pest side downtown of the Hungarian capital Budapest. It concentrates on large parts of the 6th and 7th districts, as well as on the edge of the 8th district of the downtown area in Budapest (Fig. 2). Figure 1 shows the area depicted on the play-ground of the game. All three districts were developed in the 19th century around the former city wall, and surround the Grand Boulevard. This area is one of the main tourist destinations of Budapest and includes some famous attractions. The Andrássy Avenue is a UNESCO World Heritage Site surrounded by spectacular eclectic mansions and numerous monuments, museums, theaters and cultural institutions as well as restaurants and coffee houses. It is also the most densely populated area in Budapest, and includes an extended apartment quarter characterized by deficient open spaces, green areas, and places for play and interaction. The so-called Jewish Quarter, with a lively religious community, is located in the 6th and 7th districts. The 8th district, called the "Roma District", is the densest and the poorest area in Budapest, inhabited in large part by the Roma or gypsy minority. Thus the selected parts of the city for our study are both a marvelous touristic attraction with an outstanding cultural heritage, and a deprived area with social issues and urban deficiencies. Blue, red and green markers on Figure 2 designate the so-called "priority sites", indicated on the playing field on Figure 1 by the same colors. Yellow markers highlight the Ernst Museum and the Balint Jewish Community Center, locations where testing of the game took place.
Fig. 1: The playing field of Pop-up Pest designed by Dóri Sirály (left)


Fig. 2: The selected area on the map of Budapest (right)

4.4 Target Group

The game addresses 12-17 year old children and young people living in the selected districts of Budapest. This age group is able to explore the urban environment on their own and they are important users of public places, wherein a large part of their social interactions with other children take place. As result of an unpublished survey done in 2011 we discovered that children and young people living in the selected area of the capital of Hungary have very sparse knowledge of their own living environment. The study was done within an internship at LudwigInsert, an experimental art space of Ludwig Museum Budapest in the 8th district. During various educational programs, we made a survey on the spatial knowledge of pupils at local schools. In most cases, the children and young people interviewed only knew about the micro-environment of their school and home, the shopping centers and transport hubs. Signs of isolation and their preferences staying at home were observed. For these reasons, we chose the mentioned target group. We aim to enable them to gain an access to their own living environment and to learn more about it. An important consideration regarding the target group was the variety of religious, national, ethnic, cultural, social and economic backgrounds. The integration of social skills, especially (in)tolerance, and a variety of communication patterns, had to be taken into account in the Pop-up Pest game development.

4.5 Format

The game consists of a 25 m² large playing area. As the game board lies on the floor, players can move on it as living game pieces or counters (Fig. 3). In this way the children/players can get active – not only mentally, but physically as well. The continuous motion and the variety of sensory perceptions make the gaming experience more intense and at the same time it can support the learning process. The action, in this case each of the possible urban interventions, is symbolized by a 50 cm x 30 cm building block, each with different patterns (Fig. 4). The four different kinds of building blocks are related to traffic: bicycle stands, ramps, bicycle paths, and parking places. Following them, in the second row on Figure 4, are the building blocks related to the topic culture. They represent a monument, street furniture, public art work and a festival promenade. Below them are the building blocks related to the natural environment and green spaces in the city, which includes the park, recycle bins, alleys and the community garden. The children/players can place the building blocks on the playing field. This activity represents a direct action in the environment, sometimes referred to as an intervention in the urban space.

Fig. 3: Playing Pop-up Pest

Fig. 4: Building blocks, designed by Dóri Sirály

4.6 Game Design

The players of the Pop-up Pest game are divided into three groups and strive to collaboratively improve city services, to establish more green spaces and to create a variety of cultural activities in order to improve life in the center of the city. The three groups – environmental, transport, and culture – have a common goal: they aim to improve their living environment through urban interventions. Besides having this common goal, each of the groups has its own mission to fulfill. Sometimes the individual and group goals can possibly conflict with the other groups' interests. An example of a possible conflict is the available public spaces. The players that are quicker and can cooperate better have the chance to realize their interventions faster. They can, for example, place a bench, a bicycle stand or a recycle bin around the corner faster than the members that are not willing to cooperate.

Figure 5 shows the different individual missions, different possible interventions within the three groups. The environment group strives to gain more importance for the environmental concerns and create additional green spaces in the districts. The transport group stands for a better, more ecological transportation, accessible also for handicapped citizens. The culture group strives to broaden the cultural activities and the preservation of cultural values.

Environment group	Transport group	Culture group
alley	bicycle path	festival promenade
recycle bin	bicycle stand	street furniture
community garden	parking	monument
park	ramp	public art

Fig. 5: Individual missions within the groups

Each of the groups has four players with individual missions thematically linked to the higher group goal. Each of the players has control over three building blocks contributing to his or her individual mission. The players have to first select one building block and then place it on the playing field. The players fulfill their missions when they manage to place all three building blocks on selected spots on the playground. In order to do so, the children/players have to complete different tasks and go through a variety of steps.

- Site-visit

At the beginning of the game the players have to visit a "priority site" related to their group´s goal. This can be a park, a museum, a railway station or any other famous and important place marked on the playing field. Priority sites are marked with the color of the concerned group; parks and green areas with the green of the

environment group, transportation hubs, and railway stations with the blue of the traffic group, and cultural organizations with red of the culture group. Priority sites are graphed and marked with an inscription on the fields in order to strengthen nodes and landmarks in the selected areas. Arriving at the priority site, the children/players get an information card. These cards are individual, which means that each player has his or her own set of cards (Fig. 7). The cards contain a very short description of the urban intervention connected to concrete places or phenomena in the chosen districts.

The interventions are related to the individual mission of the player and they can be either constructive or deconstructive. A possible constructive intervention for the player belonging to the environmental group (in the mission "community garden") is to create an herb garden in the yard of the apartment building. An example for a deconstructive action is to neglect the maintenance of the parcel the player rents in the community garden. Another example for a constructive intervention from the mission "public art" is to make guerilla knitting in an unattractive public place, and for a deconstructive act is to draw a graffiti wall. In the case of the mission "bicycle stand" (Fig. 6), one possible constructive intervention is to collect signs for creating bicycle stands in front of the cinemas, and something deconstructive is to lock the bicycle in places where people with wheelchairs or prams cannot cross the street. In case there is a constructive intervention on the card, the player gets a building block. In contrast, if there is a deconstructive intervention, the player has to visit another priority site and take a new card.
Fig. 6: Information card "bicycle stand". Fig. 7: Individualized information cards

- Intervention

In the next step, the obtained building block has to be placed on a free building area marked with striped patterns on the playing field. Different colors symbolize different kinds of building areas appropriate for diverse interventions. There are less building areas available to the players then the building blocks, therefore the players, need to be quick in placing them on the suitable field.

- Visting the other groups

After each intervention, the players need to visit a priority site or a fulfilled intervention of another team. For example, a player of the transport team needs to rest in a green space, an existing park or a green site created by the environment group or may enjoy a cultural event organized by an existing cultural institution or the culture group. Thus, each intervention can have a positive impact on the progress of the other players. The more environmental, vehicular or cultural elements are placed on the playing field, the easier it is to perform the obligatory visits, and the faster players can accomplish their individual missions.

- Cooperation

Players from a certain group can help the children/players from a competing group or the players within the same group. The Pop-up Pest game encourages the players to collaborate in accomplishing their individual and group goals. For example, once the player acquires a building block, she can ask a group mate to place it to a designated site, if she is closer to the area or has already completed her mission. On the other hand, when the player already completed the individual mission, she can reserve a free building area for her group mates. In the Pop-up Pest game, the players are motivated to cooperate with each other. Following Aronson's jigsaw method (Aronson and Patnoe 1997), we divided them into three different groups, and created a reciprocal dependence among them. The players can achieve their goals only by collaborating with their

team-mates. The game ends as soon as one group achieves its objectives. In order to win the game, every player of the group has to fulfill his or her own individual mission. Therefore, if someone progresses slowly, it is in the interests of her team-mates to support her. Just as in the case of a jigsaw puzzle, in the Pop-up Pest game, all players have to contribute in order to be able to renew the extensive, overall picture of the district.

4.7 Learning content and approach

Following the deductive approach of the constructivist learning theory, the Pop-up Pest game has as overriding objective – the idea of active participation in urban development. This idea has to be evident and understandable for all players of the game. The next level of learning consists of general patterns of action that players can perform in terms of the overall concept of participation. This content appears at the level of the players' activities and focuses on three thematic fields: environment, transport, and culture. Embedded patterns of action are examples for urban interventions, which players are able to realize beyond the context of the game as well (e.g. plant trees, place bicycle stands, advocate for the conservation of listed buildings). The third level of learning consists of real options for action and factual knowledge, both linked to the players' living environment. Embedded in the information cards which regulate the players' activities, these contents are integral parts of the game. The Pop-up Pest game draws attention to the existing interventions and changes in public places. Playing the game enables the players to acquire new knowledge, adding it to their existing knowledge, and to comprehend the options of practical applications and its effects.

The pedagogical concept of the Pop-up Pest game is based on a deductive approach, contextualization of the learning content and active learning (Nahalka 1997). It was influenced by the jigsaw method, developed by Elliot Aronson (Aronson, Patnoe 1997). Based on the results of the jigsaw method we proceeded on the assumption that this teaching method contributes to strengthening the players' senses of responsibility for their own environment as well as the development of empathy towards other residents and user groups, all of which encourages players to actively participate in urban development processes. Consequently, the Pop-up Pest game applies this method in the context of urban coexistence of children from different backgrounds, and districts.

5 EVALUATION OF THE POP-UP PEST GAME

An extensive evaluation of educational games or game-based learning requires a variety of criteria and methods: in general research focuses on the learning outcomes. Breuer (2011) in his study on digital game-based learning emphasizes the necessity to integrate the evaluation of both; the learning objectives or learning content and the gameplay. We aimed to integrate both aspects while testing the Pop-up Pest game in a variety of testing experiments.

In the first part of the test phase we presented the Pop-up Pest game at two open-air festivals in Budapest. The game was first presented in September 2012 during the centenary celebrations of the Ernst Museum, as well as during the European Mobility Week. Both festivals took place in public spaces of the 7th district in Budapest. This situation enabled the residents of the district to participate freely, independently from their age or social and educational backgrounds. Residents were able to join, quit, interrupt or repeat the Pop-up Pest game spontaneously. In the test phase, we investigated whether the concept of the presented Pop-up Pest game was appropriate for children engagement in planning, and whether children of the age-group 12-18 could accept Pop-up Pest as an interesting game. During the preliminary study we worked with questionnaires and interviews, in order to obtain the subjective opinions of the children/players.

From both festivals, a total of 167 players from all age groups played the game and 47 people answered the questionnaire. The quantitative survey included questions regarding the format of the game, gameplay and learning content. Most of the questions referred to the playful elements, subdivided into game dynamics and thrill, collaboration and personal achievement, motivation and reward, and visual representation as a sensory delight in the way as defined in Ritterfeld, Wagner (2006). The questionnaire included 28 different statements and the players had to decide to what extent they agree with the statements and marked their opinions on a 1 to 5 scale in which 1 meant "do not agree at all" and 5 meant "totally agree". In this way we were able to measure the attitude of the players related to certain issues.

In the preliminary evaluation of the survey, we sorted the responses by age groups. The preliminary results show that the target group accepted the game very well. Participants enjoyed playing in groups, they appreciated the graphic design and they were motivated to interact in the represented urban space. As Figure

7 shows, the players were very satisfied with the format of the game. Children 7-12 years, and young adults of 19-26 fully agree with the statement "I like the format of the game". The target group of the game, age 12-18 years, on average evaluated the format with a 4.3, which is still between good and very good. Regarding the format and design of the game, there were critical comments in relation to the design of the building blocks: "not practical", "they have been knocked over by the wind". They were also critical about the selected colors of the groups, which "should differ more from each other".

Figure 8 shows the attitude regarding the dynamics and activity of the Pop-up Pest game. The scale demonstrates that children between 7-12 were content with the dynamics. The need for activity increases with the age. The questions on collaboration within the group were valued most positively. On Figure 9 it can be seen that all children and young people up to age 25 agreed with the statement "I enjoyed playing in a group". The average value for the evaluation of this question in all questionnaires was the highest for this question.
Fig. 7: "I like the format of the game". Fig. 8: "There was not enough activity in the game". Fig. 9: "I enjoyed playing in a group"

In the second part of the test phase, we tested the Pop-up Pest game with 14 and 17 year old pupils and a group of university students. We are going to continue with the second phase of testing during spring 2013 by placing the emphasis on the learning content and learning objectives. The survey will concentrate on the effectiveness and efficiency from the learning perspective.

6   CONCLUSIONS

This article summarizes the concepts and the implementation of the Pop-up Pest game for children and youth. Our main goal was to create a cooperative educational game for children which aims to facilitate learning about the environment, and to understand planned changes in this environment and their consequences on the quality of life in the city. The Pop-up Pest game was implemented for three districts of Budapest, but the main concept of the game could be used for other cities as well. Collaboration is an important part of this game; the children/players are encouraged to collaborate with members of competitive teams in order to accomplish their tasks. Only one team can win the game. In spite of that, winning is only one of the goals of the Pop-up Pest game. Learning how to collaborate and help the players of competing teams is also one of the central goals of this game. Children and youth can gain new awareness about the meaning of collaboration and can compete and collaborate at the same time in order to become co-creators of their living environment.

Besides the aspect of collaboration and co-creation, games also can empower children and youth; their voices and opinions can be expressed while playing the game. Inclusion of children in planning has been neglected for too long. Thus it is important to develop methods which can foster children's participation in planning. Games are just one possible framework, a concept that can possibly encourage children`s participation in planning. We are testing different game concepts and designs in order to understand better the possibilities of this method on one hand and the role they could play by the inclusion of children in urban planning participation. Currently we are working on the quantitative and qualitative evaluation of the developed Pop-up Pest game. Additional evaluations will be done in a set of experiments with children of different age groups. We are interested in differences among these age groups of children and young people. Can the same or similar game concepts be developed for several age groups? How differentiated

collaborative, participation games should be in order to be able to motivate and include children from different age groups? We will set up testing experiments in the way that will enable us to accomplish research related to these relevant questions.

Games for children have yet another interesting aspect which needs additional research; they are often led by adults, but aim to involve children. Clark (2005) addresses the issue of power in communication with children in both situations: in "adults imparting 'knowledge' to children or children communicating their ideas to adults". The issue is how to deal with the differences in their status, especially when adults work with children. Clark (2005:25) suggests that "Viewing young children as weak, powerless and vulnerable may lead to high expectations of the adults' role in terms of protection and nurture but low expectations of children in terms of how they can express their perspectives, priorities and interests. Viewing young children as competent and valuable communicators requires researchers and practitioners to readdress their relationship with young children and therefore their respective roles. Games can help to change the roles by providing alternative, novel environments where the classical roles of an adult and a child "dissolve"; they can become just players and learners in a game that engages them all in topics that can help to create better, sustainable environments in which they, the adults and children, can co-exist and co-create together.

Public Space Issues in Bali Tourist Beaches

Anom Rajendra, Richard Nicholls

(Ir., MSc Architect Anom Rajendra, The University of Huddersfield, UK, ignar59@yahoo.com)
(Richard Nicholls, Senior Lecturer, Department of Architecture and 3D design, The University of Huddersfield, UK. r.nicholls@hud.ac.uk)

1 ABSTRACT

This paper presents a review of issues associated with tourist beach development in Bali. An empirical study is used to clarify the issues in Bali tourist beaches. The rationale behind this paper is because Bali is generally considered as one of the best tourist destinations in the world, and due to a key tourist asset is its beaches. Many beautiful panoramic beaches are located in the southern coast of the island; among them are Kuta, Jimbaran, Pecatu, Nusa Dua, Sanur, Candi Dasa, and other. These have developed rapidly as tourist attractions and resorts. However, most resorts have developed naturally without planning. Only Nusa Dua resort was developed through planning and design stages.

Today, the environment of the tourist beaches is under serious threats; due to erosion, leading to the environmental damage of the beaches and loss of land in some parts of the coast, though a handling effort has been done recently in the major resorts. Another threat is the development of tourist accommodation and facilities along the beach which are too close to the coastline. These do not comply with the national Law and Regulations. These two threats affect the width of the beach which becomes narrowed leading to insufficient width in accommodating public activities. These activities include; tourist activities, art and cultural attractions, ritual for the Balinese, as well as the livelihoods of fishermen. Therefore, the loss of beaches as public spaces will significantly impact on the social, economic and cultural/religious life of the Balinese.

2 HISTORICAL BACKGROUND OF BALI

Bali is a tiny island, located approximately eight degrees south of the Equator. It has a tropical zone with 5,632.86 square kilometres of extravagantly fertile land which are mostly cultivated with corps. Volcanic mountains occupy the island's hinterland sloping steeply to the sea in the northern part, and more gradual slopes in the South. With a coastline of approximately 436.80 kilometres, its abundant coastal resources are many and varied here such as white/black sandy beaches, coral reef and associates, mangroves, sea grass beds, and dunes which are important coastal resources.[1]

Bali is an enclave Hindu from the Islamic majority in Indonesia which has approximately 3.5 million inhabitants. Bali has a unique culture rooted in Hindu philosophy and their specific customs. After Independence, Bali had been proclaimed as a tourism island and a major international tourist destination. Most travel & tourism guides have chosen Bali as one of the best world travel destinations. Up to now, tourism in Bali relies mostly on the cultural and beaches.

2.1 Cultural Identity

In the early eighth century, it was recorded that the historical development of Balinese culture strongly related to the development of the Hindu religion taking place in Bali. The Hindu religion takes a key factor in the notion of Balinese cultural and religious identity. The golden age of Balinese culture took place when Bali under the rule of the Majapahit Dynasty based in East Java or West of Bali Island. During this time, the agriculture system of Subak, art and architecture, ritual ceremonies all thrived significantly on the island. The Kingdom Palaces and the Priest's houses became centres for the development of their culture. The Majapahit era occurred during the fourteenth-sixteenth century. After this era, the Dutch then colonised Bali in the earliest twentieth century in which their influence also introduced new values particularly in architecture. Even with this external influence, the roots of Balinese culture still derive from their religion. [2]

2.2 Philosophy

The basic philosophy of Balinese Hinduism is how to achieve a balance between humankind and nature in terms of micro-macro cosmos. This is referred to as "cosmological balance". They believe that a harmonious balance will bring their life into serenity and happiness. This philosophy derives from the belief that

humankind is similar to nature in that it consists of three divine parts in which each part follows its own nature and character. These puts, for example, could be described as head, body, and feet. From this, all things in nature can be distinguished abstractly as consisting of three elements. Environment or land, village, building, structure, wall, pillar, and other building details also consist of three divine divisions each with their own characteristics. Moreover, humankind is also considered to consists of three layers such as soul-mind-physical body or inside-middle-outside (inner-middle-outer). And in turn human life consists of birth, life, and dead.

2.3 Concept of Space

Within Balinese philosophy a concept of Kaja-Kelod or North-South (Mountainward-seaward) can be identified. Within this, concept of space can be divided symbolically into three zones; each of those is mountain, midland, and sea. The mountain as a head is a primary part of the zones regarded as the purest place. The midland as the body or middle zone which is a place for dwelling and other human activities, and the sea is an impure zone as a symbol of feet. The impure zone does not mean that it is unsuitable place for shrine indeed. Many shrine places are built in the three zones in order to maintain cosmological balance. The symbolisation of the three zones in the land or earth is also transferred into villages, temples, palaces, and dwelling. At the village level, for instance, there are three temples, called Tri Khayangan which form the main identity of the traditional village. These temples are located at north, middle, and south of the village.

To maintain a balanced, the existence of temples, dwellings, and open spaces are considered as essential places. These are because the three places are also associated with the philosophy of Tri Hita Karana meaning three causes of serenity and happiness of humankind. This philosophy teaches adherents to form harmonious relationships between humans and God, human and human, as well as human and the environment. The external environment is seen as one of three essential places within Balinese culture. As a consequence, it has to be preserved and protected in order to maintain a harmonious environment. To keep this, it is not only maintained through a physical approach but also through offering ceremony as one of important parts of Balinese belief. The ritual ceremony takes place usually at mountain, lake, forest, farm, graveyard, cross and T junction, coastal area, beach, sea, and others.

2.4 Beaches

From the philosophy and concept of space, a beach is an open space which amongst its function has to accommodate ritual activities. The ritual activities relate to temple, humankind and cremation ceremonies as well as harmonious beach environments. The most well attended ritual activity takes place the day before the Balinese New Year. The cremation ceremony is the most regular ritual event on the beach. Furthermore, there are a lot of temples along the beach with different functions and hierarchies. In some places, fishermen have a special shrine to offer respect before going to the sea. From this point of view, it is clear that beaches are sacred areas, though these areas are categorised as public space according to the Indonesia National Policy. This policy states that littoral regions are protected areas and disaster-prone areas which can be used for public only. [3]

3   DEVELOPMENT OF BALI TOURIST BEACHES

The tourism industry is one of the top foreign exchange industries in many countries, including Thailand, Philippines, Singapore, Fiji, and also Indonesia. [4] In addition, tourism is also known to stimulate economy of the areas, so that it is very often described as 'new kind of sugar', 'tool for regional development', 'invisible export', 'passport to development', and other terms.[5} Nowadays, the combination of domestic and international tourism has become one of the world's largest and faster-growing industries in terms to volume of income and employment generation.[6]   According to UNWTO, the annual growth of international world tourist arrival increased by 4.6 % in 2011 (nine hundred eighty three million) and 6.4 % in 2010 (nine hundred forty million). In comparison to other regions, Asia and Pacific (including Indonesia) received an increase of 6.0 % which is the second largest percentage increase in tourist arrival in the world after South America. [7] In terms of value, the UNWTO in its World Tourism barometer of June 2009 reported that the growth in income from this sector reached $ 944 million in 2008, up 1.9 % from 2007. [8] This evidence indicates that the tourism industry and tourist arrival in that region is experiencing a long period of growth.

Focusing on Bali, according to Bali Tourism Statistic in 2010, the number of foreign tourists arriving Bali in 2010 was 2,493,058 and 4,825,068 of domestic tourists, so that the total number is 7,318,126. [9] This figure was recorded from the main gate of Bali; Ngurah Rai International Airport and Gilimanuk Harbour, excluding other gates such as Padangbai, and Benoa Harbour. While the growth rate of tourist arrival in the last five years is 13.26 % per year. Data from the Statistics Office of Bali Province in late 2010 recorded that the total number of properties providing accommodation and the number of rooms in Bali was 2,190 and 45,408 respectively, it means that over the last five years there was an increase of 5.05 % in the number of hotels & other accommodation and 2.5 % in the number of rooms. Badung Regency embraces the areas of Kuta, Nusa Dua, Tanjung Benoa, Pecatu, Canggu is the largest number of total room for accommodation which is up 62.47 % of total room in Bali, followed by Gianyar Regency and Denpasar Municipality. [10]

3.1 The Development of Coastal Tourism Resort

From the beginning, the increasing growth of tourism in Bali produced a positive outcome with the opening of Bali Beach Hotel (recent name: The Inna Grand Bali Beach Hotel) in 1966 and Ngurah Rai International Airport in 1967. Both facilities are located at Sanur and Tuban/Kuta Beach. Although both facilities had negative impacts on the coastal environment, such as Bali Beach Hotel constructed its waste water treatment tank at offshore (Figure 1) and the International Airport constructed their runway crossing shoreline by approximately 800 meter (Figure 2). It seemed that Bali had been proclaimed as the centre of tourism in Indonesia and expected tourist coming to Bali could spread to other regions in Indonesia.[11] Since then, the development of coastal tourism resorts at Sanur and Kuta had grown without planning and coordination. The unplanned and uncontrolled tourism resorts indicated by lack of infrastructure especially access to the beach, lack of public facilities, worse sewerage system, discharging water disposal to the sea, building frontier offences, and others had led to a high building density and threats of environmental disaster.

Figure 1: Bali Beach Hotel's waste water treatment tank at shoreline – offshore (BBCP, 2006). Figure 2: International Airport's runway with cross structure by approx. 800 metre (BBCP, 2008)

Meanwhile the resorts of Sanur and Kuta had been abandoned to grow themselves; the central government was interested in constructing a model of tourism resort as a centre of tourism resort taking at other location in Bali. In 1968, they asked some experts in planning and design from developed countries to develop the tourism resort model. Based on the experts recommendation, in 1970 the central government reached an agreement with the United Nations Development Programmes (UNDP) as the financing agency, the World (International Bank for Reconstruction and Development-IBRD, and the International Development Association-IDA) as the executive agency for the preparation of a regional tourism plan for the island of Bali.[12] An emphasis of the need is to concentrate the development of tourism resort providing international standard accommodation in an area with minor negative impacts. The Plan was designed by the France consultant; SCETO (Societe Centrale Pour l'Equipment Touristique Outre-Mer) was completed into six reports and approved by the central government in 1971 and through President's Decree in 1972. [13]

The SCETO succeeded in designing Nusa Dua enclave as an ideal site to be the centre of tourism resort in Bali. The aims of enclave tourism resort development of Nusa Dua are to minimise the interaction between tourists and local community, to provide natural demarcation of tourist areas, and other borders. Besides producing the physical planning, they also recommended to establish two institutions for managing tourism development and control. The two institutions mentioned were Bali Tourism Development Board (BTDB) as giving consultation to the government in the development of tourism in Bali and Bali Tourism Development Corporation (BTDC) as managing the implementation of Nusa Dua Master Plan. [14] The institution of

BTDB had had a significantly important role to control and secure the impact of tourism. Unfortunately, all foreign experts as technical experts of BTDB left this institution in1979, due to the possibility of political interest and abuse of power. Since the Government of Province was taken over the function of BTDB, they were not able to control the faster-growing tourism resorts. New resorts were built in other places and beaches, such as Tanjung Benoa, Pecatu, Candi Dasa, Tanah Lot, Lovina Beach, and other beaches. An excursion road built to connect Nusa Dua resort with Sanur and Kuta resort changed to be public access, which are very crowded.

3.2 Unplanned Versus Planned Coastal Tourism Resort

Even though the central government succeeded in developing Nua Dua resort as a model of tourism resort in Bali, it failed to set out Nusa Dua resort as the centre of tourism development. And also it failed to execute the initial aims of the enclave tourism resort development. New resorts were built in other places and beaches, such as Tanjung Benoa, Pecatu, Candi Dasa, Tanah Lot, Lovina Beach, and other beaches. Even an excursion road built to connect Nusa Dua resort with Sanur and Kuta resort has changed into a public access, which has become very crowded today. From this point of view, there are essentially two types of tourist resorts in Bali: the unplanned and the planned resort.

As the only properly planned resort, Nusa Dua was designed through ecological considerations. For instance, a Central Sewage Collection and Treatment System were built too far from the sea to avoid water infiltration to the sea. Watering the garden and other landscape of the resort are supplied from the treated sewage effluent and well-field. The resort has a large open space as every plot area uses Building Covered Ratio or Floor Area Ratio of approximately 35 %, following Building Codes. [15] Whilst setback line of the structures to coastline was assumed around 60 metre from High Water Level (HWL). With wide and beautiful sandy beaches stretching along the coast supported by calm wave, it deserves this resort as one of the best resort areas in the world. Nowadays, the management of Nusa Dua resort is still under BTDC. With the authority of BTDC, the resorts' beaches, however, is not for public.

Meanwhile, other resorts were unplanned which each tourist facility was owned by private sector. The owners bought and built their land according to land certificate, although a part of their land was used previously by public as an access to the coast or to beach temples. Some cases took place in Kuta, Pecatu, Sanur, Candi Dasa and other places. They tended to ignore public interest as they are secured and guaranteed by the law. With profit oriented, they built their land as effective as possible and attempted to take advantage in every front, it includes encroaching the beach as public areas little by little. The Building Covered Ratio tends to be more than 35 %, since the owner extend commonly their facilities after operation. In addition their building structures were too close to the coastline which assumed not accurate from Local and Regional Regulation. This condition is due to less control and monitoring as well as weak law enforcement.

4   PUBLIC SPACE ISSUES IN BALI TOURIST BEACHES

As mentioned above, Bali beaches are sacred areas and also important public spaces whilst the tourist hotel operators treat the beaches in front of their properties is a vital asset to satisfy their tourist guests so that they tend to use them as much as possible. Besides the impact of tourism, beaches are also under threat from natural disaster. The issues of public space in Bali tourism beaches can be categorised into two factors; human activity and natural disaster.

4.1 Eroded Beaches

There is inevitable that eroded tourist beaches have resulted from a combination of natural disasters and human activities, leading to the significant change in their shoreline. According to the Bali Beach Conservation Project (BBCP) Inception Report 2006 recorded that eroded beaches were up to 51.5 km in the year of 1978, 70.33 km in 2000 to be 91 km in 2006.[16] The erosion took place in almost all coastal areas in Bali, which were dominantly moderate erosions (Figure 3). While hard eroded beaches were recorded at three locations, one of them is Candi Dasa Beach resort (Figure 4). The report also identified that the hard erosion taking place is due to climate change, coral mining, waste disposal, fishing activity, inaccurate hard structures built along the coast, and other human activities. Nowadays the eroded beaches in Bali are predicted to reach approximately 100 km, since there is no protection in the most coastal areas. This condition has resulted in the narrower beaches and definitely lack of public space.

Even though, the central government has rehabilitated the main tourism resorts in Bali such as Tanah Lot (2002) Sanur, Tanjung Benoa and and Nusa Dua (2006), and Kuta Resort (2008), the erosion cannot be stopped. To maintain the beach's space in these resorts, the government has prepared a sand stockpile located in West Sanur area. [17] But the cost to transport the sand to the location and to fill it on the beach needs a lot of budget which has to be financed by the government regency. The problem is not solely on the cost of beach maintenance but also after running out sand stockpile. To dredge the sand from the previous source at Geger beach, it will not be easy anymore since it needs a huge of money and also needs hard socialisation to the community in terms of getting approval from them. While the resort beaches have eroded continually, the others have been serious damaged even have lost in some parts.

Notation:
- Hard Erosion
- Moderate Erosion
- Minor Erosion

4.2 Conflict of Interest

There are different perspectives from Balinese community/public, the government, and tourism companies concerning about the function of the beach especially in tourism beaches. The different perspectives have become a conflict of interest from the beach users, and it will have a high risk to be friction even confrontation from the parties if there is no clear solution particularly from the government as the agent of policy authorities. The involvement of the government of regency and province to manage conflict of interest in these areas is essential. The National Policy No. 22/1999 and No 26/2007 state that both the governments have been responsible to manage the beaches. It means that management of conflict must be handled mainly by the government. From the both policies, the government of regency has been more responsible than the province.

However, the government of regency has given a mandate to preserve the beaches to a traditional village, called Desa Pakraman. The reason is to give their authority back as a part of the traditional village territory. But the situation is not similar to two centuries ago when the Desa Pakraman had got directly a mandate from the King to manage their territory, so they were so powerful to maintain the beaches as ritual areas. Today the situation is clearly more complex, most of them have only tasks to organise ritual rites when take places and to take parking and entrance ticket. Only Desa Pakraman of Kuta and Legian has full attention to manage their beach territory, although they could not handle all problems. They still need some helps to the regency, such as manpower, heavy equipments, and other materials.

Meanwhile, from empirical data, other villages have various problems in managing their beach territory which depends on internal and external factors. Sanur resort, for example, it seems that conflicts of interest are not only from the beach users, but it also comes from the member of villages. Among them are the administrative village of Sanur Kaja and Kauh, Desa Pakraman of Intaran Sanur, Sindu Traditional Sub-village, Youth Organisation of Batu Jimbar Sub-village, and other groups. Even though they are powerful, there is less coordination among them. On the other hand, the resort locations which are too far from the traditional village, tends to use the beach optimally, for instance Geger, Pecatu, Dreamland, Jimbaran, Candi Dasa, Canggu Beach, and others. At this time, the government of regency are still continuing to open wide investment in tourism sector in order to increase their local income. An awareness to manage conflicts of interest in the beach is not to be established yet, so that the conflict will be more complicated in the future.

4.3 Private Beach

From the first step, Nusa Dua was designed as an enclave tourist resort and private resort to avoid the negative impacts of tourism to local culture and community. This private resort was approved by the province and central government. This is because the rationale was good and reasonable; however it means that there was contradiction from the notion of Balinese Hindu Society, and also disagreement from the National Policy in which the beach is sacred and public area (Figure 5). Though an access to two temples which located at the two small islands has been available, the nuance and atmosphere for preparing ritual rites at the temples is strictly different (Figure 6). Because of this sample, the beaches at the northern and southern side of Nusa Dua resort tend to be private, even the beaches at Geger Beach. At those locations, hotel operators use the beaches in front of their property as much as possible, backed up by their security guards.

Figure 5: Nusa Dua's aerial photo with artificial reefs as Groins after Project (BBCP, 2006). Figure 6: Two small islands as an identity of Nusa Dua Resort (BBCP, 2006)

4.4 Lack of Access and Public Facility

Public access is a determining factor whether the beach is to be private or public. With the lack of public access to the beach, it is difficult to say the beach in front of the resort is public space. Most unplanned tourism resorts have been indicated by lack of public access as mentioned above. In some places, the Balinese have to get permission from the hotel operators access their beach temples for ritual ceremony. This is due to no public access to their temples. This is a very unfortunate situation. Another problem is the lack of public facility in most tourism resorts. When the beach rehabilitation took place in the four locations, the central government, through the project built some public facilities such public toilets, tourist information centres, public showers, and others, but those are only in Kuta beach. Sanur resort has some small public toilets, built by the community initiative. The main reason is lack of areas to build these facilities. And also there is no initiative from the government of regency to redevelop the existing unplanned resorts by providing public facilities along the coast. If the government state that the beaches in front of the tourism resort are public space, they ought to utilise facilities as the needs of public.

5 CONCLUSION

This paper has considered the issues associated with tourist development in the beach areas of Bali, in which it can be summarised as follows:

The initial development of Nusa Dua enclave resort designed to mitigate negative impacts of tourism on Balinese culture and local community unfortunately did not perform as expected, indicated by the rapid growth of uncontrolled beach development in other places which are close to the local community. This development growing continually that cannot be controlled again. Building codes requiring the setback of building structures from coastline by 100 metres also failed to be implemented, leaving most accommodation too close to the coastline. Weak control and monitoring might be one of the main reasons allowing the problem to occur. Moreover, a desire by the government to encourage investment in tourism for economic development without putting in place measures to protect socio-culture and environment has exacerbated problems, particularly in public space issues.

The issues have been identified such as; eroded beaches, conflicts of interest, private beaches, lack of public access and facilities. The recent issues relating to public space in the beach tourism resorts seem difficult to

be stop. Loss of the beach's space from offshore and onshore due to erosion and encroachment is an indication that the issue could not be stopped. In the future, the public spaces issue are set to become a more contentious issue and meet more resistance. Furthermore, marginalised public interests, friction and confrontation are some serious threat in the beach usages.

To manage the problems especially public space issues, there are several important steps and strategies which should be implemented immediately. These are:

There is a need for the local and regional government to evaluate the development of Bali tourism as a whole and develop a strategy for its management. The strategy should recognise that development without consideration of human and environmental conservation is a real failure and a poor step for the next generation. For this purpose, stakeholders must have the same vision and mission in setting out local wisdom of cosmological balance as the key role of tourism development, and also this has important parallels with aspects of the concept of sustainability. An organisation body like BTDB constituting a synergy between the local and regional government is essential to be established to control and monitor the development of tourism especially the tourism resorts

In addition, it is a better way to improve the existing resorts rather than to extend and develop new resorts. The beach identified as public spaces and scared areas must be a priority to be implemented, supported by tight control and monitoring. No space should be designed as private beaches for any reason or argument.

Although the implementation of regulation about setback line of building structure from the coastline to all existing buildings are almost impossible to implement, the organisation body should push the hotel owners to show their land certificates for clarification whether they take public areas or not. If they take public areas, it must be recovered leading to prosecution. After that, the placement of benchmarks is essential to monitor the position of the existing buildings and other hard structures, equipped by an advance technology in mapping and monitoring system such as Geographic Information System (GIS) for covering the whole resort beaches.

1 ABSTRACT

The most popular methods to measure urban sprawl are based on population growth and/or density measurements. The data needed for these calculations are easily available as long as the focus lies on politically drawn boundaries or jurisdictions. If however the emphasis lies on the organic de-facto town boundaries, these population data are not always readily (and cheaply) available. Here we employ and develop indicators that focus on the organically grown (functional) size of a town or village rather than its politically defined boundary. We use the structure provided by the Corine Land Cover (CLC) Project (2006) to define usage categories as well as grid size (100m x 100m).

In this paper we follow two lines. First, we identify mismatches between legal and de-facto town boundaries using land use data. Second, we employ several land-use-based urban sprawl indicators and compare their performance. Some of these indicators have been used in the literature before, others we developed ourselves. These indicators are based on the structure and/or composition of urban space.

2 INTRODUCTION

Urban sprawl is a complex phenomenon. For some the main characteristic of urban sprawl is poor accessibility, or as Al Gore defined it: "a gallon of gas can be used up just driving to get a gallon of milk". [1] For others the main components of urban sprawl are low density zoning (single family homes on large plots) or single-use zoning rules that lead to a geographical separation between residential and commercial areas. For some urban sprawl is an aesthetic criterion. Sprawl in this sense is defined as boring housing developments, interchangeable commercial developments containing malls and fast food chains. Not everyone sees urban sprawl in a negative way however, Glaeser and Kahn (2003) for example see urban sprawl as the "inexorable product of car-based living" and argue that "sprawl has been associated with significant improvements in quality of living", and that "the environmental impacts of sprawl have been offset by technological change". Brueckner (2000) also see urban sprawl as the by-product of rising incomes, growing population and a fall in car-commuting costs. His argument however takes a different note in that he argues that sprawl is associated with three different types of market failure: The failure to take into account the value of open space, the failure to take congestion and ecological consequences of urban sprawl into account, and the failure to make developers pay for the infrastructure they need. As urban sprawl means different things to different people, it is not surprising that many different definitions of urban sprawl exist in the literature. However everyone seems to agree that urban sprawl is an important phenomenon. Frenkel and Ashkenazi (2008) summed up the situation very well when they wrote: "we know that sprawl is significant, but we are not yet sure what it is exactly or how to measure it" (Frenkel and Ashkenazi, 2008).

Of course, measuring urban sprawl is important not only because experts agree on the importance of the sprawl phenomenon. Measuring urban sprawl is important because it is associated with a variety of major ecological, social, and health effects and developments. The impacts associated with urban sprawl range from the lack of scale economics (Frenkel and Ashkenazi, 2001), ecological problems such as air pollution and congestion due to increased car use associated with urban sprawl (Brueckner, 2000, Nechyba and Walsh, 2004), to social problems of increased segregation (e.g. Glaeser and Kahn, 2003) or increased isolation (Frumkin, 2002), to health problems such as obesity [2] (e.g. Ewing et al., 2003, Bray et al., 2005).

Our objective here is to compare alternative measures of urban spawl. Some have been previously used and some we have developed ourselves. Our land use data comes from the Corine Land Cover Project (European

---

[1] Quote from the speech "war on sprawl" by Al Gore during his campaign for the U.S. presidency, January 1999.

[2] Obesity and urban sprawl are statistically correlated. Most researchers argue that obesity is a negative by-product of urban sprawl, partly induced by the car dependency of the population. However some researchers argue, that the causation between urban sprawl and obesity is actually the reverse with obese people being more likely to choose to live in a sprawling environment (see e.g. Eid et al., 2008).

Environment Agency, 2010). We use the grid structure as well as the land use labelling of the CLC Project to calculate alternative measures of urban sprawl. The grid size in the Corine Land Cover Project is 100 by 100 meters. There are 42 land use classes present in the CLC Project. Cells are classified according to their dominant usage. Population is mainly found in CLC class 1 (continuous urban fabric) and 2 (discontinuous urban fabric).

In our empirical comparisons we focus on Austria's second largest city, Graz, as well as two smaller regions in the same province, Gleisdorf and Leibnitz. We choose different size urban developments on purpose, as urban sprawl does not only affect large cities: "urban sprawl is a process which can affect even the smallest of villages" (Sudhira et al., 2004).

3 DENSITY MEASURES

The most popular methods to measure urban sprawl are based on population density measurements. The main input in these measures is the number of people living in a particular area (e.g. people per square kilometer). Low population density numbers suggest high degrees of urban sprawl. We consider two different ways of measuring population density.

3.1 Density Measure 1: number of people divided by total area of district/municipality

The standard version of the density measure is to divide the number of people by the total area of a district/municipality ( ). Using this method we can see large differences in the population density for major international cities. The 6,299km^2 city area of Los Angeles has a population of 14,900,000, which corresponds to a population density of 2,400 people per square kilometre according to this method. For the 2,163km^2 area of Seoul-Incheon in South Korea with a population of 22,547,000 people, the population density is 10,400 people per square kilometre. The city of Dhaka in Bangladesh has by far the highest population density in the world with 44,400 people per square kilometer (New Geography, 2013). According to the density measure of urban sprawl, if a specific area experiences positive population growth, the population density becomes higher and urban sprawl is reduced.

The formula for this density measure reads as follows:

$$D_1 = \frac{\sum_i pop_i}{\sum_i x_i}$$

where pop_i is the population in cell i for $i = 1, ..., n$ with n as the total number of cells in the city and $\sum_i x_i$ is the whole area of the city (sum of all cells in the town).

For the three Austrian municipalities the population densities per square kilometer are more moderate. While the population density within the official city limits of Graz is 2,234 people per km^2, for the 57 surrounding communities of Graz it is only 128 people per km^2. Within the official political city limits, the density index for the regional town of Gleisdorf is 1,214 and for the southern styrian town of Leibnitz it is 1,322 people per km^2.

3.2 Density Measure 2: number of people divided by built-up cells in district/municipality

We include a second density measure here which considers the population density in built-up areas only (. The rationale for doing this is that the population may not be spread evenly across all cell types in a municipality. Suppose for example that the district/municipality contains a large park. This acts to reduce overall population density and hence increases the level of measured urban sprawl according to density measure 1. However, it could be legitimately argued that the park should be ignored when measuring population density. This is what density measure 2 does.

We use land use data from the Corine Land Cover Project (2006) to classify individual 100m x 100m grid cells according to their dominant usage into 42 possible land use classes. Our first task is to decide which of these land use classes constitute a built-up area. This may differ across regions. We define a cell as built-up if there is residential housing in that cell. While we do not have population data at the level of individual cells, we can determine which cell types contribute population uing a regression model.

The city of Graz has 285,387 inhabitants (including principal and secondary residence) in 2006. The city is divided into 259 voting districts ("Zählsprengel") for each of which we have the number and land use type of

the cells lying within that area as well as the number of inhabitants. Within Graz only 12 CLC cell types are observed.

We estimate the following regression:

$$bev_{ZSP} = \beta_i \cdot x_i, \ i = 1, \ldots, 12$$

where bev_{ZSP} is the population in a district, x_i is the number of observations of cell type i observed in that district. The regression is run over the 259 districts in Graz. We find that only two cell types are significant with a p-value [3] smaller than the significance level of 5 %: these are CLC class 1 (continuous urban fabric) and CLC class 2 (discontinuous urban fabric).

To find the relative distribution of population between CLC classes 1 and 2 within the city region, we run the regression above for the entire area of Graz and include only CLC class 1 and 2 as explanatory variables. For the city area of Graz we find an imputed average cell population of 101.85 people for CLC class 1 and 22.84 people for CLC class 2. This corresponds to a relative population weight of 0.82 for CLC class 1 and 0.18 for CLC class 2.
Fig. 1: Corine Land Cover classes of the city of Graz.
Fig. 2: The city of Graz with its surrounding 57 municipalities.

---

[3] In our case the null hypothesis is . The smaller the p-value, the more strongly the test rejects the null hypothesis which means that the tested variable has a significant influence on the population variable bev_{ZSP} .

There are 57 small municipalities surrounding Graz. Equivalent to the first regression above, we now run regressions for these 57 municipalities. The surrounding area of Graz contains 22 of the 42 possible land use classes.

This time we find that in addition to the CLC classes 1 and 2 (continuous and discontinuous urban fabric), three further CLC classes are significant for housing population, these are CLC class 18 (pastures), CLC class 20 (complex cultivation patterns) and 23 (broad-leaved forest). Even though these additional cell types are statistically significant, they house a very low number of people on average.

Population density according to our density measure   is therefore calculated as follows: For each of the 259 sub-districts within the city limits of Graz we divide its population by the sum of the number of cells of class 1 and 2 within this district. Population density for each of the 57 municipalities outside of Graz is calculated by dividing its population by the sum of CLC cells of class 1, 2, 18, 20 and 23 within that area.

Therefore the formula for this density measure reads as follows:

$$D_2 = \frac{\sum_i pop_i}{\sum_j x_j}$$

where pop_i is the population in cell i for $i = 1, \dots, n$ with n as the total number of cells in the city and $\sum_j x_j$ is the built-up area of the town.

4 ENTROPY MEASURES

4.1 Measuring entropy at the district/municipality level with population data

Entropy measures of urban sprawl focus on differences in density across districts rather than the density level itself. A high entropy score implies that population density does not vary much across districts. This is interpreted as a high level of urban sprawl. A low entropy score conversely implies high variability in population density across districts and a low level of urban sprawl.

Here we use Shannon's measure of entropy. This has been used previously to measure urban sprawl by Yeh and Li (2001) in China, Sudhira, Ramachandra, and Jagadish (2004) in India and Sun, Forsythe and Waters (2007) in Canada.

Urban spawl according to Shannon's entropy measure is calculated as follows:

$$E = \sum_i p_i \cdot \log(p_i),$$

where

$$p_i = \frac{pop_i / \sum_j x_{ij}}{\sum_i (pop_i / \sum_j x_{ij})}$$

are the weights that sum to one. The index j counts the number of land use classes, pop_i is the population, and x_i is the land area in district i. Its upper bound is $\log(n)$, where n is the number of districts. E takes the value $\log(n)$ when the population density is the same in all districts. Dividing E by $\log(n)$ provides us with an index that lies between zero and one. This normalized entropy measure makes it easier to compare entropy results between regions.

$$E_{1,2} = \frac{\sum_i p_i \cdot \log(p_i)}{\log(n)}$$

Using our two measures of density from the previous section (i.e., density measures D_1 and D_2) we obtain two different measures of Shannon's entropy (E_1 and E_2). We calculate these entropy measures for the city of Graz, the surrounding area of Graz, and greater Graz (the latter being the sum of the city and surrounding area).

4.2 Entropy measures that do not use population data

The Shannon entropy measure can also be applied to density measures that are not based on population data. One example of such a density measure for a district is the number of built-up cells divided by the total number of cells in the district. In this case, the entropy measure takes the following form:

$$E_3 = \sum_i p_i \cdot \log(p_i), \text{where}$$
$$p_i = \frac{\sum_k x_{ik}/\sum_j x_{ij}}{\sum_i (\sum_k x_{ik}/\sum_j x_{ij})}$$

are the weights summing up to one. The variable x_{ik} denotes the number of cells in district i with built-up cells k ($k = 1, 2$ for the city of Graz, and $k = 1, 2, 18, 20, 23$ for the surrounding communities of Graz) and x_{ij} is the number of cells in district i of land use class j for $j = 1, \dots, 12$ in the city of Graz, and $j = 1, \dots, 22$ in the surrounding area of the city.

5 SHAPE BASED MEASURES

Urban sprawl can also be thought of as a land use issue rather than one of population density per se. We now consider a class of methods for measuring urban sprawl that do not require any population data. This feature can be useful since obtaining population density measures can be problematic when the political boundary of a town does not coincide with its functional boundary. [4] For example, in Figure 3 we see that our town A* lies mostly within its political boundary (A). Most of its borders however lie outside its political boundaries in the political jurisdictions of B, C, and D. Data on population changes are readily available for each political jurisdiction, but these data are not geographically referenced – they do not show in which cell of each jurisdiction people live. Suppose that the town A* expands rapidly towards the north and west but not anywhere else. If we just measure population change in A, we completely miss this expansion. If on the other hand, we include all of the population growth that happened in A, B, C, and D together, we overestimate the expansion of A*, since each of these jurisdictions also has settlements that are not connected to A*. In this section we will illustrate a method to overcome this problem.
Fig. 3: Political vs. functional boundary of a town.

A class of urban sprawl measure focuses on the shape of a town's boundary. The most compact boundary is a circle. This minimizes the level of urban sprawl according to this type of measure. The more the shape departs from a circle the higher is the resulting measure of urban sprawl. Also, the wiggliness of the boundary can play a role in Fractal-type measures from this class.

The Corine Land Cover Project (European Environment Agency, 2010) provides an ideal framework for illustrating these types of methods. The landscape is divided into 100 by 100 meter cells, thus allowing the boundary to be identified at this fine level. This is a topic that we will consider in future research.

---

[4] The question of „where does a town end?" has various possible answers. We define the "end of town" as the end of cells with Corine Land Cover classification 1 or 2 (continuous or discontinuous urban fabric).

6   RESULTS

Sprawl Measures	Density Measure D_1	Density Measure D_2	Entropy measure E_1	Entropy Measure E_2	Entropy Measure E_3
Graz	2234/km²	4183/km²	0.927	0.937	0.990
Surrounding communities	128/km²	309/km²	0.917	0.932	0.979
Graz including surrounding area [5]	360/km²	735/km²	0.918	0.933	0.980
Gleisdorf	1130/km²	×	×	×	×
Leibnitz	1242/km²	×	×	×	×

Table 1: Results of Density Sprawl Measures.

7   CONCLUSION

Urban sprawl has many interpretations. Different measurement concepts capture different aspects of this complex issue. We have shown how entropy measures and land use data can be used together to capture the phenomenon of urban sprawl in new ways. Measuring sprawl at the functional settlement level rather than the political level is a big benefit for city and regional planners. Being able to do so without gathering expensive cell level population data is another benefit of our approach.

(Professor Corrado Zoppi, Department of Civil and Environmental Engineering and Architecture, University of Cagliari, Via Marengo, 2 – 09123 Cagliari, Italy, zoppi@unica.it)

1 ABSTRACT

Land take is a process of significant relevance in the countries of European Union (EU). In 2011, the European Commission (EC) put in evidence that an important milestone for the EU should be to reach the goal of no net land take by 2050, and to take under strict control the impact on land-taking processes of the EU policies in the new Structural Funds programming period (2014-2020) (Communication of the EC to the European Parliament COM(2011) 571 of 20.9.2011).

In this paper we analyze the Sardinian land-taking process as related to factors which are identified as relevant variables in several studies concerning land take, such as area size, accessibility, proximity to regional and local cities and small settlements, natural risk, proximity to nature conservation areas.

2 INTRODUCTION

The EC indicates that land take in the EU amounted to more than 1,000 km2 per year between 1990 and 2000, decreasing to about 920 km2 between 2000 and 2006 (European Commission, 2011), and that, as a consequence, the objective of no net land take by 2050 would imply a decrease rate of about 800 km2 per year.

Land take in Italy parallels the difficult general situation of the EU countries. Figures at the national level put in evidence that in 2009 a 7.3 percent of the Italian land had an artificial land cover (European Commission, EUROSTAT, 2012), with an average growth rate of about 6 percent between 1990 and 2000 and of about 3 percent between 2000 and 2006 (ISPRA, 2011, p. 479). The implementation of analyses of land-taking processes at the regional level is problematic since currently available geographic databases and information systems do not provide systemic information on the phenomenon (CRCS, 2012).

However, some Italian regional administrations, such as Lombardy and Sardinia, have set up regional information systems that address land-taking processes. The geographic information systems of these regions allow to relate land take with spatial, economic and planning-policy related variables, and to infer on correlations between such variables and the land-taking phenomenon.

We study the land-taking process through the land cover maps of Sardinia, made available in 2003 and 2008 by the Sardinian regional administration [1]. The results and inferences of our study could be easily generalized to other Italian and EU regions, under the necessary condition that geographic databases and maps were made available for these contexts as well.

This paper is organized as follows. In the third section we propose the definition of land take for the purpose of this paper. We feel that we have to clarify what we mean by land take, which is a rather controversial issue. In the following section, we discuss the set of variables that we use as covariates to frame the Sardinian land-taking process in the context of relevant studies concerning this topic. Explanatory and dependent variables are described and spatially represented in the fifth section, and correlations between covariates and the dependent (land take) variable discussed.

The sixth section presents the results of regression models which use the land take variable and covariates in order to analyze if, and to what extent, the land-taking process is related to the covariates altogether. In the concluding section, we discuss the influence of the factors/variables found relevant on land take that could be

---

[1] The 1:25,000 "Land Use Map of the Region of Sardinia – 2003 Edition" and "New Land Use Map of the Region of Sardinia – 2008 Edition" are actually two land cover maps that cover the whole island. Data were obtained mainly from photo-interpretation of aerial photographs, satellite images, and orthoimages, but other vector data sets (e.g., regional digital cartography) were also used, together with on-site surveys. The maps' minimum mapping unit (Longley et al., 2001, 151) equals 0.5 ha in urban areas and 0.75 ha in rural areas. Both maps can be freely downloaded from http://www.sardegnageoportale.it/index.php?xsl=1598&s=141401&v=2&c=8831&t=1 [accessed December 12, 2012].

taken into account to define regional planning policies to limit or possibly prevent land take, and, by doing so, help implementing the EC recommendation on no net land take by 2050 into the EU regional policies.

3 WHAT IS LAND TAKE?

As we put in evidence above, the EC considers to reach no net land take by 2050 as an important milestone for a roadmap to a resource-efficient Europe. One of the most dangerous consequences of land take is soil sealing, but other related phenomena are soil contamination and erosion, decrease of soil organic content and of agricultural production and productivity. In a recent study published by the Italian Institute of Urban and Regional Planning (CRCS, 2012), a systematic discussion on the impacts of land-taking processes is proposed; such impacts are grouped as follows:

- impacts on the carbon cycle: a decline of the power of the soil's organic content to fix carbon dioxide in the atmosphere and an increase in concentration of carbon dioxide generated by the mineralization of the carbon present in the excavated soil of new urban developments;

- impacts on the water cycle and microclimate: soil sealing implies: i. a significant decline of stored ground- and underground water; ii. an increased flood risk due to the rising quantity of rainfalls which run directly into rivers, augmenting their levels, turbulence, and sediments in the water; iii. impacts on urban microclimate, since the decrease of the soil evapotranspiration power may very possibly generate an increase of the atmospheric temperature;

- impacts on biodiversity: land-taking processes cause the soil's impoverishment and, as a consequence, the loss of huge quantities of microorganisms, which could mitigate soil contamination, filter percolation waters and make available nutrients for vegetation and pastures;

- impacts on agricultural production: potential agricultural crops are heavily and progressively hindered by land take and soil sealing.

However, if we read the relevant paragraph concerning land–taking processes of the EC communication quoted above (paragraph 4.6), it will be rather difficult to derive a rigorous definition of land take, which should be based on its unwanted impacts in order to effectively address and mitigate their consequences.

Let us consider, for example, the Land Use and Cover Areas frame Survey (LUCAS) of EUROSTAT (European Commission, EUROSTAT), and the COoRdination de l'INformation sur l'Environnement (CORINE) Land Cover vector map (CLC) of the European Environment Agency (EEA) of the EU (European Environment Agency). In LUCAS, "artificial land", that is land taken by land-taking processes, is classified into two main groups, that is "built-up" and "non built-up" areas, where the former are further classified according to the number of floors of their buildings, while a separated sub-group is represented by greenhouses (Technical reference, document C-3 – Land use and Land Cover: Nomenclature, pp. 14-16). In CLC, "artificial surfaces" are classified into four groups (CORINE Land cover – Part 2: Nomenclature, p. 1): i. urban fabric; ii. industrial, commercial and transport units; iii. mine, dump and construction sites; and, iv. artificial, non-agricultural vegetated areas. Even though both LUCAS and CLC address the issue of artificial land cover, propose definitions of artificial vs. non-artificial land cover, and identify artificial and non-artificial areas, it is quite clear that CLC and LUCAS greatly differ from each other.

The example above shows that it is quite difficult and controversial to frame and identify a precise measure of land take, which in some way can make it difficult to implement rigorous quantitative studies on this subject. From this perspective, there are at least two relevant general issues to be taken into account. First, it is rather controversial to state univocally that land take is always negative in terms of the negative impacts indicated above, since there are types of land take which do not generate those impacts. For example, soil sealing, one of the most dangerous impacts, is not a necessary consequence of land-taking processes, as indicated by the EC, which puts in evidence that soil sealing is limited to about a 50 percent of the land taken: "In the EU, more than 1,000 km² are subject to 'land take' every year for housing, industry, roads or recreational purposes. About half of this surface is actually 'sealed'." (EC COM(2011) 571, paragraph 4.6)

Second, there is the trade-off critique. This critique considers land take as a process caused by a strong pressure in favor of settlement development, which implies that the land taken will increase its market value once new land uses displace existing uses. So, why, in principle, existing uses should be preferred over the new ones? Moreover, is a prohibitionist, normative, approach the most efficient way to prevent the negative

impacts of land-taking processes from taking place in the long run? Neo-liberist positions support this critique (see, for example: MacCallum, 2003; Moroni, 2007). From this point of view, heavy taxation on land rent could possibly be the most effective means to counter demand for land take, which is consistent with Henry George's proposal of eliminating land monopoly "by shifting all taxes from labor and the products of labor and concentrating them in one tax on the value of land." (George, 1971, p. viii)

In this paper we do not propose ethic narratives or value judgments on land take, but we analyze land-taking processes in order to detect which factors, and possibly to what extent, can be considered relevant to explain the phenomenon. We implement our analysis with reference to the Sardinian region, one of the two Italian islands which are governed by regional administrative bodies. Sardinian is located to the west of Central Italy, off the west coast just below the French island of Corsica. Sardinia has advanced land-cover maps based on the CLC classification, available for 2003 and 2008, that make it possible to analyze the dynamic of land cover through the comparison of land cover classes which are consistent with each other. So, we use the CLC-based maps of Sardinia to study land take processes, since the LUCAS data, available for 2008 only, would have not allowed us to study land take as a dynamic process.

In the CLC classification, non-artificial surfaces are classified into four classes (at Level 1): i. agricultural areas; ii. forests and semi-natural areas; iii. wetlands; and, iv. waterbodies. The land-taking process is identified in this study as the passage of areas from non artificial classes in 2003 to the artificial land-cover class in 2008. Sardinia has experienced an increase in artifical land from a 2.75 percent in 2003 (66,206 hectares) to a 3.22 percent in 2008 (77,516 hectares).

Table 1 shows the variables that describe non-artificial and artifical land cover and their descriptive statistics. The variables refer to spatial units identified with the 377 municipalities of Sardinia.

Variable	Definition	Mean	St.dev.
ARTIF03	Artificial land cover in 2003 (ha) (source: Corine Land Cover Map of Sardinia – 2003 Edition, next "CLCMS03", level 1)	175.62	318.47

Table 1. Definition of land-cover variables and descriptive statistics.

4 FACTORS RELATED TO LAND TAKE

Land take is related to location-related, socio-economic and planning code determinants (Sklenicka et al., 2013; Huang et al., 2006) and it is essentially a consequence of pressure for future land development (CRCS, 2012).

In terms of location-related and physical determinants, we consider the average size, slope and distance from the closest market place, that is the closest urban center, of a municipality's non-artificial-land areas in 2003 which became artificial in 2008, as these are frequently cited as important factors for land development (Sklenicka et al., 2013; Cheshire, 1995; Palmquist and Danielson, 1989). Accessibility is another characteristics related to the physical location of non-artificial land (Stewart and Libby, 1998), which we describe through: i. endowment of roads which connect regional town and city centers, which the Italian Code concerning Road Regulation (Italian law enacted by Decree no. 1992/285) classes as "Highways", "Main extra-urban roads" and "Secondary extra-urban roads;" ii. proximity to the regional administrative capital city, that is Cagliari, which is also the most important city center of the region; iii. proximity to the nearest province administrative center.

In the case of Sardinia, an island which coincides with an administrative region of Italy, the distance from the coast is of particular importance, since the so-called "coastal strip" (CS) is defined in article 19 of the Planning Implementation Code (PIC) of the Regional Landscape Plan of Sardinia (RLP, approved by the

Regional Government of Sardinia in 2006 [2]) as a "strategic resource, vital for the achievement of sustainable development in Sardinia, that requires integrated planning and management." Under article 20 of the PIC, as a general rule, new development of land and transformation of current land uses are not allowed in the CS; in particular, construction of new major roads, of new industrial or commercial developments, of new camping sites and of facilities associated with golf courses is forbidden within the CS. Some exceptions to the general rule are allowed, provided that municipalities and developers abide by regulations and procedures given by the PIC. Due to these particular restrictions in force in the CS, it was believed that the amount of municipal land area included in the CS could be a relevant impact factor on the ability of cities and towns to spend funds allocated for public services and infrastructure (Zoppi and Lai, 2013). So, a proximity-to-coast effect could be expected, since coastal land is demanded for future tourism development. If land-taking processes related to tourism development are forbidden, it seems very possible that land take will occur in the proximity of the CS. This argument is discussed by Dewi et al. (2013), who found that the establishment of protected areas in Asian and African tropical forestry regions determines an increased exploitation of the marginal lands just outside the protected areas.

Variable	Definition	Mean	St.dev.
PARCSIZE	Municipality's average size of areas classified as non-artificial in 2003 and artificial in 2008 (ha) (sources: CLCMS03, CLCMS08)	0.33	0.29
SLOPE	Municipality's average slope of areas classified as non-artificial in 2003 and artificial in 2008 (percent) (sources: CLCMS03, CLCMS08, Digital Terrain Model of Sardinia, cell size 90 m)	8.97	6.60
PROXSETL	Municipality's weighted average distance from areas classified as non-artificial in 2003 and artificial in 2008 CLC to the closest urban center (km); weight = area size (sources: CLCMS03, CLCMS08, Spatial Dataset of the Regional Geographic Information System of Sardinia, next SDRGISS[3])	2.62	1.64
ACCESS	Endowment of roads connecting regional town and city centers per unit of municipal land area (km/km2) (source: SDRGISS)	0.95	0.47
DISTCAPC	Distance of a municipality from the regional capital city, Cagliari (km) (source: Google Maps)	126.45	71.17
DISTNEAC	Distance of a municipality from the closest province administrative center (km) (source: Google Maps)	30.98	16.67
DISCOAST	Municipality's weighted average distance of areas classified as non-artificial in 2003 and artificial in 2008 from the shoreline (km); weight = area size (sources: CLCMS03, CLCMS08, SDRGISS)	21.02	13.99
CONSAREA	Municipality's total protected area in 2008: parks, reserves, etc. (ha) (sources: CLCMS03, CLCMS08, SDRGISS)	1,342.74	2,632.62
NATAR	Municipality's landscape components with an environmental value, defined as natural and seminatural areas that change from non-artificial to artificial land cover in 2003-2008 (ha) (sources: CLCMS03, CLCMS08, RLP spatial dataset)	11.67	26.05
AGRFORAR	Municipality's landscape components with an environmental value, defined as agricultural and forestry areas that change from non-artificial to artificial land cover in 2003-2008 (ha) (sources: CLCMS03, CLCMS08, SDRGISS, RLP spatial dataset)	25,70	50.83
COASTRIP	Percentage of a municipality's area included in the CS (sources: SDRGISS, RLP spatial dataset)	11.18	24.96
OLDPLAN	Municipality's area classed under the planning code in force before 2006 as area where land transformations and new developments are almost totally forbidden that changes from non-artificial to artificial land cover in 2003-2008 (ha) (sources: CLCMS03, CLCMS08, SDRGISS)	14.85	43.06
DENSITY	Municipality's population density in 2008 (residents per square kilometer) (source: web site Sardegna Statistiche: http://www.sardegnastatistiche.it [accessed December 12, 2012])	77.42	209.25
INC2008	Municipality's real per-capita income in 2008 (euros; 2008 consumer price index = 1) (source: web sites Sardegna Statistiche and Comuni-Italiani.it: http://www.sardegnastatistiche.it and http://www.comuni-italiani.it [accessed December 12, 2012])	9,212.95	1,391.61

Table 2. Definition of land-cover covariates and descriptive statistics.

Among planning-code-related determinants, we consider the endowment of protected areas, since these areas provide environmental amenities. Proximity to protected areas should increase the demand for new residential, commercial or recreational developments, which may possibly generate a change from agricultural to artificial land cover. The argument is even stronger than the Dewi's cited above, since, from this perspective, land take is also driven by the availability of environmental amenities.

Other planning-code factors are related to the class of an area according to the PIC of the RLP. The PIC establishes a rigid conservative regime with respect to areas classified as "landscape components with an environmental value, defined as natural and seminatural areas." It should be comparatively fairly more difficult that an area classified in this way changes its status from non-artificial to artificial land cover. The other class of landscape components with an environmental value is defined as "agricultural and forestry areas." Since the conservative regime is less rigid for these areas, areas located there could be more likely to

become non-artificial than the former. As we put in evidence above, the CS is a class for which the PIC of the RLP establishes a very restrictive and conservative regime, so areas located in the CS should be particularly unlikely to change their non-artificial land cover. Finally, a planning-code-related variable is represented by the areas for which the planning code in force before the PIC, that is before 2006, forbade almost completely any land transformations and new developments.

Moreover, we consider two socio-economic factors as possible determinants. First, population density, whose correlation with land cover change, which puts in evidence a positive agglomeration effect, is underlined by several studies (Sklenicka, 2013; Guiling et al., 2009; Forster, 2006). Second, we use change in per-capita income from 2003 to 2008 to control for a possible income effect. It is quite likely a significant factor, although we do not have a definite expectation as to the sign of the coefficient, since, for example, increasing per-capita income could make a municipality more willing to invest in agriculture or could displace agriculture if the available investment from increased income is diverted elsewhere (Lai and Zoppi, 2012).

Table 2 shows the variables which describe factors related to land-taking processes and their descriptive statistics.

5 LAND TAKE AND ITS COVARIATES: SPATIAL REPRESENTATION AND CORRELATIONS

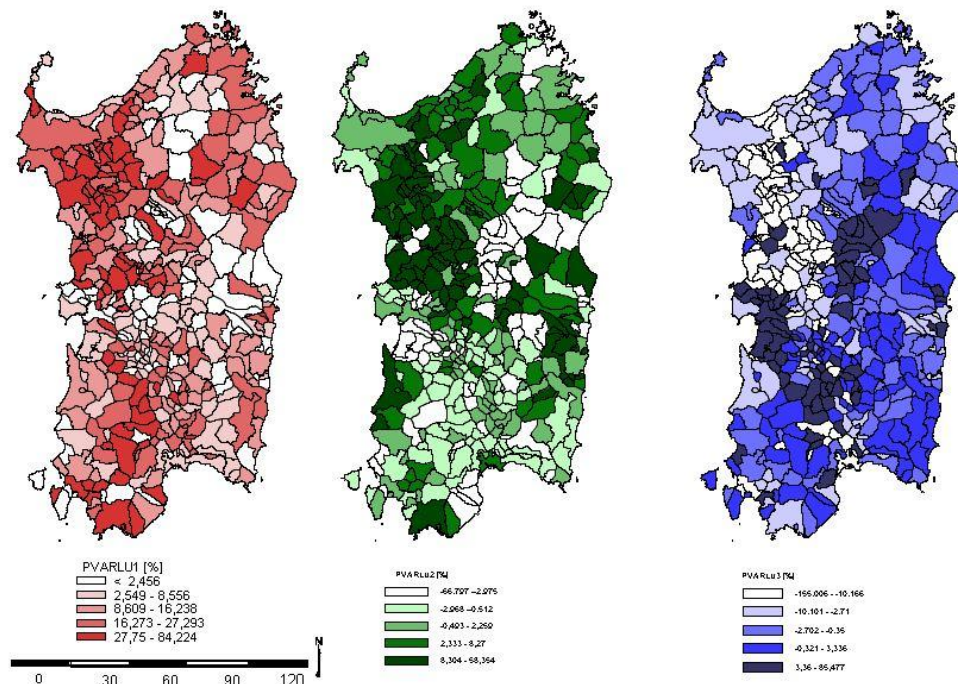
Except for DISTCAPC and DISTNEAC, none of the land-cover variables and covariates listed in Table 1 and Table 2 were available "off the shelf"; therefore, some kind of analysis was required and performed on data (both geographic and non- geographic) collated from different sources. In most cases, GIS-based analyses consisting in combinations of basic geoprocessing operations were performed; in some cases (e.g. to estimate the values of SLOPE, PROXSETL, DISTCOAST), however, more advanced analyses were performed using algorithms built in two open source software programs. [4] This made it possible to develop a geographic dataset, to calculate the value of each land-cover variable and covariate for each of the 377 Sardinian municipalities, and to analyze their spatial distributions.


Fig. 1: Spatial representation of the land-cover variables PVARLU1, PVARLU2 and PVARLU3 at the municipal level (20th, 40th, 60th, and 80th percentiles).

The spatial distribution of three of the land-cover variables is shown in Fig. 1: in the first map (PVARLU1), darker polygons correspond to municipalities with the highest values of the ratio of amount of land taken

---

[4] "Quantum GIS", available at http://hub.qgis.org/projects/quantum-gis/wiki/Download, and "gvSIG", available at http://www.gvsig.org [accessed December 12, 2012].

between 2003 and 2008 to amount of land that was already classed as artificial in 2003. In the second map (PVARLU2), paler polygons highlight those municipalities which lost the highest share of their agricultural areas between 2003 and 2008 (positive values of PVARLU2 indicate that between 2003 and 2008 agricultural areas increased); similarly, in the third map, paler polygons higlight those municipalities which lost the highest share of their forests and semi-natural areas between 2003 and 2008 (positive values of PVARLU2 indicate that between 2003 and 2008 forests and semi-natural areas increased). Such maps only put in evidence changes in land cover between 2003 and 2008, without necessarily implying that land take actually occurred; for instance, where PVARLU2 is negative and PVARLU3 is positive, part of the decrease in agricultural land might be due to forestation or to abandonment of agricultural uses, rather than to urbanization.

	ρ		ρ		ρ
PARCSIZE	0.68	DISTNEAC	-0.21	COASTRIP	0.19
SLOPE	-0.22	DISTCOAST	-0.20	OLDPLAN	0.21
PROXSETL	0.06	CONSAREA	-0.06	DENSITY	0.40

DISTCAPC	-0.08	AGRFORAR	0.33		

Table 3. Pearson product-moment correlation coefficients between PERLTAKE and all of the land-cover covariates in Table 2.

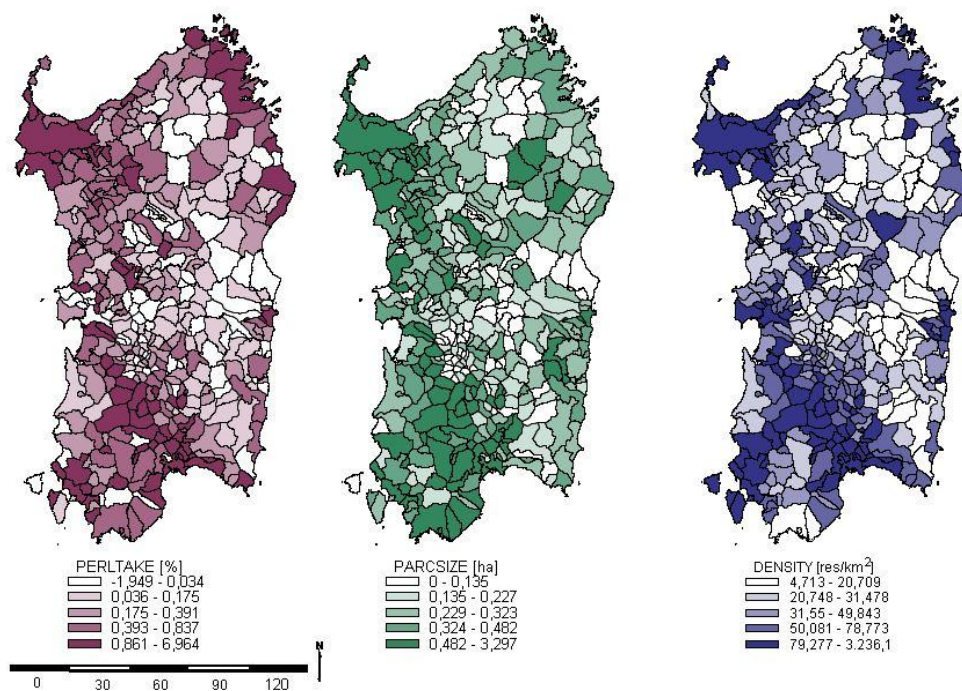
The values of the correlation coefficients (ρ) measuring the linear dependence between the variable PERLTAKE (accounting for land take at the municipal level) and its covariates are shown in Table 3, where a high and positive correlation between PERLTAKE and PARCSIZE is put in evidence (ρ=0.68). This means that, in general, the higher the value of land take, the larger the size of parcels whose land cover changed from non-artificial to artificial between 2003 and 2008. Lower, and yet relevant (between 0.40 and 0.30), are the positive correlation coefficients between PERLTAKE on the one hand and DENSITY, NATAR, AGRFORAR and INC2008 on the other hand. This means that, usually, higher values of land take occur in municipalities where the residential density is higher, where areas artificialized between 2003 and 2008 that were classed by the RLP either as natural and seminatural areas or as agricultural and forestry areas are larger, and having a higher per-capita income. The highest negative values of the correlation coefficient are those between PERLTAKE on the one hand and the variables SLOPE, DISTNEAC and DISTCOAST on the other hand, although the linear correlation is not very relevant (ρ takes values between -0.20 and -0.22).


Fig. 2: Spatial representation of the variables PERTAKE, PARCSIZE and DENSITY at the municipal level

(20th, 40th, 60th, and 80th percentiles).

Maps in Fig. 2, where polygons represent Sardinian municipalities, depict the spatial distribution of the variable PERTAKE and of its two covariates having the highest positive values of the correlation coefficient, that is, PARCSIZE and DENSITY. They unveil similarities in the geographic distribution of the variables with reference to both high and low level of the variables: large dark clusters of polygons are clearly identifiable in the south-western, north-western and north-eastern parts of the island in all of the maps. To the contrary, small clusters of polygons having paler colors emerge in some inner parts of the island and close to the Gulf of Orosei (middle-eastern coast).

6   RESULTS

In the first place, we use a simple ordinary-least-squares (OLS) model to analyze if and to what extent each factor which the literature quoted in the fourth section identifies as possibly related to land-take processes. Table 4 shows significant correlations, at 10 percent level of statistical significance, for the average size of areas classified as non-artificial in 2003 and artificial in 2008 (PARCSIZE), endowment of roads connecting a municipality to the main regional urban centers (ACCESS), which is a measure of a municipality's accessibility, distance from Cagliari (DISTCAPC), the regional capital city, which is another accessibility indicator, extent of protected areas (CONSAREA), extent of areas where transformations were prevented by the planning code in force before year 2006 (OLDPLAN), and population density.

The distance of a municipality from the closest province administrative center (DISTNEAC), the average income level of a municipality (INC2008) and the size of a municipality's environmentally-valuable landscape components (NATAR), are less-significantly correlated to land take (25-30 percent), while no significant influence on land-take processes is put in evidence by the other covariates. In particular, there is no significant correlation between land take and proximity to the coast or to the closest urban center, nor is there with reference to the land taken's status of agricultural and forestry landscape component or inclusion in the CS.

Moreover, we estimate an OLS-regression model which includes the covariates whose coefficients are significant at 30 percent. The model's results are reported in Table 5. The model with a reduced set of explanatory variables substantially confirms the estimates of the model whose results are shown in Table 4. The values of the adjusted R-squared's are almost the same as well, so we are quite confident that the excluded variables would not have contributed to the goodness of fit of the estimated OLS model, while uncertainty remains on the influence of DISTNEAC, NATAR and INC2008.

7 DISCUSSION AND CONCLUSION

This paper analyzes the Sardinian land-taking process as related to factors which are identified as relevant variables in several studies concerning land take in several studies of the mainstream literature, through censored and OLS regression models. We tentatively consider a set of variables which includes location-related and physical determinants, planning code rules, and socio-economic factors.

We find that there is a double agglomeration effect, since land-taking processes are positively and significantly related to high population density and high concentration of land which changes its status from non-artificial to artificial. This indicates that saving non-artifical land, or limiting land take, could be effectively supported by low-density settlements and extensive and light land-taking processes, since the concentration of land take in a limited number of municipalities would imply a larger extent of land which becomes artificial, being non-artificial in the first place.

Table 6. Marginal effects of covariates estimated on a censored-regression model based on Lai and Zoppi (2012), dependent variable PERLTAKE is censored between 0 and 1.

Secondly, the more a municipality is accessible, the more it is suitable to land-taking processes, which indicates that balancing the accessibility opportunities would be a strategic regional policy in order to limit the concentration of land take and, ultimately, to mitigate the agglomeration effect which characterizes land take. This goal could be reached by increasing the endowment of public roads connecting regional town and city centers to small municipalities, giving particular care to road connections to the regional capital and province cities.

Thirdly, we find that the presence and size of protected areas is negatively and significantly connected to land take, as expected. So, conservation of natural resources, habitats and environment could be strategically important in order to deal with land-taking processes, and to influence their territorial layout. This is also confirmed by the estimates related to the covariate OLDPLAN, which is positively correlated to the change

---

[5] The censored-regression model is estimated following the methodology proposed by Lai and Zoppi, 2012. Censored-regression models are also known as Tobit models. Censored-regression models allow to estimate the covariates' marginal effects on the dependent variable. We omit the model specification, which is discussed by Lai and Zoppi (2012).

of land from non-artificial to artificial. This indicates that the more conservative planning rules are weakened, the more land-taking processes occur, which is what happened (in year 2003) in the areas where the old regional landscape plans were not in force any more. A similar phenomenon is put in evidence by the covariate NATAR, which is positively, even though not significantly, correlated to PERLTAKE, which suggests, as before, that the more conservative planning rules are weakened, the more land-taking processes occur: in the case of NATAR it is evident that the conservation character of the RLP PIC was weak if non-artificial areas defined as landscape components with an environmental value were allowed to change their status from non-artificial to artificial land between 2003 and 2008.

The fact that protection of nature, environment and natural resources matters is also put in evidence by the absence of correlation between land-taking processes and the variables COASTRIP and DISCOAST, which indicates that land take was not a coastal phenomenon in the period 2003-2008. Since in the eighties and in the nineties the Sardinian regional land-taking processes were almost exclusively concentrated in coastalmunicipalities, the non-coastal characterization of land take between 2003 and 2008 could only be related to the conservative planning rules that the regional landscape plans in force before 2006 and the RLP, from year 2006 on, have implemented.

Moreover, there is a slight, statistically-significant at 25 percent only, positive income effect, which indicates that a more balanced income distribution could help limit territorial concentration of land-taking processes. This slight income effect is consistent with the previous findings concerning the effectiveness of the 2000-2006 Sardinian Regional Operational Programme funded by the European Agricultural Guidance and Guarantee Fund (EAGGF) in maintaining and possibly increasing agricultural land use (Lai and Zoppi, 2012), that is, the higher the average household income of a municipality, the more agricultural (non-artificial) land is maintained and possibly increased.

In this paper, we tentatively consider a set of variables which includes location-related and physical determinants, planning code rules, and socio-economic factors. As we stated in the third section, we do not assume ethic narratives or value judgments on land take. Nevertheless, the findings imply a set of policy statements which can be taken into account in order to influence land-taking processes. Agglomeration effect both in terms of land which becomes artificial being non artificial in the first place, and of residential concentration increases the intensiy of land take. As a consequence, extensive urbanization and planning codes which prevent the artificialization of vast contiguous areas should be effective in saving-up non-artificial land. A balanced accessibility of regional cities and towns and a comprehensive regional policy concerning protection of nature, natural resources, environment and endangered species and habitats should be important as well. Moreover, supporting a more balanced distribution of the regional household income and restrictive planning rules concerning new development in the CS are policies which help to counter and limit land take.

This paper analyzes the Sardinian land-taking process as related to factors which are identified as relevant variables concerning land take in several studies of the mainstream literature, through censored and OLS regression models. The methodology can be easily replicated and exported with reference to other Italian and European contexts and results could be straighfowardly comparable. Policy implications of the findings could be a point of reference for future Italian and European land-use and planning policies which entail a careful consideration of the negative impacts of artificialization of land, as the Communication of the EC to the European Parliament COM(2011) 571 of 20.9.2011 puts in evidence. Future research should also relate to the construction of a spatial data infrastructure to monitor and control land-taking processes, with a view to the objective of no net land take by 2050.

1 ABSTRACT

The recent economic crisis has strongly affected the spending capacity of local governments which have had to adopt austerity policies and increase their territorial competitiveness. Regions and global-cities are then looking for "original" plans and programs, tailored on resources available in a given territory, respectful of its settled communities and their identity, and able to provide sustainability to the global competition.

In Europe many regions have identified in landscape planning based on historical, cultural and environmental heritage the way to a sustainable future. Despite this, in Italy the regional landscape project culture acts through the instrument of the obligation. Only recently it has been discussed the possibility to make the restrictions become a shared instrument for landscape project, as demonstrated during the first revision of the Landscape Plans drafted after the adoption of the Italian Code of Cultural Heritage and Landscape in 2004.

The paper aims to investigate the innovative methodologies introduced by the landscape planning in building set of rules referred to stratified, historical and cultural sites within planning instruments and according to territorial competitiveness principles. It is taken into account the case of the Sardinian Regional Landscape Plan (2006), now in redraft, in which they were introduced new problematic categories of cultural assets detected on the bases of their identitary value.

The objective is to defining a set of rules in order to clear up Identitary Heritage concept and its implementation in urban and regional planning in order to ensure an effective sustainable territorial competitiveness.

2 CULTURAL HERITAGE IN URBAN PLANNING: A RESOURCE FOR TERRITORIAL COMPETITIVENESS

2.1 Introduction

The recent economic crisis has drastically reduced the government spending budget persuading local administrations to narrow down the fields and objectives for intervention on the basis of territorial excellences which, due to their scarcity and irreproducibility, are considered as the only chance to conquer some niches of the "new new economy" and take part in the global competition (Crivello, 2010; Florida, 2003, 2005; Grandi, 2010). Consider, for example, the recent Anglo-Saxon policies relating to culture, creativity and urban regeneration (Landry, 2000; Evans, 2001).

The Italian cultural heritage, famously characterized by a wide geographical spread, a notable historical extension and a high symbolic and identity significance, could not escape this new approach and has therefore become a central topic in the search for alternative policies for sustainable local development (Amari, 2006; Carta, 2002, 2004; Ponzini, 2008; Sacco et al., 2006; Scandale, 2005). It investigates on the assets with a territorial nature and, above all, on the landscape assets that, with the Convention of Florence of 2000, have become the starting point for the development of new forms/rules of territorial government guided by the Right to Landscape and commonly contained under the definition of landscape planning (Cortesi et al., 2009; Gambino, 2009). In Europe emblematic is the introduction in the UK of maps of landscapes and landscape character assessments in the implementation of the European Landscape Convention (ELC).

In Italy, the ELC's implementation was carried out through the Code of Cultural Heritage and Landscape[1] (hereafter the Code) which updates the system of protection by providing, on the one hand, the transfer to

---

[1] Legislative Decree No. n.42/2004

Regions of jurisdictions in heritage valorization and, on the other hand, the preparation by the same of Landscape Plans, higher-level planning tools than ordinary (Barbati, 2008; Sciullo, 2008; Cartei; 2008).[2]

Landscape Plans approved since 2004 show that Regions interpret the changes introduced by the Code above all in relation to their statutory position and their previous urban policies. This is particularly evident in the implementation of the article 143 of the Code which recognizes to Regions the opportunity to identify new categories of landscape assets in addition to those already provided by national laws and subject them to protection through the Regional Landscape Plan, by virtue of their identity value (Barbati, 2008; Cartei, 2008; Ponzini, 2008; Sciullo, 2008).

In order to identify innovative methods of reading and planning of landscape assets within the Italian landscape planning, we analyze the Landscape Plans of Tuscany and Puglia, two regions with ordinary statute considered a model to follow in the literature of the field, and then the Landscape Plans of Sicily and Sardinia, two regions with a special statute who, due to their autonomy, can defined with greater freedom their identity dimension.

2.2 The national legislative framework: the innovations introduced by the Code of Cultural Heritage and Landscape

The set of rules concerning the protection of cultural heritage, given the breadth and richness of Italian heritage, has ancient origins,[3] but to have specific laws on this matter Italy had to wait until 1939 with the approval of the laws No.1089 and No.1497, respectively dedicated to "things of historical and artistic interest" and "natural beauties".

With the Law n.431/1985, known as the Galasso Law, the protection of the landscape and natural beauties has passed from State to Regions that take on the task of drawing up enviromental territorial plans to institute and manage the restrictions on enviromental assets (Antonucci, 2009). These contents has been afterwards incorporated in the Consolidation Act on the Protection of Cultural Heritage and Environment, adopted in 1999[4] (hereafter the Consolidation Act).

The coming into force of the Code of Cultural Heritage and Landscape in 2004 has re-affirmed the central role of State and Regions in cultural heritage's protection and enhancement with the attempt to preserving both national identity and local communities' memory (Antonucci, 2009).

Cultural heritage is defined by Article 2 of the Code as a complex system consisting of cultural and landscape assets which are further divided into categories. The entry of an asset within the above categories may happen by operation of law or by an assessment of cultural interest,[5] ie an administrative act aimed at the recognition of values and significances of the asset and its consequent classification (Sandulli, 2012).[6]

Innovative is also the concept of protection, a State competence, which is connected in the Code to the asset's fruition allowing overcoming the existing gap between the conservation and valorization activities, these latter subject to concurrent legislation between State and Regions (Ferretti, 2010). In fact, even if it picks up on the Consolidation Act of 1999, the Code states that the fruiton and valorization of the asset represent the finalities of the conservation activity establishing a link between the two moments of the cultural chain[7] (Sandulli, 2012).

---

[2] In order to put right the historical conflict between urban development and protection of cultural heritage born with the National Urban Planning Law of 1942

[3] It has its roots in the Law No.2359/1865 concerning the expropriation for public utility, in which encouraged the Italian State and its Local Governments in acquiring every monument and historic building whose preservation was at risk.

[4] Legislative Decree No. 490/1999

[5] Pursuant to LD. No. 42/2004 Art.10 paragraph 1 (except in case of negative verification of Article 12), Art. 10 paragraph 2, Art.11, Art. 91 and Art.142.

[6] Pursuant to LD. No. 42/2004 articles 10 paragraph 3, Art.13, Art.136, Art.143 and Art.156.

[7] Pursuant to LD. No. 42/2004 Art.1 paragraph 6; Art.2 paragraph 4; Art.6 paragraph 2.

In the light of the innovations introduced by the ELC of 2000 is attributed to the characteristic landscape of uniqueness and its protection must therefore be exercised as a whole rather than on single portions of the territory.[8]

The article 10 of the Code identifies the types of properties which are included into the category of cultural assets, distinguishing those of public belonging (paragraphs 1 and 2) from those of private belonging (paragraph 3). This distinction reflects perfectly the distinguished methods for their inscription in the cultural heritage and their protection. In fact, for public properties the title of 'cultural asset' is given ex lege, while for private assets this feature is acquired through the assessment of cultural interest (Cammelli, 2004).

The Article 134 of the Code defines the categories of landscape assets, distinguishing among: buildings and bound areas by an administrative act that declares their significant public interest, areas protected under the provisions of Law 431/1985, additional buildings and areas specifically identified and subject to protection through Regional Landscape Plans provided by Articles 143 and 156.

The drafting of Regional Landscape Plans must be made jointly between the Ministry of Cultural Heritage and Activities (italian: Ministero per i Beni e le Attività Culturali, MIBAC) and the Regions, limited to the aspects relating to the discipline of the landscape assets (Art.135 paragraph 1).

3 CULTURAL HERITAGE IN THE REGIONAL LANDSCAPE PLANNING

3.1 The landscape planning in the ordinary statute Regions

3.1.1 The Regional Territorial Landscape Plan of Apulia

The Region of Apulia had already had a Territorial Plan on Landscape (Italian: Piano Urbanistico Territoriale tematico per il Paesaggio, PUTT/P), which has come into force in 2000 in accordance with the Galasso Law. In 2004 the PUTT/P's conceptual and operational limits made disadvantageous its adaptation to the new rules introduced by the Code, therefore it was decided to draw a new Regional Territorial Landscape Plan (Italian: Piano Paesaggistico Territoriale Regionale, PPTR).

The first PPTR's Report highlighted many critical aspects of the previous instrument: shortage in cartographic representation of the legally bound protected assets, exclusion from the plan of the most important urbanized and rural areas; excessive fragmentation of the knowledge framework; set of rules difficult to understand and to apply; a major focus more on restrictions rather than on concessions.

The preparation of the new PPTR started in 2007 with the Decision No. 357 of the Regional Council. Subsequently, the Apulian legislation has been implemented with the Regional Law No. 20/2009 on the "Standards for landscape planning." The PPTR's first draft has been approved by the Regional Parliament in 2010,[9] however, it has not been adopted yet. So far, it is still in force on the PUTT/P.

In the PPTR it has been experienced the theoretical approach of the territorialist school which have its roots in Alberto Magnaghi's work on landscape, meant as a common good for a self-sustainable local development.[10]

To ensure the Landscape Plan's effectiveness in the government of the territory it is necessary that the same Landscape Plan could be able to interact with other plans and programs. For this reason the PPTR establishes, on the one hand, a robust institutional framework of clear and effective rules with statutory character and, on the other hand, a strong process of negotiation and participation with a bottom-up strategy (Magnaghi, 2011).

Assuming the centrality of territorial heritage, in its different components (environmental, infrastructure, urban, landscape and socio-cultural) in sight of a future socio-economic development based on the sustainable and durable valorization of its assets, PPTR passes from a restrictive conception of the plan to a vision of itself as an instrument of social mobilization aimed at developing strategies for the improvement of

---

[8] Landscape is meant as "an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors" (European Landscape Convention, Florence, 2000, Article 1).
[9] Regional Council Resolution No. 01/2010
[10] Magnaghi is also the designer in charge of drafting the new PPTR.

environmental and landscape quality of living of the population.[11] The development of participatory methods to improve public awareness of landscape asset has proved to be a necessary condition for the support from local communities to the objectives of the plan (Magnaghi, 2011).

The construction of the knowledge framework, which precedes the drafting of any planning tool, in the PPTR assumes a complementary role to the collection of data and knowledge, traditionally aimed at legitimizing of the plan's regulatory apparatus and to its diffusion/communication. The description of local identities and the definition of a repertoire of good practices play a fundamental and strategic role, referred to as "statutory", for the territory's project. The representation of the identity elements of the different regional landscapes, through the so-called "territorial figures," and the definition of the relational rules existing among them, allow assessing the consistency or inconsistency of territorial interventions with respect to ongoing evolutionary trends in building landscapes (Lucchesi, 2011).

A fundamental document for Apulia's cultural heritage management is the Charter of Cultural Heritage which identifies and distinguishes: the ancient city; the modern city; cultural assets of uncertain identification; cultural assets of certain identification and areal nature; cultural assets of certain identification and punctual nature; topographic stratified contexts (Italian: Contesti Topografici Stratificati, CTS).[12] This classification has made possible to describe the innumerable types of cultural and landscape assets without having to use the traditional disciplinary distinctions (archaeological, architectural, artistic, etc..) and made possible to overcome the overlapping problems between cultural goods of different nature or historical period, thanks to 'introduction of the concept of multilayered site. The theme of the cultural landscape has been addressed with a holistic vision aimed at identifying and mapping "[...] every place where the story is sedimented, as a form of stratification, ie each site". The CTS's identification not only detects the concentration of cultural goods into a specific area, but it highlights the relationships that linked in time cultural and environmental heritage, determining their identity characteristics (Volpe, 2011).

In the plan it is possible to identify a structure defined as "identity and statutory" in which the assets are identified with their transformation rules, and another one defined as "strategic" that identifies transformative projects using the regional heritage as a development resource[13] (PPTR's Report, pp.18-19). With regard to the "statutory" structure, the plan's designers, having noted the crisis of building sector, suggest to overcome the difficulties related to the construction of shared rules aimed at the production of ordinary territory, and cultivate the idea to extend authoritative restrictions to a destructive ars aedificandi (PPTR's Report, pp.21-23).

The protections apply to hydro-geomorphological structure, environmental and ecosystemic structure, antropical and historic-cultural structure. In this latter they are delineated two cultural asset's categories, landscape assets and additional landscape contexts. Landscape assets are defined as areas subject to landscape costraint; areas on which there are civic uses and areas of archaeological interest.[14] Additional landscape contexts are identified on the basis of Article. 143 of the Code and consist of: historic city; evidence of stratification settlement (Italian: Testimonianze della Stratificazione Insediativa, TSI), monumental olive groves, agricultural areas of scenic interest.[15]

The TSI consists of "all the sites affected by the presence and/or stratification of historic-cultural assets of particular landscape value as expressions of the identity characteristics of the region." They comprise: the architectural heritage worthy of protection widespread in suburban area of particular traditional value and expression of the historical memory of the land, including buildings already protected under Article 10 of the Code; areas with polygonal boundary, which identify buried archaeological sites still readable (discovery of

---

[11] Among the projects proposed by the landscape PPTR there are: the Regional Ecological Network and the Covenant town and country, the infrastructure system for soft mobility, enhancing and upgrading integrated landscapes; regional systems for cultural heritage fruition.

[12] See the elaborate No. 3.2.5 "La Carta dei Beni Culturali"

[13] Regarding this aspect see the regional systems for cultural heritage fruition in the elaborate No. 4.2.5. "I sistemi territoriali per la fruizione dei beni patrimoniali (CTS e aree tematiche di paesaggio)"and PPTR's Technical standards for implementation, Art. 34 paragraph 1 and 2.

[14] PPTR's Technical standards for implementation, Art.74 paragraph 2

[15] PPTR's Technical standards for implementation, Art. 76. The definition of historical city includes that part of urban centers that goes from the nucleus of the foundation up to the urbanizations compact made in the first half of the twentieth century.

artifacts on the surface, presence of traces identified by aerial photography or other innovative diagnostic tools), a buffer-zone of protection from the outer perimeter of property and areas of the depth of 100 meters or as otherwise defined by the municipal plans adapted to PUTT/P.[16]

Local authorities, in adapting their planning instruments to PPTR, should increase the level of knowledge of the regional Charter of Cultural Heritage, specifically analyzing the values expressed by areas and buildings surveyed; adjusting, where necessary, the perimeter of the cultural good or by defining the exact location for the objects with identification uncertain identifying antropic, historical and cultural components for which it could be considered the existence of significant public interest in accordance with Article 136 of the Code or of cultural interest pursuant to Section 13 of the Code and activating the provided proceedings; redefining the width of the buffer-zone around the evidences of stratificate settlement, ensuring the protection and enhancement of the landscape in which these assets and areas are included, depending on the nature and significance of the relationship with their surroundings in enviromental terms, both of contiguity and integration of forms of use and visual enjoyment..[17]

The change from an individual-use of the assets to a more complex one, consisting of cultural-turistic territorial systems, shows the PPTR's proactivity as revealed by the choice of going beyond the definition of adequate safeguard rules throught the prevision of new valorization forms, as projects for site's knowledge and its integrated fruition. PPTR's territorial projects are focused on the study of regional local landscapes' features for the proposition of measures able to enhance enviromental quality, territorial fruition services, accessibility and the internal connections (Volpe, 2011).

3.1.2   Regional Landscape Plan of Tuscany Region

The landscape planning of Tuscany finds its foundations in the Regional Law No.4/1990 by which the Region put an end to the distinction between landscape and urban planning by adopting a unique territorial planning instrument where the essential resources of the territory, including the landscape, shall form the "structural invariants" to future changes. The principle of territorial unity of this law found its effective application through the Regional Law No.5/1995 which has provided for responsibilities allocation in the field of urban planning thanks throught the following instruments (Gregorini, 2007):

Regional Territorial Address Plan (Italian: Piano di Indirizzo Territoriale regionale, PIT): it contains rules regarding urban-territorial and identifies landscape values under L.431/1985, Art. 6,   paragraph d;

Provincial Territorial Coordination Plan (italian: Piano Territoriale di Coordinamento Provinciale, PTCP): it has the value of territorial urban plan with specific consideration of landscape values, according to Law 431/1985 art. 16, paragraph d;

Municipal Structure Plan (Italian: Piano Strutturale comunale, PS): it defines the strategic directions for the government of the municipality and contains the municipal environmental-landscape discipline, pursuant to L. 431/1985, Art.1-bis.

The Regional Law No. 1/2005, concerning urban planning, kept the structure of the previous two but its "Regulations on the Government of the Territory" (Italian: Norme sul governo del Territorio) contained several novelties about natural and cultural heritage related to the Code of Cultural Heritage and Landscape and its subsequent amendments.[18] However they contained also an internal contradiction: under Title IV Chapter I, infact, the articles 30 and 33 stated that the PIT's Statute had the value of Regional Landscape Plan and any instrument of planning and/or territorial government of the had to be adapted to it, while articles 32 and 34 gave to Municipalities the power to plan and protect their landscape in an autonomous manner, in compliance with the guidelines and requirements of the PIT, in derogation from the Regional Landscape Plan pursuant to Art. 143 paragraph 5 of the Code (Morelli et al., 2010). This contradiction was resolved by the judgment No.186/2006 of the Constitutional Court which affirmed the unlawfulness of Art. 32 paragraph 3 and Article. 34 paragraph 3 of PIT's Statute.

---

[16] In the buffer-zone of 100 meters around areas of archaeological interest (as landscape assets) and evidence of stratification settlement (as additional landscape contexts), it is deleted any change in visual integrity and pursued the redevelopment of the context. It is eliminated each land use incompatible against PPTR's objectives of safeguard. See PPTR's Technical standards for implementation, Art. 77 paragraph 2.

[17] PPTR's Technical standards for implementation, Art.78 "Direttive per le componenti culturali e insediative".

[18] L.D. 24 March 2006 No. 156 and 157; L.D. 26 March 2008 No. 62 and 63

Due to this, the L.R. 1/2005 was modified giving to the Region the skills on the definition of the landscape assets and of their discipline pursuant to Art. 143 of the Code (Regional Law of Maintenance of 2008) and PIT was integrated into its lanscape contents (Cinquini, 2008):

Plan Document: Section 6.5. – The "landscape" as forming the Tuscan territory and its government;

Technical standards for implementation (Italian: Disciplina di Piano): technical standards for landscape assets;

Charts of landscapes identification and quality objectives (relative to the territory of each Province): Recognition of the structural features; Recognition of natural, historical, cultural and aesthetic-perceptive values; Recognition of local dynamics, quality objectives and priority actions; Recognition of lanscape assets subject to protection under Article 136 of The Code and ist subsequent amendments.

Cartography bearing the identification, definition and scaled representation of properties and areas declared of significant public interestin accordance with Art.143, paragraph 1, letter b) of the Code

Cartography bearing the identification, definition and scaled representation of properties and areas declared of significant public interestin accordance with Art.143, paragraph 1, letter c) of the Code

Documents containing technical standards for landscape assets have been drawn through a conjunction of institutional collaborative agreements consist of: Memorandum of Understanding between the Region of Tuscany and the MIBAC's General Directorate for Architectural Assets and Landscape;[19] Memorandum of Understanding del novembre 2008 tra MIBAC's General Directorate for the Quality and Protection of Landscape, Contemporary Art and Architecture, Tuscany Regional Directorate for Cultural Heritage and Landscape, MIBAC's Provincial Superintendences, Tuscany Region, ANCI, UNICEM and UPI Toscana[20] (Regione Toscana, 2009).

To sum up, the PIT's last version, adopted June 16, 2009, separates the Tuscan landscape discipline, which is general and applied to the territory as a whole, from the discipline of landscape assets, which is specific and site-oriented according to the the Code and the ministerial concept of 'scenic beauty' identified and protected by law or by Ministery Decree after a positive assessment of cultural interest (Regione Toscana, 2009). The PIT provides therefore a participative assessment of cultural interest for the identification of the landscape assets, as required by art. 143 of the Code, which involves municipalities, local Superintendents, the Region and interested Ministries and concludes with the issuance of a restriction decree by MIBAC (Cinquini, 2008; Poli, 2012).

This procedure was adopted during the PIT rewriting, between 2007 and 2009, and it is now applied in the process of adapting provincial and municipal tools to regional landscape planning. To this end, the Region has instituted provincial committees with the task of identifying new landscape assets and it has set up the Landscape Observatory with tasks of monitoring and coordination (Regional Law No.1/2005 Art.33 paragraph 6). In addition, benefits are provided for the Municipalities who have actively participated to the rewriting phase between 2007 and 2009. For example, in the event that the municipal urban plan has proved to be adeguate to the PIT, Tuscany Region forwards directly the "advice of conformity" to the Regional Directorate of MIBAC while, if the municipal urban needs of additional measures and integration, the Region starts a variation to the plan.

From the examination of the Tuscan landscape planning emerges a strong sense of identity linked to the territory in its unity that can be preserved, maintained and restored only through the knowledge of its structural components (invariants), its dynamics as well as the natural, historical, cultural, aesthetic-perceptive values of local landscapes (Marson, 2012; Poli, 2012). However, this holistic approach has collided with the MIBAC's need of clearly defining the object of protection, whether an individual asset or a complex one, so as to adopt a restriction decree. Within the PIT there are thus general rules for landscapes protected at regional level for their identity value and, at same time, lists of landscape assets bound by Ministerial Decree by operation of law or pursuant to a participative assessment of cultural interest.

---

[19] Signed 23 January 2007 and subsequently amended by an act of integration of the July 24, 2007
[20] November 2008

Synthetically, the landscape assets of regional unitary interest,[21] originally removed with the repeal of Articles. 32 and 34 of PIT's Statute and Art. 32, 33 and 34 of PIT's Technical standards for implementation, are now inserted in the lists of ordinary landscape assets,[22] for which it is expected the presence of a restriction decree and the compliance with the conditions of use contained in the priority actions set out in the Cards of landscapes identification and quality objectives attached to PIT: << These quality objectives and priority actions represent, with reference to landscape assets, the shared use conditions for municipalities planning tools and acts of government land under article 143 of the Code >> (Art.1 of PIT's Technical standards for landscape assets).

3.2 The landscape planning in the regions with a special statute: the island context

3.2.1 The Regional Landscape Territorial Plan of Sicily

Landscape planning in Sicily finds its basis in the Landscape Territorial Plans (italian: Piani Territoriali Paesistici) prepared in accordance with the Guidelines for the Regional Landscape Territorial Plan (Italian: Piano Territoriale Paesistico Regionale, PTPR) dated 1999, which have, as normative reference, the Galasso Law and the ex Consolidated Law on cultural and environmental heritage (Legislative Decree No. 490/1999). Due to the the Code's introduction, it has been started a process of revision and adaptation of these instruments that, because of the autonomy statutory, has led to a reorganization of the Sicilian landscape planning on different levels (Costantino, 2009; Costantino et al., 2009):

Regional Planning: consists of the PTPR's Guidelines which define strategies and general objectives for the Sicilian landscape, identify landscape units (Italian: ambiti di paesaggio) with their systems, subsystems and components, provide guidelines and requirements for each of those components.

Sub-regional planning: consists of the Provincial Landscape Plans (Italian: Piani Paesaggistici Provinciali, PPP), prepared by MIBAC's Provincial Superintendences for the landscape units which fall within the province of their competence, and Landscape Unit Plans (Italian: Piani d'Ambito) relating to the island (Ustica and Pantelleria) and the archipelagoes (Pelagie and Egadi), which are considered freestanding landscape units fo their peculiarities.

This architecture is the result of a long path began in 2004, thanks to funds of the Regional Operational Programme 2000/2006, and not yet completed in which it is possible to recognize some topical moments.

The first is the preparation of the Provincial Landscape Plans for Trapani Province during 2007 (hereafter the Trapani's PPP). The plan included the contents of PTPR's Guidelines for the Lanscape Unit No.1 "Rilievi del trapanese" (systems, subsystems, components, guidelines, prescriptions) and, through a process of understanding and interpretation, it pointed out their systemic interactions in order to define "Local Landscapes", ie the territories relatively cohesive, open and interacting identified according to the main components and relationships that characterize them and determine their identity[23](Costantino,2009; Costantino et al., 2009). For each "Component" and "Local Landscapes" the Trapani's PPP defined objectives, priority actions and rules of use that reflected objectives, guidelines and prescriptions from PPTR's guidelines. The rules of use re-broke up Local Landscape in systems, subsystems and components defining for each one the terms of use/restriction. Considering landscape assets, these rules were prescriptive if they fell on properties protected under the law[24] (they can limit interventions without permission[25] and instruments of territorial government have to respect them) viceversa they assumed a proactive and adressing value.

The structure of Trapani's PPP became soon the model for subsequent sub-regional plans, but it was already clear that the weakness of collaboration between the Regional Office of the Plan and MiBAC's Provincial Superintendents produced tools very different for content and method. For this reason, in February 2008 the the Regional Office of the Plan submitted to Superintendents a Scheme of Regulatory Apparatus (italian:

---

[21] Covered by Art. 143 paragraph 1 letter c) of the Code

[22] Covered by Art. 136, 142, 143 paragraph 1 letter b) and d) of the Code

[23] Considering the handbook Landscape Character Assessment (LCA). Guidance for England and Scotland edited by the Countryside Agency and Scottish Natural Heritage in 2002, the Sicilian "Local landscape" includes both Landscape Character Types (LCT) and Landscape Character Areas (LCA).

[24] It comes to assets safeguarded by Art.134 paragraph 1 letter a) and b), 136 and 142 of the Code,

[25] See Art. 149 of the Code

Schema Apparato Normativo) for the drafting of PPPs technical standards for implementation, that represent also the second topical moment of the process.

The Scheme extended to whole Region the three protection levels[26] provided by the Landscape Provincial Plan of Caltanissetta (hereafter: Caltanisetta's PPP) for the Landscape Units No. 6-7-10-11-15 and aimed at landscape heritage in Art. 134 of the Code (Provincia di Caltanisetta, 2008):

Level of protection 1: affects areas with perceptive values essentially due to the recognized value of the geomorphological configuration; perceptive emergencies (structuring components); panoramic visual and intervisibility basins (or visual afference). In these areas, the protection is accomplished through the authorization procedures laid down in Art.146 of the Code.

Level of protection 2: affects areas characterized by the presence of one or more qualifying components with their contexts and landscape sceneries. In these areas, in addition to the procedures referred to in the previous level,it is required impacts mitigation of visual detractors

Level of protection 3: covers the areas that owe their recognisability to the presence of various qualifying components with their relevant contexts and landscape sceneries, or in which the presence of a significant element of exceptional importance, at least at regional level, requires specific requirements of protection.

Five years after the process is not yet complete and the frame of sub-regional landscape planning is partial and fragmentary: many plans are still under review or drafting, some have been adopted and wait for final approval, only one has been approved and it is in force. Perform an examination of the Sicilian landscape planning as a whole is therefore difficult, especially when it comes to assessing the effects produced by the new levels of protection on landscape heritage and, in particular, on the assets identified at regional level under Art.134 paragraph 1 letter c) of the Code and bound by ministerial decree, following the agreements between Provincial Superintendent, MIBAC and Region.

Nevertheless it is possible to make some general observations about Sicilian Region activity. The element that emerges most strongly is the complexity of landscape planning due to the fragmentation of the Landscape Unit on the basis of the provinces in which it falls. This is mainly due to the absence of an organic discipline regarding the protection of landscape and cultural heritage, matters on which the Autonomous Region has exclusive legislative competence under article 14 of its Statute. Not being present a regional law, the Code of Cultural Heritage and Landscape has replaced the Region in landscape planning determining its content, criteria and procedures as usually happen in the ordinary statute regions. From this point of view, Sicily, therefore, has not properly taken advantage of the opportunities provided by its autonomy, deferring the merge between landscape and territorial government, a process undertaken instead with great courage and determination by other regions with ordinary statute, such as Tuscany.

In addition, in the rules of use for "Components" and "Local Landscapes", the application of levels of protection exclusively to landscape assets protected by operation of law (Art. 134 paragraph 1 letter a and b of the Code), seems to have forgotten the innovations introduced by the European Landscape Convention and The Code, returning to L.1497/1939 even though contemporary landscape heritage includes new assets categories (under Article.134 paragraph 1 letter c of the Code) (Costantino,2009; Costantino et al., 2009). In this regard it should be noted that a definition of identity in relation to the content of the regional landscape planning could find consistency and completeness only when all sub-plans will be adopted and Municipalities will have adapted their planning tools to them. Sicilian identity is now defined in a rather generic and theoretical way only by the PTPR's Guidelines of 1999.

4 CULTURAL ASSETS IN THE REGIONAL LANDSCAPE PLAN OF SARDINIA

Landscape planning in Sardinia finds its basis in the Galasso Law, which lead to the Regional Law No.45/1989 on Urban Planning and fourteen Landscape Territorial Plans (italian: Piani Territoriali Paesistici, PTP).[27]

---

[26] See Art. 20 in Technical standards for implementation of Caltanissetta's PPP

[27] Previously there was only the Landscape Territorial Plan of Molentargius-Monte Urpinu, approved on the basis of L.1497/1939

The initiative to develop a regional landscape plan was taken with the Regional Law No. 8/2004[28], after the annulment of all PTPs approved under Galasso Law, except for PTP No. 7 of "Sinis", by the Regional Administrative Court between 2001 and 2003 (Falqui, 2011).

The Regional Landscape Plan of Sardinia (Italian: Piano Paesaggistico Regionale, PPR), was approved in September 2006 as the first Landscape Plan complies with the Code's amendments adopted during the same year.[29] The PPR identifies twenty-seven landscape units located along the coastline, the protection of which is considered a priority by the plan with respect to the interior of the island. They are analyzed in their identity and peculiarities based on three levels of reading: environmental framework, historical and cultural framework, settlement structure.

The discipline of protection contained in PPR's Technical standards for implementation was aimed primarily at five categories of properties: landscape units, individual landscape assets, complex landscape assets, landscape components and identity assets. These latter were defined by PPR under Art. 134 paragraph 1 letter c) of the Code and included those types of properties, areas and/or intangible assets that allow the recognition of the sense of ownership of local communities to the specificity of Sardinian culture.[30]

Identity assets were usually defined in their perimeters by PPR cartography or, later, by Municipalities in the adaptation of communal planning tools to PPR. In both cases, the implementation of PPR's provisions took place primarily through an agreement between the regional and local authorities on the basis of which were defined land transformations compatible with PPR's landscape quality objectives. Until the adoption of a municipal planning tool adequate to PPR (transitional period), PPR's Technical standards for implementation established a buffer zone of integral protection of 100 metres around each landscape asset identified in PPR's cartography.

The depth reconnaissance of Sardinia's historical and landscape heritage was made during the preparation of the PPR through an analysis of multi-archive sources (wealth of knowledge of provincial planning tools, archives of MIBAC's Provincial Superintendents, State Archives, specialized archives, historical cartographies, etc.) (PPR Report, p.110). However, this research was not followed by inspections aimed at the verification of the real consistency and preservation of the asset during the preparation of PPR's cartography and, afterward, during the Region-Municipality co-planning phase, reaching sometimes to impose the buffer zone on areas without any element of historical or landscape value.

To overcome such problems has been enacted the Regional Law n.13/2008 on landscape assets and the delimitation of their protective perimeters, with regard to those included in historical centers. Considering the assets of regional interest,[31] the so-called identity assets, the law specifies the need for them to be promptly recognized and demarcated in municapal and regional cartography in such a way as to be easily identified, even in the transitional period. The agreement between the City and Region is expected to define the boundaries of the historic center in case where the existing perimeter does not coincide with the one developed by PPR. The agreement is also applied to define protective perimeters of landscape assets protected by operation of law and identity assets protected after a positive assessement of cultural interest. The buffer zone of 100 meters for the landscape and identity assets does not apply if the same fall within the perimeter of the historical center (Art.2 of Regional Law No.13/2008). Despite the novelties, the law has been strongly criticized because, during the transitional period, it excludes from protection different categories of identity assets, not already identified/mapped at regional and comunal level, such as the typical Sardinian rural settlements.

In conclusion, it can be said that PPR's guidelines and prescriptions, should be punctually adapted within the municipal planning instruments in order to build appropriate valorization proposals. So adapting the municipal planning tools to PPR represents today the most delicate moment of Sardinian landscape planning because there takes place the negotiation of protection principles expressed by PPR, determining its real effectiveness (Bitti, 2008).

[28] The so-called "Save Coasts" Law
[29] L.D. 24 March 2006 No. 156 and 157
[30] See Art. 6 paragraph 5 of PPR's Technical standards for implementation.
[31] Identified by PPR and bound by ministerial decree after an assessement of cultural interest with a positive result, as determined by Art.134 paragraph 1 letter c) of the Code

5 CONCLUSION

The landscape and cultural heritage assume a central role in the definition of policies for sustainable development based on the protection and enhancement of local identity. The Landscape Plan, in the light of the directives of the Legislative Decree n. 42/2004, becomes the main instrument for the protection of the regional heritage and its enhancement in a perspective of sustainable local development. However, the comparison between the regional plans of Apulia, Tuscany, Sicily and Sardinia, shows a widespread and shared difficulty in the identification of local landscapes and identitarian heritage that does not depend on their statute or on the previous planning advancement. This fact emerges especially considering the cataloging phase, which is often postponed and carried out during the adaptation of the provincial and municipal tools to Regional Landscape Plan.[32] A further confirmation is provided by the delay registered in Apulia, Sicily and Sardinia in the enforcement of the safeguard rules provided by their Regional Landscape Plans, which has involved the creation of a constrained buffer zone around each landscape asset, independently from its real substance or existance. So, Plans often become ineffective in respect to heritage valorization and building activity's regulation leading to a premature revision of the instruments themselves.

Referring to the definition of regional landscape assets as provided by the article 143 paragraph 1 letter c) of the Legislative Decree n.42/2004, it can be said the concept varies from region to region: in Tuscany the landscape assets are called "assets of regional unitary interest", in Apulia "further landscape contexts", in Sicily "Local Landscapes and their Components", in Sardinia "identity assets". The only element that joins these regions is the choice to apply to the regional assets the procedure laid down by the articles 136 and 142 of the Legislative Decree n.42/2004 for properties with landscape value of significant public interest and for protected areas with environmental value. Despite the identification of specific elements of the territorial reality is considered to be the main strength of landscape planning, due to the fact that, as submitted by the European Commission in 2005, each region has a specific territorial capital, the difficulties encountered in the development of standards and guidelines for each regional asset, has led Regions, Provinces and Municipalities to activate the traditional verification of interest through memoranda of understanding between local authorities and MIBAC that, if successful, have taken the form of a ministerial decree of restriction under LD. 42/2004.[33]

Apulia is the only positive example with the introduction of an innovative protection system that classifies the landscape heritage according to the real possibility of a punctual identification of the property and its buffer zone, going beyond the traditional distinction by type of asset (archaeological, architectural, etc.) and reinterpreting in an innovative way the relationship between the individual goods through a system of "multilayered topographical contexts" to be protected and enhanced. In Sardinian Regional Landscape Plan, it can be read an attempt to organize the "identity assets" in interconnected networks for integrated use but, operationally, this translates into a map of the cultural heritage with a restrictive approach, far from the Puglia's model from which it had been originally inspired.

The application to the regional landscape assets of the verification of interest and the ministerial restriction decree, as in case of property protected by operation of law (articles 136 and 142 of the LD n.42/2004), it seems almost a waiver by the Italian regions in defining their own identity in relation to cultural territorial heritage though the issue has also been addressed in the rules of governance of the territory of each regional landscape plan through the definition of binding guidelines for the areas of protected landscape (despite the garbled bureaucratic difficulties the regions had to face). It should be also acknowledged that, if the planning has reached a certain maturity and has established itself at the local level, it has been possible to legitimize the idea of regional identity through propositions of plan that take into account both the aspect of properties (landscape assets) that of the landscape (landscape character areas and types) as demonstrated by the "multi-layered topographical contexts" in Puglia.

---

[32] As in the case of Tuscany Region where the allocation to municipalities of the task of cataloging the regional landscape and identity heritage, through the articles 32 and 33 of the PIT, led to the ruling of the Constitutional Court and the repeal of these two articles as unconstitutional.

[33] Significant is the case of Tuscany: deprived by the Constitutional Court of the possibility of delegating to municipalities the definition of technical standards for each landscape regional asset, the Region has decided to equate the "assets of regional unitary interest" to the other goods protected by the LD. 42/2004.

1 ABSTRACT

The change of urban regional spatial structure influenced by information technology has become a hotspot of foreign and domestic scholars' research. This study tries to analyze China's city network characteristics from the social network space perspective, by using Sina Microblog as an example. The result showss that China's city network based on the Micro-blog social space has a clear hierarchical structure and level distinction. Firstly, the result shows the existence of regional characteristics, performance as a visible regional development pattern which contains "Three Main-regions and Four Sub-regions" according to the analysis of the level distinction in the city network and the connection rate between cities. Specifically speaking, the three main regions contains the Beijing- Tianjing- Hebei region represented by Beijing, Pearl River Delta region presented by Guangzhou and Shenzhen, the Yangtze River Delta region represented by Shanghai, Hangzhou and Nanjing. The four sub-region contains Chengdu- Chongqing region, Hercynian region represented by Fuzhou and Xiamen, Wuhan region presented by Wuhan and Changsha, Northeast region represented by Shenyang, Harbin and Changchun. Secondly, the result shows a significant difference of the network links among the Eastern, Central, Western China. Links within the Eastern region and the links between Eastern region and Central region, Western region constitute almost all of the current network system. The result also finds that the high-level cities has an absolute dominance in the city network pattern, Beijing is the contact center in China's city network, with an overwhelming advantage. Shanghai, Guangzhou and Shenzhen is the sub contact center in China's city network.

2 INTRODUCTION

Spatial relationship between cities has always been a key research topic of urban and economic geography. Since 1990s, information technology, represented by the Internet, has developed rapidly and globally, which not only changed the human social system and economic structure, but also reconstructed the structure of the global physical and virtual space (Graham S, Marvin S., 1996). Considering globally, nationally or regionally, the development of cities has crossed their own boundaries. Cities and their facilities are closely linked to each other through a variety of high-speed network to form a diversified global or regional urban network (Zhen Feng, Liu Xiaoxia, 2007). With the growing impact of information technology, many scholars began to take information factors into consideration in the study of urban network, and network paradigms based on the complex links between cities also emerged (Batty M., 1991). From then on, urban network under the influence of globalization and informatization has become the main research field of urban and regional spatial relations. The Space of Flow proposed by Castells emphasizes the value of urban nodes in shaping the entire network system (Castells M., 1996), which provides an important theoretical frame for the urban network research at home and abroad. For the shaping of information flow on the relationship between cities, western scholars have studied parcel mail, Internet traffic, network bandwidth and other information flow (Mitchelson R., Wheeler J O., 1994; Townsend A M., 2001; Malecki E J.,2002), as well as the influence of traffic flows like flights and cargo volume, port throughput, highway and railway traffic flow on urban network system (Goetz A R.,1992; Ho Shin K , Timberlake A, 2000; Mat sumoto H, 2004). Later, western geographers represented by Zook, Townsend and Moss, based on the data of Internet domain names and network capacity, Internet names and IP addresses, conducted lots of meaningful studies on network information space from the global, national or regional, and inner city levels (Zook M A., 1998, 2000, 2001; Castells M., 1999; Townsend A M., 2001; Moss M L, 1997, 1999, 2000).

In recent years, Shoko et al (2011) collected more than ten million Twitter data with geographical tags through the geographical collection system of Twitter, constructed the Japanese social geographical boundaries, and simulated the urban characteristics based on social urban crowds according to the Vironoi

diagram and the geographical laws of human activities in daily life. Croitoru et al (2012) conducted a systematic study of the urban or regional characteristics by constructing the social geographic analysis platform (G-SAW). This shows that, current studies on urban characteristics reflect the activities and local characteristics of the entire city and made quantitative representations on the relatively qualitative geographical features mainly through the research on the network activities of a large number of residents. Gautier et al (2009) adopted the communications information of 25 million users provided by the Belgian mobile phone operator, established urban social network based on the corresponding zip codes of the mobile phone billing addresses of the users, and studied the communication activity between cities and found the urban structure in the communication network. Seeing from the existing research results, the way of employing users' communication information to carry out studies on urban structure is in its infancy and has a relatively single method. Although its data acquisition is difficult, the research results are found to be accurate and thus should be paid more attention to. At the same time, as the flow data are often difficult to obtain, many western scholars attempt to analyze the network links between cities through urban function contacts. The impact of globalization makes the global city become a production base of advanced producer services (Sassen S., 2001). Based on it, some scholars judged the function contacts and changes between cities, and the distribution of corporate headquarters, large banks and other global producer services have been used to analyze the structure of these world cities (Friedmann J., 1986; Taylor P J., 2004).

Since 2000, Chinese scholars also have become concerned about the urban network system and achieved lots of results. Similar to the western research ideas, Chinese scholars mainly interpreted the development pattern of urban network on the national level and its changes based on the infrastructure networks of air transport and railway (Jin Fengjun, Wang Chengjin, 2005; Xue Junfei, 2008; Wu Wei, et al., 2009). In recent years, the network paradigms of western world cities were comprehensively introduced to China (Yang Yongchun, et al., 2011). Some scholars studied the national or regional urban network system from the perspective of enterprises (especially producer services) (Zhang Xiaoming, 2006; Jin Zhongfan, 2010; Yin Jun, Zhen Feng, et al., 2011; Ning Yuemin, Wu Qianbo, 2011), while others also studied from the relationship between Internet facilities (Wang Mingfeng, Ning Yuemin, 2006; Sun Zhongwei, et al., 2010), both of which explained the changes in Chinese urban network system under the influence of globalization and informatization.

The network constructs a new human social form, while the spread of network logic substantially changes the operation and results in production, experience, power and culture. In addition to the emphasis on the roles of information infrastructure and information nodes, in the theory of Space of Flow constructed by Castells, there is another important content, that is, "spatial organizations of the work, games, and sports of the world's elite. However, in the research literature of world and national urban network, the power of social network space is seemingly ignored, while it is playing an increasingly large spatial influence. Currently, the research on China's urban network from the perspective of interpersonal networks is rare. The emergence of social network sites like micro-blog not only enriches and expands the social relation network, but also provides a new perspective for the interpretation and analysis of urban network structure. Micro-blog, a system similar to blog, can release real-time news. Its text content is limited to 140 words and can achieve real-time sharing. By the end of June, 2011, the total number of netizens in China has amounted to 485 million and Internet penetration rate has reached 36.2 %. The number of micro-blog users has increased to 195 millions, while the netizen utilization rate has been expanded to 40.2 % from 13.8 %, becoming the fastest-growing Internet application.[1] From the world's first micro-blog of Twitter to the Sina Micro-blog and Tencent Micro-blog in China, micro-blog has gradually become an influential social media platform. The return of voice to the public rebuilds the social space. More importantly, compared to the point-to-point contact characteristics of the previous network communities like BBS and QQ, micro-blog itself is a completely open and civilian interactive network platform. It gets a lot of people involved and has strong social mobilization ability, making it ideal for the utilization of fragmentized time and space under the influence of information technology (Liu Yang, 2010; Zhan Zihua, 2011). As a result, this paper tries to study China's urban network architecture and its spatial characteristics with the help of this emerging network media and interactive platform of micro-blog.

---

3 RESEARCH METHODS

According to the survey data of "White Paper of Sina Micro-blog in 2010", Sina Micro-blog is a mainstream micro-blog with the highest market visibility and highest user utilization rate.[2] Therefore, this paper selects Sina Micro-blog as the research object, analyzes the social relation network from the perspective of the relationship between network users, and then interprets the changes in China's urban network system.

3.1 Research ideas

Sina Micro-blog has a wide range of national influence and adequate user distribution, so we can use the relationship between micro-blog users to effectively support and reflect the linkages between cities. In Sina Micro-blog, the relationships between users include three types, namely, follower, following and friend. As we can see in Figure 1, follower and following reflect the unidirectional information transfer between users. A follows B, meaning that A is willing to accept B's updated real-time information and make comments as well as exchange ideas. Under this circumstance, for A, his relationship with B is the "following"; for B, his relationship with A is the "follower". Compared to the relationships of followers or followings, the users with the relationship of "friend" can accept the updated real-time information from each other and make comments as well as exchange ideas. It is better to achieve the bidirectional transfer of information. From the geographical perspective, the cities can be understood as the nodes in the network communities, and the friend relation between cities can be interpreted as the information flow between nodes in the network communities. These understandings will facilitate the analysis of the state in which strong and weak relationships exist, so as to construct a city's network system based on network community. As a result, if more friend relation between the micro-blog users in City(A) and the micro-blog users in City(B) exists, then more closely related information contact can be found in the network systems of City(A) and City(B); if more friend relation between the micro-blog users in City(A) and the micro-blog users in other cities exists, then City(A) enjoys a higher degree of importance in the whole network system as well as a higher hierarchy.

According to the current status of China's urban network system, this paper first selects the cities which are economically powerful and highly informatized and likely to become the backbone notes in micro-blog space as the representative cities based on certain screening criteria, then uses Sina Micro-blog site to make a statistics of the micro-blog users of each representative city. Then, we collect the data of friend relation between the selected micro-blog users and other geospatial data, and construct a matrix of the network community friend relation between the representative cities referring to the research method of world city networks proposed by P. Taylor. Finally, with the help of Arcgis analysis software, we reflect the network community friend relation in the geographic space, and analyze China's urban network system
Fig. 1: The relationship between users based on user A

3.2 Data collection

This paper selects several representative cities in Mainland China as the research units, and reflects the friend relation between Sina Micro-blog users of each research unit in the geographic space.

(1) The selection of urban network notes in social network space

According to the indicator of "Number of the Internet Users" in the China City Statistical Yearbook of 2011, we select the top 100 cities. Combined with the existing study of China's urban hierarchical scale (Gu Chaolin, 1990; Gu Chaolin, Hu Xiuhong, 1998), we finally select 51 note cities and build a urban network framework in social network space (Table 1).

---

[2] Sina Micro-blog neice was made on August 14, 2009. It became the first portal website which provided micro-blog service. Currently, greater than 3 million micro-blogs are released each day, and nearly 40 micro-blogs are released in a second.

Table 1: The 51 selected node cities

(2) The selection of micro-blog users of each note city in urban network

With the selected 51 representative cities as the strongholds, we choose 20 users from each city as the research samples. These samples should meet the following three conditions: (1) The user lives in the selected city; (2) The user is the "grassroots", but not a "celebrity",[3] which helps to reflect the real social network relations and excludes those relations without actual communication but for influence expansion or celebrity worship; (3) The user is active, has 400 followers and followings respectively, and releases more than 6 micro-blogs every day. Finally, with the help of the application module of "Finding Someone" in Sina Micro-blog, we collected data on December 4, 2011, and obtained 1020 samples from the 51 representative cities for Sina Micro-blog research.

(3) The acquisition of friend relation of the micro-blog research sample

Due to the large amount of data, we collected the micro-blog IDs of the followers and follow users of the 1020 research samples through the establishment of a crawler program,[4] find out the micro-blog users with friend relations and recorded their geographic information data. Finally, by running the program, we got 243451 effective friend relation data (excluding the friend relations of overseas, Hong Kong, Macao and Taiwan regions and default data). There are 183597 friend relation data among the 51 research samples, accounting for 75.41 % of the total data, which also verifies the reasonability of the city selections in data collection.

3.3 Data calculation

The data calculation includes four steps. The first step: standardize the collected friend relations data of the 51 note cities, and construct a matrix of the number of friends of the 51 cities. The formula is as follows:

$$V'_{ij} = V_{ij} / \sum_j V_{ij}$$

(1)

---

[3] In Sina Micro-blog, the users can be generally divided into "celebrities" and "grassroots". Compared to "celebrities", the words and deeds of the "grassroots" are usually the information communication with other users and play the role of maintaining the social relations between users, so they can reflect the links between cities more truly.

[4] A crawler program can enter the Sina Micro-blog web page of each user, and calculate the numbers of the user's followers, followings and friends automatically, making the data collection more convenient and feasible.

Where V_{ij} is the number of the friends of the collected City$_{(i)}$ in City$_{(j)}$; $\sum v_{ij}$ is the sum of the numbers of City$_{(i)}$ in each City$_{(j)}$ (51 note cities); V_{ij}' is the standardized number of the friends of City$_{(i)}$ in City$_{(j)}$.

The second step: on the basis of the above calculation, calculate the city's external connectivity index in the network system. The formula is as follows:

$$N_i = \sum_j V_{ij}' - V_{ii}'$$
(2)

Learning from the Central Place Theory proposed by W. Christaller, we use the external connectivity index to represent urban hierarchy. In the formula, N_i is a city's external connectivity index, reflecting the sum of the ratios of the friend relations of City$_{(i)}$ in other cities; V_{ij}' is the standardized number of the friends of City$_{(i)}$ in City$_{(j)}$; V_{ii}' is the standardized number of the friends of City$_{(i)}$ in the same city.

The third step: calculate the network connectivity between cities to reflect the closeness of contact information between cities in the network. The formula is as follows:

(3) $R_{ij} = V_{ij}' * V_{ji}'$

Assume that =100, we adopt the maximum standardization:

$$R_{ij}' = \frac{R_{ij}}{Max(R_{ij})} * 100$$
(4)

Where V_{ij}' is the standardized number of the friends of City$_{(i)}$ in City$_{(j)}$; V_{ji}' is the standardized number of the friends of City$_{(j)}$ in City$_{(i)}$; R_{ij} is the network connectivity between City$_{(i)}$ and City$_{(j)}$; $Max(R_{ij})$ is the maximum of the calculated network connectivity; R_{ij}' is the standardized network connectivity between City$_{(i)}$ and City$_{(j)}$.

The fourth step: calculate the network connectivity of each city to reflect the contact intensity of the city in the network system. The formula is as follows:

$$M_i = \sum_j R_{ij}' - R_{ii}'$$
(5)

Where M_i is the network connectivity of City I; R_{ij}' is the standardized network connectivity between City$_{(i)}$ and City$_{(j)}$; R_{ii}' is the network connectivity of the inner City$_{(i)}$.

4 CHINA'S URBAN NETWORK CHARACTERISTICS FROM THE PERSPECTIVE OF MICRO-BLOG SOCIAL SPACE

Based on the above methods, we analyzed and calculated the friend relations of the micro-blog users of the selected 51 representative cities. Combined with the geospatial urban network patterns, we made the following analysis of China's urban network system based on the micro-blog social space.

4.1 Analysis of the Overall Structure of Urban Network System

The micro-blog social space itself should be flat and without centers. However, the analysis of the micro-blog friend relations shows that, the urban network system in the network space is obviously influenced by the urban network relations in real life, exhibiting the following characteristics.

4.1.1 The relative consistency of network connectivity and urban structure in the network

In Figure 2, the abscissa is the city ranking based on its external connectivity index ( ) with a descending order and a lower ranking suggests a lower hierarchy in the network system; the ordinate is the corresponding network connectivity of each city ( ), reflecting the contact intensity of the city in the network system. It can be drawn that, a city's network connectivity is positively correlated with its hierarchy and shows a downward trend with the decreasing of the urban hierarchy, which means, the higher the urban hierarchy is, the higher the city's network connectivity will be. However, the inconsistency between network

connectivity and urban hierarchy also exists in cities like Shenzhen, Chengdu, Tianjin, Fuzhou, Zhengzhou, Qingdao, Nanjing and Harbin, while these cities are often the network node center of the small region where it belongs. For example, the network connectivity in Chengdu and some western cities is relatively high. This suggests that, although some cities have a low hierarchy, they have relatively higher network connectivity due to its strong network connectivity in the small region.
Fig.2: The relationship between the connection rate and the hierarchy system of the cities in the network

4.1.2   City-level distribution in urban network

In order to further subdivide the city level, we sequenced the cities' network connectivity ( ). As shown in Figure 3, the ordinate is the ranking sequenced according to the city's network connectivity; the abscissa is the corresponding city. The lower the ranking is, the weaker the city's contact role in the network will be. According to K-means clustering analysis, these 51 research cities are divided into 6 levels (Table 2). Beijing is in the first level: its network connectivity is more than 600, being the contact center of the national network; Shanghai, Guangzhou and Shenzhen are in the second level: their network connectivity is between 200 and 600, being the sub-centers of the national network; Chengdu, Tianjin, Hangzhou, Wuhan and Fuzhou are in the third level: their network connectivity is between 100 and 200, being the contact centers of regional networks; Zhengzhou, Xiamen, Nanjing and Qingdao etc. are in the fourth level: their network connectivity is between 50 and 100, being the contact centers of sub-regional networks; Changsha, Dalian, Liuzhou and Kunming etc. are in the fifth level: their network connectivity is between 10 and 50, being the contact centers of local networks; Lianyungang, Daqing, Xining and Huhehote etc. are in the sixth level: their network connectivity is less than 10, being the contact nodes of local networks and having the weakest contact roles in the network.
Fig.3: The rank of the connection rate of cities in the network

Considering from the six levels, several cities like Chengdu, Fuzhou, Nanjing, Harbin, Lanzhou and Kunming only play the roles of regional network contact sub-centers or local network contact center, totally inconsistent with the existing urban system-level characteristics related to the entity economies or infrastructure, especially for the regional, sub-regional and local levels. This reflects to some extent that the

spatial expansion of the micro-blog network is not in full compliance with the existing based geospatial. The hierarchy of a city in the network system is not entirely determined by the level of economic development, but the result under the influence of socio-economic level and geo-culture.

Level	Network connectivity	Cities
Center of the national network	＞600	Beijing
Sub-center of the national network	200-600	Shanghai, Guangzhou, Shenzhen
Center of the regional network	100-200	Chengdu, Tianjin, Hangzhou, Wuhan, Fuzhou
Sub-center of the regional network	50-100	Zhengzhou, Xiamen, Nanjing, Qindao, Nanning, Ningbo, Suzhou, Xi'an, Jinan, Haer'bin, Shenyang, Chongqing, Wenzhou, Changchun
Center of the local network	10-50	Changsha, Dalian, Liuzhou, Kunming, Guilin, Nanchang, Hefei, Taiyuan, Jilin, Shijiazhuang, Xuzhou, Tangshan, Wulumuqi, Yantai, Guiyang, Lanzhou, Changzhi, Xiangyang, Haikou, Handan, Sanming
Node of the local network	＜10	Lianyungang, Daqing, Xining, Huhehaote, Baoji, Yinchuang, Lasa

Table 2: Level distribution of the city network

4.1.3   City contact intensity partition in urban network system

Sequencing the network contact intensity ( ) of the 1275 ( ) groups of contact between each two cities from low to high, we found that significant levels exist in these data. Specifically speaking, there are 984 groups of contact between two cities whose network connectivity is between 0 and 1, accounting for 77.17 % of the total number; there are 149 groups of contact between two cities whose network connectivity is between 1 and 3, accounting for 11.69 % of the total number; there are only 112 groups of contact between two cities whose network connectivity is greater than 3, though only accounting for 8.78 % of the total number, the sum of all the network connectivity of these 112 groups reaches 1254.72 which accounts for 70.59 % of the total urban network connectivity. This reinforces that there is a greater level in the network contact intensity between cities. We sequenced the network connectivity of these 112 groups from small to large and also found a significant level. As shown in Figure 4, with the increasing of sequence, the network intensity between cities shows a growth trend similar to an index.
Fig.4: The rank of the connection rate(＞3) between cities

4.2 Spatial Analysis of Urban Network System

With Arcgis analysis software, we prepared the thematic maps about the urban hierarchy in urban network system and the network connectivity between cities to further analyze the spatial characteristics of urban network system. We also divide the network connectivity of the 112 groups of contact between each two cities into six levels.

4.2.1   Significant difference between Eastern China and Midwest China

According to the traditional division method of three regions, namely, Eastern China, Central China, and Western China, we conducted a geographic division of these 51 node cities. As shown in Figure 5, the horizontal axis is divided into three major regions of Western China, Central China, and Eastern China from left to right. We then sequenced the cities in each region according to their network connectivity. The

analysis showed that, although cities with higher city levels also exist in Western China and Central China, the average city level in Eastern China is significantly higher than those of Central China and Western China. However, the difference between Central China and Western China is not so significant. The 29th Statistic Report of China Internet Network Development Status newly released by China National Network Information Center (CNNIC) also pointed out that, the provinces and cities whose Internet penetrations are above the national average level are mostly concentrated in the eastern coastal areas. This suggests that, the difference in the Internet development level directly affects the city's network connectivity and further widens the development gap between Eastern China and Midwest China.
Fig.5: The rank of city level distribution in the Western, Central, Eastern China

We further made a comparative analysis of the information contact intensity and geographical characteristics in the internal Eastern China, between Eastern China and Central China, Eastern China and Western China, Central China and Western China. It can be seen from Figure 6 that, the internal relations in Eastern China is still the main body of current network system. In the statistics of the network system topology whose network information contact intensity is greater than 3, there are 59 connections in the internal Eastern China, accounting for 52.68 % of the total number. The network connectivity totals 846.56, accounting for 67.4 % of the whole network. Secondly, the contacts between Eastern China and Central China, Eastern China and Western China are relatively close. In the network system topology, each has 18 connections, accounting for 16.07 % of the total number respectively. In the cumulative network connectivity, they are nearly the same, which are 132.4 and 138.38 respectively, accounting for 10.54 % and 11.03 % in the entire network respectively. Meanwhile, the network contacts in the internal Central China, in the internal Western China, and between Central China and Western China are obviously weaker. As a result, we can conclude that, the contacts in the internal Eastern China, between Eastern China and Central China, Eastern China and Western China constitute almost all of the current network systems. Besides, the network contacts in the internal Eastern China are the strongest, which reflects the levels of Internet development and economic ties. At the same time, there is no significant difference between Central China and Western China and the contacts between them are also weak.

Fig.6: The network connection among Western, Central, Eastern China

4.2.2 Hierarchical agglomeration in urban network

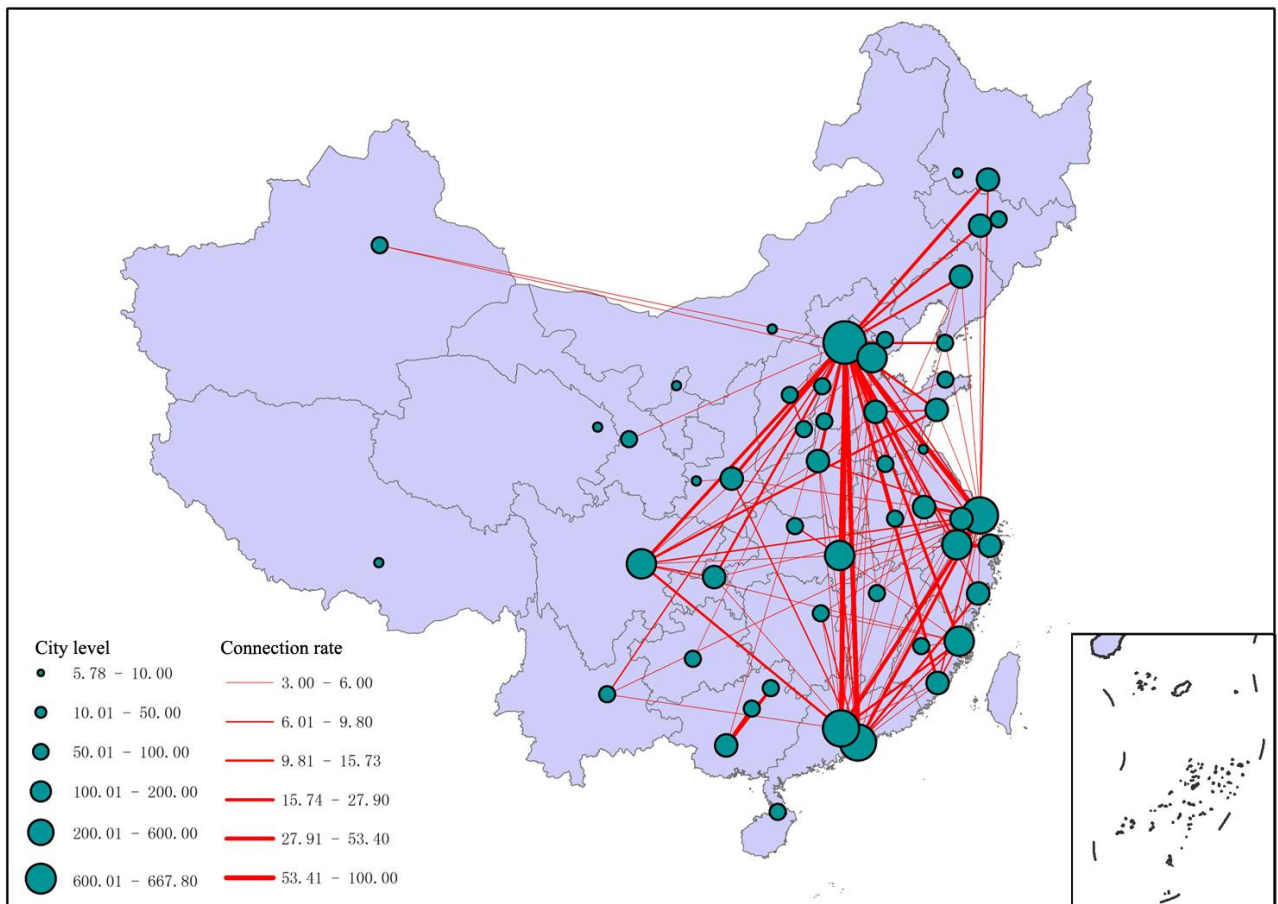
Analyzing the urban network pattern from the perspectives of city level and network contact intensity (>3) between cities, we can found that, hierarchical agglomeration exists in China's urban network system, the specific performance of which is the spatial pattern of "Three Majors and Four Smalls". Figure 7 directly shows the important roles of the three major regions of the Beijing-Tianjin-Hebei, Yangtze River Delta and Pearl River Delta in the entire network system. It shows a great similarity with the urban network system pattern in the geographic entity space, especially the emergence of three gathering areas of the Beijing-Tianjin-Hebei, Yangtze River Delta and Pearl River Delta in the entire network system.


Fig.7: The pattern of China's cities network based on the social network space

Specifically speaking, the "three majors" include the Beijing-Tianjin-Hebei region (Beijing, Tianjin, Shijiazhuang, Tangshan), the Pearl River Delta (Guangzhou, Shenzhen), the Yangtze River Delta (Shanghai, Hangzhou, Nanjing, Ningbo, Suzhou, Wenzhou); the "Four Smalls" include Chengdu-Chongqing region (Chengdu, Chongqing), Hercynian region (Fuzhou, Xiamen, Sanming), Wuhan (central) region (Wuhan,

Changsha, Nanchang, Hefei, Changzhi, Xiangyang), Northeast China (Shenyang, Harbin, Changchun) (Table 3). Table 3 is based on the statistical analysis of the network levels of the note and key cities in the seven regions and the network contact intensity between them and the outer world, elaborating the urban network architecture characteristics and division basis more detailedly. The hierarchical agglomeration in China's urban network structure based on network communities is still significant. However, combined with the previous analysis on the characteristics of city level distribution, as an interactive network platform, micro-blog still strengthens the "horizontal contacts" between cities, especially in the local level. This can also explain the emergence of the localized agglomeration of the "Four Smalls" regions.

City-region	Node cities	City level	Connection rate of cities (＞3)
Beijing-Tianjin-Hebei region	Beijing, Tianjing, Shijiazhuang, Tangshan	Beijing is the center of the natioanl network;Tianjing is the center of the regional network; Shijiazhuang and Tangshan are the centers of the local network;	There are 39 connections between these four cities and other cites, accounting for 32.0 % of the total of connections; and the commulativeconnection rate of these four cities are 675.94, accounting for 53.87 % of the total.
Pearl River Delta	Guangzhou, Shenzhen	Guangzhou and Shenzhen are the sub-centers of the national network	There are 31 connections between these four cities and other cites, accounting for 25.4 % of the total of connections; and the commulativeconnection rate of these four cities are 384.33, accounting for 30.63 % of the total.
Yangtze River Delta	Shanghai, Hangzhou, Nanjing, Ningbo, Suzhou, Wenzhou	Shanghai is the sub-center of the national network; Hangzhou is the center of the regional network; Nanjing, Ningbo, Suzhou and Wenzhou are the sub-centers of the regional network;	There are 39 connections between these six cities and other cites, accounting for 32.0 % of the total of connections; and the commulativeconnection rate of these six cities are 448.06, accounting for 35.71 % of the total.
Chengdu-Chongqing region	Chengdu, Chongqing	Chengdu is the center of the regional cetwork; Chongqing is the sub-center of the regional network;	There are 13 connections between these two cities and other cites, accounting for 10.7 % of the total of connections; and the commulativeconnection rate of these two cities are 104.28, accounting for 8.31 % of the total.
Hercynian region	Fuzhou, Xiamen, Sanming	Fuzhou is the center of the regional network; Xiamen is the sub-center of the regional network; Sanming is the Center of the local network;	There are 12 connections between these three cities and other cites, accounting for 9.8 % of the total of connections; and the commulativeconnection rate of these six cities are 102.07, accounting for 8.13 % of the total.
Wuhan (central) region	Wuhan, Changsha, Nanchang, Hefei, Changzhi, Xiangyang	Wuhan is the center of the regional network; Changsha, Nanchang, Hefei, Changzhi and Xiangyang are the centers of the local network;	There are 18 connections between these six cities and other cites, accounting for 14.8 % of the total of connections; and the commulativeconnection rate of these six cities are 108.22, accounting for 8.63 % of the total.
Northeast China	Ha'erbin, Shenyang, Changchun, Jilin	Ha'erbin, Shenyang and Changchun are the sub-centers of the regional network; Jilin is the center of the local network;	There are 9 connections between these four cities and other cites, accounting for 7.4 % of the total of connections; and the commulativeconnection rate of these six cities are 81.21, accounting for 6.47 % of the total.

Table 3: The overall city network structure

Figure 8 further shows the status of the regions of "Three Majors and Four Smalls" in the national urban network system. Beijing-Tianjin-Hebei region enjoys a widest coverage in the network system and covers the whole country, bearing the status of the country's center. The coverage of the Pearl River Delta region and the Yangtze River Delta region in the network system is less than that of Beijing-Tianjin-Hebei region. There is a certain correlation between the coverage and the geographical entity pattern. The Pearl River Delta region shows obvious characteristics of the network system center in South China, while the Yangtze River Delta region shows the characteristics of the network system center in East China. At the same time, the network contacts between the three major regions dominate the entire network system. In addition, Chengdu-Chongqing region, the Hercynian region, Wuhan region, and Northeast region also occupy a certain position in the whole network system. In addition to reflecting the characteristics of local contacts, each region of the "Four Smalls" shows a unified spatial directivity towards the three cities of Beijing, Shanghai and Guangzhou. It is worth noting that, the geometric center of Wuhan region in the network system is obvious, showing the central characteristics of the blending of North and South, East and West and a significant regional advantage.

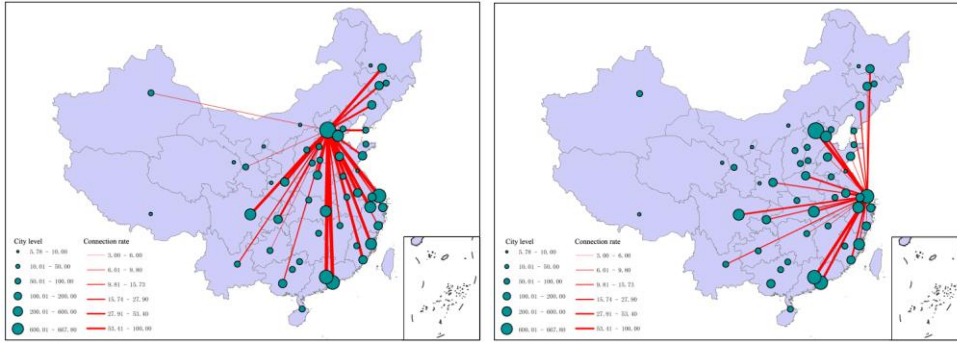
Fig. 8: The position of different region in China's city networks

4.2.3 High level city-dominated urban network system

In order to analyze the importance degree of the core cities in the network system, we extracted the first four cities in the urban network system, which are the national network contact center---Beijing and the three national network contact sub-centers---Shanghai, Guangzhou and Shenzhen. The study shows that, cities with high hierarchy dominate the urban network system. It differs from the previous study of China's urban system based on aviation network, railway network and Internet in that the difference between Beijing and

Shanghai, Guangzhou, Shenzhen are significant and they cannot by measured in the same level. In the national level, Beijing has the strongest network connection directivity and involves the most widely (Figure 9). Beijing's network contacts nearly cover the whole country, including 33 connections with other cities and accounting for 29.46 % of the total number. The cumulative network connectivity reaches 645.43, accounting for 75.66 %. It is not difficult to see from the figures that the urban network systems constructed between the four cities of Beijing, Shanghai, Guangzhou, Shenzhen and other cities are basically consistent with the national urban network system, which further reflects the dominance of the four cities in the network.


The network connection between Beijing and other cities (left). The network connection between Shanghai and other cities (right).

5 CONCLUSIONS AND DISCUSSIONS

Information technology has an increasing influence on the development and changes of China's urban network system. From the perspective of social space, with the help of the social relation network reflected in micro-blog friends, this paper studies the patterns and characteristics of urban network system in the social network space. This is a new attempt of the urban network research under the influence of globalization and informatization. The result analysis also proves the effectiveness of the relations between micro-blog users in the study of urban network system.

Based on an empirical analysis of Sina Micro-blog, from the perspective of micro-blog social space, the paper finds that significant hierarchical relationship and level distinction exist in China's urban network. A city's network connectivity is positively correlated with its comprehensive strength and hierarchy, which means that, the higher urban hierarchy is, the higher its network connectivity will also be. The city's network connectivity shows a downward trend with the decreasing of its hierarchy. It is worth noting that, the social network space itself has no center and level, but the social relations of its participants-human beings, reflect the geospatial characteristics of the socio-economic and cultural ties. This result has a great similarity with the urban network system pattern of the geographic entity space. But it does not mean that, the urban network in the social network space is a simple projection of the geospatial urban network. This paper finds an inconsistency exists in the hierarchies of cities like Chengdu, Fuzhou and Xiamen in the urban network system based on micro-blog space and in actual entity urban system, suggesting that the spatial expansion of micro-blog network is not in full compliance with the existing based geospatial.

Based on the city's network level and network contact intensity, the research results show significant spatial differences between the three major regions of Eastern China, Central China and Western China, but the difference between Eastern China and Midwest China is more significant. Hierarchical agglomeration exists in China's urban network system, the specific performance of which is the spatial pattern of "Three Majors and Four Smalls". They are the Beijing-Tianjin-Hebei region (Beijing), the Pearl River Delta (Guangzhou, Shenzhen), the Yangtze River Delta (Shanghai, Hangzhou, Nanjing); Chengdu-Chongqing region (Chengdu, Chongqing), Hercynian region (Fuzhou, Xiamen), Wuhan (central) region (Wuhan, Changsha), Northeast China (Shenyang, Harbin, Changchun). This further verifies the domestic scholars' research on China's urban network system. It can be said that the emergence of micro-blog network space promotes the further agglomeration of the original geospatial urban network system. Its main performance is to accelerate the development of the densely urbanized areas formed by surrounding the cities with high hierarchy. This also shows that, the economic factor and the original urban structure still play their roles in shaping the urban network pattern. However, when gathering together, as an interactive network platform, micro-blog social space still strengthens the horizontal contacts between cities. The roles of the hierarchy of some cities are weakened a bit, especially in the regional and local levels. For example, the emergence of the Hercynian region and the Northeast region as regional network space, not only shows the equilibrium of network information diffusion, but also reflects the local characteristics in the social network space like micro-blog.

Of course, as a newly emerging network community, micro-blog is still in its infancy. Its influence on the geographic entity space remains to be verified. But undoubtedly, the spatial "flow" and "viscosity" brought by this powerful social dynamics will have a positive impact on the reconstruction and networking of national and regional urban systems. For the mechanisms behind it, further studies should still be conducted.

1 ABSTRACT

The cornerstone of turning the Indian city a smart city, is towards an integrated approach of ecology and the conservation of the natural resources for City Planning. During the last century Urban Population of India increased ten folds from 27 million to some 270 million. Cities today are in the centre-stage of environmental pollution, and degradation and loss of bio-diversity. Concentration of intense economic processes and high level of consumption in cities increase their resource demands. The main problem with cities today is that they have become centres of mobilisation rather than civilisation. They are nodes of an increasingly intense economic activity, with the volume of travel having reached unprecedented levels in recent years. The urban economic culture has a deep impact on the human mind, which has become too pre-occupied with the pursuit of personal gain. The city of the future, to be sustainable, will have to re-establish the concept of green spaces development and mangement, with greater dependence on smart local community partcipation, with concern on the liveability of local environments and with a greater emphasis on creating public spaces for people to enjoy.

New Delhi, the fast growing Capital City of India has presently a population of about 17 million persons (census 2011) and is estimated to grow in a 23 million population Mega City by the year 2021. After Independence Delhi had 1.43 million populations by 1951 and has increased to 8.42 million by 1991. Despite a land locked situation and with such a big concentration of population, it is a liveable city with natural landscape and with very high percentage of landuse under green/open spaces. Out of total area of 1483 sq km in NCT Delhi, about 150 sq km has been proposed as Green Belt at the peripheral area of the city to act as lung spaces for City, 100 sq km land is in River Zone as Green Space to facilitate ground water recharge and about 90 sq km of Aravali ranges and water bodies with biodiversity parks for enriching the environment and natural flora and fauna in its original style in the city. The built up areas also contain more than 15 % area in form of city and neighbourhood level parks allocating about 5 sq km open space per person at city level. The area under recreational/ green use i.e. 7145 ha is in the form of District Parks, City Parks, Community Parks etc. comprising around 15 % of the total urban land area. The norms for City green for Delhi as Master Plan of Delhi 2021 varies from City Park for 100 ha to housing area parking as 0.5 ha for certain population.

The present paper analysed about how New Delhi lungs spaces can be used though smart community participation over time. Whether this open space is utilized by the comuniy for the community and to the community? The paper explores the upcoming virtual technology for transformation of community ideas and design to influence the decision making, strategy planning and predictive modelling for conservation and sustainable development of urban green spaces local level and management of problem of climate change at global level. Smart Community participation through 'Bhagidari System' to improve the urban environment and to revitalized Green Spaces of New Delhi over time was also analysed in the current paper.

2 INTRODUCTION

The cornerstone of turning the Indian city a smart city, is towards an integrated approach of ecology and the conservation of the natural resources for City Planning. During the last century Urban Population of India increased ten folds from 27 million to some 270 million. Cities today are in the centre-stage of environmental pollution, and degradation and loss of bio-diversity. Concentration of intense economic processes and high level of consumption in cities increase their resource demands. The main problem with cities today is that they have become centres of mobilisation rather than civilisation. They are nodes of an increasingly intense economic activity, with the volume of travel having reached unprecedented levels in recent years. The urban economic culture has a deep impact on the human mind, which has become too pre-occupied with the pursuit of personal gain. The city of the future, to be sustainable, will have to re-establish the concept of green spaces development and mangement, with greater dependence on smart local

community partcipation, with concern on the liveability of local environments and with a greater emphasis on creating public spaces for people to enjoy.

New Delhi, the fast growing Capital City of India has presently a population of about 17 million persons (census 2011) and is estimated to grow in a 23 million population Mega City by the year 2021. After Independence Delhi had 1.43 million populations by 1951 and has increased to 8.42 million by 1991. Despite a land locked situation and with such a big concentration of population, it is a liveable city with natural landscape and with very high percentage of landuse under green/open spaces. Out of total area of 1483 sq km in NCT Delhi, about 150 sq km has been proposed as Green Belt at the peripheral area of the city to act as lung spaces for City, 100 sq km land is in River Zone as Green Space to facilitate ground water recharge and about 90 sq km of Aravali ranges and water bodies with biodiversity parks for enriching the environment and natural flora and fauna in its original style in the city. The built up areas also contain more than 15 % area in form of city and neighbourhood level parks allocating about 5 sq km open space per person at city level. The area under recreational/ green use i.e. 7145 ha is in the form of District Parks, City Parks, Community Parks etc. comprising around 15 % of the total urban land area. The norms for City green for Delhi as Master Plan of Delhi 2021 varies from City Park for 100 ha to housing area parking as 0.5 ha for certain population.

The early urban life in Delhi was environment centric and full of plant lore, intimately concerned with the day to day life of our ancestors the hermitages. With the increase in population and the rapid spread of townships Delhi urban community have become more and more alienated from Nature. The scale of present urbanization is unprecedented and posses daunting requirements for Capital city of India to transform the urban community to, "Green Urban Community". Deforestation is increasing alarmingly and is disastrous. Apart from the aesthetic aspect, the loss of vegetation cover affects the soil, air and water balance adversely. The environment is badly affected due to deforestation and the consequent ecological imbalance. The capital city of India Delhi now face the mounting challenges with unprecedented rural and urban migration and population growth. The growth of Delhi/ National Capital Teritory (NCT) cities is beyond manageable limits. Therefore, complex urban issues demand smart, innovative actions and increasing attentions to combat. The natural landscape provides a vital background to urban community. The ever increasing urbanization process escalating socio-economic demands which alter the lunges spaces of the city. It is essential to emphasize the role of green spaces or urban forest for planning in New Delhi. The information technology and rich heritage of urban community offer significant opportunities for green cover to improve its quality through smart community participation or existing Bhagidari System. (Bhagidari System is a participatory approach addopted by the Government of Delhi in 2003 for provision of public services through involvement of the local Resident Welfare Organisations, local stakeholders, local professionals, local polititions, local City Government, local police and NGOs etc) refer website: www.delhigovt.nic.in/bhagi.asp .

The present paper analysed about how New Delhi lungs spaces can be used though smart community participation over time. Whether this open space is utilized by the comuniy for the community and to the community? The paper explores the upcoming virtual technology for transformation of community ideas and design to influence the decision making, strategy planning and predictive modelling for conservation and sustainable development of urban green spaces local level and management of problem of climate change at global level. Smart Community participation through 'Bhagidari System' to improve the urban environment and to revitalized Green Spaces of New Delhi over time was also analysed in the current paper. (figure 1).

3   CONCEPT OF SMART URBAN GREEN COMMUNITY SYSTEM (SUGCS)

A Bhagidari Green Community System (BGCS) to revitalize the green spaces for urban cities to act as the engine of smart growth and transforming the urban system to a smart sustainable system. BGCS will create the functional connectivity between physical and green spaces within the cities on the one hand and act as a buffers and recreational opportunities for urban fringe communities on the other hand. Such system might also promote greater ecological and biological diversity development, greater use of green infrastructure and multifunctional green spaces. By increasing the density of green through BGCS can also help to mitigate the climate discomfort generated within urban heat island as a result of concentration of roads, concrete buildings and pavement. Generation of micro-climate through provision of shading trees in the parking lots and pavement control the heat generated by buildings.

Figure 1: Impact of Urban Green Community through Bhagidari System

However, it is important to select or grow trees that will perform the best in the city climate. In addition to helping cut down carbon emissions globally, BGCS may aid in improving urban air quality. The problem of air pollution is one of the most important problems faced by Indian cities like smoke, noise, chemical effluents, garbage dust which act as the chief pollutants of the atmosphere. In the technical term there are main five elements responsible for creating pollution in the NCT like sulfur dioxide, nitrogen dioxide, ozone, particulate matter, and carbon monoxide and with the help of BGC System these can be combat with low cost. It is estimated that in order to remove one pound of pollutants required Rs200/- cost to mitigate while cost with the BGC System the same can be mitigated for Rs. 20/- or even less. Through management of green space strategically in combination with the watersheds region can reduce runoff and recharge the ground water and thereby controlling the problems of floods in the Delhi. Apart from creating strong biodiversity and ecosystem BGC System also generate the psychological and public health benefits. Implementation of BGC System will focus on the framework of Green Urban Land-use policies in order to create environmental justices. Thus, more effective partnership is required between the planner and local communities to establish the BGC System. In short, BGC System is urban and regional planning and environmental management efforts where green land-use located in the designated city area. BGC System is developed in pursuit of synergies derived from combined efforts in waste treatment, environmental preservation and promotion of industrial development.

3.1 Features of BGC System

- Strong regulation development control in support towards a recycling based community.
- Centre, State and local Government spearheading the drive to propagate the concept of BGC System.
- Foster the research and training in the field of environment and town planning through public and private sectors.
- Creating the Knowledge base for environmental system technologies and innovative solutions to solve the urban and regional problems.
- Focusing on energy conservation, eco-material development and integrated waste management
- Promoting the eco-business market domestically and internationally.
- Contribute to reducing, reusing and recycling of resources.
- Promoting the establishment of a sound material-cycle by local community involvement

For Urban and regional Planner, the development and implementation of BGC System provide incentives on a number of issues that may go beyond their professional boundaries. This, therefore, calls for

comprehensive multi-disciplinary partnerships that will enable the achievement of the goals and objectives of a BGC System. The Planner will need to provide inputs and facilitate such partnerships to plan and develop a BGC System.

3.2 Support infrastructure to Establish BGC System

a)   Policy and Strategy Development: BGC System requires adopting environmental base Urban and Regional Planning regulation and development control to succeed. Standards and codes to achieve targets and development goals need to establish besides integrating BGC System into Master and Zonal Plans of the Delhi. It should also have financial and other incentives to ensure that local community will adopt voluntarily.

b)   Develop Networking and creative economy: BGC System will be stronger if networking system should be developed by involving the local community for the community and from the community. Creation of common ground provides opportunities for private and public to meet and exchange information, solve problems and plan together of green environmental friendly infrastructure and services (eco-services). A group of technical professional will be formed to work across the professional boundaries and support to generate the propulsive creative economy.

c)   Application and Implementation of Environmentally sound technologies: BGC System can implement cutting edge and innovative technology demonstrations that are environmentally-friendly and also provide opportunities for capacity building and training on related issues.

d)   Information Access: BGC System will provide reliable and credible information to ensure the success of cites towards sustainable development. Software support and decision making tools will be generated to evolve the sustainable strategies and technologies for the development control concept. To take advantage of research and development in the international and national marketplace and private experts.

4   GENERATION OF KNOWLEDGE MANAGEMENT BANK.

To stay ahead in today's highly unstable and competitive urban environment, Planner needs to develop new ways to organized and deliver services with better quality of life and faster response to the urban community need there by a higher satisfaction. It has become increasingly apparent that potential bottlenecks in achieving these goals lie not just in Planning management or policies frame but also in the ability to effectively manage 'Planner's Knowledge'. Especially the profession like Urban and Regional Planning are defined by working relationships governed by functional interdependencies rather that creating professional boundaries. Knowledge Management is a major challenge for creating Smart Urban Green Community through BGC System. The rapidly growing importance of knowledge is highlighted by the fact that many organizations now attempt to organize and to make available the relevant collective knowledge for Planner to design and plan the sustainable cities. However, at the national level there is a need to build 'Green Community Knowledge Repository System' unlike the one attempted under National Urban Information System (NUIS) Scheme for generation of digital databases at City level. Urban forestry and green research are given us much more detail information and can provide smart way to collect the information and database for sustainable management of green spaces for the region or cities. Invent of information technology, entrepreneur GIS, satellite imagery and aerial photography provides smart ways to plan or monitoring the urban forest or green spaces.

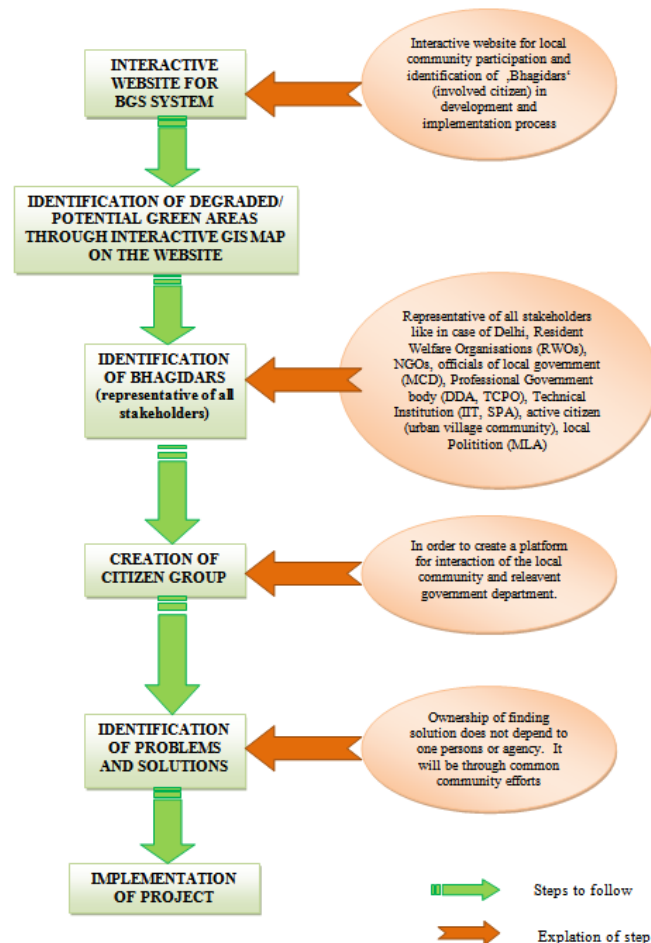
Through the satellite imagery one can measure the degree of canopy cover over urban areas at various time and period and can also identify the urban heat island and increase or decrease of temperature and so can understand the climate change. Since 1972 Land-sat satellite is efficient in even creating documentation of trees in urban areas and help to generate the database on tree cover over time. But Cartosat series of satellites can offer much higher resolution data which help planners to access specific detail data for even tree at the site level, will revolutionize the decision making process. With the help of Aerial Photography technologies we can even identify the ecological system and functions of urban forestry and its linkages with other land-use system within the urban community. Hence, even while analyzing the Google map image, one can smartly generate the base line data for creating or achieving the desired tree density goal. These goals can also be managed by target percentage of green cover/ urban forest in the city.


Figure 2: Steps for creation of BCG System

The Corporation's part department in Chennai and the State Forest Department are conducting tree survey for the city covering more than 426 Sq. Km., first of its kind in the country. Even a website – www.hashtrees.in – is also created to help the Chennai Corporation to put the check on trees being axed without permission and plan further to combat climate change. In the similar ways a GIS based software/ database tool is required to be develop at National/ Regional/ and City level in order to analyze the ecological and economic benefit of the green cover/ urban forest. In a way green/ forest based urban ecosystem gives sound money value for the urban community as a whole. Thus every tree is of more money value than only environmental benefit. Hence, BGC System services will provide environmental function by absorbing storm water runoff, removing air and water pollutions, stop soil erosion, reduce energy consumption, maintained ground water and help storing carbon. Municipal Corporation of Delhi (MCD) or Delhi Development Authority (DDA) can even use urban forest as a means of reducing carbon footprint and generate finance through carbon trading. Several studies show that, when urban forest is strategically planned, can reduce the demand of energy based on fossil fuels and consequently reduces the air and water pollution. Now the question arises that how to generate the BGC System for preparation of Master Plan/Zonal Plan and policy level in order to create SMART CITY for sustainable future. This problem can be solved in much way by creating a single knowledge base platform in Town and Country Planning Organization (TCPO) through Bhagidari (involment) of Resident Welfair Organistion, town planner, politicians, city managers, environmentalist, bio-scientist, software expert and ecologist.

5 METHODOLOGY FOR BGS SYSTEM:

Basic idea is to empower citizen to look after there green areas at decentralized community level. This will enhance inter action between the resident civil society ad releavent Government departments. The methodology of creation of BGS System is given in Figure 2.

6 STRATEGY OF REVITALIZATION OF GREEN SPACE THROUGH BGC SYSTEM:

In the above stated background the following three fold approach and strategy needs to be adopted through BGC System:

6.1 Land-use Efficiency Management:

Despite a land locked situation and with such a big concentration of population, it is a livable city with natural landscape and with very high percentage of land-use under green/open spaces. Out of total area of 1483 sq km in NCT Delhi, about 150 sq km has been proposed as Green Belt at the peripheral area of the city to act as lung space for City, 100 sq km land is in River Zone as Green Space to facilitate ground water recharge and about 90 sq km of Aravali Ranges and water bodies with biodiversity parks for enriching the environment and natural flora and fauna in its original style in the city. The built up areas also contain more than 15 % area in form of city and neighborhood level parks allocating about 5 sq km open space per person at city level.

6.2 Regional Park:

The Aravalli Range in the NCT of Delhi comprises of the rocky outcrop stretching from the University in the North to the NCT Border in the South and beyond, and sizeable areas of the same have been designated as the Ridge. This is not a continuum as various intervening stretches have, over a period of time, been brought under urbanization – for example the Central Ridge area was planned as an integral part of New Delhi, at the time of the development of New Delhi as the Capital in the early part of the twentieth century. The Master Plan of Delhi – 2001 identified the Regional Park into four parts as below:

- Northern Ridge 87 ha.
- Central Ridge 864 ha.
- South Central Ridge 626 ha.
- Southern Ridge 6200 ha.

The area of Regional Park is 7777 hectares. Part of this has been notified as Reserve Forest.

6.3 Green and Recreational Area

The area under recreational/ green use i.e. 7145 ha is in the form of District Parks, City Parks, Community Parks etc. comprising around 15 % of the total urban land area. In addition to this, a large chunk of green area is provided in the form of Neighbourhood Parks/Tot lots in the gross residential use zones, plantations/greens in large campuses like President's Estate, JNU, IARI, Delhi University, plantations along drains and roadside plantations. In addition to above, two Bio-diversity parks are under development.

In the Urban Extension the green cover is to be provided at the rate of 15 % of the total land, excluding the Ridge Regional Park. Out of this, some area shall be developed in the form of formal parks for the community and the rest shall be developed as woodlands and incidental greens for balancing the environment. This will be in addition to the development of specialized parks like Bio-Diversity Parks, plantation along the roads, drains, riverbank, etc.

6.4 Management of Natural Resources

The major natural features and eco-systems of Delhi are the river Yamuna, together with a network of streams/drains that empty into the river, and the Aravalli Range. Both of these are in a state of considerable degradation, and it is of vital importance to conserve and rejuvenate these ecosystems. This ecological reserve area has regional carrying capacity; therefore, surrounding States also have to contribute towards their conservation and rejuvenation.

Delhi has 18,000 parks and gardens under various civic agencies, measuring more than 8,000 ha which are managed by civic agencies alone or in association with NGOs/RWAs/Private Sector. Huge road length, railway lines, drains play an important role in greenery. Beside this, Forest Department and other agencies have about 9,500 ha under forests and other green patches ranging from 3 Acres to 6,200 Acre continuous forests. Forest Department of NCT Delhi has set up twelve City Forests in Delhi.

Civil society of Delhi (RWA), committed NGOs awareness in schools (Eco-Clubs), NGOs and so on are actively participate to enhance the urban forestry in Delhi.. The total green cover is much more than the recorded forest area (Forest Survey of India, 2009)over here. An unusually large number of agencies control land in Delhi and as a result the creation and management of green cover is a task shared by official agencies in Delhi namely, Delhi Development Authority, New Delhi Municipal Council, Municipal Corporation of Delhi, Airports Authority of India, Delhi Cantonment Board, Central/State Public Works Department, Forest Department and other civil agencies, including Railways.

Various issues related to urban greenery are – protection of created greenery, involving people in colony park maintenance, development of degraded parks, creation of greenery along roads, drains, railway track etc. Furthermore, blank institutional areas, village fallow lands and scrub forests need to be planted with suitable tree species for sustainable ecology. Only then 33 % of Delhi area can have green cover on sustainable basis.

Urban green spaces play a critical role in maintaining biodiversity and augmenting quality of life of a city's residents. Rapid population influx, inadequacies in city planning and regulations result in inadequate availability of land for greenery and landscaping. Redevelopment of the city through new infrastructure projects to cater to old and new needs creates additional pressure to remove trees even where they exist to provide necessary space to new developments.

Delhi is no exception so far as these pressures are concerned but still Delhi has managed to keep its green cover growing compared to other urban regions despite faster increase in population and other infrastructure developments than anywhere else in India.

To mitigate these adverse impacts and to restore and preserve the heritage of Delhi, the Delhi Development Authority (DDA) and University of Delhi have jointly initiated a major conservation effort to create a network of Biodiversity Parks which will not only serve as heritage sites but also act as home for thousands of vanishing species living together and provide a wide range of services to the human population inhabiting the city. It is a first landmark collaborative initiative by any infrastructure agency in India which has thought real estate development with ecosystems services in real sense. The concept of Biodiversity Parks if taken together with Real Estate will open new gateways in creating Green Civil Society.

Delhi has been hailed as a one of the greenest metropolitan cities of the world. Considerable work has gone into bringing tree cover to Delhi. It is estimated that the current green cover in Delhi is 20 percent, a quantum jump from that of only 3 percent in 1998. The current plans are to increase this green cover to 33 percent in 2012 and this involves several civic agencies like the Delhi Development Authority (DDA), New Delhi Municipal Council (NDMC), Public Works Department (PWD), Delhi Jal Board (DJB), Central Public Works Department (CPWD) and the Municipal Corporation of Delhi (MCD).

MCD is at the forefront of these efforts as it : a) Maintains about 14500 parks in the city, (ii) Provides greenery along MCD Roads(Road sides, Central Verges, Traffic Roundabout and traffic channelisers) (iii) Maintaining greenery in MCD establishments like schools, offices, hospitals, dispensaries, sanitary land Fill Sites spread all over Delhi and other vacant lands under its jurisdiction.

MCD has now embarked upon a new policy of involving other stakeholders to give a push to its targeted greening program names as "Public Private Partnership (PPP) in Development and Maintenance of Colony Parks". This institutional mechanism involves partnership of MCD and Registered Welfare Association/ Residents' Society, Residents' Social Welfare Association, NGO in the maintenance and development of the colony parks.

Municipal Corporation of Delhi today looks after 14500 parks in city. Some of the parks are in precarious condition. This is often due to shortage of staff at best and delinquency/absence at worst. In a city as large and complex as Delhi with the constraints in tow, public private partnership in management of city parks is not only desirable but an imperative if we are to deliver our residents the parks that they look forward to. MCD is now proposing to involve Resident Welfare Associations in maintenance of city parks. While the new policy is welcome a lot of institutional issues need to examined and resolved. Foremost, it is necessary to review the level of financial support to RWA to achieve the desired objectives as meager allocations are bound to dilute the efforts, and as a result the impact the new policy initiative.

6.5 Conservation and Development of resources

Green cover of the capital has increased the tree cover of Delhi from 36 sq km to over 300 sq. km. This could be possible because of the understanding & active participation of the citizens especially the school children: A Bhagidary System. Over the past three years the concept of City Forest has been given a new fillip. With the intent of having forest where ever it is possible to have it in Delhi. As a result in these past 3 years at least 28 forests have been setup. The idea is to set up at least 42 forest clusters to promote conservation of biodiversity, improve the quality of city's environment and create a better quality of life for Delhi's resident. In order to ensure that city's green spaces reflect the diversity and character of our rich flora Delhi Government has set up Delhi Parks and Gardens Society (DPGS) under the Department of Environment. A part of DPGS's ambitious mandate is to incorporate plant species that can adapt to Delhi's climatic conditions which seem to be going through a transition. There are already two biodiversity parks in Delhi, one in the northern part of Delhi and other in the foot hills of Aravali near Vasant Vihar. There is a third one coming up in the Vasant kunj area. These biodiversity parks are expected to play a stellar role in promoting a better understanding of the real ecological needs of Delhi and identify plants that can best flourish in the climate of Delhi. In order to enhance tree cover, the Delhi Preservation of Trees Act was enacted in 1994. The act had a provision, according to which, anybody cutting a tree for any purpose has to plant ten trees as compensatory plantation. But now an alternate arrangement has been made according to which, the person will have to pay Rs 28000 to the Department of Environment and Delhi Parks and Gardens Society so that they grow trees and also take care of them.

7 CONCLUSION

Finally as the result of implementation of BGC System will ensure wise use of the natural resources; generation of creative economy; creation of scientific and knowledge base; transforming gray land-uses into green for gaining the status of aesthetic luxury; and, reducing the budget of cities for combating environmental pollution. BGC System, therefore, calls for comprehensive multi-land-use partnerships that will enable the achievement of the goals and objectives of an Smart Government, Smart transportation, Smart economy, Smart planning, Smart innovation, Smart databank and thereby Smart NCT Delhi.

1 ABSTRACT

Examining Serbian housing policy in the past two decades which has been radically transfered from the communist version of "welfare state" to the neoliberal concept of housing market, this paper firstly identifies major subjects and activities in the field of social housing and systematizes kinds of action related to these activities. Sudden state's withdrawal from the housing matter, followed by the lack of land regulations and permanent economic crisis, caused almost unsolvable problem of adequate provision of housing for the most of the population in Serbia.

The initial course, performed through privatisation of 98 % of public housing stock at the beginning of the last decade of the 20th century, took place apart from the few other housing policy initiatives and processes that were unconformably to each other. The state successively abandoned introduction of housing policy, untill it almost ran short of its institutional and active capacities that had been developing by decades in communism. Until 2004 housing policy was trying to achieve short-dated political aims, but since then, the need for introducton of new systematic housing solutions, including social housing above all, emerged. Serbian government began to act in two separate ways, although without yet established long-term national housing policy: First was to try to support, financially and legislatively, production of affordable housing, so called "cheap flats" for subsidized sale; and the other was to try to establish public rented housing, but this time based on economic sustainability instead of general social equity proclaimed in communism. Several projects of "cheap flats" for subsidized sale have been developed, while some of them are stlill under construction, or in the planing stage. On the other side, the initial impulse for public rented housing foundation in Serbia was the 15 milion euros pilot project – Settlement and Integration of Refugees Programme (SIRP 2003-2008.) – financed by the Italian government, that was realized in seven Serbian municipalities. Thus, first non-profit Public Housing Agencies in Serbia were established, and new public housing stock was built and inhabited.

Considering serbian social housing policy in general and highlighting some of their characteristics related to several projects, this study focuses on both of these two recognized courses by analisys and critic review of achieved results.

2 MAIN CHARACTERISTICS OF HOUSING POLICY IN SERBIA AT THE TURN OF THE 21 CENTURY

In the past two decades, Serbian housing policy has been radically transferred from the communist version of "welfare state" to the neoliberal concept of housing market. Sudden state's withdrawal from the housing matter, followed by the lack of land regulations and permanent economic crisis, as well as significant political changes caused almost unsolvable problem of providing adequate housing for the most of the population in Serbia.

The initial course, performed through privatisation of 98 % of public housing stock at the beginning of the last decade of the 20th century, took place apart from the few other housing policy initiatives and processes that were uncomfortably to each other. The state successively abandoned introduction of housing policy, until it almost ran short of its institutional and active capacities that had been developing by decades in communism. Different subsidised programmes and various measures of development of housing policy in Serbia on which, in the 90-ties, were spent between 800 million and 1 billion euros (Mojovic, 2009) did not produce significant effect in the overall picture, simply as there was no comprehensive project of housing development. Usually, individual programmes were in the promotional role of political parties at the time and also represented huge financial burden for local authorities where the sluggishness contributed to the fact that some were late or even they were not started to this day.

2.1 Public housing stock privatisation

Milestone event in the Serbian housing policy occured in 1990 when the Government put an end to the four-decade financing practice of so-called "social residental building". Privatisation of so-called "cheap flats" primarily was carried out according to the Law on Residental Relations[1] (Official Gazette SRS and Official Gazette RS, 1990) and according to the Residental Law[2] (Official Gazette RS, 1992), after the next five years, resulted in 98 % of privately owned apartments.

Although Serbian government intended to gain remarkable sum of money through the privatisation process and planned to transfer that money to the next residental building cycle, because of the hyperinflation and decentralized manner of flat buyout, the whole process ended without any positive financal impact on the proposed aims.

Serbian Constitution[3] (Official Gazette SRS, 1990) from 1990 had forseen that citizens should satisfy their residental needs by acquireing residental space (flats, residental buildings or houses) on their own, either by buying it or renting it on the free market. Yet, according to the same Constitution, the State was still in obligation to provide a certain public housing stock for socially endangered households.

2.2 Development of residential market after democratic changes in Serbia

Increasing demand for new apartments as a result of rising number of households compared with increased population brought the new concept of housing market. Unlike EU in the 90-ties, where number of households have risen by 15 % and number of apartments was larger than number of households, in Serbia, in number of households increased by 6 % and number of apartment by 7 % (Petovar, 2003). After year 2000 in Serbia there was larger number of apartments than number of households by 8 % (2002 Census) and according to the 2011 Census by as much as 30 % (Statistical Office of the Republic of Serbia). This data confirms drastically increase of demand for the apartments. Present estimate that only in Belgrade city there is a need for 40.000 appartment units supports the previous statistics. On the other hand, rising number of households prompted the increase market of private rental housing units which represent a significant share in total housing stock (today in Serbia there is approximately 500.000 subtenants, including 100.000 in Belgrade alone) (B92, 2008).

Since 2004., in order to encourage and support normal function of housing market, the state established governmental insurance and subsidies for housing loans, enacted an efficient Mortgage Law[4] (Official Gazette RS, 2005) SRS and initiated Real estate registry.

Idea of subsidized loans for real estate purchase is not an invovative, nor is the idea of "mass low cost housing construction", as starting from 1999 local governments have been advertising it, though it was never fully implemented. The establishment of Natioanal Mortgage Insurance Corporation (NMIC)[5] in 2004 was followed by signing of first agreements with approximately 20 banks regulating mortgage procedures that was primarily based on reduction of annual interest rate below 9 % instead of regular 12 %-15 %. According to NMIC data for the period from 2004 to 2008, the total sum of several thousand loans subsidized by the state was about 205 million euros. By the end of 2012 number of such approved loans was more than 70.000 (National Mortgage Insurance Corporation, 2013). For Serbian economic and social circumstances, this type of financing also represents the really good bust for the housing industry.

All these governmental activities are directed towards the attempt to encrease the potential number of solvent clients on the housing market, which has nothing to do with social housing itself. Main doctrine of state's policy still remains the same: agitation for personal possesion of a real estate neglecting noumerous positive aspects of rented housing as an equal housing concept.

3 SOCIAL HOUSING IN SERBIA AFTER YEAR 2000

This complex issue of social housing in Serbia is lead by the fact that social housing are not built just for the low income population at the bottom of the income ladder, but are also needed for the middle income population which is restricted by the high property price, unfriendly interest mortgage rates and can not afford appropriate standard of living at market prices due to overall economic situation.

Untill 2004 housing policy was trying to achieve short-dated political aims, but since then, the need for introducton of new systematic housing solutions, including social housing above all, emerged, although without yet astablished long-term national housing policy.

Serbian government began to act in two separate ways, although without yet astablished long-term national housing policy: First way was to try to support, finacially and lagislatively, production of affordable housing, so-called "cheap flats" for subsidized sale; and the other way was to try to establish public rented housing, but this time based on economic sustainability instead of general social equity proclaimed in communism. The initial impulse for public rented housing foundation in Serbia was SIRP programme. On the other side, several projects of "cheap flats" for subsidized sale have been developed mostly in Belgrade, the capital city of Serbia, while some of them are stlill under construction or in the planing stage. The estimate is that in the past two decades over 15.000 housing units were built in Serbia via state budget and various donations (Mojović, 2009).

3.1 Re-establishing of social rented housing in Serbia after year 2000

The Settlement and Integration of Refugees Programme (SIRP), devoted to solve the housing problem of Serbian refugees from Bosina and Herzegovina, Croatia and Kosovo, was based on the "National Strategy for resolving the problems of war refugees and forcedly displaced persons" from 2002.

Re-establishing of social rented housing in Serbia and all the necessary institutions on the municipal level, as well as the erection of a certain number of social housing real estates (531 flat in total) in the period from 2005 to 2008, are the teamwork results of: seven Municipal Housing Agencies and other communal departments at the local level,[6] amenable state ministries and the UN-HABITAT international experts team. SIRP programme was partly financed by the Italian government with the amount of 15 million euros for covering the 70 % of estimated costs (UN-HABITAT, 2008).

Primal aims of SIRP programme was to conceive, evolve and test the basic elements of future system of social rented housing, as well as housing policies on the municipal level.

The series of architectural and urbanistic competition were held during 2005 and 2006 in order to get the best design solutions for the social housing buildings. Serbian architects showed great interest on this topic, which resulted with over 130 competitional entries in total that were disposable on the seven SIRP competitions.

Fig. 1: SIRP programme – Social housing in a) Pancevo built in 2008 and b) Stara Pazova built in 2007.

---

[6] SIRP programme was realised in seven major Serbian municipalities and cities: Cacak, Kragujevac, Kraljevo, Nis, Pancevo, Valjevo and Stara Pazova.

a)   b)

Fig. 2: SIRP programme – Social housing in a) Nis built in 2007 and b) Kragujevac built in 2007.

Although social housing buildings were built at urbanisticaly and morphologically different sites (Fig. 1, Fig 2, Fig. 3 and Fig. 4), thus unique and recognizable, there are some common characteristics of these sites and buldings, such as:

- Access to the comunal services and infrastructure.
- All buildings consist of small flats (20 m² – 55 m²)[7] for 2-5 tenents.
- All social housing real estates function as multy-dwelling residental housing.
- Buildings have ground floor plus 2 – 4 stories.
- Basement, if there is any at all, is never used for residental purposes.
- There are no lifts in these buildings.
- Additional exterior spaces for common use (playground for children, parking spaces, green spaces with benches, etc.) are obtained in the surrounding of buildings.

User households that were chosen through a transparent system of criteria and selection rules are: refugees, former refugees and local socially endangered population (single parents with children, homeless, families who lived in the inadequate housing conditions, etc.), which means that a social mix have been achieved, according to the European social housing practice.

Fig. 3: SIRP programme – Social housing in Cacak built in 2008.

---

[7] Serbian housing standards define the structure of a flat by counting all the rooms. For example, "two-room flat" consists of 1 bedroom and 1 living room.
Fig. 4 a) and b): SIRP programme – Social housing in Valjevo built in 2008.

3.1.1 Usage and maintenance of new social rented housing stock

These social housing buildings in Serbia are in use only 3-5 years so far, and this period coincide with the first contract period of flat renting. At this moment, it is possible to make a cetrain overview of usage and maintenace of these buildings.

Generally, SIRP programme was targeted to obtain temporary homes for Serbian refugees in municipal owned housing stock. Obviosly, refugees were glad to move from the refugee camps, shelters and collective centers to separate housing units. Generally speaking, these people, before the war, lived in good housing conditions in their native countries, and this program was an attempt to restore their dignity by giving them housing conditions which are familiar to them.

First conflicts between users and Municipal Housing Agencies (MHA) occured when they realized that social flats they are using are meant to be "social rented flats" owned by Municipality and there will not be any subsidized purchase of these, as they expected. Moreover, in many municipalities certain number of chosen users refused to sign 3-year housing contract when they bacame aware they can not become owners of these flats by no means (Damjanovic and Gligorijevic, 2010).

Expectations and demands of users in the first months of using social rented flats were great and unrealistic: they expected Municipal Housing Agencies to repair damage they made, to finance replacements of water boilers, bulbs etc. (according to 3–year housing contract, these were users obligations).

Original enthusiasm of users and their delectation with new homes soon was suppressed by fury and frustration. Suddenly, they felt that social rented housing (as is obvious, is nothing more than temporary solution) can not be adequate way for "permanent integration in Serbia", and they started to wander "what kind of integration can be achieved with temporary housing?".

Whereas SIRP programme was not a donation but a subsidized loan, very precise plan for cost recovery from the flat renting have been made. Programme has forced Municipal Housing Agencies to be obliged to amortize 30 % of the loan to Republic Housing Agency in 30-year period based on annual interest rate of 0,5 %. In theory, this system was meant to be sustainable, but in practice, some arised problems can compromise the entire cost recovery system.

Although rents for social rented flats are lowest possible even for the Serbian standard,[8] Municipal Housing Agencies are confronted with quite a number of users who do not pay their rent regularly or even refuse to pay as a kind of protest for impossibility of flat purchase.

Furthermore, lot of users often delay the monthly payment of their bills for electricity, heating, telephone etc. or do not pay at all. Due to this problem which is present in all municipalities, some Municipal Housing Agencies (for example in Kragujevac) were forced to react: one of the main conditions for new 3-year housing contract is that the user is obliged to pay all his debts.

[8] EUR 25 per month for the flat of 20 m² up to maximum of EUR 88 per month for the 55 m² flat

3.2 Belgrade experience in the social housing development after year 2000

In the new social and legal environment with increased burden of socio-economic problems as a result of so called transition, just ended wars and NATO intervention, Belgrade newly elected authorities starts two parallel activities:

- City Council in cooperation with Funds for financing low cost "solidarity housing" starts Programme of building of solidarity housing 2001-2005, with target of 2000 units, where only 1421 were finished.

- City Council adopts the decision of building so called "social-non-profit apartments"[9] and social apartments for governmental employees and other social categories.

First of such projects was "Project of 1100 flats in Belgrade" in 2003. This project was accompanied by the Decision on conditions and manner of disposal of apartments built according to project "1100 apartments in Belgrade".[10] The ownership of apartments would be still in the governmental hands, but the City of Belgrade could offer it for sale (1000 flats so-called "cheap flats") or rent for the certain period of time to the persons with clearly defined social needs (100 flats – Public Rented Housing), Project was done on the basis of analysis of various available locations owned by city Council, namely Cukaricka padina, Retenzija (Fig. 5a), Vojvodjanska Street (Fig. 5b) and Olge Alkalaj Street. The project was finished by 2007.

a)   b)

Fig. 5: Social-non-profit apartments in Belgrade – a) Retenzija built in 2006 and b) Vojvodjanska street built in 2007.

By the end of 2007 "Project of 2000 social-nonprofit flats in Belgrade" started. Locations proposed for realization of this project were: settlement Dr Ivan Ribar (Fig. 6a), Vojvodjanska Street (Fig. 6b), Cukaricka padina, settlement Kamendin and New Belgrade's blocks 62 and 29. First 1000 units were offered for sale in 2012 following terms of who could be buyers. Buyers that were chosen through a transparent system of criteria and selection rules were governmental employees such as teachers of elementary and high schools, university employees, law enforcement employees, local councils, young married couples, war veterans, artists, sportsmen and disabled persons with their families.

The terms for apartment's sale were 20 % deposit, 20 year loan with 0,5 % annual interest rate. This has provided the possibility for future customer's loan with a maximum of ½ total monthly incomes per household to meet monthly obligation for debt repayment. Price was 1.050 euros per sq. meter. Though it was so called non-profit development, nowhere one could publicly find the price of design, construction and infrastructural part of the selling price.

So far 2.150 "social-non-profit flats" have been built in Belgrade. Due to long lasting planning and other procedures the second project for another 1000 flats is still in the drafting phase.

---

[9] There is "social housing" and there is "non-profit housing building", but there are no "social-non-profit apartments". What amaze is the fact that City government in official communication with public uses non-existent term demonstrating elementary ignorance and misunderstanding term of social housing.

[10] In Serbian: Одлука о условима и начину располагања становима изграђеним према пројекту 1100 станова у Београду, Службени лист града Београда, Бр.20/2003

Fig. 6: Social-non-profit apartments in Belgrade – a) settlement Dr Ivan Ribar and b) Vojvodjanska street, both built in 2012.

Simultaneously, with the construction of social-non-profit flats started the construction of social apartments for renting to people in state of social need in locations: settlement Dr Ivan Ribar (Fig. 7a), Kamendin and Veliki Mokri Lug (Fig. 7b). From the beginning up to today 450 social apartments has been built in Belgrade.

Fig. 7: Social apartments in Belgrade – a) settlement Dr Ivan Ribar and b) Mali Mokri Lug, both built in 2012.

Taking into consideration already mention data, the number of social housing units in Belgrade represent negligible share of housing units in total housing units stock, unlike countries like Germany, Austria and Great Britain where share of social housing units is about 25 % (Petovar, 2003).

3.2.1 Planning and legislative documentation

So-called General Plan of City of Belgrade 2021[11] (Official Gazette of the City of Belgrade, 2003) is the first planning document which clearly defines and introduces the definition of social housing as it is known in developed countries.

General Plan gives the definition of vulnerable social groups which need special attention and help in obtaining adequate housing (young families with income insufficient to purchase an apartment, single parent families, big families with children, refugees, temporarily displaced persons, disabled persons, unemployed, etc.); gives guidelines for social living standards stipulating 5-15 m2 per person; states the criteria for location for social housing and gives two systemic solutions for obtaining locations:

- Construction of social housing dwellings in the planned residential group of more than 250 apartments, within which 5-8 % should be assigned for social housing.
- Construction of social housing dwellings on 58 designated locations of various capacity prevised by General Plan.

In essence, problems which are recognized in Belgrade, and are mostly the same for other locations within Serbia for social and non-profit housing, are (Damjanovic and Gligorijevic, 2010):

---

[11] In Serbian: Генерални план Београда 2021, Службени лист града Београда, Бр. 27/2003

- None existing legislative and regulations which would constitute a consistent legal support and channelling of development of such programs and projects.

- Small number of locations for such purpose – problems arising from obtaining such locations in the existing legal frame. Suggested locations are in accordance with General plan but there are still ownership issues to be resolved.

- Problem of implementation of social housing due to the intolerant neighbouring population – so-called NIMBY syndrome.[12]

- None existing standards for social housing.

3.3 Law on social housing

Final result of these programmes was the Draft of Law on social housing, which task was to initiate legislative establishing of basic instruments and institutions, on both national and local level, that would secure implementation of public intervention in housing policy in Serbia.

Concepts and principles that the Draft of Law proposes are (Damjanovic and Gligorijevic, 2010):

- Public intervention in the realm of housing policy (i.e. social housing) allude to much wider set of measures then traditional concept of social rented housing

- Financial support for social housing programmes should be obtained at the national level, but the implementation should be done at the local level

- System of financing has to be based on non-profit but recoverable cost principle

- All subsidies must be transparent

- Social housing must be based on economical, financial, social and ecological sustainability

Law on social housing[13] (Official Gazette RS, 2009), based on previously mentioned Draft of Law, came into force at the end of August 2009, after several years of legal procedure.

On its very beginning, the Law states that social housing is not a part of some special housing policy, but more likely a part of broader housing policy that has to be defined in the future by changable strategic documents. The realm of public intervention is not bounded by this Law and it purports widest possible comprehension of non-profit, affordable and social housing which corresponds to the definitions of social housing given by European associations.[14]

Law on social housing suggests urgent need of enactment of "National strategy for social housing" and apropriate "Action plan", as well as establishing of Republic Housing Agency. Republic Housing Agency, as an national institution that resembles to those in most european countries, was finally founded according to Law in July 2011. by Serbian Government, but no "National strategy for social housing" or "Action plan" have been enacted or even concidered so far.

First Municipal Housing Agencies (MHA) in Serbia, as major institutions in charge for setting and implementation of local housing policies, in fact were established in 2003, before the SIRP programme: City Government of Nis and Kragujevac transformed existing public institutions that remained from the communimst period (so-called "City Funds for Solidarity Housing Construction") into Municipal Housing Agencies. After that, more MHA-s were established during the SIRP program (Kraljevo, Cacak, Valjevo, Pancevo). Apart from SIRP, MHA-s were found in Leskovac, Kikinda and Smederevo, while there are few more cities an municipalities that are preparing foundation of their own MHA, according to the Law.

4   CONCLUSION

Intensive development of social housing programmes worldwide happened during two last decades when Serbia experienced the toughest political and economic time in its recent history. In the context of socio-economic problems caused by the transition, wars and bombing by NATO, the long-term national social

---

[12] Not In My Back Yard (NIMBY) – English phrase refers to the fact that is generally agreed that there is residential care for socially vulnerable groups somewhere else, "but not in my backyard".

[13] In Serbian: Zakon o socijalnom stanovanju, Службени Гласник РС, Бр. 72/2009

[14] Such as for example: CECODHAS Housing Europe

housing policy has not been established as yet and its clues in practice are still rare. Republic and Municipal Housing Agencies as main institutions are establishing the basic instruments that would secure implementation of public intervention, identifying needs on both national and local level and gaining experience from recent projects and programmes. This paper is aimed in showing the results of two different approaches to social housing policies.

It absolutely clear today that it is not realistic to expect good quality apartments to be give as a "free gift" nowadays to any group of population, no matter how poor it is in the context of today's economic, political and social circumstances in Serbia. The solution maybe lies in the blend of existing models for social housing which in the existing moment has to prevent rigid interpretation of the rules and regulations for housing developments of this kind and create flexibility which will be able to adapt to living dynamism of an individual person. In that sense bigger flats should be built without finishing and interior works opposing to smaller completely finished units. As a result of this model low building price can be achieved and needs of the future tenants easier met, where they would be tailoring the interiors to their taste and will not be spending extra money as it is now, when the full product is on the market. This in return will give more financial space to local government for infrastructure development projects on the designated locations.

Housing construction has to be complex process that starts on the concept phase to the realisation phase going through wide range of carefully selected activities and stakeholders, where the role of the architect as "demijurg"[15] of living space can not be neglected even in the process of decision making and implementation of various housing programs. As there is no relevant experience, rules, models, as well as guidelines for the design of social housing in Serbian practice, recommendations for further research and development should be sought at the intersection of global (European) experience and local (regional) characteristics, in order to find solutions that are socially acceptable and economically feasible.

The disadvantages caused by delays in introduction of housing policy, might be used as advantage by adopting the best experiences and solutions. However, it is of vital importance to identify characteristics of local culture and context, the legislative base, as well as of social housing features, that significantly differ from the standard European milieu. Just with identified local specifics it would be possible to find optimal solutions for further establishing National strategy for social housing and Action plan.

Providing higher public intervention and financial support for social housing programs and establishing set of regulations and standards, as well as straightening connections between national and local institutions, will be of the highest priority for the further development of social housing in Serbia.

Solid Waste Management, an Environmental Challenge in Millennium Cyber City in India, Gurgaon

Sanhita Bandyopadhyay

(Sanhita Bandyopadhyay, Environmental Planner, Phd Scholar, D-79, 1st Floor South City II , Gurgaon, bsanhita2@yahoo.co.in)

1 ABSTRACT

The cities only encompass two percent of the world's land surface, yet they are responsible for consuming over 75 percentage of the planet's resources and produce 75 percentage of the world's waste. The most pressing problem faced by any urban centre in India today is Municipal Solid Waste Management (SWM). Rapid urbanisation and changing lifestyles have led to the generation of huge amounts of garbage and waste in the urban areas. Over the past few years, the handling this SWM has become a major organizational, financial and environmental challenge.

As one of the signatories of the resolutions regarding Agenda 21, India is committed to the implementation of Agenda 21. Accordingly, India is considering applying the Green City concept to Gurgaon City as "Model for Sustainable Urban Management" by incorporating environmentally sustainable solutions with major urban issues in India. Gurgaon is "satellite" town in National Capital Region, Delhi, today turned over a new leaf, joining important position on the industrial map of India challenged by a very fast growth rate and is home to major icons in information technology recognized as 24 x7 hrs city. Its close proximity 25 km to Delhi, the capital of India is become an ideal showcase for the whole of India. A land locked city Gurgaon, with a standard urban area at about 167 square km. and a resident population of about 228,820 in year 2001 become 1,514,085 populations by year 2011. It generates 600 metric tons of solid waste every single day. The collected waste on 15th August 2012 was 521.27 metric tons for ultimate recycle plant whose capacity is only 400 metric ton solid waste everyday. Low lying area near the iconic DLF City (costliest residential colony in Gurgaon as well as in India) is being used for dumping. Close proximity of Aravalli Ridge, an ecological fragile area is another favorable place for illegal disposal site.

The SWM is a low priority. The existing SWM is constrained by institutional weakness, lack of proper funding, management and operational systems, public apathy, lack of municipal will. Waste dumping is the only favorable method to urban local body without any further action. Day by day increasing trend practice of dump to dump yard won't sustain the function. Developing countries, such as India, are undergoing a massive migration of their population from rural to urban centres. New consumption patterns and social linkages are emerging. India, will have more than 40 per cent, i.e. over 400 million people clustered in cities over the next thirty years (UN, 1995). Modern urban living brings on the problem of waste, which increases in quantity, and changes in composition with each passing day. There is, however, an inadequate understanding of the problem, both of infrastructure requirements as well as its social dimensions. Urban planners, municipal agencies, environmental regulators, labour groups, citizens' groups and non-governmental organisations need to develop a variety of responses which are rooted in local dynamics, rather than borrow non-contextual solutions from elsewhere. This paper aims to highlight the major challenges in Municipal SWM in Indian arena with the case study of millennium cyber city Gurgaon.

2 INTRODUCTION

Gurgaon, with a standard urban area at about 167.5 square km. and a resident population of about 1,514,085 (2011 census), the floating population is 1,00,000 per day. Average annual population growth is 18-20 %. The district headquarter is situated in Gurgaon city. Now Gurgaon has become one of the most important corporate and industrial hubs of state Haryana in India. Gurgaon also known as 'Guru Gram' or 'Guru Gaon' (village of the spiritual teacher) was named after Dronacharya, a character in the Epic Mahabharata. It is said that Guru Dronacharya of the Pandavas and the Kauravas gave spiritual instructions to them at this place. The office and manufacturing plant of India's largest car maker Maruti Udyog Limited is situated here as a large number other industries. Another area in which Gurgaon is excelling is the IT industry and software development. Real estate is booming here with new buildings coming up at an astronomical pace. Now this city is chosen for a showcase for sustainable urban development as a model for other Indian cities.

As one of the signatories of the resolutions regarding Agenda 21, India is committed to the implementation of Agenda 21. Accordingly, India is considering applying the Green City concept to Gurgaon City as "Model for Sustainable Urban Management" by incorporating environmentally sustainable solutions with respect to:

- water supply and waste water treatment;

- energy supply, energy savings and renewable energy development;

- waste management, soil pollution and air pollution;

- cleaner industrial technologies and environmental management;

- agriculture and food industries;

- building construction and urban ecology management;

- urban traffic and transportation.

The aim is to achieve lasting harmony between man and nature and to protect the interests of future generations. An integrated medium to long-term planning and implementation strategy, close public-private participation, public awareness and responsibility constitute a basic approach to a holistic solution to urban environmental concerns.

3   GROWTH & EXPANSION OF CITY

Gurgaon city is located at 28°53' N latitude and 75° 35' E longitude and is situated at a distance of 25 kms south-west of Delhi, the National Capital and 285 km from Haryana state headquarter of Chandigarh. It lies at 229 meters above mean sea level and forms a part of the National Capital Region. Gurgaon district is an area of confluence of aravalli hills, Indo-Gangetic plains and Indian desert, Gurgaon urban area can be broadly classified under two district sections namly the HUDA (Haryana Urban development Authority) area and the old town (municipal area limit). The area under HUDA can be further subdivided into (i) private coloniser area, (ii) Huda sector (iii) Institutional area and (iv) the urban villages. The population of Gurgaon including the urban area, the existing town, and the 18 village surrounded by urban development was in 2001 400,000 (HUDA 2001). The projected total population of the urban area for the year 2011 is 1.5 million.

The Gurgaon city has been the head quarters of Gurgaon district, the southern most district of Haryana since 1816, and has exhibited steady growth after the independence of country. Spread over an area of 15.33 sq km the Gurgaon town had a population of 1,73,542 in 1991 and the Gurgaon urban area had a population of 2, 29,243 spreading over an area of 30.2 sq km according to 2001 census. The population density shows that Gurgaon city and urban area are densely populated as compared to the Gurgaon ditrict. The most important factor for this is its close proximity to Delhi. National Highway No. 8 passes throgh its main core of city. This Gurgaon originated as a village called Guru gram. Since that time it has been undercontrol of various rulers who come to rule from Delhi like Maurya, Tomar, Chauhan and Mughals. The Gurgaon district passed into British hands in 1803 and revealed in 1851. In 1966 Haryana took birth and it was designated as district and has been Tehsil and district headquater. The first development pro was started in 1971, 77 and further 82 and NCR in 1989 asigned as important hub for development. In 1981 haryana model has been eveolved as public-private partnership and it was boost up as Electronic City. But it was boost up where Maruti udyog has been set up in 1984 and in 1997 been develop Corporate park.It becomes recognise as Class I town in 1991.The city has developed into 5 phases:

1968-71 1st Phase, 1975-78 2nd phase, 1985-95 3rd Phase, 1995-2001 4th Phase, 001-2021 5th Phase

| 1971 landuse | 1986 landuse | 2001 landuse | Indexing of Landuse | 2021 Propsed landuse |
The existing demographic profile of the city plays an important role in understanding the growth pattern and changes witnessed by the city during the last decade. As per the 2001 Census, the population of Gurgaon urban area (Gurgaon UA andUrban villages) was approximately 3,42,000 (Gurgaon MCG -2,01,322; Towns-47,645; and urban colonizers was about 1,20,000 in 2001). Therefore the total population of Gurgaon urban

area was estimated to be 4,60, 000 persons in the year 2001. Gurgaon has also developed on similar trends as the NCT of Delhi and NCR.

Table 1.1 shows that during the past two decades, the urban population in Gurgaonhas registered a higher growth rate.

Area	Population in Year (No)			Growth Rate in %	
	1981	1991	2001	1981-1991	1991-2001
Urban NCR excluding Delhi	33,51,972	52,73,159	80,12,939	57 %	52 %
Delhi	62,20,406	94,20,644	137,82,976	51 %	46 %
Haryana State Sub Region	49,38,541	66,43,046	86,89,268	34 %	30 %
Gurgaon	1,00,877	1,35,884	2,29,243	34.7 %	69 %

Table 1.1: Growth of Urban Population, Gurgaon Municipal Area. Source: Census of India, 2001

The development plan for Gurgaon published in 1971 estimated the Citys population at 0.125 million. Later in 1977 and 1982, it was revised for a perspective population of 0.225 and 1 million respectively for 2001. The NCR Regional Plan 2021 has proposed the population of Gurgaon could grow to 1.65 million by 2021. However, the Department of Town and Country Planning, Government of Haryana expects the population to grow to 3.2 million. As per Census 2011 the population of Gurgaon is become 1.5 million.

The settlement pattern of Gurgaon city can be categorized as; Gurgaon developed area (HUDA sectors and private housing colonies), urban villages and informal housing or slums. Gurgaon developed area comprise of the residential colonies within the Guraon Municipal Council, and sectors within HUDA area. Approximately 60 % of the total population resides in these. This also includes areas, which have been developed by the private developers.

As per the census 2001, approximately 21 % of the total population of the city urban area lives in the 18 villages within the city. These urban villages have become incorporated in the urban extension.

The city started witnessing the squattering settlement from the early 90s,with setting up of new industries, townships and business parks due to huge influx of migrants. There are currently 14 slums in Gurgaon, accounting to 18 % of the total population of the town.

According to the new guidelines,the population density has been calculated at 48 people per hac, compared tothe earlier population density of 44 people per hac.

4 SOLID WASTE MANAGEMENT SYSTEM IN GURGAON

Rapid urbanization along with increases in population has led to the deterioration of physical environment in Gurgaon. Effective Solid Waste Management is one of the major challenges faced by the local authorities. High volumes of waste generation, inefficient collection and transportation system and limited disposal options are continuously impacting the health, environment and quality of life in the area. Field study indicates that availability of land for disposal is major area of concern in Gurgaon. Real estate boom coupled with NIMBY (Not in My Back Yard) issues have left very less land available for disposal of waste in the urbanized area.

Field observation indicates that large volume of waste is being generated per day within the urban area of which only a very-small portion is being collected and disposed in accordance with the Waste Management Rules of India. It generates 600 metric tons of solid waste every single day. The collected waste on 15th August 2012 was 521.27 metric tons for ultimate recycle plant whose capacity is only 400 metric ton solid waste everyday.

The provision of infrastructure for solid waste management by HUDA is sub optimal. The infrastructure for solid waste include 1.5 cum capacity bins, placed indifferent sectors for collection and three refuse collector trucks owned by HUDA and tractor-trailer deployed by private contractor. A site alone the Faridabad-Gureaon road is being used as a waste disposal site.

Public cooperation or participation in the solid waste management is non-existent at present and careless disposal of waste on vacant plots and streets is prevalent, this has the potential to cause health problems. Absence of a ground and surface water monitoring can not confirm the environmental sustainability of the disposal site.

5 CHARACTERISTICS

The majority of waste is generated by residential, commercial and institutional sources and municipal activities such as street sweeping and drain cleaning. The municipalities do not maintain records of waste generation by source itself. Contractors have kept record for total quantum of collection.

Municipal waste generation in Gurgaon is not formally tracked by MUNICIPAL CORPORATION GURGAON or HUDA. There are no controls or weighbridges at Municipal dumping gounds and no records were available to assist in establishing waste quantities. As a result, no quantitative municipal data is available for estimating waste generation in Gurgaon. The approach in establishing waste quantities used information obtained from other studies conducted in India or on line record of collection of waste by contractors and total potential generation quantum of city.

5.1 Generation

Per capita waste generation had assumed for Gurgaon is 320 gm/day which includes residential, commercial, institutional waste by govt. It is attributed to a number of factors which includes food habits, standard of living and degree of commercial and industrial activities in the area. Currently, about 400 MT of municipal waste is collected per day within the controlled area as per Govt record, of which about 75-80 MT is generated within MUNICIPAL CORPORATION GURGAON (MCG) area and balance is contributed by HUDA sectors, private developers' area, and urban villages. Municipal solid waste in Gurgaon, as per Indian scenario, is expected comprises of 50-52 % biodegradable, 12-15 % dry recycles and 30-35 % inert component. But actually the total quntum is 600 Metric tonns. The Municipal Solid Waste (MSW) generation of Gurgaon city in different areas are as under:

Sl No.	Area	Total Quantity of MSW Generated (MT) per day
1.	Gurgaon Old Municipal Area (MCG)	110
2.	DLF (Private Developers)	35
3.	Ansal (Private Developers)	7
4.	HSIIDC area (Industrial area of HUDA)	70
5.	HUDA area	120
6.	Other Private Developers & Commercial	58
Total		**400**

Table 1.2: MSW Generation (based on study conducted by MCG, 2006). Source: MCG, 2006

Population increases, economic activities and personal income levels will influence future waste generation in Gurgaon. Future waste generation for Gurgaon is calculated based on the estimated population carrying capacity of Gurgaon and the per capita increment in waste generation as 1.33 % per annum based on available national data (MCG, 2013). Waste projection for year 2011 and 2021 has been highlighted in the Table 1.3.

Year	Population	Per Capita Waste Generation (gm/capita)	Total Waste (MT/Day)
2006	1,250,000	320	400
2011	1,514,085	350	525
2021	2,600,000	400	1040

Table 1.3: Waste Projection. Source: MCG, 2013

5.2 Collection & Transportation

Municipal solid waste in Gurgaon is being managed by a number of organizations and there is no single authority responsible for waste management of entire urban area. MCG is responsible for collection, transportation and disposal of waste generated within the municipal limit; HUDA manages the waste generated in HUDA sectors; individual private developers in their respective colonies; and village Panchayat in the urban villages. Municipal Council and the private developer area have some level of waste management system, whereas waste management in HUDA sector is highly dismal and need immediate attention.

HUDA sectors: Waste management in HUDA sectors is undertaken by private contractors, RWAs as well as by permanent employees of HUDA. RWAs with financial assistance from HUDA manages the waste generated in sectors 4,7,9 and13; waste generated in sector 10 and 34 is being managed by HUDA itself and for rest of the HUDA sectors private contractors are deployed for street sweeping, collection and transportation of waste.

There is no planning for waste management system to meet the current or future needs. The provision of infrastructure is sub-optimal. The infrastructure for solid waste includes 1.5 cum bins, placed in different sectors for collection and 3 refuse collectors owned by HUDA and tractor-trailer deployed by private contractor.

Staff deployment pattern indicates that road length to be covered per sweeper is relatively high. About 30 sanitary staffs are in the regular role of HUDA and the balance is provided by RWAs and Private contractor. HUDAs SWM contract with the private operator neither specified the number of work force or road length nor the equipment and vehicles required for collection and transportation. This has resulted in adequate sweeping of the main roads, while interior roads and by-lanes are often left unattended. There is no need-based allocation of waste, which has lead to accumulation of waste in respective pockets.

Public cooperation or participation in the solid waste management is non-existent and careless disposal of waste on vacant plots and streets is prevalent resulting in littering of waste. In addition, absence of a proper monitoring mechanism has resulted in poor supervision of waste management activity.

MUNICIPAL CORPORATION GURGAON manages the waste generated only in the municipal area i.e. Gurgaon Town, with an operational staff of 387 sanitary workers, under the overall supervision of chief sanitary inspector. Storage of waste at source and segregation into organics and inorganics fraction, MSW rules is not practiced and street sweeping continues to be the principal system of primary collection of waste. Although some primary collection system has been initiated in the recent years, it is still in its infancy with no synchronization with secondary collection and transportation. While door to door primary collection has resulted in a dramatically improved level of cleanliness within neighbourhoods; it has resulted in a much dirtier appearance at the secondary storage or community bins abutting such neighbourhoods, as the city service at these collection points is not complementary and adequate.

Three different types of waste storage points exist in MCG area viz. Dhalao (community bin), refuse container and the dumper placer containers. The capacity of the waste storage receptacles is sufficient to store the waste generated within the municipal limits. The system of waste collection is predominantly manual, with only 25-30 % of the waste being collected mechanically using dumper placer container, loader and trucks. Waste transportation is done collectively by municipal and private operator. Although the number of vehicles deployed for collection and transportation is sufficient, designed transprtation network are not followed and waste is not cleared at regular intervals. The garbage clearance efficiency for MCG area is 60-70 %.

PRIVATE DEVELOPER: Private developers have engaged private contractors for door todoor collection, street sweeping, and transportation and disposal of waste. Door-to-Door collection is done by cycle rickshaws and tractors trolley or dump trucks are used for transportation of waste. In the absence of any designated site, collected waste is disposed in the vacant land or amenities in the develop area is also done on contract basis.

URBAN VILLAGES: There is no system of waste management in the urban villages (villages within urban pockets) within the controlled area boundary. Waste is normally thrown in the vacant landwithin or outside the village limit. In some villages, village Panchayat have employed sweeper for sweeping of villages roads

and collection of waste from the doorsteps, whereas in other villages, no proper measures has been adopted for waste management. Households throw waste directly on the streets, and there are no sweeper to collect them. As a result, waste is accumulated on the roads, adversely affecting health of the people and environment of the area.

Apart from different Contractor there is some sanitation contractor also transporting the Garbage to Landfill from some villages/colonies, Approx 50 to 75 ton/day with rate of per ton/per Km basis.

5.3 Physio-Chemical Composition of Waste

Test Results on Physical Parameters of MSW Samples of Gurgaon isprovided at Table 1.4

Sl No.	Physical Parameters	Civil Line Area (MCG)	Station Area (MCG)	Vyapar Sadan, M. G. Road (HUDA)	HSIDC Area (HUDA)	DLF Area (Private developer)	Present Dumping Site	Weighted Average
1.	Paper	1.8	2.0	1.42	1.87	3.3	4.5	2.341
2.	Plastic	3.63	3.33	3.57	3.75	2.5	2.7	2.912
3.	Metal	-	1.33	3.57	6.25	8.3	4.5	3.715
4.	Glass	-	3.33	-	9.37	-	0.9	1.693
5.	Cloth	27.2	6.63	7.14	25	16.6	18.2	15.84
6.	Stone	2.0	20	-	6.29	2	2.7	5.69
7.	Sand & Grid	2.72	2.6	-	2.5	2.4	1.46	1.94

12.	Organic Matter	54.5	53.3	71.4	37.5	54.1	56	56.01

Table 1.4: Test Results on Physical Paramaters of SW Samples of Gurgaon (On Moisture Free Basis in Percentage). Source: MCG, 2013
The overall weighted average of Gurgaon waste physical characteristics is varied. The maxium value is under organic matter. Next is Cloth material and after that leather material which can be reused. The trace of metal in waste is also remarkable notice which shows the unhygienic disposal procedure of waste management practice. The debris quantum is also showing the characteristics of the real estate town. The organic content of the waste was found to vary considerably at various sites due to the variations in origin of waste and it is ranging very high. The average share of this biodegradable component was found to be 56.01 % against 35 % for the national average of Class-I cities in India. Compared to this, the average organic waste content of USA is 11.2 % (EPA, 2004). Around 15-20 % of the generated waste does not reach the disposal sites since part of it gets recycled even before reaching the dumps, part is dumped locally in rural areas, and part of it remains uncollected at several sites. Test Results on Chemical Parameters of MSW Samples of Gurgaon is provided at Table 1.5

Sl No.	Chemical Parameters	Civil Line Area (MCG)	Station Area (MCG)	Vyapar Sadan, M. G. Road (HUDA)	HSIDC Area (HUDA)	DLF Area (Private Developer)	Present Dumping Site	Weighted Average
1.	Free Moisture	36	30	42.39	32.8	34.7	21.4	34.02
2.	Dry Matter	82	61	72	86	62	75	71.5
3.	Volatile Substances	18	49	28	30	48	25	34.1
4.	Ash Content	62	37	46	56.3	42	43.8	47.41
5.	Organic Matter	18	11	24	12	7	30	16.2
6.	Total Nitrogen	0.49	0.36	0.08	0.43	0.43	0.42	0.357
7.	Phosphorus	0.012	0.021	0.032	0.029	0.022	0.024	0.0227
8.	Potassium	0.029	0.029	0.046	0.38	0.040	0.042	0.071
9.	pH(10%)	6.84	7.11	6.29	7.03	6.80	6.0	6.711
10.	Calorific value (Gross cal/gm)	2033	1303	2703	1504	981	3707	1925.1

Table 1.5: Test Results on Chemical Parameters of SW Samples of Gurgaon (On Moisture Free Basis in Percentage). Source: MCG, 2013
The overall weighted average of Gurgaon waste chemical characteristics is more compostable in nature. The maxium value is under dry matter constituting. Next is ash content which is recyclable material too. Organic matter has also high value. Volatite substances are very high which is obnoxious. The pH value is 6.7 i.e acidic which is near to normal. Calorific value is also high. So, overall the content of SW is most suitable for composting plant. Total nitrogen, phosperouys and potassium (NPK) value is marginal.

5.4 Processing and Disposal

1000 TPD Combined solid waste management facility plant set up at Bhandwari (Faridabad-Gurgaon toll road) for processing the MSW for Faridabad (another town) and Gurgaon Municipal corporation in PPP model under JNNURM (Jawaharlal Nehru Urban Renewal Mission) scheme for a project cost of euro. 5.3 million where 50 % fund has been funded by Govt: of India, 30 % by Municiapl council of Faridabad (town of Haryana) , 20 % by Govt: of Haryana and the Land is provided by MCG at free of cost with an agreement between MCF & MCG . The MCG is using the facility for dumping the MSW at the processing plant where no charges incurring for processing the garbage for MCG. The AKC Developers is the Operator for the plant for 30 years and the National Building Construction corporation (NBCC) is the consultant for the setting of the plant. All monitoring & Administrative control is under MCF. This plant is RDF (Refuse Derived Fuel) plant which is taken 600 tons from Faridabad waste and 400 tonns from Gurgaon waste.

In developing countries like India with MSW which has a low calorific value (7.3 MJ/kg compared to values greater than 10 MJ/kg in Europe, Japan and US) and high percentage of inerts, processing of waste is necessary to make it suitable as a fuel. This makes RDF an important alternative to WTE combustion. One of the less expensive and well-established technologies to produce RDF from MSW is mechanical biological treatment (MBT). An MBT plant separates out metals and inert materials, screens out organic fractions (for stabilization using composting processes), and separates out high-calorific fractions for RDF. RDF can also result from a 'dry stabilization process' in which residual waste (after separating out metals and inert materials) is dried through a composting process leaving the residual mass with a higher calorific value

(USEPA, 2010). The RDF thus produced is either used directly as floc/fluff or is compressed to make pellets. RDF fluff (as it is called in India) can be directly combusted in dedicated WTE plants whereas making RDF pellets increases the marketability of the product as they can be used for co-combustion in various solid fuel industries like cement kilns, coal fired power plants, etc.

RDF plants which make fluff are located near Hyderabad, Vijayawada, Jaipur and Chandigarh (other city in India). RDF produced at Hyderabad and Vijayawada is taken to dedicated WTE plants for electricity generation, whereas RDF from Jaipur and Chandigarh plants is transported to cement plants to be used in place of coal.

National Solid Waste Association of India (NSWAI) assuming 6 % of all MSW generated in India is treated in MBT facilities, out of which, 60 % is compost rejects which could be used as refuse derived fuel (RDF), India is currently generating 2.48 million TPY of RDF. Such a huge source of energy is being generated and landfilled every year. This is equivalent to landfilling nearly 4 million barrels of oil because there are no facilities which could use them. This RDF can be used in the already well established solid fuel industry in India. India would have landfilled 58 million barrels of oil in the form of RDF alone by 2041 if there were no RDF co-combustion or WTE facilities to generate energy out of it (NSWAI, 2010). Review the fact RDF is the best posible option for Gurgaon Wsate processing technlogy. It is being calculated that about 1-2 % area of total geographical area of urban premise are occupied by crude landfill site. By using different processing unit the requirement for dumping inert material is about 10 % to total present area. Gurgaon inert material is still disposed nearby RDF plant which should be placed as regional dumping yard far away from city boundary of Gurgaon and other town.

6   ENVIRONMENTAL CHALLENGES

The rapid urbanization process lead too many problems in which solid waste is one of the aspects which are changing the environment of Cyber City Gurgaon. The solid waste management is a low priority but can create social and environmental problem with risks to public health and environment. The existing solid waste management is constrained by institutional weakness, lack of proper funding, lack of proper management and operational systems, public apathy, lack of municipal will to become financially self-sufficient through municipal taxation and whole sole no administrative control on ultimate waste management stage i.e. disposal and processing system. Waste dumping is the only favorable method to urban local body without any further action. Day by day increasing trend practice of dump to dump yard won't sustain the function. The MSW facility with waste recycling plant is planned at a 30-acre (12 Hac) site in Bandwari village at Gurgaon-Faridabad road. Already 50 % land is occupied within 2 years of operation as dunmpyard where it is carrying two towns garbage. So there is a requirement of taking integrated policy and technology to use less land as land is precious. Different part of India's dumpyard has started to reclaimed and process of SWM to reach zero waste city tag. Recycling, composting and ultimate power generation makes this city also zero waste city status. Sanitary landfill system does not make sustainable mechanism process in city development plan as per Agenda 21. Different techonology has initiated in India to become energy efficient mechanism of ISWM process. Delhi the Capital of India has also started year marking step to run RDF. Footstep to sustainable development it is an imperative requirement to understand the basic concepts concerned to the solid waste management practice and bare minimum requirement of land at each level. The following options with respect to solid waste management for cyber city have been described:

- Processing of MSW and recycling of construction and demolition debris (C&D) has been emphasized upon to minimize landfill space requirement.

- Reservation of land for processing and disposal of solid waste in the Zonal Plans suggested.

- The most important concern currently is reduction in land requirement for disposal by maximize appropriate treatment of different waste streams, in order to reduce volumes of waste requiring being land-filled. MCG has privatized collection and transportation in 4 zones under Public Private Partnership (PPP) module. The balance areas are also under consideration for privatization. It is envisaged that gaps in these aspects will be met by the private sector in such a manner that required performance criteria are met. Under transportation total availability of trucks are available but there is shortfall of management.

- The basic thing in waste disposal is separation of polythene, iron and metal, using densifiers and magnetic system. Between bio-degradable and non-degradable, inert material is dumped, while degradable waste will be processed to make manure. By 2021 Processing capacity to be increased to take care of total generation through PPP (1000 TPD) for one city itself. In order to mitigate adverse impact to the environment, the immediate development of incineration process is proposed. Alongside this, the closure, capping and landscaping of existing dump-sites would have to be undertaken. Composting plant is proposed with segreagated compostable waste.

- Household level segragation should mandatory in policy planning stage. Removal of community bin is proposed. This would have to be accompanied by intermidiate transport vehicle to carry out to dispose in ultimate destination (composting plant or landfill site).

- Improvement of service delivery is critical in ensuring that quality of the environment in the city is maintained and should monitor by citizen charter itself. The proper wing under MCG should be developed. In order to build this, sustained training for all the municipal staff as well as staff of any private operator involved in waste management for their capacity building and planning capability, has also been proposed.

- Overall contrary to RDF plant only Biomethanation Technology for electricity from waste should be operated in Bandwari village.

1 ABSTRACT

Industrial areas are among the main land use categories causing locational conflicts in human settlements. In Romania, this type of problem mainly appeared as a result of the forced industrialization carried out in the communist era (1949 – 1989). In this period, compact, multi-family, high density residential areas were built in order to accommodate the workforce necessary to the large industrial platforms developed in close proximity. As a result, some of the city's residential neighbourhoods were developed in the influence area of the industrial sites, negative side effects being neglected in favour of social and economic benefits. In the post-communist period part of these conflicts disappeared with the reconversion of the industrial units, while others changed their characteristics due to their abandonment. New conflicts emerged between declining industrial activities and residential areas because of the unplanned urban development and increased density of the urban fabric.

The paper is aimed to analyze the changes that occurred in the relationship between the residential and industrial areas during the post-communist era.

In order to fulfil the objectives we created a spatial database containing information about the residential and industrial areas in Bucharest for two different periods. We used spatial analysis, models and scenarios for the analysis. The main findings highlighted the surface decrease of residential areas directly affected by the proximity of industrial function due to the reconversion processes and the emergence of distressed brownfields or abandoned industrial sites (which also have negative externalities on the nearby areas still causing locational conflicts). The main tendency characterizing the dynamics of residential areas is represented by the replacement of individual residential areas with collective residential (blocks of apartments) meanwhile the industrial areas are affected by abandonment, reconversion and relocation. In order to establish the appropriate planning solutions for the future management of industrial areas situated within the urban fabric we studied the reconversion process that took place in Bucharest in the last years and analyzed the advantages and disadvantages of each.

2 INTRODUCTION

In 2010, the urban population represented over 50 % of the total world population (UN, Department of Economics and Social Affairs, 2011). Although the surface globally occupied by urban ecosystems is reduced, with only 4 % urban areas with average density over 200 inhabitants/km2 (Small, 2002), the large population and building concentrations generate challenging problems of system sustainability. Specific fields of research were proposed in order to deal with this phenomenon, such as urban ecology, an interdisciplinary approach aimed at understanding the manner in which the human society interacts with ecological processes in artificial and artificialized systems (Marzhuff et al, 2008).

Urbanisation is increasing through the outward spreading of a city, often non-regulated, and/or infill development inside the city perimeter, leading in either case to the appearance of environmentally inefficient human settlements (Pauleit et al., 2005) and low quality of life. The expansion of built surfaces determines the accentuation of certain problems, such as the pollutants emissions, urban heat island, locational conflicts (such as the industrial – residential association) or the absence of adequate infrastructures.

The association between residential and industrial areas represents one of the most frequent land use conflicts. Industrial sites influence proximity areas with negative externalities such as emissions of pollutants in the air, water and soil, noise due to production and transport activities (Sofer et al, 2012), large quantities

of waste (Lejana & Smith, 2006). Consequently, there is a general decrease in the quality of life, while the health risk increases (Morra, 2009; Marques & Lima, 2011). These consequences were for a long time conscientiously or unconscientiously ignored, as industry is an important factor influencing economic growth, contributing directly and indirectly to the creation of services and sustaining large material, energy, human and information flows between the city and its surrounding environment (Ianos, 1987).

Pre-industrial cities were characterized by a division of urban functions, rather on a vertical than on a horizontal gradient (Chelcea, 2008), with a large incidence of housings situated at the upper floors, above shops, workshops, restaurants and other services. With the appearance of large industrial areas and the intensification of commerce and services, residential areas needed isolated from other functions with negative impact on the quality of life and living. Between 1970 and 1980, most of the cities created a system of exclusive zonation for their different functions (Chelcea, 2008). Although initially industry occupied the peripheral areas of the cities, urban growth determined their physical inclusion inside the settlement. Consequently, the industrial activities, some with high environmental and health impact needed relocation. The industrial relocation to the peripheral areas or satellite cities has certain benefits: lower land prices, permissive environmental regulations and fewer administrative levels of control (Chelcea, 2008).

The relation between residential and industrial areas is a complex one. From the economic efficiency point of view, the production and the residential area need to be in proximity, as it reduces travel time and costs for the workforce. The population searches areas with high quality of the environment, often isolated form industrial sites. The two functions are complementary, but the spatial relation is of mutual exclusion. In order to characterize this complex relation, we can use statistical methods (determining the population exposed or segments of sensible population in industries with high impact upon health), spatial methods (mapping of industrial activities in residential areas (Sofer et al, 2012), mapping and analyzing the patterns of residential segregation (Marcinaczak, 2012)), temporal analysis (diachronic analysis), models, scenarios, interviews and questionnaires (exploring the experience of residents in relation with the industrial activities nearby (Sofar et al, 2012)).

In Romania, the characteristics of this relation have been modified by the transition from the communist and centralized system to a market-based economy. The communist period forced industrialization led to a situation where most of the cities had at least one large industrial unit (even if it was unsustainable, the centralized system ensured its survival for social or even propaganda reasons). The post-communist period determined a decrease in the productivity, extractive and manufacturing industries were closed as the subsidies ceased (Ianos, 2004) and the privatization emerged. If in 1989 the industry represented 58.1 % of the national GDP (Ianos, 2004), in 2011 its contribution decreased to 26.28 % (INS, 2012).

The present study has the purpose of analyzing the manner in which changes from the economic and political system affected the spatial relation between industrial and residential areas from Bucharest. Previous studies realized for this area focused on the historical evolution of the industrial landscape in Bucharest (Mirea, 2012), the reconversion of industrial area (Chelcea, 2008) or the present characteristics of the industrial sector (Cepoiu, 2009).

The objectives of this paper are: 1) to analyze the dynamics of residential surfaces located in the proximity of industrial areas between 1990-2011 in Bucharest, 2) to identify the residential areas currently exposed to negative externalities generated by industrial areas in different stages of reconversion and 3) to develop planning solutions in order to minimize the impact of industrial areas on the residential ones.

3   STUDY AREA

Bucharest is the most important political, economic and urban centre of Romania. With a surface of 228 km2 and a stable population of almost 2 millions inhabitants (INS, 2012), Bucharest is an European metropolis struggling with the environmental and planning problems of large urban areas.

The historical evolution of industrial areas in Bucharest can be differentiated into four main stages: incipient industrialization (until 1918), industrial expansion (1918-1944), communist (1944-1989) and post-communist period (after 1989) or de-industrialization. Each stage had its own environmental and landscape impact, influencing the city as a whole and the residential areas in particular.

The industrial surface in Bucharest has continuously increased (Fig 1) from the begining of the 20th century, reaching its maximum value in the final period of the communist era (1976-1989),

Diana Andreea Onose, Ioan Cristian Iojă, Gabriel Ovidiu Vânău, Mihai Răzvan Niță, Cristiana Maria Ciocănea, Delia Adriana Mirea

The industrial activity started with small handcrafting production in the 15th century, in small shops situated generally in the central area of the city, with no separation for the residential areas (Giurescu, 2009). At the beginning of the 20th century in Bucharest 178 industrial units were recorded, with small and non-polluting industries located in the central area and larger ones at that time periphery (now the central ring of the city (fig. 2)). In the industrial expansion period, Bucharest became the most important industrial center in Romania. Since the city developed and increased its spatial footprint, old industrial areas were now comprised within the city, and new residential areas were developed in the proximity of newly created industrial cores (CFR Grivita, Viilor, Titan). Between 1944 and 1989, the communist industrialization led to the development of large compact industrial platforms accompanied by dense residential areas inhabited by the workers (fig.2). The city enclosed in its urban fabric old industrial areas, now with central placement.
Fig. 1: Dynamics of industrial surfaces (ha) in Bucharest in the last century (after Planul orasului Bucuresti, 1911, 1923; Harti topografice 1977, Ortofotoplanuri, 2008; Mirea, 2012).

Building industrial sites next to residential areas was considered the best solution for eliminating the contrast between central and peripheral districts (Giurescu, 2009) in terms of available public infrastructure, as the industrial activity came together with the necessary transport and public utilities infrastructure. Also, this proximity meant cost and time economies for the workers. In the same time, it generated functional conflicts and discomfort for the residents (exposure to pollutants, noise and odors) overlapped over the insufficiency of green areas and the large proportion of built areas.

The industrial areas encountered in Bucharest in 1989 are very diverse. They include industries with an important negative impact on the environment (~22 % of the industrial areas) such as chemical industry, rubber industry, plastics industry or energy industry, industries with a medium negative impact on the environment (~41 % of the industrial areas) such as machinery industry, transport industry and industries with a low negative impact on the environment (~37 % of the industrial areas in Bucharest) such as food industry or textile industry.

The post-communist era (1989-present) is characterized by the relocation of industrial activities outside the city; process that may generate abandoned distressed brownfields (Dingsdale, 1999), and the reconversion of certain activities. The chaotic development of residential areas due to a lack of legislation represents another phenomenon characterizing Bucharest.

Currently, the residential areas in Bucharest are represented by two main categories: the low density residential (single unit housing or individual residential) which represents 15.15 % of the surface of the city (57.44 % of the surface of residential areas in Bucharest) and the multi-family, medium or highly dense residential areas (multi unit housing or collective residential) which represent 10.26 % of Bucharest surface (38.9 % of the residential areas in Bucharest).
Fig. 2: Residential and industrial area in Bucharest (2011)

4 DATA AND METHODS

In order to assess the spatial and temporal dynamics of the residential areas exposed to industrial function a spatial database was created. The geospatial information was extracted using the 1976 edition of the topographical maps (scale 1:25.000) and 2008 edition of aerial images with an average resolution of 0.5 m (www.ancpi.ro). We used as a start point for the analysis the 1976 maps. We considered such an approach is suitable because the large industrial platforms in Bucharest were already built at this point in time and so were the compact, multi-family, high density residential areas which are the main characteristics of this period. We couldn't use satellite images to cover the 1989 moment because even if they permit the differentiation of built and natural areas, the identification of different kinds of functional zones inside an urban area is almost imposible (Chen et al, 2011) being suject of personal interpretation of the urban morphology.

The spatial database contains information about the localization of different categories of residential areas (low density residential areas or individual residential and multi-family medium or high density residential areas or collective residential) and industrial surfaces, their surfaces, the current situation of industrial areas (abbandoned or demolished industrial areas, active industrial areas, industrial in conversion and industrial areas affected by improvised conversion) and the main tendency regarding the conversion phenomenon (conversion in residential areas, comercial units, offices building, transportation areas or other uses). The database was validated through field surveys realized in random points.

We used the multiple ring buffer method (a proximity analysis), with an option of excluding the surface of the industrial areas from the resulted buffer (Sumathi et. Al, 2008) for extracting the residential areas situated at certain distances from the industrial areas. For the multiple ring buffers we used the distances mentioned in the Romanian legislation (Order 536/1997) – 300m, 500m and 1000m corresponding to areas strongly, medium and little affected by the industrial function. These distances correspond to the protection areas that should isolate certain industrial activities according to their level of aggresivity in relation with the environment or the human health. Beside the proximity analysis that took into account all industrial areas existing in 1976 and 2011 in Bucharest, for the second moment of interest the analysis was realized also using as imput only the still active industrial areas and the abandoned or demolished ones, as these two categories were considered capable to affect in a negative manner the residential located in proximity. The other two identified categories, industrial in conversion and industrial aggectef by improvised conversion, were considered to have a considerable lower potential of causing problems or discomfort to the nearby residential.

The spatial and temporal dynamics analysis and the modeling of the relation between industrial and residential areas were conducted in ArcGIS 9.3 (Environmental System Research Institute, California, CA) and the statistical analysis was realized in Microsoft Office Excel.

5 RESULTS

The residential area in Bucharest represents around 25 % of the city's surface both in 1976 and 2011. The difference is made especially by the change that took place in the structure of the residential, not in its surface.The spatial analysis highlighted that the main process that characterize the final period of the communist era is the transformation of low density residential areas (individual residential) in multy-family, medium or high density residential areas (collective residential). This process affected about 3 % of Bucharest surface (~15 % of the area occupied by individual residential in 1976 which is considered the start point of the analysis) and resulted in the construction of Rahova (fig. 2) and Crangasi neighborhoods and of the area between Unirii Square and Titan neighborhood.

The figures underline the stagnation of the residential development in the first years of the post-communist period. After 2005 there can be noted a new tendency in the direction of residential areas expansion (~1 % of Bucharest surface is converted to residential uses).

Regarding the industrial areas, their surface increased by 6 % (which means 0.75 % of Bucharest surface) untill 2005. That is if we include in this category all the industrial areas (many of them closed, abandoned or demolished) which still kept their image and characteristics untill that moment in time. The real conversion process of industrial areas started in Romania after 2005. The spatial analyze, validated through random field surveys, highlighted that the traditionally industrial areas in Bucharest are divided in 4 categories (Mirea, 2012): abandoned and/or demolished industrial areas (12.41 % of the surface occupied by industrial areas in 2005), active industrial areas (47.75 %), industrial in conversion (15.52 %) and industrial affected by improvised conversion (24.3 %) (fig. 6).

In order to evaluate the surfaces of residential areas exposed to the industrial function side effects, a proximity analysis was realized (fig. 3). It highlighted that in 1976 92.57 % of the collective residential areas were located at less than 1000m from an industrial unit (34.94 % within the first 300m, 26.03 % between 300-500m and 31.59 % between 500-1000m) (fig. 4). The percentage was inferior in the case of individual residential – 80.06 % (33.21 % within the first 300m, 18.23 % between 300-500m and 28.6 % between 500-1000m) (fig.5). The situation remains almost the same untill 2005 (94.1 % of the collective residential at less than 1000m from an industrial unit (fig. 4) and 79.03 % of the individual residential (fig.5)) with the most important modifications in the surface of the collective residential situated within 300m from an industrial facility. The increase of 5 % is especially due to the construction of Rahova neighbohood in the proximity of Progresului Industrial Platform.

Interesting to notice is that 65 % of the residential built between 2005 and 2011 is also located in the first 1000m from the industrial units (22.27 % at less than 300m, 21.63 % between 300-500m and 21.88 between 500-1000m).
Fig. 3: Distance from industrial areas in Bucharest (including the industrial surfaces which were abandoned, demolished or converted) (2011)

The proximity analysis was also realized for the active industrial areas (fig. 6) and for the abandoned and demolished ones as they were categorized in 2011. Only these two categories of industrial were chosen for the analysis (of the four identified) because these two are the ones which generally cause locational conflicts when situated in the proximity of a residential area. The collective residential areas were were exposed in proportion of 57.25 % to the active residential areas (9.46 % in the first 300m) and 51.76 % to the abandoned and demolished ones (14.01 % within the first 300m) (fig. 4). Meanwhile, the individual residential had 40.66 % of its surface affected by active industrial areas (10.58 % within the first 300m) and 51.29 % (12.22 % within the first 300m) by abandoned and demolished industrial sites.

The residential areas built after 2005 have a good localization in relation to the abandoned and demolished industrial areas only small surfaces being in their proximity (2.92 % within the first 300m and 18.32 % within 1000m) but an average one in relation with the active industrial (15.28 % within the first 300m and 54.77 % within 1000m).

Fig. 5: Percentage of individual residential areas (of the total surface of individual residential in Bucharest) affected by the industrial function

6 DISCUSSION

Once the communist era ended and the market-based economy begin to replace the centralized system, the expansion of built up areas (both residential and industrial) in Bucharest stagnated. The construction projects left unfinished by the previous regime were part abandoned and part finished after years. However there can be noticed the tendency of ignoring the potential problems that could raise from the vicinity of industrial areas when building new residential.

Regarding the residential areas, the communist era was characterized by the transformation of individual residential areas in collective residential ones and the post-communist era at first by stagnation in construction works, and after 2005 by urban sprawl and infill development.

The reasons that triggerd the transformation of individual into collective residential in the communist era were the desire of maximizing the accomodation capacity of the city in order to assure the needed number of workers in a developing economy (Rahova neighborhood was built in the proximity of the industrial units which formed Progresului Platform), the implementation of important planning projects and the desire for improving the quality of life and the image of the city (the construction of Morii Lake which closed the flood protection system of Bucharest lead to the disappearance of part of a slum area, while the rest was transformed in multy-family high density residential; the extensive demolition works in the center of Bucharest carried out in order to make room for the House of Parliament were followed by te remodeling of the area and the construction of both administrative and residential buildings).

The dynamics of industrial areas in Bucharest was influenced by the political and economic measures that characterized the first years of post-communism. In those years the industries received important subsidies which helped even the unsustainable ones to continue to function. Slowly, with the subsidies termination, part of the industrial units closed, others were abandoned and some were privatized which in many cases led to the previous mentioned situations. After 2005 the conversion process of industrial areas became an important factor in shaping Bucharest landscape. With the closure of many industrial units, more than half

(52.25 %) of the industrial area previously existing in Bucharest changed its use. As a direct consequence the residential area affected by this locational conflitct almost halved.

Fig. 6 shows that active industrial areas are situated almost entirely in the peripheral areas of Bucharest, the industrial areas near Bucharest central road ring (fig. 2) being abandoned or in conversion. 12.41 % of the ex industrial areas are currently abandoned or demolished, representing brownfields (Oliver et al, 2005). Currently they cause a locational conflict through the negative externalities they produce (PM, odors, noise, historical pollution, feral and stray animals, etc) but better planning solutions may increase the environmental quality in those areas.

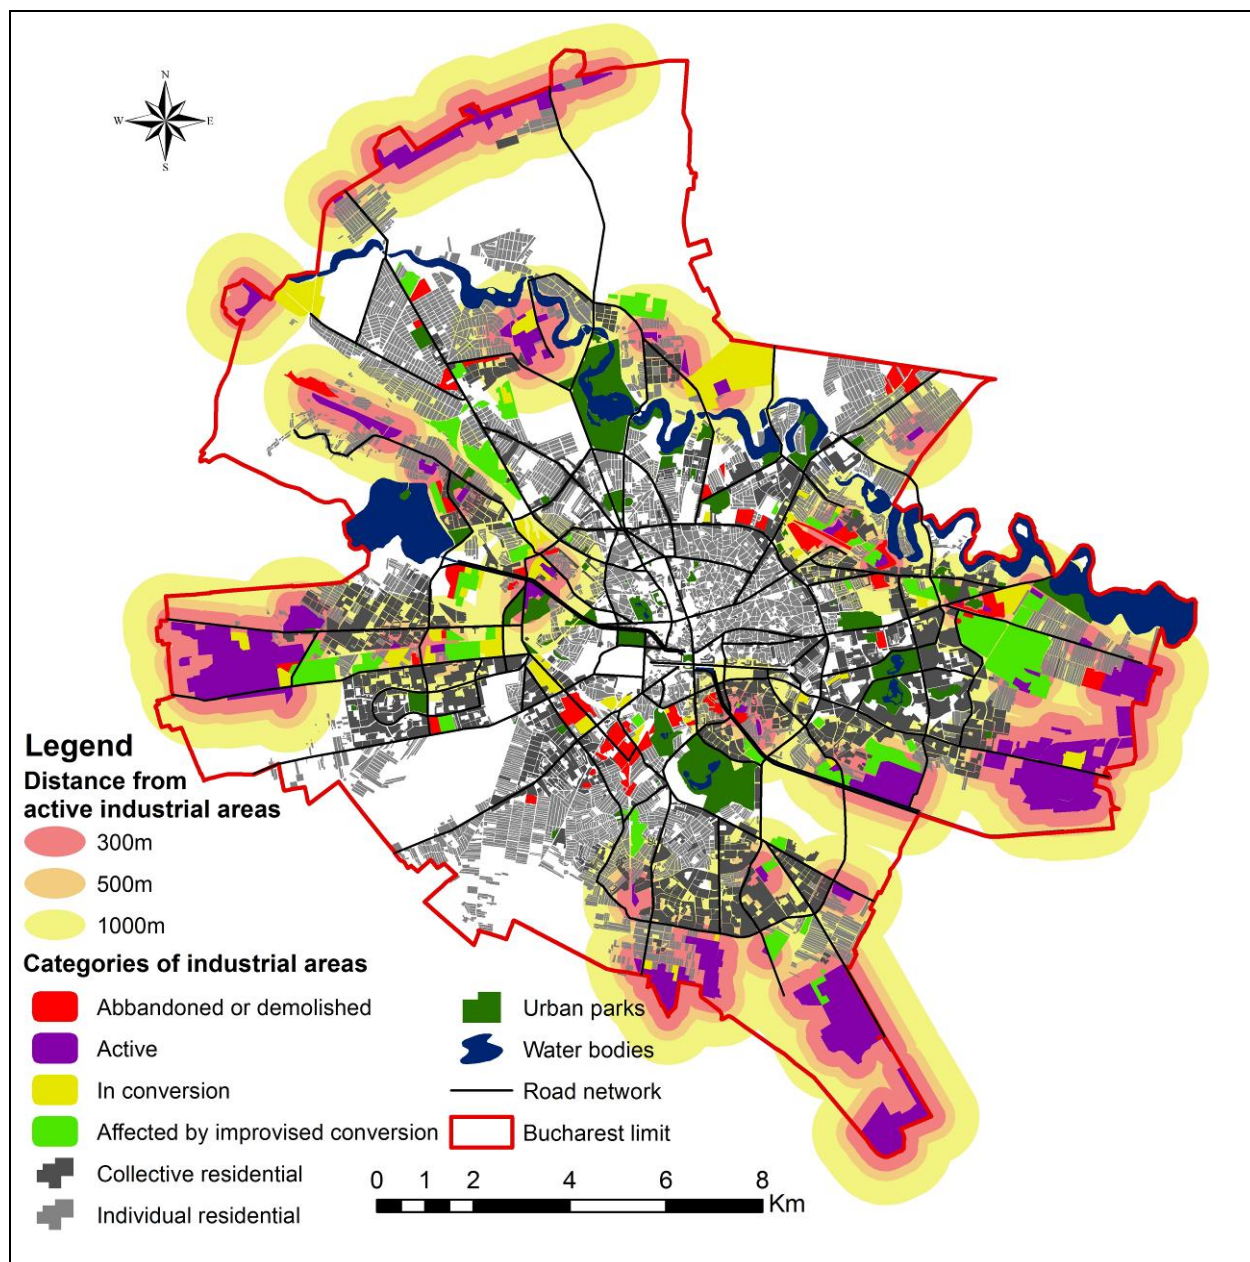
Stratton (2000) has identified five directions of the industrial conversion: comercial areas, small and performant industries, residential areas, offices and cultural or retail use. The most used conversion solution in Bucharest appears to be the transformation of previous industrial areas in important commercial facilities (hypermarkets or malls), 35.91 % of the surface of already converted industrial having this function. This surface will increase more once the already approved projects of comercial centres will transform more of the relict land in comercial area. The rest of the industrial surface was converted in offices (38.48 %), residential areas (7.73 %) and other uses (17.84 %). Just a little part of the converted industrial area kept its industrial function and that was possible only due to new approaches such as organizing units for the assembly of different products.


Fig. 6: Categories of industrial areas in Bucharest and the surfaces they affect (2011)

It is important to mention that the distances of 300, 500 and 1000 metres, used in the analysis, were taken from the Romanian legislation. They may vary in other countries and should vary in relation with the magnitude of the negative impact the industrial activity may cause to the environment or human health. Also important is that if an industrial area is separated from a low density residential area by a front of high buildings (offices, collective residential) the latter may not be exposed to the negative impacts the industrial area produces, but the front of high buildings will be affected more. Such an analysis may be the subject of a future research along to the correlation of people's perception of industrial areas and their conversion with the area where they live.

7 CONCLUSION

The study area represents a good example of the changes that can occure in a post-communist city with important economic and demographic impact. It offers an exemple of how a neglijent planning (both from an economic point of view and a territorial one) can lead to locational conflicts of high spatial importance. Although currently the surface of residential areas directly exposed to industrial function has decreased, the diversity of locational conflicts caused by the former industrial surfaces has diversified (emergence of abandoned and demolished areas, brownfields, new uses that may still not fit to the proximity of residential areas). A special attention must be directed to the conversion of industrial areas because this process may importantly increase the environmental and life quality in the proximity by promoting projects suitable for each area.

Spatial Resilience of Megacities based on Conceptual Model from Concept to Implementation. Case Study: Greater Cairo, Egypt

Ahmed Abdelhalim M Hassan

(Ahmed Abdelhalim M Hassan, Institute of Landscape Ecology, Muenster University, Robert-Koch str.28, D-48149 Muenster, Germany, e-mail: ahmedahalim@uni-muenster.de)

1 ABSTRACT

Analysis and understanding of megacities' properties such as rapid spatial growth, rate of population increase and development, loss of fertile land, urban sprawl, water and air pollution, and others are becoming a sophisticated and a complicated task in environmental management approaches especially in developing countries. The European Environment Agency recommends a concept which distinguishes driving forces, pressures, states, impacts, and responses (DPSIR) to develop a strategy for integrated environmental assessments.

In this study, the DPSIR model is used to identify and to determine the framework to find and describe the development indicators of megacity in relation to ecology and environment and also to provide a deduction of main transformer indicators in Greater Cairo.

Accordingly, the relationship between the human activities (society) and the dynamic processes of land-use cover change are understood and implemented into management strategies. Hence, the population growth and fast increase of investments represent the main drivers which lead to environmental and spatial changes in land use and land-cover. As a result of exerting pressure, the state of urbanization and losses of fertile land are major indicators of transformation that shows dynamic processes through the DPSIR chain. Therefore, the spatial monitoring can identify hot-spots (objects) of changes. Based on the application of DPSIR model and their looping mechanism, new planning strategies could be elaborated to improve management of a megacity such as Greater Cairo.

2 INTRODUCTION

Megacities are increasingly vulnerable systems because they often harbour pronounced poverty, social inequality, growing pressure and environmental degradation, all of which are linked together by a complex system supplying goods and services (Megacity report 2005 http://www.yearofplanetearth.org/). That figures out the scale of the challenge to understand and analyse megacity's indicators such as rapid growth, rate of population and development, loss of fertile lands, urbanization sprawl, water and air pollution, and others in developing countries. So, this is one of the main challenges faces the studies of a rapid development of big cities; because the fast growth is accompanied by dramatic changes in the socio-environmental structure and land utilisation.

To monitor such complex changes for sustainable information and to integrate and manage the relation between indicators, a conceptual model and a good tool to support the management of ecosystems is needed. In a similar way, Ines et al., 2004 stated that, determination of indicators is an excellent way of representing the environmental components avoiding the measurement of too many parameters. Indicators are often adopted to avoid and reduce the complexity of environmental data. However, most conceptual models deal with ecosystem in one direction of analysis such as; from top to down (i.e., hierarchy constitutes), key constitutes to link and find relation between elements, and fuzzy which concerns with the changed core and fuzzy boundary in system. Furthermore, Cumming et al. (2005) defined a resilience social-ecological system as consisting of essential actors, components, and interaction. And the system identity consists of maintaining these elements through space and time. The state of susceptibility to harm from exposure to stress associated with environmental and social change is mentioned as "Vulnerability" by Adger (2006). Regarding the sustainable development and sustainability, Norberg and Cumming (2008) responded them as "the equitable, ethical, and efficient use of natural resources".

3 CONCEPTUAL MODEL

Because of the spatial and temporal scope of the phenomena addressed by social ecological system (SES) theory ranges from local to global and over time scales that are relevant to human usage of natural resources (Pickett et al., 2007).

In this point of view, some authors described and simplified the system complexity of the real world to capture key aspects of interest of social ecological system.

Holling (1995) simulated hierarchies framework of complex system based on agent-based model, and he at (2001) proposed that social-ecological system are composed of series of interconnected adaptive cycle at different scales. While, Kay and Boyle (2008) assumed hierarchies of structures and processes; focuses on flows, feedbacks, and thresholds based on self-organization of resources dissipation (energy). And, Ostrom (2009) divided the social-ecological system (SES) into four interacting levels: resource units, a resources system, a governance system, and users, which aimed to identify relevant variable and provide a common set of variables for organizing comparisons of similar SES.

In order to develop a strategy for integrated environmental assessment, The European Environment Agency (EEA) recommended a concept, which distinguished driving forces, pressures, states, impacts, and responses (DPSIR) (Figure. 1) that has been developed by OECD (The Organisation for Economic Co-operation and Development).

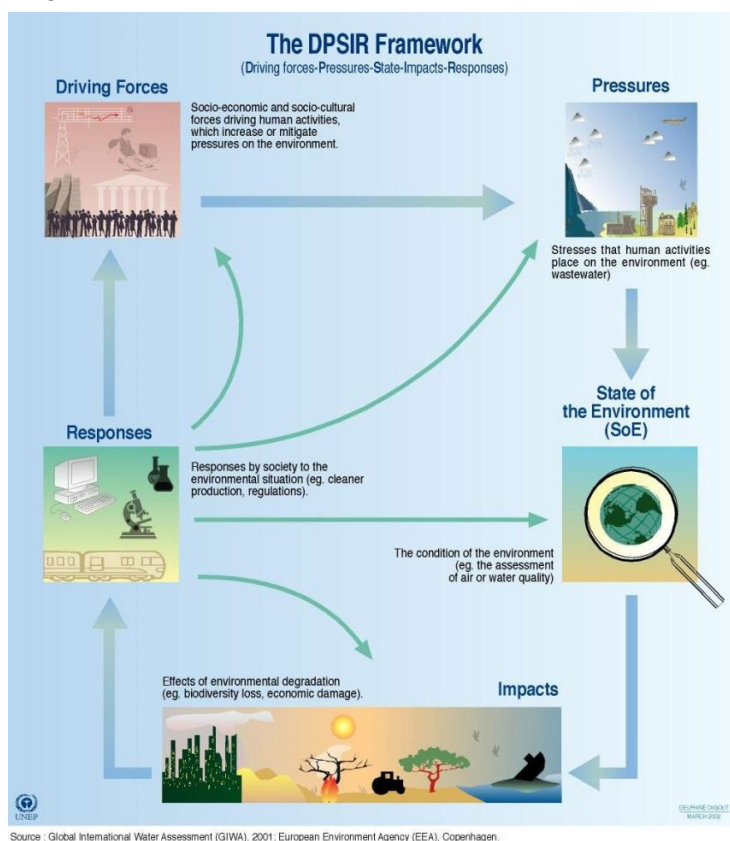
Furthermore, DSPIR described by Kristensen (2004), Mara et al. (2007) and others as a logic relations and causal links of the bulk of socio-environmental reactions starting with 'driving forces' (functions and activities that exert pressures on the environment) through 'pressures' (the act of driving forces on the environment) to 'states' (the influence of acting pressure on the environment) leading to 'impacts' (the reactions of environment due to changes of states) , which eventually may lead to political "responses" (prioritisation, target setting, indicators).


Fig. 1: DPSIR scheme.

4 STUDY AREA

The selected area of study is the metropolitan area of Greater Cairo and its surroundings, which is known as the capital of Egypt and one of the fastest growing megacities worldwide (Figure 2). The area covers about 600 km2, encompassing major parts of the governorates of Cairo, Giza, Six October, and Helwan. The Nile forms the administrative division between these governorates, with Cairo and Helwan on the east bank of the river and, Giza and Six October on the west bank. The area includes a variety of land uses associated with a complex mix of land cover, such as a central business district (CBD), urban/ suburban residential areas and

some rural areas (e.g. cultivated areas and soil). This area has encountered rapid urban development and population growth in the last 20 years.

Consequently, immense strain put on cultivated areas in the greater Cairo from a serious problem of urbanization. This problem has caused an irretrievable loss of very fertile suitable soils. A very severe status and rate characterized the problem while the risk is severe.
Fig. 2: Location of the study area

Consequently, immense strain put on cultivated areas in the greater Cairo from a serious problem of urbanization. This problem has caused an irretrievable loss of very fertile suitable soils. A very severe status and rate characterized the problem while the risk is severe.

5 GREATER CAIRO MODULES IN THE LIGHT OF THE DPSIR FRAMEWORK

There is many socio-ecological indicators are identified in Greater Cairo metropolis (Figure 3) which are concern the rapid increasing and physical change of the city. This means that, the scope of conceptual framework for such megacity (G.C) in current study would be included historical and/or temporal questions, such as how rapid development drive land use and land cover changes.

The author mentioned that the application of DPSIR-model on monitoring of mega-city meets most of components identified and described in other previous theories and frameworks concern the social economical system.

So, in this study, the DPSIR model used to identify and to determine a framework to find and describe the development indicators of megacity in relation to ecology and environment, and also to provide a deduction of main transformer indicators in Greater Cairo Metropolis.

Hence, the environmental status scheme (DPSIR), which could be applied for G.C is described as following (Figure 4).

By using the DPSIR scheme mentioned above, the relationship between the driving forces and the dynamic process of land use are guided in G.C. Hence the population growth and fast growing of investments (human activity) were representing the main drivers, which lead to environmental and spatial changes in land uses and planning. As a result of exerting pressure on the land, the states of Urbanization and loss of fertile land will be concerned in this study as major transformer indicators implemented and linked between dynamic processes through the DPSIR chain. Moreover, the spatial monitoring was applied to determine what and where the effect of the failures were and to put them into place responses to manage these changes.

Accordingly, the relationship between the human activities (society) and the dynamic processes of land-use cover change would be understood and implemented into management plan.
Fig. 3: The main megacity's indicators.

6 CHANGE DETECTION BY USING REMOTE SENSING TECHNIQUES

Remotely-sensed information is of particular relevance in the worlds developing countries because it provides fundamental information on growth-related processes and their effect on the environment that are not available from other sources (Miller & Small, 2003). Hence, this study describes and discusses different remote sensing (RS) techniques to monitor and analyse dynamic expansion and change detection in Greater Cairo Metropolis. While the availability of different resolutions of satellite images, which launched in different dates by different sensors, encouraged most of spatial and environmental planners to specify different applications to improve spatially and spectrally historic data and collected information of the land. Furthermore, archived remote sensing data has been used to examine the possibilities of multi-temporal imagery for mapping and monitoring changes in land cover (Sobrino and Raissouni 2000). As well, monitoring information can then be combined with different layers to help predict which areas are affected in the past and which could be at risk in the future, allowing secure decisions to be taken where it is needed most. Therefore, successful utilization of remotely sensed data for land-cover and land-use monitoring requires careful selection of an appropriate data set and image processing techniques (Lunetta, 1998). Consequently, Landsat 5TM and 7 ETM+ provide an opportunity to extend the area and frequency with

which we are able to monitor the Earth's surface with large geographic cover (Curtis 2001). This address that monitoring LULCC on large cities could be processed and give fast-recent information of alternative indicators, which are dynamically and dramatically transformed.

Recently, change detection of a particular object between two or more time periods, which lead to produce a quantitative spatial analysis in an area of interest (Macleod and

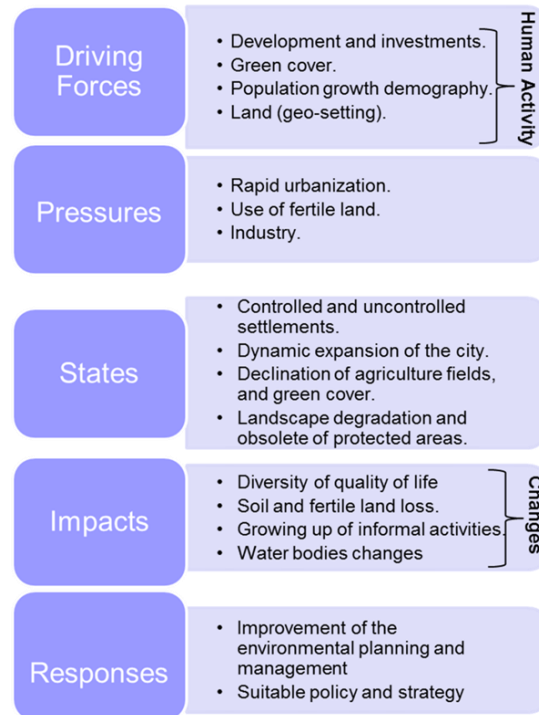
Congalton, 1998), are provided by several remote sensing satellite sensors. Thus, different satellite systems have different characteristics, e.g. resolutions, number of bands, and have their own importance for different application.


Fig. 4: General scheme of DPSIR for Greatre Cairo.

7 MATERIAL AND METHODOLOGY

7.1 Data

Beside the ground information, the selected satellite data and its time span represented the whole study area spatially, and two main phases concern the rapid development, expansion of infrastructure services, and investment economically. To classify the whole area of Greater Cairo metropolis during the last two decades of the last century and the first decade of new millennium, the low to medium resolution images of Thematic Mapper TM and Enhanced Thematic Mapper ETM were used with about 28 m pixel size.

The close relation between land use cover changes and economic growth and reforming has been putting on the track of change detection researchers and they emphasized some phrases. For example; Luc 2001 mentioned that a spatial econometric approach is not exclusively a consequence of the nature of the data, but may also be required to quantify the "spatial" components of a theoretical specification.

Therefore, the three different time series with sixteen years difference started from 1884 (which is considered as the reference year for the other images), then 1990, to 2006 have been chosen. Consequently, the time span from 1984 to 1990 represented the continuity of a phase of market economy which was introduced at the end of 1970´s by Sadat's regime (http://www.mideastweb.org/egypthistory.htm). From 1991 Mubarak undertook a number of important laws and decrees which have been significantly reformed the domestic economic program to reduce the size of the public sector and expand the role of the private sector (IDRC report 1996).

7.2 Image processing

If A series of processing operations was performed on these images. The images were georeferenced using UTM map projection for zone 36 and WGS84 datum. The images were resampled to 30 m for bands 1, 2, 3, 4, 5, 7, to 15 m for panchromatic and to 60 m for thermal bands using the nearest neighbour technique. In order to produce a test area, false colour composites from ETM+ bands 7, 5 and 3 were used, while all of the six bands (ETM+ bands 1, 2, 3, 4, 5 and7) were used for pixel-based classification.

7.3 Object-based classification

Since pixel-based analysis in complexly structured land-use and land-cover (LU/LC) areas is limited because the semantic information necessary to interpret an image is usually not represented in single pixels, and also, the statistical independence assumption pixel-based classifications involve the DN values individually without considering the neighbourhood pixels (Castelli et al., 1999), the Object segmentation module was used for object-oriented analysis and classification.

Segmentation is the main process in the classification module in eCognition Developer software and its aim is to create meaningful objects. This means that an image object should ideally represent the pattern of each object in question. This pattern combined with further derivative colour and texture properties can be used to initially classify the image by classifying the generated image objects.

Thereby we found that, the classes are organized within a process tree and sophisticated class hierarchy that has been compatible with the concept of DPSIR framework and it looping mechanism.

In other hand, the multi-scale behaviour of the objects can construct a semantic hierarchy by detecting a number of small objects, which could be aggregated to form larger objects (Matinfar et al. 2007). The latter is used for back-forward analysis.

8   IMPLEMENTATION OF LUCC BY USING DPSIR

The main selected elements of land use / land cover (LULC), which have been examined and classified, are investigate the relation between human activity and landscape surface in Greater Cairo (G.C) and expose their linkage status and impact. For the sake of classification and monitoring, the six land classes were considered to refer to the urbanization (dense and lose), cultivated, surface water, desert (hinterland), cultivated-to-urban areas, and bare soil. These classes provide a practical means to dynamic change in spatial resilience to achieve management objectives, and also, they can be used for predicting coming changes and assessing development challenges.

As we addressed before the needs of conceptual model to explore key aspects of human-environment relations in Greater Cairo metropolis, here is the first impression of the implementation of DPSIR model to clarify the interaction between different stages in this model and land classes selected for Greater Cairo regarding the back-forward mechanism (Figure. 6).

According to, Luc (2001) concluded that the uses of an appropriate" spatial" methodology can one hope to discover the "true" underlying relationships. This study assumed that the land classes or indicators in the term of land use/cover classification are representing the spatial driving forces, exerted pressures, and affected states of increasing or shrinks of Greater Cairo. In spite of the population rate are changed through the time span but it is represented here as static indicator during the spatial classification of each selected year. While the other indicators defined as anthropogenic drivers such as "urbanization, cultivation, and artificial water bodies" and natural drivers such as (natural surface water and geo-cover). These indicators defined as dynamic drivers which could be detected and monitored spatially by using remote sensing techniques. As a result, the impacts of the human activity could be reanalysed and implied as driving forces in sub-scheme of DPSIR, that mechanism is called here internal looping process or reiterate analysis.

Therefore, this study modified the DPSIR scheme to be adapted and used effectively in back-forward manner in spatial analysis of a Megacity knotty system. That permits to reselect elements (objects) within the system and repeat the analytical process through the system framework. This process named by author as "Looping Mechanism" of spatial analysis and resilience.

The back-forward (Looping Mechanism) is working by two ways regarding new data or information coming from the change of time span and/or spatial information (resolution). The first one (main vision) is the flexibility to add and modify the data through the main framework (Figure 6). The second one (minor vision)

is the ability to extract from the main framework a specific object and reanalyse and monitor it by using subsidiary DPSIR scheme (Figure 7). This means that, the monitoring system of spatial changes took place, which leads to irritation iterate of change detection program in any level of working flow and prospective date. For instance; choosing the green cover and urbanization changes as main objects to use them separately in work scheme and monitoring system has been applied (Figure 7).

9 RESULTS

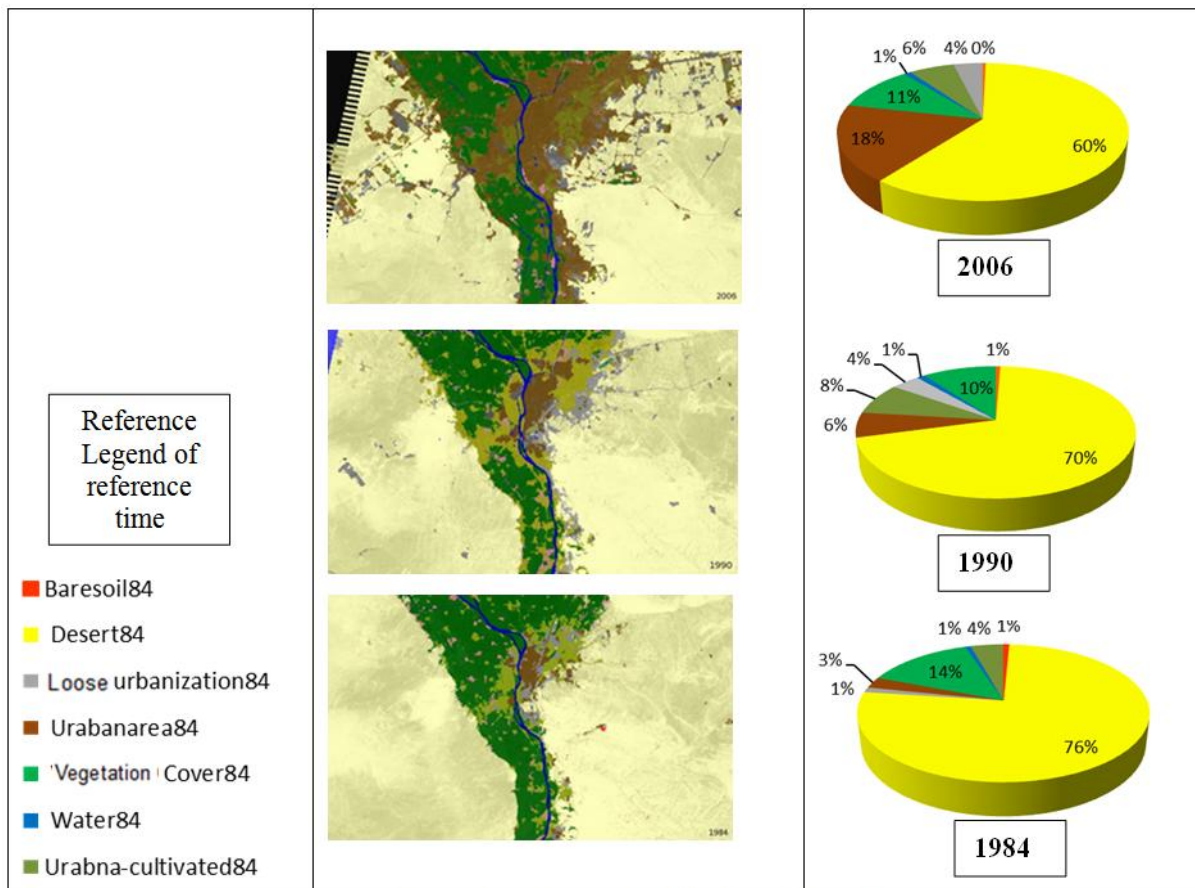
The analyses of LU/LC state of each year in different time series show that, the mutual linking between the six environmental indicators is representing a first level of classification (Figure 8) (Table 1). This level of classification can lead directly to individual time response. This response is ineffective for growing cities and monitoring studies. As a result, the subsidiary DPSIR frameworks and other level of classification were applied to compare and detect the change of any key element (object) separately such as agriculture activity (green cover) and urban development through time span is based on and part of the main frame work and classification tree (Figure 7, 9&10).
Fig. 6 (left): Implementation of LUCC analysis by DPSIR. Fig. 7 (right): Back-forward process analysis (Looping Mechanism)of changed indicators by using DPSIR for G.C.


Fig. 8: The classified images and their distribution analysis.

LU/LC (Land use/cover)	1984 %	1990 %	2006 %
U (Urban areas)	3	6	18
CL (Cultivated land)	14	10	11
CU (Cultivated to urban)	4	8	6-
D (Desert area)	76	70	60+
BS (Bare soil)	1	1	0+
WB (Water Bodies)	1	1	1
(LU) Loose Urban	1	4	4

Table 1: Land cover-use change analysis of Greater Cairo.

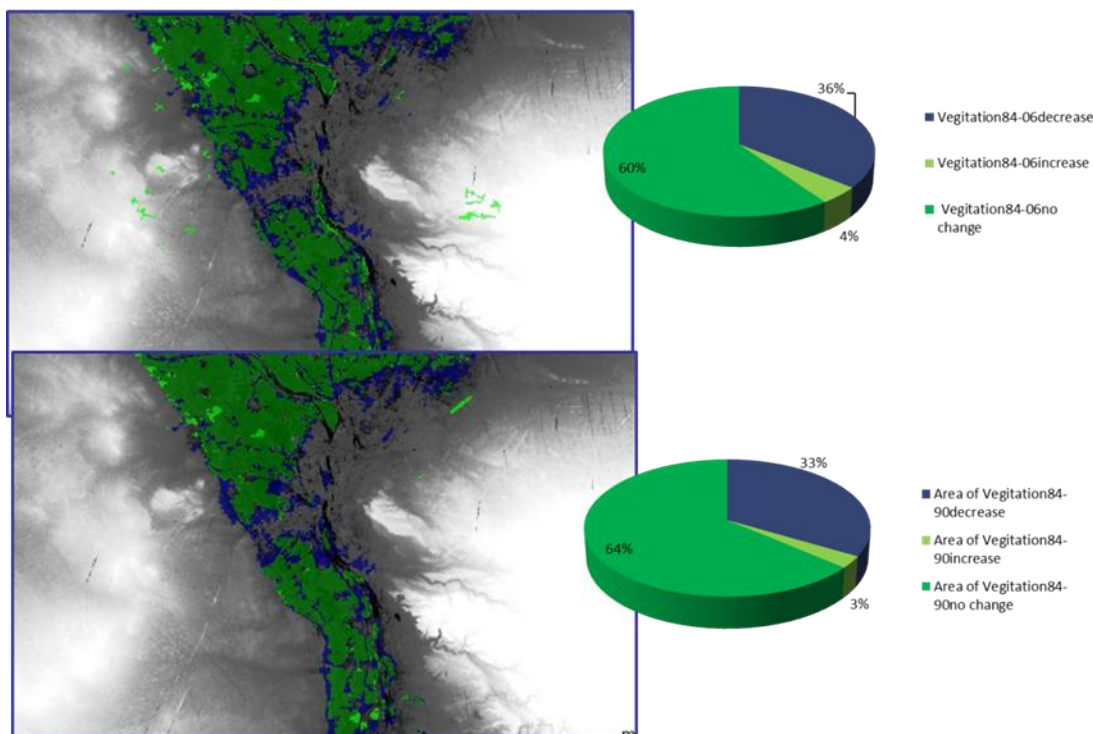
There are two main contrasting aspects have been affecting the green activity in area of concern, the first one is the reclamation and the second one is encroachment. Additionally, the new cities and urban sprawl represent the main forces when the spatial development and dynamic of urbanization in Greater Cairo takes place.


Figure 9. Green cover changes in G.C (Impact)

In these two sub-schemes, the two keys are used as drivers to move to another level of monitoring and classification which is strongly connected with the basic classification and main framework. Moreover, any change, addition, or erase of time span or image resolution rather than classification algorithms do not affect the main structure of the analytical framework and their subsidiary schemes. But, such changes can contribute smoothly and systematically to the interconnected sub-DPSIR-responses which can be aggregated and used to develop a data base of management planning and to update monitoring information.

According to such approach, it is possible to examine the accuracy of using tool to analyse and mention the criteria of more affected objects (spots) for further processing and estimation of the change levels.

So, the sub-DPSIR scheme for urbanization shows that the impact in water is mainly dealing with the drinking water, unlike; the sub-scheme for green activity expresses its impact on irrigation water (Figure 7). This means that, the strategy of analysis and purposed plan has been oriented by selected object.
Figure 10. Urbanization changes in G.C (Impact)

10 CONCLUSIONS

- The spatial monitoring and change detection of megacity is not based only on the classification and remote sensing techniques but also on effective conceptual model to understand the environmental indicators and to identify the more effective hot-spots (objects) of changes.

- In this study we found that the applications of DPSIR model are useful to identify and analyse the causal link between the socio-environmental indicators of megacities (e.g. Greater Cairo metropolis) based on goal oriented and tracked flow of a conceptual scheme.

- Flexibility and elements interaction characters of DPSIR could be modified and used as looping process analysis for wide range of uses in different levels, approaches, scales and times.

- It could be concluded that, the object oriented classification technique is very compatible with DPSIR model in monitoring and change detection approach.

- New and modifies planning strategies could be elaborated based on the main DPSIR framework and its subsidiary schemes, these would contribute to improve management and support the decision makers and stakeholders to choice an individual element or group of elements to understand and response.

- The using of Socio – Envirronmental Models are useful to build knowledge system of megacites, that would be used for geo-spatial information service and data mining with what means (e.g. planning system, national and regional spatial development policies, other legislation, etc.).

Strengthening Alexandria Urban Fabric by Planning Urbanism's Walkable Area

Shahira Sharaf El Din, Ghada Ragheb

(Dr Shahira Sharaf El Din, Ass. Prof., Pharos University Alexandria, Egypt, shahira.sharafeldin@pua.edu.eg)
(Dr Ghada Ragheb, Ass. Prof., Pharos University Alexandria, Egypt, ghada.ragheb@pua.edu.eg)

1 ABSTRACT

Nowadays city of Alexandria has a very wide range of urban development projects, some of them has a major influence to the physical being of the city meanwhile others just have a small interpretation to its characteristics. The rapid growth of Alexandria city in the nineteenth century led to calls for parks to be provided for the health of all categories in the society. This could be seen as an early precedent to highlight the role of open spaces in supporting what we now call sustainable development.

This paper proposes an urban development project which make a replacement of an urban crawl in Alexandria city into unique open space through presenting a comprehensive approach for assessing this suggested project to create a walkability area based on a combination of its conceptual and applicable aspects. Discussion of the sustainability modules to this new urban development project in Alexandria will be accomplished, by the aim of investigating its ability to stand against the future challenges.

It is concluded that a significant attribute of urban design achieves continuity of the urban fabric and streets, because this facilitates flows. Wherever movements occur, there is vitality and flow creates eyes on the street producing spontaneous surveillance. Also, Comparison of contextual and neighbourhood before and after the project revealed the positive impact of the suggested project either on the built (physical) environment's or health and social well-being.

2 INTRODUCTION

Alexandria is the chief port of Egypt and is located in the north and occupies a T-shaped peninsula and strip of land separating the Mediterranean from Lake Maryout. (Fig.1).[1] The city was founded in 331 BC by Alexander the Great and was the capital of Egypt for over 1000 years.

Alexandria witnessed a continuous urban growth from the beginning of the Mohammed Ali era (1805) up to the present time. In 1905, Alexandria's 370 thousand inhabitants lived in an area of about 4 km2 between the two harbors. Since that time the city has expanded rapidly, eastwards and westwards, beyond its medieval walls. It presently occupies an area of about 300 km2 and has a ten-fold increase in population at 4million, with a density exceeding 1,200 per km².[2] Population is projected to become 5.4 million by 2015 (Figure.2). Because of this, Alexandria is the second largest urban governorate in Egypt. At an international level, the city was ranked 62 in 1996 and it is predicted to become rank 54 by 2015.[3] This enormous urban growth requires precise detection with good management, prediction and planning to solve circulation and traffic problems especially in the city center.

Fig. 1: Area of Study.

3   CHANGING ALEXANDRIA URBAN FABRIC:

The rapid growth of towns and cities in the nineteen century led to calls for parks to be provided for the health of factory workers and consequently it benefited society as well. This could be seen as an early precedent to highlight the role of open spaces in supporting what we now call sustainable development. This achieved a wide range of benefits to the economy (healthier, happier, and therefore more productive workers), social life (people relaxing and meeting in the parks) and the environment (as open spaces were created amongst streets, mines and factories).[4]

One of the main urban problems in Alexandria is lack of Structured Public Squares. The primary public squares do not offer enough enclosure. Not only are the surrounding buildings too large (in plan), they are all separated by streets. Another problem with the public spaces is their large provision for traffic and parking.

Public open spaces can take the responsibility as key design elements for enhancing urban life quality and to reduce the negative effects of urbanization. For that sake, open spaces must meet the expectations of potential users and offer the suitable mix of environmental, economic, social, and even political conditions.[5]

Strategies for sustainable growth in Alexandria can be summarized in strengthening of the central parts of Alexandria, a particular focus on a strategic node such as sidi gaber terminal and the connection of city areas which until now have been separated and the creation of a vibrant urban environment.

Designing public spaces for pedestrians, is a challenging task for urban planners as it deals with the built environment which includes buildings, streets, plazas, trees and platforms, and also extends to people activities that play the important role in urban design as mentioned by previous researchers.[6]

Good urban design is not only the design of aethetically acceptable places, but actually it depends on making places usable for people.

Redesign of urban places can always be the catalyst for change in cities. Alexandria city must increase the quantity and quality of well-planned beautiful public spaces that are human in scale, sustainable, healthy, safe, and lively. City streets, parks, and squares are important sites for social, economic, and political activity.

4   THE CASE STUDY AREA (SIDI GABER TRAIN STATION) :

4.1 History of the station

The interior section of the Eastern District in Alexandria; Egypt, contains the Sidi Gaber railway station, the main rail entry point to Alexandria for most travelers. The station is one of the oldest in Egypt, having served

[5] BRUSE, M. : Simulating human thermal comfort and resulting usage patterns of urban open spaces with a Multi-Agent System. Proceedings the 24th International Conference on Passive and Low Energy Architecture PLEA, pp. 699-706.Singapore, 2007.

[6] RASLAN, R., BAKR, A., & AYAD, H.: Simulation of Pedestrian Behaviour in Urban Spaces. A Case Study of "Sidi Gaber" PublicSpace,Alexandria, Egypt. In: Schrenk M.; Popovich, V.V.; Zeile, P. (Eds.): Proceedings REAL CORP 2011, pp. 863-872. Essen, 2011.

the eastern regions of the city even before their transformation into major urban districts (they had previously been summering resorts for foreigners and wealthy and middle-class residents).

The station Sidi Gaber is also one of the oldest Egyptian stations, is the first railway line outside Europe, and the second in the world, started to create between the cities of Alexandria and Cairo in 1851, following the start-up the rail line linking the cities of Manchester and Liverpool in Britain in 1830.[7]

The Khedive Abbas the first in 1851 had contracted with British Robert Stephenson, son of George Stephenson inventor of the ferrous tractor, and paid $ 56 thousand pounds sterling for the establishment of a railway linking the Egyptian capital and Alexandria length of 209 km.

First locomotive on the line between Alexandria and the city of Kafr El Zayat in the Delta region was in 1854. The train cars was crossing the Nile water in different cities by ferries prior to the establishment of iron bridges on the waterway.

The Sidi Gaber station witnessed many events such as in twenties of the last century reception Saad Zaghloul Pasha after his return from exile, as celebrated by Alexandrian people with Sayed Darwish song famous specially composed for the occasion «safety safety ..We went and return safety". Also the train offered by France in 1862 to Khedive Said, which was a locomotive containing a luxury salon, which remained used by the rulers of Egypt to move between El-Montaza and Ras El-Teen in Alexandria until 1898.

The famous train station building has a special architectural style and unique Dutch character building that was constructed instead of the traditional old wooden one, in 1948 and was built with yellow brick. The station is distinguished with a clock tower, and major map in front of it a showing the main streets of the city of Alexandria and the most important tourist attractions.

Fig.3: the old and new facades of Sidi Gaber station.

Fig. 4 Perspective of the new project as shown in advertising

4.2 New development project at the station:

As of 2011, the station is undergoing expansion, with the intent to turn old parts of the station into a railway museum, and include space for commerce in the newer parts.

Development project has been implemented to use the top of the station to provide large halls for passengers either for commercial or recreational services. The cost of the project was estimated by 225 million Egyptian

---

[7] http://www.aawsat.com/default.asp

pounds. The station serves nearly 4 million passengers annually and now will provide more than 7,000 square meters of commercial spaces and cafeterias as well as places for 850 cars parking.

The two-storey mall over the station equipped with escalators, elevators, central air conditioning and alarm systems and fire-fighting up to date system, is considered an integrated service for station's clients.

The ground floor will serve as train station with highly equipped ticketing tools and services.

4.3 New development project design philosphy:

The philosophy of the new design was based on the new design elements added to the internal train station with services and new activities to entertain passengers in the waiting times next to the events of economic boom. The building of the station is a sensitive quality in public building and brings a symbol of expression on the public spaces more than just a service relying on community service. This station is the welcoming gate of Alexandria for all passengers.

The philosphy of the project design idea begins with the influence first given in the design of the building and with the emphasize of the internal strength and depth with new technologies used either in materials finishing or in the construction methods to create a dominant building and a place to remember while arriving or leaving the city.

The design concept was inspired from Egyptian symbol of the Sun God as he was stripped of its wings and took and put them to send a date centric lighting ressembling the new building embracing the old one. Industrial lighting next to natural adopted from sky light reflecting images from the juxtaposed buildings. Use of transparancy and the blue color of the glass indicate the color of the Nile and life to the Egyptians. Despite the dominance of the design idea but the spirit of the age has been confirmed with the most recent technological manner (High tech) and through materials and transparent glass wall, where all are full of cylindrical columns of concrete coating aluminum metal ore, fig. (5).[8]
Fig. 5 The new development project of sidi gaber station photos showing the use of modern finishing materials.

The designer tried to link between the old building with its unique character and modern style in architecture.

But the difference between the two buildings was clear and obvious even in the functions performance and quality of materials.

---

[8] http://www.bonah.org/news

From another point of view, the new design had to encompass the old building and to cope with it in harmony, which was never accomplished in reality, fig.6.

Fig. 6 The new facade with new finishing materials over the old train sation building causing aesthetic pollution.

5 PROBLEM DEFINITION:

With the new design of Sidi Gaber station project, the need for pedestrian walkable area becomes a must.

Pedestrians usually cross the street from extremely critical access that is in conflict with vehicles traffic. In order to eliminate such behavior, the local authority constructed a pedestrian bridge and escalators that in reality are not used by pedestrians according to previous studies, fig. 7.(7)

Fig. 7 the pedestrian bridge that in reality is not used by people.

The new design of the station either accepted by people or rejected is a reality that must be dealt with as soon as we can. The change of the train station and the new designed building have caused change in population densities to increase and require spatial development as soon as possible. Pedestrian flow coming to the station besides the flow of the people visiting the mall will create Chaos.

It is important that urban design achieves continuity of the urban fabric and streets to facilitate flows. Wherever movement occurs, there is vitality and flow creating the need of street surveillance. From the field observations on the selected space there are a number of pedestrian that have been noticed as pedestrian movement destinations. Within these paths, pedestrians need to cross " Al- Horreya Avenue" in order to arrive to their targets.

There are interferance between private and public activities either inside or outside the train station , giving the feeling of confusion to the users of the train station. The organization of this area will allow people to find their way clearly. There also a need to minimize the impact of the new invasive mall building in the surrounding public space. There must be a system to manupilate the flow of people either entering the station or visiting the mall.

Fig. 8 : Pedestrians crossing Horreya street to arrive at Sidi Gaber with higher flow.

In urban spaces, people must be the decision makers, and they are free to choose their next steps. Where spaces are supposed to be designed to meet pedestrians' needs and support their activities. Most of our urban spaces are not giving pedestrian movements the enough priority and that cause a mis-use problem.

Norman Foster design in Santa Giulia provides a very safe pedestrian condition, thanks to the addition of clear walking paths and the public surveillance from the presence of stores.[9]

Fig. 9: Different circulation flow of people going to and from station with an obvious disorder.

6 SUGGESTED PROPOSED PROJECT

Open spaces in neighborhoods are defined as " any unbuilt land within the boundary or designated envelope of a neighborhood which provides or has the potential to provide environmental social and/ or economic benefits to communities, whether direct or indirect.[10]

---

[9] McNeill, D. (2006). Globalization and the ethics of architectural design. City,10(01), 49-58.

[10] Campbell, K. (2001). Rethinking Open Space, Open space Provision and Management: A Way Forward, Report presented by Scottish Executive Central Research Unit, Edinburgh, Scotland, UK.

The proposed project composed of either greenspaces represented in vegetated land or water elements and greyspaces represented in paved or hard landscaped areas with civic function can be an enhancement to the urban structure of this central crowded part of Alexandria, Egypt, fig.9.

Fig. 10 the proposed plaza in front of the train station to solve the problems resulted from the new development project of Sidi Gaber.

The new design of a plaza in front of the station relating it with the tram line on the other side and creating an urban public space offer the urban quality to the place as well as solving the chaos problem in this district. The Ground floor will be the entrance for users both coming from the front street of the station or from the plaza or from the back street, fig. 10..

In general, in the previous solution as shown in fig. 10, Landing cars level in the way of Horreya street under the ground, and raise the level of the tram as a monorail, leads to organize cars circulation and seperate between them and the pedestrian as an important improvement that must be considered. Creating a plaza outside the train station untill the tram side will allow people to walk or sit with maximum safety. It organizes the people flow either coming to the station or visting the new mall and other public spaces in harmony and logical way.

In such a central terminal, wakable paved greyspaces is required to develop the quality of the urban space outside the train station.Using patterns and new materials in pavements can facilitate the direction of people path.

The new planning of the site will organize the pedestrian places and seperate the cars allowing the pedestrian to cross street safely. Alhough, greenspaces especially trees, palms and flowers led to the shading of some parts in the space. The presence of fountain in the middle give psychological effect of satisfaction, beauty and climate mitigation that could send joy in the space. Provision of greenspaces in this crowded area is a source of recreation to the residents specially Sidi Gaber Towers, which overlooks it directly. So comfort and pleasure is provided for train station users and residents in the same time. Fire fighting alarm and Extinguisher must be distributed according to the new building design and people flow. Also guidance signs must be provided in prominent and clear places for the eye.

The huge height of the existing towers in the background has always led to distort the fine harmonious impressive image of the station. The new building juxtaposed to the old train station can give good impression to the viewer now especially with the disposing of visual obstacles in the old situation.

We note that the provision of green areas will restore the sense of scale of the station and the surrounding space.

7   EVALUATING SUSTAINABILITY PERFORMANCE OF THE PROPOSED PROJECT

Urban quality is the overall key word for the understanding of how the relationship between cities and people works. When urban quality is low the number of pleasure visits and activities are low. The activity is limited to the most necessary visits and walks which people do because they are compelled to carry them out.

A number of issues affect the public spaces and the way we act when we are in the city. These issues are presented in a keyword list for urban quality, which is used when identifying problems, potentials or possible solutions to issues of different character as shown in the next table.[11]

Protection	**Traffic** - protection against traffic accidents - pollution, fumes and noise - visibility	**Security** - lived in / used - street life - street watchers - overlapping functions on spaces and time - overlapping functions in space and time
Comfort	**Walking** - room for walking comfortably - interesting layout for streets - interesting facades - good surfaces - no obstacles - good accessibility to key points - few footway interruption - convenient crossings - Access for everybody, ramps, elevators, etc.	**Staying** - staying zones - good possibilities for sitting, view, sun , people to watch - good seats - good local climate - soft edges, inviting facades for resting - points of support for leaning - benches for resting - points of support for leaning
	Seeing, talking, hearing - reasonable seeing distances - free vistas - interesting views - good lighting (evening / night) - low noise level - bench arrangement - talks capes	**Activities and interaction** - invitation to physical activities, play, and entertainment day and night and summer and winter
Enjoyment	**Climate** Protection against - wind / draft - rain / snow - cold / heat possibilities for - sun / shade - warmth / coolness - breeze / ventilation	**Aesthetic quality** - good design and good detailing - views / vistas - trees, plants, water - clean streets and squares - good lighting quality - good materials - building scale dimensioned to the human scale

Fig. 11: Key words list for urban quality criteria.

Applying the previous list of urban quality criteria on the research proposal indicated that besides the new plaza fulfill most of the list, it also it creates a well public functionning domain offering a wide range of attractive public activities for people.

Sustainable design takes the circulation of people on foot and bike and the effectiveness of public transport as starting points. However, creating neighborhoods where walking is the natural and pleasurable means of access between activities achieves much of sustainability goals and objectives (quality of life-health economics of communities and community participation).[12]

The role of open spaces to play within the neighborhood structure, to achieve sustainability goals and objectives, is formulated in three key issues; space management, space function (circulation of people and permeability), and the role of objects within space (sustainable landscape).(11)

The detailed study of these issues can be the set of sustainability checklist applied to open spaces. Applying the matrix of sustainability parameters used in previous research[13] on the proposed project (table(1), can reveal many conclusions. The project, as shown in the table below, achieved 66.5 % of the first sustainability parameter in the space management issue, 80 % of the second space function issue and 85 % of the last issue

concerning the role of objects within space, respectively. The space function in our case is the key issue to be discussed as it is the solving procedure of the pedestrian's dilemma in order to reach the station or to enter the mall. Presence of accessible, active spaces can socially support children, young people and people with disabilities. Also, it can improve visual appeal, enhance social cohesion opportunities for active socialization and generate a more sustainable healthy system.

	Sustainability Parameters	Proposed project Achievements
Space Management	Encouraging sustainable lifestyles	×
	Making maximum use of existing features assets.	×
	Strengthening the sense of place	×
	Incorporating local or recycled materials	
	Encouraging community participation and involvement	×
	-Reducing inputs of non-renewable resources during construction and subsequent maintenance	
	Eliminating or reducing the use of herbicides and resources that affect other ecosystems	
	Encouraging habitat creation and native planting.	×
	Managing resources carefully.	
Space Function	reduce the level of car reliance,	×
	Effectiveness of public transport.	×
	Reduce the need to travel.	×
	Social benefits of increasing transport choice for all groups in the population.	×
	Enhancing local security and community.	×
Role of objects in Space	Return to original sources of inspiration, whether nature or culture.	×
	Respond to the site:	
	creating connections and themes (functional and perceptual as well as spatial) within and across sites while defining and delineating boundaries;	×
	• transforming site constraints into environmental opportunities;	×
	•Minimizing negative environmental impacts (including sensory as well as physical pollution);	×
	• maximizing positive impacts, off-site as well as internally.	×
	- Minimize inputs of materials and energy and maximize outputs of renewable and reusable resources.	
	Maximize resilience and dynamic stability in the :	
	• maximizing the diversity of landscape elements and the diversity of relationships between elements;	×
	Creating opportunities for the emergence of self- sustaining and self-regulating systems in the landscape.	×
	Create 'place' as distinct from merely manipulating space, in such a way that the design maximizes the potential for user Interaction with the environment.	×
	Make systems visible, which means making environmental processes apparent and celebrating them.	×
	Minimize maintenance.	
	Meet the varied recreation and leisure needs of users.	×
	Involve local communities.	×

Table (1): Sustainability parameters achievement of the proposed project.

8   CONCLUSION

In Alexandria, residents are in real need of having walkable areas especially in the center of the city and in crowded places. In the new sustainable design of the city, the quality of the urban space is equaly important with the effiecency of the space. The previous research project is an attempt to solve a major aesthetic and functional problem that Sidi Gaber, a major terminal in Alexandria, is facing and will be elaborated with the new extension.

The research discussed the prompt and accurate solution, especially with the high increase of population in the city. Once the mall at the train station will be opened a real traffic jam will occur in the center of the city.

Also, the proposed solution creates green and open sustainable spaces and provide walkable areas which are the most important issues to be considered in Alexandria new planning to enhance the city urban pattern or the residents behaviour and safety. Our urban design sustainable solutions of Public Urban spaces should prioritize life quality, health, safety and an inclusive environment for all. We regard the public realm as a place for all people, regardless of ethnic background, age, socio-economic class, disability, religion, or the like. Residents, visitors, students, workers, children, and the elderly are all invited to meet in the public realm.

A city public spaces must be available and open to invite and include all people, having different activities and possibilities and thereby ensuring multiplicity and diversity. Well-designed cities inspire the people who live in them, whilst poorly designed ones brutalize their citizens.

Study on "Micro-Participation" of the City – Emergency Management in the Age of Micro-Blogging

Xi Guangliang, Zhen Feng

(PhD. Candidate Xi Guangliang, School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing, China, nju_xgl@163.com)

(Prof. Zhen Feng, School of Architecture and Urban Planning, Nanjing University, Nanjing, China, zhenfeng@nju.edu.cn)

1 ABSTRACT

With the rapid development of information technologies, the Internet and mobile terminal facilities, the network information platform has been widely used, and the number of micro-blogging users (such as twitter, Sina micro-blogging,…) is growing rapidly as well. By the end of June 2012, the number of micro-blogging users had reached 274 million, accounting for 50.9 % of netizen based on the statistical report of Internet development in China. The dissemination of information with micro-blogging is more timely and interative than tranditional Internet platforms. Micro-blogging is playing an increasingly important role in the dissemination and diffusion of urban hot topics.Some local governments and urban planning experts use Micro-blogging to interact with the public and respond to localresidents' needs. So, how are we to use mirco-blogging in dealing with city emergency and help facilitate government management?

The rainstormon 21 July 2012 in Beijing caused serious desaster in the whole city, especially on infrastructure. Roads, bridges, water conservation projects as well as some landscape and historical sites were destroyed. Meanwhile, the rainstorm also caused great losses of lives and property, totalling an economic loss of nearly ten billion. Fortunately, different parties such as the government, the media and the pubic were able to use different Intenet platforms to disseminate information related to the rainstorm disaster through interaction and discussion of relief hot topics, that finally led to effcient emergency management in the rainstorm disaster.

Taking Sina micro-blogging as an example, this paper researches emergency management process with micro-blogging during the "7.21" rainstorm disaster in Beijing, analyzes the different stages and the main content of the micro-participation, and focuses on the participation method of different subjects, such as the government, media, the public and experts. Meanwhile, this paper puts forward a mechanism for information dispersion and interactive communication, the mechanism of public participation and public opinion guidance. Lastly, some strategies for enhancing the level of urban management are given, and they are, the new paradigm of public participation in urban management, improving system security mechanisms, the real-time public participation and smart city service management system.

2 BACKGROUND

New media based on network and mobile information plays more and more important roles in urban emergency management, especially in the Sanlu milk powder scandal, the Wenchuan and Yushu earthquake, the Wenzhou high-speed rail accident. New media can be used as a way of hot topic dissemination and diffusion. People can receive information more quickly as well as interactive communication with others through the new media platform compared to the traditional media(e.g., Newspaper, TV, Radio, ...). So, it is very important to adapt to the new media such as micro-blogging network to build an urban emergency management system in the network and information age(Gu fumei, Zhai Guofang,2012). The Beijing storm disasters on July 21, 2012 caused significant damage on roads, bridges and water conservation projects. Many houses collapsed, hundreds of cars and many scenic spots were ruined, causing huge economic loss in the storm. The government, the media and the public body interchanged the rainstorm disaster information through micro-blogging information platform, delivered rainstorm information and discussed the hot topic of disaster relief. Micro-blogging played a key role in the storm disaster emergency management.

Domestic and foreign scholars have conducted research on public participation in urban management in the network and information era, analyzed the realization method of participation in urban planning, and designed the public participation geographic information systems (PPGIS) with network, and was applied to public participation in urban planning(Emma J. Stewart,etal,2008). With public participation geographic information systems, e-government was developed in the city (Sukumar Ganapati, 2011; Milan Tung-Wen Sun, et al, 2009), and the governments monitor the dynamic process of urban development(Gregory Brown, Delene Weber, 2013). New information technology offers new possibilities for public participation in urban planning, and provides an interactive communication platform that can be used for long-distance

communication (Malgorzata Hanzl, 2007). The researchers analyzed the methods of public participation in urban planning, mainly through public government information, television and online media, and studied on their characteristics and existing problems (Xu MY, Tao Dekai, 2012; Zhou CS,Wang F.,2006). Using the theory of association planning, they summarized the characteristics of public participating in urban planning with network mass media, and advised that the departments and the staff memebers of urban planning should learn to integrate mass media into the public, and exchange opinion with other public participants (Chen Yao, 2007). With network and information platform, we can break the traditional "top-down" mode, and build the "bottom-to-top" participation mechanism in information dissemination of urban planning and urban disaster outbreaks.

It is timely and interactive to communicate and disseminate information with each other by Micro-blogging. Micro-blogging has more advantage than traditional information platforms in public participation in urban management. According to the 30th China Internet Development Statistics Report surveyed by the China Internet Network Information Center, micro-blogging users in China reached 274 million, accounting for 50.9 % of Internet users, and cellphone micro-blogging users reached 170 million by the end of June 2012. China has fully entered a micro-blogging era. With the rapid growth of users, micro-blogging plays an increasingly important role in information dissemination of urban government management and emergencies such as mudslides, earthquakes and other disaster outbreaks (Liu Hua,2011). Administrative departments can release information and communicate with the public through official e-government micro-blogging platforms (Seong Eun Cho, Han Woo Park,2012; Li Xiaofang,2011). The use of Sina and Tencent micro-blogging platform greatly promoted public participation and interaction on hot topics of urban security, urban planning, public services, and urban management.

3   MICRO-PARTICIPATION IN URBAN EMERGENCY MANAGEMENT

3.1 The connotation and characteristics of micro-participation

Micro-blogging is a platform for freely sharing, disseminating and accessing information based on user relationship. Micro-blogging sites are always operated and managed by some enterprises, but the governments keep the power of supervision on public opinion. Micro-participation in urban emergency management, an information releasing and interactive discussing process involved in urban emergencies through the micro-blogging platform, is a new network form for public participation in urban emergency management. Micro-blogging shares the characteristics of the civilian interaction, interactive and fragmented, and its information is shorter than others. Ordinary people can be free to release and disseminate information, so micro-blogging participation in urban emergency management can be called the "micro-participation" process.

Receiving and transmitting information by means of Internet based mobile terminal equipments, micro-participation can happen anytime and anywhere, therefore it has the following characteristics: Firstly, information about urban disaster outbreaks can be published freely. Anyone who uses internet and its terminal equipment can use micro-blogging to release information of urban sudden disasters timely, and prompt administration to respond actively and reduce losses. Secondly, it can help realize immediate interaction with micro-blogging. Being highly interactive, micro-blogging can realize the sharing and communication of unexpected disasters between different populations, shorten the reacting time for urban emergent disasters, and improve the efficiency of disaster response and preparedness. Thirdly, it is easy to generate recognition on disaster information. There are some linkage between social networking in micro-blogging and the actual social intercourse circle, and the majority of users can be identified, so it is easier for people to trust the interaction content in micro-blogging, and behaving accordingly.Micro participation in urban emergency management can generateattention and induce actual rescue efforts from those involved.

3.2 The significance of micro-participation in urban emergency management

The popularity of the network changed the traditional social imbalances that was caused by lack of the public rights to speak in real life (Hu Yi, Zhang Jingxiang,2010). Micro-participation can play the role of diffusing information, hot topic discussions and supervising public opinion. Micro-participation also has the characteristic of active participation, and netizens achieve social management through the care of their own interests and the interests of the social community. Through the diffusing effect of micro-blogging, information on disaster warning, the disaster situation and the rescue situation could be disseminated timely,

and can alert urban residents to take action and help improve efficiency of relevant departments' rescue efforts in disaster prevention and reduce disaster losses. As a method of social management, network mobilization can be used for mobilizing resources and efforts of social organizations, civil society and individual citizens of all sectors of society in a short time to form a huge disaster relief force (Liu Xiaolan, Li Jun,2011). Micro-blogging involved in disaster discussions can play the role of the public participation in the management of the public domain to promote the mode of government administration to shift from the traditional top-down governance to modern management (Zhao Min,Liu jing,2010). Meanwhile, Micro-blogging information often forms a certain public opinion against bad behaviors and promote the city spirit, which is another aspect of urban society management.

4   DATA AND ANALYSES

4.1 Samples

Using "rainstorm" as key words, the author adopted the methods of hierarchical statistics and hot micro-blogging ranking to search and record real-time posting status and popular Sina micro-blogging from 20 to 31,July 2012. The process of data collection include three steps. First, recorded number of original real-time daily micro-blogging in whole China and Beijing. Second, after sorting the daily blogging information by relevance,   more than 1,000 pieces of representative information were chosen from the browsed total of nearly 10,000 entries of hot topic information. Finally, Selected four types of identifiable micro-blogging users (government departments, media, planners and ordinary Internet users) and their entries for indepth understanding and recorded the micro-blogging status, the discussions involved and comments of 53 micro-blogging users about the Beijing rainstorm.

4.2 Descriptives of samples

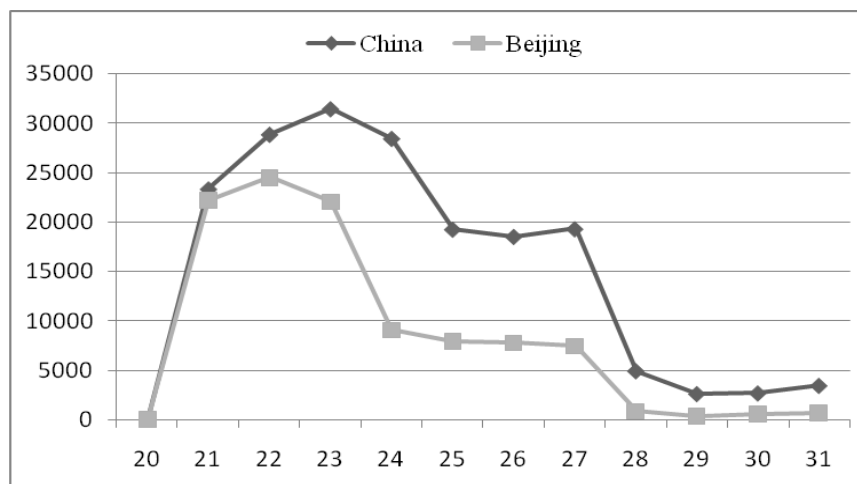
The real-time original micro-blogging was recorded from 20 to 31, July in China and Beijing. According to the general stages of disaster emergency management and the collection dates, rainstorm disaster outbreaks in Beijing is divided into four stages: warning period (July 20,2012), disaster outbreak (July 21-22,2012), spreading(July 23-26) and recovery period (27-31 July). The number of micro-blogging in whole China in different stages shows that only 26 pieces of micro-blogging information in the warning period, a large number of original micro-blogging in disaster outbreak period and spreading period, and that is 52,214 and 97,701 respectively, and 32,972 original micro-blogging in disaster recovery period. This suggests that the number of people involved in micro-participation and degree of concern are relatively higher during disaster outbreak period and its spreading period.


Fig 1: The number of original micro-blogging about Beijing rainstorm

993 pieces of blogging entries were picked from over 1,000 entries based on their relevance with the Beijing rainstorm disaster, then the selected blogging entries were coded according to the text content of its recorded information. First, the themes that best represent the meaning of micro-blogging content was explored, and a total of 37 basic themes were identified and named as thematic content. Second, themes with the same meaning were sorted into one class according to the logical relationship between different themes, and 12 types was formed (Tab.1).

Themes(number of micro-blogging)	Types(number of micro-blogging)	themes(number of micro-blogging)	types(number of micro-blogging)	themes(number of micro-blogging)	types(number of micro-blogging)
Rainstorm forecasting（77） Rain characteristics（61） Causes of rainstorm disaster (3)	Rain condition（141）	Help seeking information（10） People and object searching（13） Offering help of disaster relief（23）	Disaster relief Information（56）	drainage（23） urban infrastructure（5） urban planning and construction（9）	urban construction（37）
Rainstorm warming（57） Contingency plans（2） Flood control and emergency questions（8）	Warning and Contingency（67）	Offering living services（5） Appealing for disaster aid（5） Safety strategies（74） Suggestion for precaution and help disaster（30）	Coping strategy（104）	Action of government（23） deed of helping disaster（47） Bad behavior（6）	Social performance（76）
Disaster scenes（24） broadcasting situation of disaster（112） damage statistics（12） The number of death toll（24）	Disaster condition（172）	donation（8） recovery after disaster（66）	rehabilitation work（74）	Society and economics influence（6） Government regulation（4）	post-disaster impact（10）
The actions of disaster relief（48） Progress of disaster relief（31） Organizing disaster relief spontaneously（4）	rescue operations（83）	urban emergency management（30） Urban infrastructure management（7） Road and traffic Condition（68）	Urban emergency management（105）	ridicule（6） touching（19） Criticism（5） praising（6）	personal emotion（36）

Table 1: The themes and types of micro-blogging information
Fig 2: Main content of micro-participation in rainstorm disaster

5 EMPIRICAL STUDY ON MICRO-PARTICIPATION OF BEIJING "7.21" RAINSTORM DISASTER EMERGENCY MANAGEMENT

Taking micro-participation of Beijing rainstorm disaster as an example, we analyzed the process, different means and mechanisms of micro-participation, and explored urban emergency management in the micro-blogging information age.

5.1 Main content and process of micro-participation

Micro-participation content of the rainstorm in Beijing suggests that the proportion of micro-blogging information about disaster situation, rainstorms, coping strategies and urban emergency management is relatively high, accounting for 17.9 %, 14.7 %, 10.8 % and 10.9 % respectively, and the proportion about warning, emergency relief, rescue operations, aftermath work and social performance ranks medium, and

less blogging entires relate to urban construction, personal emotional expression, and post-disaster impact. It shows that micro-blogging plays a huge role in weather forecast, reporting rain condition, disaster coping strategies and the urban emergency management process, and helps inform the public and the government of the rainstorm, disaster-related information, disaster responses, and the implementation of the rescue timely. Micro-blogging platforms can also be used to release information of helping, rescuing, and rehabilitation efforts to improve the efficiency of disaster relief, and reduce social and economic loss. At the same time, publishing social efforts and personal emotion in rainstorm disaster through micro-blogging platforms could boost the spirit of the urban society. Discussions on city building and socio-economic impact triggered by rainstorm disasters can help promote urban planning and construction, and guide socio-economic operations gradually to more sustainable and scientific direction.

Based on the analysis of the content of micro-participation in Beijing rainstorm disaster, the main content of micro-blogging information was divided into six aspects of hot topics, including disaster forecasting and emergency, disaster situation, relief process, and urban construction management. Then the hot topics and features of each micro-participation stage were summed up as follow:

5.1.1   Disaster warning period

The hot topic of this stage was disaster possibility forecasting. The government and media released weather forecast, warning information for rainstorms, and alerted the residents of travel safety. Meanwhile, residents adjusted their travel activities in advance, changed travel plan and means of transportation.

5.1.2   Disaster outbreak period

This period has the highest degree of micro-participation. The hot topics include disaster forecasting and emergency coping strategies, disaster situation, relief process, management of urban construction, the spirit of the city and the quality of residents. The government, the media and the public released disaster information (such as disaster scenes, disaster broadcast, etc) and disaster relief information (such as Help seeking, people and object searching, rescue scenes, etc) with different concerns. At the same time, the information about urban emergency management, urban public services, test of urban drainage facilities and other topics was released, including the good deeds and bad behaviors in the rainstorm.

5.1.3   Disaster spreading period

The hot topics of this stage include disaster response strategies, disaster statistics, urban construction, daily management and socio-economic impact. The information related to detailed distribution of disaster, socio-economic loss, real-time progress of the relief operations and rehabilitation work were released accordingly. People began to reevaluate the existing problems on urban planning, daily maintenance of urban facilities and the model of urban development, and discussed the socio-economic impact of disaster such as rising prices.

Hot topics	Disaster warning period	Disaster bursting period	Disaster spreading period	Disaster recovery period
Disaster forecasting and emergency	Rainstorm forecasting, rainstorm warming, resident's travel activities adjustment	rainstorm warming, contingency plan, security protection of rainstorm, trip reminder	Rainstorm coping strategies, questions in flood prevention	Disaster consciousness and learning security, emergency management approach
Disaster condition	—	Rainfall characteristics, disaster scene, disaster broadcasting	Distribution of disaster, statistics for loss, disaster situation reporting	Statistics and analyzing disaster
Process of disaster relief	—	Information of calling for help, People and object searching, rescue scene	Rescue operations, donation for disaster area, rehabilitation work	donation for disaster area, maintenance recovery, victims placed
urban construction management	—	Urban emergency management, urban public services, urban drainage facilities	Problem of urban planning and construction, daily management of urban infrastructure, urban developing mode	Urban building strategies, formulating urban construction and management standard
social performance and personal emotion	—	Positive action of government, praising good people and deeds in rainstorm, criticizing bad behavior in rainstorm	Touching story, condemning bad behavior	Investigation on bad behavior
Socio-economic effection	—	—	Rising price, stock market volatility	Stable prices

Table 2: The hot topics of micro-participation in different rainstorm disaster stage

5.1.4   Disaster recovery period

The information in micro-blogging mainly concerns the problems of disaster exposure and follow-up efforts. Micro-blogging users published knowledge of security education and disaster prevention, disaster statistics and compensation, discussed more scientific and rational city emergency management approaches, urban construction & management standards and urban building strategies. The government carried out investigation on those involved in the blaming and bad behaviors.

5.2 Different roles of micro-participation in urban emergency management

Different users played different roles on micro-blogging platforms, the number of concerns and follows were different among micro-blog users, and the number of posts was also different, which led to the different manner and extent of micro-participation(Fig.3,Fig.4).

5.2.1   Government: micro-participation in affairs management

Through announcing official micro-blogging accounts (such as Beijing released, Beijing meteorological, Beijing planning,etc), government departments played positive roles in social management innovation, government information opening up, offering guidance to news report and the media, political participation of the civilian matters, listening to the voice of public and establishing the image of government. Beijing government departments at all levels, especially the Beijing Municipal Government, planning & construction bureau, transportation bureau, public security bureau and district-level departments, played an important role in urban management during the Beijing "7.21" rainstorm through the Sina micro-blogging platform.

With micro-blogging platforms, government departments released contingency plans according to real-time weather forecasts timely, and prompted city residents to take rainstorm prevention action, ensure the safety of travel and prevent landslides and other secondary disasters. During the rainstorm, government departments posted the information of urban emergency management, such as urban disaster emergency plan, locations of damaged roads and other infrastructure, urban emergency transportation and services. During the recovery period, government departments actively responded to hot topics of urban planning & construction and urban management to which residents showed concern. Through micro-participation in the process of urban sudden disasters, government departments could timely disclose the information, strengthen the coordination of work between government departments, and follow disaster information of the public, and this played an important role in reducing disaster losses and improving the city's public service capacity.

5.2.2   Media: micro-participation in disaster spreading

Mobile Internet and interactive media are the main trend of modern media, With the help of micro-blogging platforms, traditional media and online media can disseminate information more timely and conveniently to provide services for urban residents. News media, such as Beijing TV, Beijing News, Financial Network and ordinary people, all participated in information dissemination of Beijing "7.21" rainstorm sudden disaster through the Sina micro-blogging platform. During disasters, the micro-blogging of news media spread information of rainstorm, disaster and rescue conditions and provided the information quickly through different channels to the public. Media micro-blogging reported the touching stories and positive behaviors in the rainstorm disaster, which can improve urban cohesion and enhance urban disaster emergency response capability. During the recovery period, the media conducted investigations on hot topics that the public showed concern for and the surveyed results announced by media micro-blogging to promote urban planning and construction management in a scientific, fair and efficient way.

5.2.3   The public: micro-participation during disasters

The public accounts for the majority of micro-participation. They posted micro-blog entries and commented on others' blogging to achieve information sharing. The content of micro-participation of the public in Beijing rainstorm disaster were as follow: (1) releasing disasters and help information. With micro-blogging platform, the public released floods location, the degree of disaster and help tracing information. (2) Organizing activities of rescue. Enthusiastic netizens called for others to provide help for residents trapped in the rainstorm, involve in disaster relief work and offer donations to disaster affected residents. (3) Personal emotional expression. The public published personal views and attitudes of disaster-related things, and commented on the right and wrong of other people's behaviors.(4) urban drainage systems, urban planning management and urban emergency management issues.

5.2.4   Urban planners: micro-participation in urban planning and disaster emergency management

The micro-participation of urban planners was less compared to the above three types. This is because the number of planners involved in micro-blogging is smaller. Most planners in the micro-blog social network had dual identity of the planners and ordinary people, and communicated with similiar or the same occupation, so they have limited influence on society. Fortunately, more and more urban planning and design institutions begin to use enterprise microblogging to communication with the public on urban planning and management .

During the Beijing rainstorm disaster, planners posted and discussed on urban planning relevant problems as follow: analyzing the causes of waterlogging disaster from urban site selection and facility layout, discussing on current China's urban drainage system construction standards and the problems with reference to United States, Japan, Germany, France and other cases and ancient China urban drainage system, as well as on the concern for China's future urban construction.
Fig 3: The number of follows and followings of different roles
Fig 4: The number of postings and responses of different roles

5.3 The mechanisms of micro-participation in urban emergency management

5.3.1   The mechanism of information diffusion and interactive communication

Information diffusion and interactive communication through the micro-blogging platform is the main operating mechanism of micro-participation in urban emergency disasters. Diffusions of information include the top-down information disclosure mechanisms led by the government and the bottom to top information diffusion mechanisms led by the public. In this process, the government, the media and the public can realize immediate dialogue and interactive communication.

(1)Top-down information disclosure mechanism

The government disclosed the information of rainstorm warning, contingency plans, disaster situations, relief and aftermath work to the public through the official micro-blogging timely. Through media diffusion, direct communication to the public and other ways, the government achieved top-down disaster information diffusion. When the official disaster information and the public demand are consistent, the public will make positive response and participate in disaster prevention and rescue. While when the official public disaster information and the public demand are not consistent, the public will question the official information, and the governments give responses and interpretation on the inconsistencies.

(2) Bottom-up information diffusion mechanisms

The public released information on rainstorm, disaster scene information, rescue information, enquiries and other information with their personal micro-blogging account, and part of the public released information directly to official and media users to attract their attention. If the information released by the public is relevant to the official administrative responsibilities, the government will respond and take appropriate disaster relief operational measures to reduce disaster loss for the public. Although part of information released by the public is not within the scope of the administrative duties of the government, it will lead to information dissemination and cause other social groups to pay attention.
Fig 5: Information spreading and interactive communication in urban emergency management
Fig 6: The mechanism of micro-participation in urban management

5.3.2   Mechanism of public participation in urban emergency management

Urban infrastructure, urban planning, urban emergency management, public services and other problems exposed in the Beijing rainstorm disaster got plenty of attention from the public and the media. During the Beijing rainstorm disaster, the public discussed around the topic of urban drainage systems and other infrastructure construction with the Sina micro-blogging platform. Netizens posted messages, such as "drainage system represents the conscience of the city", " waterlogging reveals the problems and defects of the urban underground drainage line", "municipal traffic often failed, what about the warning services?", etc. Based on these problems and questions, the government responded timely and announced some key strategies, like "the maps of dangerous sections in the Beijing rainstorm", "the urban road maps of

hydrocephalus", "emergency shelter maps in the Beijing rainstorm" and other information. At the same time, the government improved the concept of urban planning and adjusted the standards of urban emergency management according to the advice the netizens gave on urban planning and construction. The new measures and management practices will be published and modified according to further opinion of the public.

During the period of disaster recovery construction and rehabilitation, the government announced the official service phone numbers and strengthened interactive communication with the public through micro-blogging. Meanwhile, the administration departments carried out maintenance on facilities, resettlement housing construction work and timely opened information through micro-blogging.

5.3.3   Supervision and guidance mechanisms of public opinion

Supervision mechanisms of public opinion by the network means to keep the implementation process of public decision not be distorted in the implementation process of public decision-making (Zhai Guotao,2007). With the features of more direct and real-time interactive communication, micro-blogging plays a more and more important role in the supervision of public opinion. But due to the asymmetry of information and personal emotional factors, there are some incorrect even wrong views in the public opinion that is easy to cause misunderstanding and social panic, so correct guidance of public opinion is of supreme importance.

The public discussed on the disaster relief efforts of the Beijing rainstorm and other hot topics to achieve adaptation and constraints on the behavior of the implementation policies by the pressure of public opinion. The discussion on the number of death in the disaster is a case in point. First the official death toll statistics were published, but the public questioned the truth of the death toll. Due to pressure of public opinion and the attention of senior leadership, the Beijing official department eventually announced the new death toll list. Meanwhile, Public suspicion and inaccurate messages that government actively guided and corrected had said the Zijingguan reservoir in Juma river upstream would spill. On this topic of public concern, the Beijing water authority and other departments denied the micro-blogging rumor that the Juma River upstream reservoir spill was not real and eliminated the concerns of the public and unnecessary panic.

Bad behaviors in urban disasters can be supervised and the urban spirit can be propagated by public opinion through micro-blogging. The public discussed and condemned the rising price of taxis, hotels and other bad behaviors which caught the attention of the government and the media, and triggered relative investigation into related issues. The collaboration between officials and the public, self-sacrifice and other good spirit of the city was passed on by micro-blogging. This was good for enhancing the credibility of the government and spreading positive energy of the city.

6   POLICY RECOMMENDATIONS ON PROMOTING URBAN MANAGEMENT IN THE AGE OF MICRO-ERA

6.1 Constructing a new paradigm for public participation in urban management

Using the micro-blogging platform of information disclosure and the subject of different interactive functions to make a new paradigm for public participation in urban management, we can change the traditional city management mode of the centralized mechanism led by the government, keep the mechanism of interactive communication on city infrastructure function and urban public space management and urban emergency management, and build a comprehensive management mode for the city. The government should perfect micro-blogging network platforms of public participation in urban management functions, set up official micro-blogging and also different management department ones, clarify full-time personnel government micro-blogging of city management as well as the micro-blogging topic response department. Due to the large amount of information of micro-blogging and their redundant nature, even valid information is likely to be covered by other invalid ones.A new mechanism is to be established to make sure micro-blogging information can be released publicly in through straight and directional ways to improve the efficiency of public affairs of information management. Establish a proper system so as to extract effective public information to respond to through the network or start interactive commucation on relevant issues,and will take the public demand into account for government departments and the urban management in the implementation process.

6.2 Establish and perfect the security mechanism system in public participation

Micro-blogging of public participation have corresponding laws and regulations system as a backup in western countries. As early as 2009, the British government issued a "government Twitter use guideline" that can make clear system requirements through the contents of Twitter micro-blogging platform for information disclosure and public interactive communication and so on. Although government through micro-blogging has been widely used in China, the corresponding rules and regulations are yet to be established. We need to establish a systematic mechanism for micro-blogging of government affairs and public participation in urban management urgently. The powers and responsibilities in the network hot topic information should be clearly defined between the government, the media, social organizations and experts. The administrative activities with micro-blogging should be made a routine so as to further enhance social democracy and toestablish a response mechanism of hot topics and take response actions to meet the social needs of the public. Norms of participating in social hot topics discussion need to be established for the media, social organizations and experts to define the main duties of different bodies. Institution on the micro-blogging information posting mechanisms for the public and the information processing mechanisms for the government should be established to improve the efficiency of micro-blogging participation in urban management, and the guiding mechanisms of public opinion in micro-blogging network should be established for discussing the urban management strategies and key elements.

6.3 Toward collective decision making and real-time participation in urban management

Using micro-blogging platforms, the government can lead public participation in the decision-making process of urban planning and urban emergency management to realize collective democracy of urban management. The government could expand the scope of public participation in urban management affairs through micro-blogging information dissemination and difussion, and lead more extensive public participation in topic discussion of urban management so that the city management decisions reflect the most democratic willingness. It is necessary to build a real-time participation in formulating urban management policies, implementing urban management and other stages, and build the response mechanisms of "participation- feedback – and then participation" in order to have an inclusive attitude to listen to all kinds of public voices and encourage sincere and open dialogues and exchanges (Luo pengfei, 2012;Zou Bin, et al., 2011). The entire process of public participation in urban management can play the role of public decision-making and supervision in urban management, as well as contributing to improvegovernment credibility in the process of urban management.

6.4 Establishing the service management systems of smart city

With the help of micro-blogging platforms, information can be shared in urban areas. Urban constructers can use location information services (LBS), social network services and other technical means to create public service platforms as an important aspect of smart city. China's economically developed urban areas should take the lead in constructing intelligent services and information management control center, which can then be associated with resident's location information and service needs through the positoning capabilities of mobile terminal devices to structure the smart city public service mode of "releasing urban resident's service needs through micro-blogging-the resident location information positioning-wisdom service center information processing-intelligence services providing and responses". The combination of micro-blogging information and public services of smart city can provide mobile services (toward personal services) functions, such as vehicle maintenance, food service, medical services that will improve the efficiency of urban public services and make urban life more livable and convenient.

1 ABSTRACT

Today, spatial planning strongly relies on computerized Spatial Information Systems (SIS) which, thank to continuous improvements, provides increasingly better techniques for handling, visualizing, and analyzing quantitative (geometric or geographic) spatial data. An important typology of instruments today largely lacking in SIS is concerned with the management and analysis of qualitative spatial information. Indeed, although quantitative spatial information is necessary when it comes to precise computations, a qualitative approach is to be preferred in situations where preciseness is not necessary or even undesired. This is typically the case when it comes to the interaction with human beings. In this paper we outline an extension for a generic SIS that enables the system to handle qualitative spatial information and discuss how this can support spatial planning in several ways.

2 INTRODUCION

Geographic Information Systems (GIS) and Computer-Aided Design (CAD) applications play a central role in spatial planning. Such computerized systems, indeed, provide increasingly sophisticated representational and analytical means which support spatial planners in carrying out improved land studies and in making more accurate decisions.

In spite of continuous improvements, however, GIS and CAD keep on relying mainly on quantitative spatial (i.e., geometric or geographic) representations, while some important features largely missing today are concerned with the management and the analysis of qualitative spatial information. Indeed, although quantitative analysis is necessary when it comes to precise computations, a qualitative approach is to be preferred in situations where preciseness is not necessary or even undesired. This is typically the case when it comes to the interaction with human beings, which, as argued in the past (K. Lynch, 1960), naturally represent and reason about space in a qualitative manner: for example, people prefer to express relative position between two objects resorting to predicates like "*left of*" and "*right of*" rather than reporting the angular distance among them. Predicates of this type are called *qualitative spatial relations*, and, accordingly, a set of them describing a spatial scene shall be called a qualitatively-described spatial configuration or, more simply, a *qualitative spatial configuration* (Fogliaroni, 2012).

In this paper we outline an extension for a generic Spatial Information System (SIS) that enables the system to handle qualitative spatial information and, more specifically, qualitative spatial configurations. We elaborate how this can benefit spatial planning in several ways:

(1) Natural planner-SIS interaction: the identification of a spatial plan location can be done either by describing in natural language or by sketching its position with respect to other elements of the embedding environment;

(2) Design phase support: according to the type of plan being designed, the extended SIS suggests a list of items that should be placed in the workspace as well as the best spatial arrangement;

(3) Public participation enabling: a spatial plan eventually yields a change in the structure of a real environment whose quality is best assessed by its users; assessment (at least partly) relies on the (qualitative) spatial configuration of environmental elements. Thanks to its capacity of qualitatively representing spatial configurations, the extended SIS allows for the collection of public feedback which can be used to enhance the support provided in the design phase.

The remainder of this paper is organized as follows. In Sections 3 and 4 we provide an overview on the relevant state of the art in Spatial Information Systems and Qualitative Spatial Representation and Reasoning, respectively. Section 5 reports about an extension for a SIS developed in (Fogliaroni, 2012) that enables the system to deal with qualitative spatial information. In Section 6 we further extend the system and discuss how it allows for supporting spatial planning whereas in Section 6.1 we present an approach for

computing prototypical spatial plans out of previous designs. Section 7 is devoted to show how the described system can be integrated with standard web-based pooling platforms to refine plan prototypes according to public expectation. Finally, conclusions are drawn in Section 8.

3 SPATIAL INFORMATION SYSTEMS

With the term Spatial Information System (SIS) we shall intend, in the scope of this paper, any system of hardware and software elements that allows for surveying, storing, analyzing, manipulating, retrieving, sharing, and presenting spatial data. Two well-known examples are Geographic Information Systems (GIS) and Computer-Aided Design (CAD) applications. From a logical perspective a SIS consists of a series of specialized layers interacting and collaborating with each other; at the lowest level lays the storage layer: a support to persistently represent data in a computer. Data storing can be done by means of purposely designed file encodings—e.g., shapefiles (ESRI, 1998). Nonetheless, the usage of a spatial database in this role is the most common scenario, since its optimized access methods notably improve data storage, retrieval, and, thus, analysis performance.

A spatial database is a database furnished with data types and functions suited for handling spatial information, which, in the (geo)spatial domain is concerned with real and factitious entities: Real entities comprise physical objects, natural or artificial (e.g., a lake or a building), whereas factitious entities are those that are not physically distinguishable from surrounding ones or that refer to agglomerations of single entities as a unique concept (e.g., administrative districts or countries). An ontological perspective on this issue is taken by Smith (1995) who distinguishes between entities with bona fide and fiat boundaries, respectively. Modeling spatial information is done mainly following two approaches that in the literature (Longley et al., 2005; Worboys & Duckham, 2004) are typically referred to as field-based and object-based. The field-based approach looks at the properties that have to be modeled as continuous fields and discretizes them via the superimposition of a (typically regular) geometric structure (e.g., a grid). The resulting data model is commonly known as raster. Conversely, in the object-based approach the main focus is on the spatial entities, whose geometry is modeled by means of a series of line segments called vectors.

Any manipulation of spatial data (drawing, analysis, selection, and so forth) in a SIS corresponds, at the database level, to the employment of a series of so-called spatial operators: functions defined over a set of spatial objects that perform some kind of geometric operation over the input data and return a result. The OpenGIS Consortium released a set of specifications for spatial operators (OpenGIS Consortium, 1998) intended to serve as guidelines for any spatial database. An important typology of spatial operators is concerned with the determination of the topological relationship between pairs of objects. However, as pointed out in (Clementini & Di Felice 2000), topology is not the only spatial aspect one might be interested in. Thus, further operators should be defined to deal with other aspects of space (e.g., direction and distance).

4 QUALITATIVE SPATIAL REPRESENTATION AND REASONING

Qualitative Spatial Representation and Reasoning (QSR) (cf. Cohn & Renz, 2008 and Cohn & Hazarika 2001 for an overview) is a subfield of artificial intelligence that aims at developing spatial representation techniques and computational models capable of simulating human spatial cognition. Such computational models draw upon the development of so-called qualitative spatial calculi.

A qualitative spatial calculus is a sound mathematical structure providing (*i*) a finite set of symbols (called qualitative spatial relations) that can be used to model spatial scenes and (*ii*) a set of operations defined over such symbols that allow for performing symbolic reasoning. Typically, a qualitative calculus focuses on one specific aspect of space. More than thirty years of research efforts in the field of QSR led to the birth of a vast and heterogeneous set of theoretical frameworks addressing a variety of qualitative spatial aspects (e.g., topology, direction, and distance among the most fundamentals). One of the best-known qualitative spatial calculi is the 9-Intersection Model (9-IM) (Egenhofer, 1989) which defines the 8 topological relations that can hold over a pair of spatial regions homeomorphic to the closed unit disk. They are depicted in Fig. 1 and arranged according to their *conceptual neighborhood graph* (Egenhofer & Al-Taha, 1992).

The term conceptual neighborhood has been first introduced in (Freksa, 1992) and refers to the property of a qualitative relation holding among a sequence of objects to change into another relation when the spatial objects it relates are continuously deformed according to a certain type of transformation (e.g., a topological transformation: movement, stretching/shrinking, or twisting). For example, the conceptual neighborhood

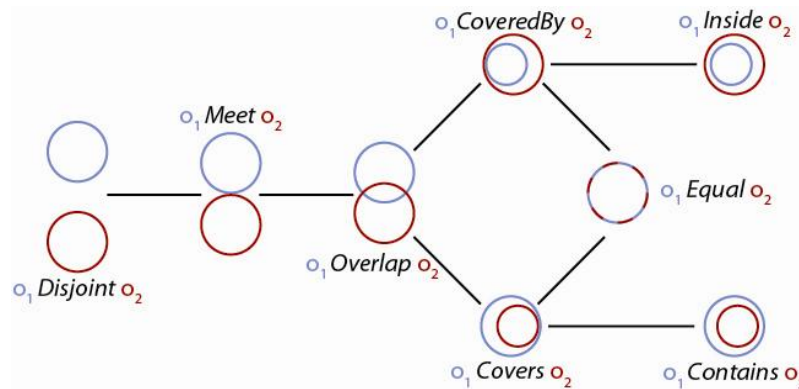
graph for 9-IM correctly shows that *Meet* is the nearest relation to *Disjoint* and *Overlap*. This means that, if at time t_i two objects are *Disjoint* and at time t_k they *Overlap*, there has to exist a time point t_j when they *Meet* such that $t_i<t_j<t_k$. In other words, the relational transition between *Disjoint* and *Overlap* goes through *Meet*.


Fig. 1: the 8 possible topological relations between convex regions in the plane, as defined by the 9-Intersection Model (Egenhofer, 1989) and arranged to form the neighborhood graph.

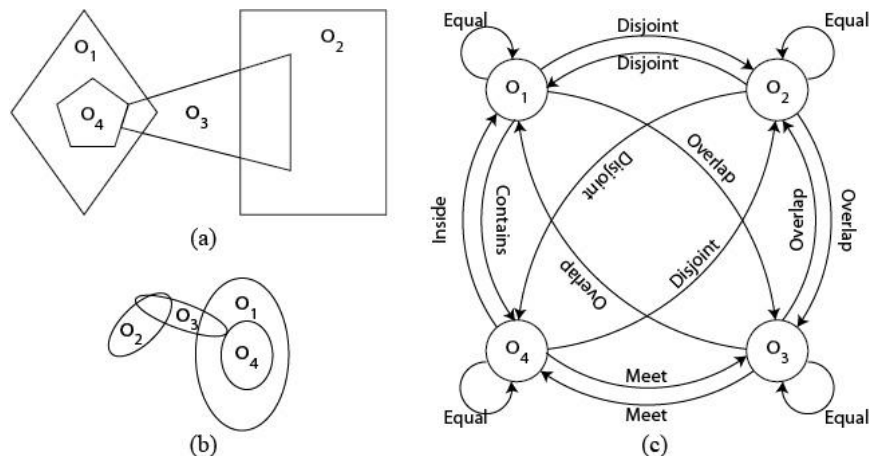
As mentioned above, qualitative spatial calculi can be used to represent and reason about a configuration of spatial objects. One of the most spread methods resorts to the utilization of so-called Qualitative Constraint Networks (QCNs) (cf. Dechter, 2003 for a detailed discussion). A QCN can be seen as a labeled, directed (hyper)graph: each node represents a spatial object in the configuration; each (hyper)arc indicates which relation (reported in the label) holds among a sequence of spatial objects (those represented by the nodes connected by the hyperarc). For example, the spatial configuration depicted in Fig. 2(a) can be topologically described by the QCN in Fig. 2(c) taking relations (arc labels) from the 9-Intersection Model. Note that while the QCN associated to a geometrically described spatial configuration is unique, the opposite is not true: the same QCN can represent geometrically different spatial configurations. For example, the network in Fig. 2(c) also describes the configuration reported in Fig. 2(b), where object shapes, orientations, and relative positions are distorted and the only unchanged aspect is the topological one.


Fig. 2: The spatial configuration in (a) is uniquely represented by the qualitative (topological) constraint network in (c). However, note that the same network also represents the configuration in (b), meaning that the two configurations are topologically equivalent.

5 QUALITATIVE SPATIAL INFORMATION SYSTEM

In spite of continuous improvements in spatial data management and analysis, the interaction modalities between humans and Spatial Information Systems (SIS) keep remaining largely artificial and cognitively unnatural. One main motivation resides in the different ways SIS and humans deal with spatial information: SIS mainly draw upon quantitative spatial representations typically based on raster and vector data models, whereas human beings naturally resort to a qualitative and relational approach. For example, we use expressions like "the lake is to the right-hand side of the wood" or "is there a supermarket close to the university?" which qualitatively locate a spatial entity with respect to another.

Nowadays, such a gap in representation has to be plugged by the system user: He has to translate his mental, qualitative representation of space into a series of numerical constraints and to encode the latter in an

artificial language which the system is capable of elaborating. As a result, this augments the cognitive effort of the interaction and, consequently, denies casual users (non-experts) the possibility to exploit the system.

One possible solution to this problem is presented in (Fogliaroni, 2012) where a theoretical and practical framework is detailed which allows for enabling any SIS relying on a spatial database to explicitly deal with qualitative spatial information: The database is enhanced with an extensible pool of qualitative spatial calculi in such a way that the spatial relations provided by the latter are available to the system as spatial operators. Such relational operators extend the artificial language of the system, allowing for a direct encoding of spatial descriptions naturally produced by a human. More specifically, they allow for modeling by means of Qualitative Constraint Networks (QCNs) both, a quantitatively described spatial dataset and a natural spatial description coming in either verbal (written or spoken utterances) or pictorial (sketch maps) format. The QCN representation of a spatial dataset is referred to as qualification (or more explicitly as qualitative dataset) whereas that of a natural spatial description is called Qualitative Spatial Relation Query (QSRQ).

QSRQs consist of sets of predicates of the form

<div align="center">(spatial relation, spatial object, …, spatial object)</div>

taking spatial relations from those provided by the calculus pool; they are classified according to the level of indeterminacy of the spatial predicates they encode: the more numerous the elements of the predicate left unspecified, the harder the query to be solved. The hardest (realistic) query type consists of a series of predicates having only the spatial relation specified. A query of this category qualitatively describes the spatial arrangement of a set of undetermined objects (spatial variables) and, accordingly, it is called Qualitative Spatial Configuration Query (QSCQ). In (Fogliaroni, 2012) a set of algorithms and data structures has been designed that allows for efficiently solving such queries.

6 SUPPORTING SPATIAL PLANNING IN SPATIAL INFORMATION SYSTEMS

In this section we outline a further enhancement for the qualitative spatial information system (QSIS) discussed in Section 5 that allows for supporting spatial planners in the design phase. We suggest equipping the QSIS with two domain ontologies providing a hierarchical categorization of spatial objects and spatial plans, respectively. For the sake of exposition it is necessary to distinguish between the design of a spatial plan and its realization in the real world: we shall refer to the first as plan design and to the second as plan environment. Moreover, in the case the location for a spatial plan is not predetermined, but rather has to be decided by the planner, we also shall discriminate between workspace location and environment location: the first indicates the location a planner has to identify within a spatial dataset according to certain given constraints whereas the second denotes the actual location of a plan environment in the real world.

Spatial object categories define classes of spatial objects like dwelling, road, and grocery. Moreover, we assume that the ontology defines some categories like public green, industrial area, and residential area which describe agglomerates of spatial objects (factitious entities). Object categories can be used in place of generic spatial objects within a QSCQ to provide a more accurate definition of the searched configuration, although still general. For example, the following is a QSCQ describing the arrangement of two dwellings, one road, one grocery and one agglomeration of objects that is a public green zone:

{dwelling(o1) adjacent to road(o2), dwelling(o1) right of road(o2),

dwelling(o3) adjacent to road(o2),

grocery(o4) adjacent to road(o2), grocery(o4) close to dwelling(o1),

public green(o5) close to dwelling(o1), public green(o5) right of road(o2)}

Plan categories potentially coincide with object agglomeration categories and we shall assume that to each of them is associated a QSCQ describing the optimal spatial configuration for that specific plan category. In particular, such an optimal configuration defines the number of objects of each category that should be placed in the design (and, consequently, in the environment) as well as in which manner they should be spatially arranged.

A QSIS enhanced in this way can support the design of a spatial plan in several ways:

(1) In the case the environment location is not decided a priori and it is on the planner selecting an appropriate one, the planner can complement a standard search (based on object attributes like land usage or

land type) with a sketched or a verbally described spatial configuration (i.e., a QSCQ) that the workspace location has to satisfy. As an example let us consider the search for an optimal location of a residential area. Several conditions must be met: The noise level should be low, transport capacity of the nearby transportation network must be adequate, the impact on nature shall be limited, and there should be not excessive risk of flooding or avalanches. These conditions are expressed as a QSCQ and suitable areas can be found.

(2) Once the workspace location is decided and selected, the planner states the plan category he intends to design. The system exploits the optimal configuration associated to that plan category to suggest to the planner a list of spatial objects (divided by category) that should be placed in the workspace and how they should be arranged. Possibly, the system might already suggest an arrangement taking into consideration the morphology of the land parcels covered by the workplace. For example, a residential area comprises more than just buildings and gardens. A road network, green areas, public services, etc. are also necessary. Using basic predicates (e.g., green areas should be accessible for all inhabitants) a starting distribution can be computed.

(3) During the design phase, the planner can drag and drop new objects in the workspace or transform objects already placed. The system continuously parses the design and produces the corresponding QCN which is compared with the optimal configuration associated to the plan category. The outcome of the comparison is used to point out to the planner which elements does not fit the optimal configuration and for associating an overall "optimality" score to the current design. For example, one might design a road going through a park and, if the spatial arrangement of such elements would conflict with the one reported in the optimal configuration, the system would point this out to the planner. Of course is up to the planner deciding whether taking care of the suggestion (i.e., the arrangement was a mistake) or not (i.e., the arrangement was intended to be like that).

While the scenario described in point 2 does not require anything more than retrieving the optimal configuration associated with plan category and use it to produce a prototypical design, points 1 and 3 give raise to a number of more advanced issues. Particularly, in the scenario described in point 1, the system shall return a location perfectly matching the given constraints. However, if such a perfect matching does not exist a best matching location might be suggested to the planner. The problem raised in point 3 is concerned with similarity assessment.

Since qualitative constraint networks (QCNs) naturally lend themselves to be represented as hypergraphs, such problems can be stated as (sub)graph matching problems. In particular they are: perfect matching, best matching, and similarity measurement.

The problem of finding a perfect matching can be solved via an adaptation of famous Ullmann's subgraph isomorphism algorithm (Ullmann, 1976) as described in (Fogliaroni, 2012, Section 3.4.1). In (Wallgrun et al., 2010), another variant of Ullmann's algorithm is used to find the best matching between a pair of QCNs. Although apparently very similar to the first problem, the problem tackled by Wallgrun et al. differs in two main points. (i) They look for best partial matchings rather than for complete matchings, namely, they try to match the highest number of (hyper)arcs. This means that they are faced with a maximum common subgraph problem instead of a subgraph isomorphism. (ii) They also consider ambiguous QCNs, i.e., hyperarcs may be labeled with disjunctions of relations. Accordingly, they employ an A* algorithm to drive the matching process, employing consistency checking as the main constituent of the forward checking function.

The last problem can be solved as a combination of the two techniques above in the following manner: If a perfect matching is found, the two networks are equivalent (i.e., maximum similarity score), otherwise the best partial matching is detected which has a number of unmatched hyperarcs. The qualitative relation encoded by each such hyperarc differs from the relation reported in the QCN describing the optimal configuration and the distance in the conceptual neighborhood graph between each such relation pair can be used to compute a similarity score between the two networks.

Let us resume the exemplary qualitative configuration given in Fig. 2 and refine it by including object categories as depicted in Fig. 3(c). The QSCQ reported in Fig. 3(a) perfectly matches such a configuration. Indeed, it is easy to verify that the only variable assignment that ensures the matching is the following $\{x1=o2, x2=o1, x3=o4\}$. Conversely, there is no way to assign all the variables of the QSCQ in Fig. 3(b) in such a way that all its arc labels match those in the given configuration. In this case only a partial assignment

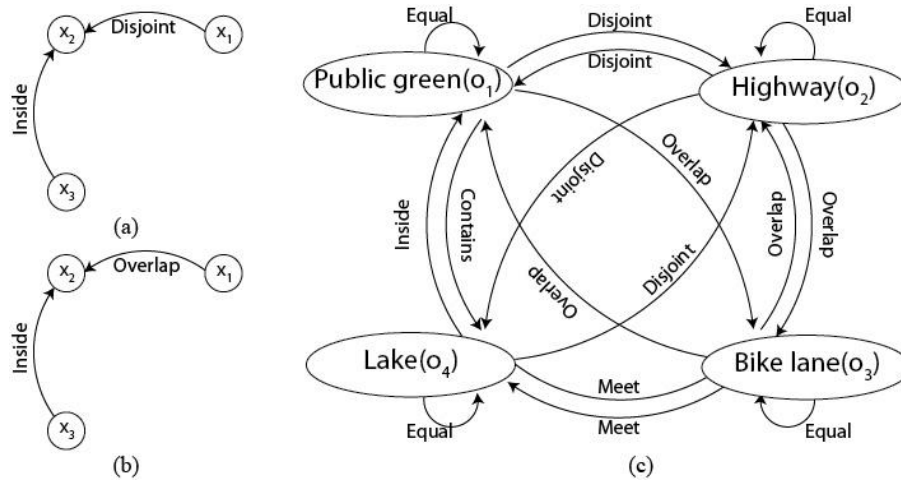
is possible that maximizes the number of matched variables, it is: {x2=o1, x3=o4}. Starting from this partial assignment a complete one can be generated. In the example it is: {x2=o1, x3=o4, x1=o2}. Such a complete assignment yields a mismatch between the arc (x1 Overlap x2) of the QSCQ and the arc (o2 Disjoint o1) of the configuration. The distance between the mismatching relations in the conceptual neighborhood graph (cf. Fig. 1) is equal to 2. Such a number can be used to assign a similarity score to the matching that is an index of how close the QSCQ is to the qualitative configuration (i.e., the optimality score).


Fig. 3: The QSCQ in (a) perfectly matches the qualitative configuration in (c) while the QSCQ in (b) matches partially.

6.1 Computing the optimal plan

In this section we describe an approach to compute optimal configurations for spatial plan categories. Thanks to its features, the qualitative spatial information system we described in Section 6 is capable of maintaining a list of qualitative datasets for each plan category. Such datasets are, simply, the qualification of spatial plans designed within the system. As such, each of them shall embody at least a subset of common-sense, best-design, environmental, and urban rules that should be commonly fulfilled in the design phase.

To compute the optimal configuration for a given plan category we suggest to compare all the corresponding qualified datasets in the following manner.

(1) Normalize the qualitative datasets by

(1.1) computing the maximum common set of spatial objects (separated by category) involved in the plans;

(1.2) removing from each qualitative dataset the objects not contained in the common set as well as the relations in which they are involved.

(2) Compare the normalized datasets (via hypergraph matching) to find the minimum common hypergraph.

The resulting minimum common hypergraph represents the optimal spatial configuration we look for.

7   FITTING SPATIAL PLANS TO PUBLIC EXPECTATIONS

Public participatory online applications are web platforms developed to collect public opinions about a given topic of common interest. One recently established form of public participatory applications integrates standard pooling techniques with Geographic Information Systems to obtain public feedbacks about spatial matters. Such a form of public participation is referred to as Public Participatory Geographic Information System (PPGIS) and in (Poplin, 2012) it is shown how it can benefit spatial planning.

In the previous section we outline a method to compute for a given type of spatial plan an optimal configuration which conveys rules of good planning design. Now we show how our qualitative-enhanced spatial information system allows for automatically exploiting people feedback conveyed through a PPGIS application to let the optimal configuration fit public expectation.

The fact that human beings mentally map space in a qualitative manner means that the assessment of the quality of a certain environment is (at least partly) based on the presence (or absence) of a number of objects of a certain category and on their spatial arrangement within the environment. The quality assessment might also be influenced by a number of aspatial aspects including air pollution, price of a service, and weather

conditions. However, in the scope of this work we shall disregard aspatial aspects and assume that the assessment of an environment can be directly associated to its qualitative representation (i.e., a QCN).

Accordingly, we suggest two slightly different approaches that resort to people feedbacks on the quality of an environment to compute optimal configurations.

The first approach draws on the idea that the quality of an environment (eventually resulting from a spatial plan) can be reliably assessed by its users: people working, living, or, more generally, carrying out an activity in the environment itself. Accordingly, we suggest asking users to evaluate the quality of a given environment by a numeric score. Such quality scores can be collected within the system and their average (or any other meaningful statistical operator) can be used to weight the plan design which the environment has been realized from. Every time the weight of a plan changes the optimal configuration for its category has to be recomputed as described in Section 6.1, this time taking into consideration the computed weights.

The second approach takes advantage of an online participatory application like, for example, the B3 project (http://www.geogameslab.de). B3 is a web platform that allows the registered user to actively participate in the planning process of Billstedt (a market place in Hamburg, Germany). The application consists of a 3D design environment displaying the actual (empty) location. The user can drag and drop environmental items from a predefined list or move them around within the scene until he obtains an environment satisfying his expectations. We suggest integrating our system to tools like B3 in such a way that the plan designed by each user can be qualified into a QCN which can be added to the list of qualitative datasets of a certain plan category. In such a way the optimal spatial configuration will fit not only good design rule, but also public expectation.

8 CONCLUSIONS

In this paper we presented an extension for a generic Spatial Information System (SIS) designed to benefit spatial planning. The extension builds on top of a framework presented in (Fogliaroni, 2012) which provides a standard SIS with qualitative spatial representation and reasoning capabilities. We suggested complementing such a framework by means of two domain ontologies providing hierarchical categorizations for spatial objects and spatial plans, respectively. The result is a qualitative-enhanced SIS that can benefit spatial planning design in several ways. As a basic functionality it provides more natural interaction means by bridging the representational gap existing among human beings (qualitative) and spatial information systems (quantitative). It also offers a mechanism to suggest the planner which environmental items should be placed in the design (according to the type of plan) and in which way they should be arranged in the workspace. The system is capable of assessing the plan being designed by comparing it with an optimal plan that accounts for good design rules; moreover it is also capable of pointing out which objects should be rearranged (if any). Finally we presented two approaches to integrate the suggested system with standard web-pooling techniques to collect public feedback and discussed how such a feedback can be used to refine the optimal plan; namely, to include public expectation in the spatial plan design phase.

1 ABSTRACT

The purpose of this paper is to identify goal conflicts – both actual and potential – between climate and social policies in government strategies in response to the growing significance of climate change as a socio-ecological issue (IPCC 2007). Both social and climate policies are political responses to long-term societal trends related to capitalist development, industrialisation, and urbanisation (Koch, 2012). Both modify these processes through regulation, fiscal transfers and other measures, thereby affecting conditions for the other. This means that there are fields of tensions and synergies between social policy and climate change policy. Exploring these tensions and synergies is an increasingly important task for navigating genuinely sustainable development. Gough et al (2008) highlight three potential synergies between social and climate change policies: First, income redistribution – a traditional concern of social policy – can facilitate use of and enhance efficiency of carbon pricing. A second area of synergy is housing, transport, urban policies and community development, which all have potential to crucially contribute towards reducing carbon emissions. Finally, climate change mitigation will require substantial and rapid shifts in producer and consumer behaviour. Land use planning policy is a critical bridge between climate change and social policy that provides a means to explore the tensions and synergies that are evolving within this context. This paper will focus on spatial planning as an opportunity to develop strategies to adapt to climate change, and reviews the challenges of such change.

Land use and spatial planning involve the allocation of land and the design and control of spatial patterns. Spatial planning is identified as being one of the most effective means of adapting settlements in response to climate change (Hurlimann and March, 2012). It provides the instrumental framework for adaptation (Meyer, et al., 2010) and operates as both a mechanism to achieve adaptation and a forum to negotiate priorities surrounding adaptation (Davoudi, et al., 2009). The acknowledged role of spatial planning in adaptation however has not translated into comparably significant consideration in planning literature (Davoudi, et al., 2009; Hurlimann and March, 2012). The discourse on adaptation specifically through spatial planning is described as 'missing' and 'subordinate' in national adaptation plans (Greiving and Fleischhauer, 2012),'underrepresented' (Roggema, et al., 2012) and 'limited and disparate' in planning literature (Davoudi, et al., 2009). Hurlimann and March (2012) suggest this may be due to limited experiences of adaptation in developed nations while Roggema et al. (2012) and Crane and Landis (2010) suggest it is because climate change is a wicked problem involving an unfamiliar problem, various frames of understanding and uncertain solutions. The potential for goal conflicts within this policy forum seem to outweigh the synergies. Yet, spatial planning will be a critical policy tool in the future to both protect and adapt communities to climate change.

2 INTRODUCTION

There is a strong scientific consensus that climate change is happening, that it is the result of human activity, that it is global, cumulative and destructive of human and environmental well-being (IPCC, 2007; Patz, J. and Kovats, 2002). However, this scientific consensus has not led to any meaningful coherence between economic and social policy, planning laws and climate change policy in developed countries like Australia (Koch, 2012; Gough, 2011). Without an integrated public policy framework and an inclusive approach to planning the vision of fair, prosperous and sustainable urban and regional communities will not become a meaningful reality (Gough, 2010, Stern, 2009). The broad policy challenge is to create conditions for human flourishing within the ecological limits of a finite planet (Jackson, 2009). Meeting this challenge will require the social and planning dimensions of public policy to be integrated with the environmental dimension. The integration of these policy dimensions in the critically important policy domain of land use planning presents a significant opportunity for synergies and goal conflicts to develop.

While this problem of coordination is acknowledged by some scholars, there is as yet little empirical research being done to understand the dynamics between economic, social policy/planning and

environmental policies and programs. In part, this is a problem of competing paradigms and knowledge systems, a clash between dominant economic models that have reached their ecological limits on one hand (Jackson, 2009) and scientific discourses that struggle to engage and incorporate the knowledge of local communities on the other (Whatmore and Landstrom, 2011). The result is increased uncertainty and knowledge controversy. What will be needed to address this uncertainty are more deliberative planning processes and more radical policy solutions, which can not only tackle the social equity and justice issues but also improve energy performance, land-use planning and reduce reliance on carbon based energy consumption. The purpose of this paper is to identify and explore existing and potential goal conflicts in pursuing social and economic objectives and climate change goals within the policy field of land use planning. This is done to aid in building synergies and minimising conflicts between environmental, economic and social policies and integrating principles of justice and sustainability in planning in the context of climate change. Section 2 identifies three macro scale approaches to social policy and climate change; Section 3 explores the role of and various approaches to land use planning in the context of climate change; Section 4 identifies three categories of goal conflicts; and finally, Section 5 suggests a role for planning in dealing with goal conflicts and knowledge controversies generated by competing policy paradigms and policy objectives.

3 CLIMATE CHANGE AND SOCIAL POLICY

Governments confront climate change with varying degrees of willingness to change economic, planning and social policy directions. In terms of social policy and climate change Gough (2011) identifies three scenarios which that provide some useful macro analytical tools. The first scenario, 'irrational optimism', is associated with freer markets and technological optimism and exemplified by mainstream Republican positions in the US. The prevailing idea is that economic growth will 'equip future populations to cope with climate change, mainly through adaptation …' (Gough 2011: 16). Favoured solutions are first and foremost deregulated drilling for oil in combination with some federal subsidies and loan guarantees for alternative energy sources, in particular nuclear energy, as well as carbon capture and storage.

The second scenario is 'green growth' or ecological modernisation, to which most European countries subscribe (Gough, 2011: 18). The incorporation of environmental interests, including climate change mitigation, will require a much more active state or 'a return to planning' (Giddens, 2009) to set goals and targets, manage risks, promote industrial policy, re-align prices through taxation and regulate externalities otherwise neglected by business interests. Especially in circumstances of financial crisis, economic recovery is seen to demand public investment, and this should be targeted towards energy security and low-carbon infrastructures. By reducing energy costs and reliance on the fragile geopolitics of energy supply, providing jobs in the expanding 'green' sector and meeting carbon emission reduction targets, the intention is to achieve synergies between economic, ecological and welfare goals.

While the second scenario in Gough's (2011) typology argues for an essentially Keynesian and green reorganisation of the economy, the third scenario questions economic grow per se. It is this scenario that involves more radical policy change and coordination. In 'slow-growth' approaches, researchers such as Victor (2008) and the UK Sustainable Development Commission stress the distinction between relative and absolute decoupling of GDP growth and CO2 emissions, the former referring to 'decline in the ecological intensity per unit of economic output' (Jackson 2009: 48). While emissions decline relative to GDP in some countries, they do not do so in absolute terms. To stabilise CC at the levels of relatively optimistic assumptions, emissions would need to decline absolutely. There is as yet no empirical evidence that this is being achieved (Garnaut et al 2009; Gough 2011). However, it is important to assess to what extent governments follow welfare and social policy strategies 'beyond growth' – that is, their preparedness to initiate a controlled transition towards a low or no growth strategy. This will mean going beyond what Hamilton (2003) calls the 'growth fetish', which he defines as the unchallengeable consensus that the overriding objective of modern government in developed countries must be continued economic growth.

Acknowledging the limitations of economic growth raises fundamental philosophical questions about what constitutes a 'good life' and 'the good society' within the ecological limits of a finite planet. Sen's (1984) early work on the 'living standard' is a useful point of departure for an adequate understanding of welfare and wellbeing under slow-growth conditions, where he argues that the material requirements for physiological flourishing tend to be fairly similar in all societies and that reported life satisfaction has

remained more or less unchanged in most advanced economies over several decades in spite of significant economic growth. Further insights are provided from philosophers such as Soper et al (2009), who argue that consumer society has already passed a critical point where materialism is now actively detracting from human well-being, and psychologists such as Kasser (2010; 2011), who provides evidence that people with higher intrinsic values are both happier and have higher levels of environmental responsibility than those with materialistic values. What is consistent across these frameworks is an appreciation that societal well-being needs to be defined in ways that are not only focused on the distribution of wealth, but also the distribution of time and opportunities not instrumentally tied to labour market status or potential for profit.

Developing these capabilities and measures will require public dialogue and debate about risk management, and the role of government, markets and civil society in climate change adaptation, the design of cities and regions and community and individual well-being. What is clear is that science cannot be the ultimate authority to settle these policy and value conflicts (Gottweis, 2003). It is this acknowledgement that underpins deliberative policy making and planning, an approach that seeks to keep problems and issues contestable (not to deny their controversial character), and ensure that the boundaries between experts and non-experts and between science and non-science are more permeable (Healey, 2003; Gottwesi, 2003). This deliberative and discursive approach to policy analysis and planning will inform climate change governance at the national and sub-national levels, as it moves beyond traditional policy analysis and 'top-down' planning and it has the potential to build inclusive public understandings, climate change strategies and redistribute scientific knowledge.

However, the challenge extends beyond a democratic and discursive approach for land use planning. Land use and spatial planning, as a method of moving knowledge to action, has inherent conflicts as a policy tool. These conflicts often occur at the substantive level, where spatial planning is a broad instrument that affects many aspects of the community such as affordable housing, economic development, hazard zoning, and environmental protection. This broad application is a strength of land use planning as it integrates important community goals into one vision. Yet, substantive elements within a plan often conflict: economic development with environmental protection; affordable housing with single family zoning restrictions; and hazard protection with tourism development. The paradoxical nature of planning is to both constrain and liberate land owners: to protect individual property owners from infringement, and yet act in the greater community interest. If we extend this range of conflict to include climate change the task becomes considerably more complex.

4   CLIMATE CHANGE AND LAND USE PLANNING

Land use and spatial planning involves the allocation of land and the design and control of spatial patterns. The United Nations and European Commission define land use planning as 'the systematic assessment of physical, social and economic factors in such a way as to encourage and assist land users in selecting options that increase their productivity, are sustainable and meet the needs of society' (UN, 1993; EU, 2006). The world bank similarly defines land use planning as 'a public policy exercise that designates and regulates the use of land in order to improve a community's physical, economic, and social efficiency and well-being' (WB, 2010). These definitions identify the broad range of factors which land use planning must consider and the ambiguous goals of sustainability, meeting the needs of society, efficiency and well-being. This broad scope underpins the opportunity for conflicts and synergies between the various and equally legitimate goals and policies of land use planning and the emerging 'adaptation turn' in planning.

Climate change introduces and intensifies a range of spatial impacts on settlements and results in dimensions of change and uncertainty in the social, environmental and economic context of human activities. Existing spatial configurations, particularly urban areas are both significant contributors to climate change and highly vulnerable to climate change (UN Habitat, 2010). Spatial planning is identified as being one of the most effective means of adapting settlements in response to climate change, particularly flooding associated with more frequent storm events and sea level rises (Hurlimann and March, 2012). This is generally argued on the basis of the spatial dimension of climate change impacts and the ability of planning to facilitate anticipatory action and cross-sectoral coordination. The critical role of planning in relation to climate change is recognised in both climate policy literature (IPCC, 2007; Stern, 2007) and spatial planning literature (Crane and Landis, 2010; Davoudi et al., 2009; Wilson and Piper, 2010). As Priemus and Davoudi (2012, p1) urge, urban planners need to revisit their traditonal concepts, methods and ways of thinking. However the

acknowledged role of spatial planning in adaptation has not translated into comparably significant consideration in planning literature or practice (Davoudi, et al., 2009; Hurlimann and March, 2012). The discourse linking adaptation and spatial planning is described as limited and disparate (Davoudi et al., 2009), sparse (Blanco et al., 2009), underrepresented (Roggema, Kabat, et al., 2012) and a paucity (Hurlimann and March, 2012) in planning literature and missing' and 'subordinate in adaptation plans (Greiving and Fleischhauer, 2012).

The exact nature of the role planning plays in relation to climate change adaptation comprises two complementary capacities. First spatial planning is expected to provide the instrumental framework or delivery mechanism to implement strategies and measures to influence spatial development patterns in a way that reduces vulnerability and increases resilience (Meyer et al., 2010). Second spatial planning is suggested to provide a forum or arena to negotiate priorities, explore options and create synergies between adaptation and at times conflicting mitigation and sustainability objectives and social and economic goals (Biesbroek et al., 2009; Davoudi et al., 2009). The first is an outcome oriented technical task while the second is a process oriented socio-political task. Davoudi et al., (2009, p16) explains that 'Spatial planning can play a pivotal role not just as a technical means by which climate change policies can be delivered, but also as a democratic arena through which negotiations over seemingly conflicting goals can take place, diverse voices can be heard, and place-based synergies can be formed'. These roles reflect top-down synoptic and bottom-up communicative approaches grounded in traditional planning theory (see Allmendinger, 2009).

The broader climate change science and policy literature emphasises the role of planning as an instrumental framework and delivery mechanism, while the planning literature is more likely to consider planning's role as a democratic forum or arena. However the merits of a more direct implementation approach verse a participatory approach in the context of climate change is contested. For example Dymen and Langlais (2013) argue that a more direct calculation and implementation of adaptation measures is required while Bulkeley (2009, p294), challenges the notion that spatial planning can provide a linear translation and delivery of top gown policy goals: 'Spatial planning should not be considered as a delivery mechanism for climate change policy. Rather, what it means to respond to climate change is defined, contested and made material through processes of negotiation and conflict'. In its capacity as a communicative and participatory forum for negotiation, the potential for goal conflicts is recognised and the capacity of planning to consider and resolve these conflicts is emphasised.

5 GOAL CONFLICTS

In negotiating climate change and social policies, governments often have to deal with contradictory goals (Jessop, 2002). Three levels of goal conflicts are identified: (1) philosophical conflicts between different ways of thinking and different fundamental values, (2) policy conflicts which involve incompatible or competing policy objectives, and (3) instrumental and implementation conflicts which involve incompatible or competing approaches to implementation. These categories of goal conflicts are interrelated. A philosophical conflict for example often leads to subsequent policy conflicts and instrumental and implementation conflicts.

Conflict Type	Explanation	Conflict Between:
Philosophical Conflicts	Divergent Approaches to Planning	Different Planning Cultures Different Planning Rationales
Policy Conflicts	Incompatible Policy Objectives	Social Wellbeing Objectives Economic Development Objectives Environmental Protection Objectives
Instrumental and Implementation Conflicts	Incompatible or Competing Approaches to Implementation	Different Timeframes Different Spatial Scales Different Governance Structures Different Resource Allocation

Figure 1: Goal conflicts in planning for climate change

5.1 Philosophical Conflicts

Philosophical conflicts involve different ways of thinking and different fundamental values. Various rationales have been provided as justification of the legitimacy and value of planning. These are important because they not only explain the reason planning is needed but underpin concepts of how planning is should be undertaken. Public interest rationales (Klosterman, 1980; Campbell and Marshall, 2002) support planning based on notions that some actions are in the common interest and general welfare of society. Social justice

rationales (Davidoff, 1965; Markusen, 2000) pursue some sense of equity and see planners as advocates who represent the interests of and facilitate the involvement of marginalised and underrepresented groups. Economic rationales (More, 1978; Klosterman 1985) identify planning a having a legitimate role in cases of market failure such as in public goods, externalities and high transaction costs. The underlying rationales dictate to some degree whether planning is primarily concerned with serving a collectively held interest, combating conditions of inequity and injustice or in correcting market failures. These different rationales not only underlie different approaches to planning but are linked to the different scenarios discussed in Section 2: irrational optimism, green growth, and slow growth.

Each rationale can be seen to support a consideration of climate change in planning. Action on climate change is in the public interest in that it impacts the whole of society. It is also supported in terms of social justice because impacts are disproportionally felt by the socioeconomically disadvantaged groups, (Leichenko and O'Brien, 2008) of instance observe that patterns of climate change vulnerability correlate with patterns of socioeconomic vulnerability originating from neoliberal globalisation. From an economic perspective climate change is an uncontrolled externalities and a stable climate can be construed as a public good. However conflicts arise from the divergent focus of each rationale.

Value conflicts do not need to be well defined and distinct. Even amongst the planning profession – value differences abound. Stead (2013) identifies forces of convergence and divergence in spatial planning in Europe and argues that path dependency and planning cultures can operate as a force against convergence. The importance of planning cultures and their impact on decision-making is poorly understood in the literature (Stead, 2013). Indeed, the value and cultural differences provide both opportunities for conflict and poor integration of policy to application.

5.2 Policy Conflicts

Policy conflicts involve incompatible or competing policy objectives. Planning may fail to deliver climate change policy goals because of the number of planning concerns which involves diverse social and economic objectives. Bulkeley (2006, 2009) argues that the adaptation agenda may cause tensions between other legitimate dimensions of planning, and notes cases where conflicting planning objectives have obstructed climate change mitigation and adaptation and increased levels of vulnerability. This occurs when adaptation objectives such as the development of renewable energy infrastructure and limiting development on floodplains conflict with, and are subordinated by other legitimate planning objectives such as visual amenity and provision of affordable housing through spatial planning processes (Bulkeley, 2009). Tensions can also exist between mitigation strategies and adaptation strategies and perusing one independently may hinder the other (Biesbroek et al., 2009; Howard, 2009).

Other planning objectives can compete with and constrain adaptation. This occurs when, due to the breadth of planning concerns and the scarcity of planning resources, other planning objectives compete with adaptation objectives for priority and resources (Measham et al., 2010). These situations are attributed by Owens and Cowell (2010) to competing interpretations of sustainability and the relative emphasis placed on the environmental, social and economic dimensions which ultimately originate from divergent concepts of the public good. Under these situations even if adaptation is supported at the strategic level it may not be successfully carried into implementation. And while the prioritisation and reconciliation of objectives is a necessary role of planning which may legitimately qualify the achievement of some objectives (Owens and Cowell, 2010), this process has historically resulted in an over prioritisation of economic interests and undervaluation of social and economic interests. Thus, perhaps the role of planning becomes focused on arbitration, as Greiving and Fleischhauer (2012, p.41) argue that at the policy level "the main challenge for planning is to identify synergies and conflicts between the different problems a city is confronted with".

5.3 Instrumental and Implementation Conflicts

As discussed earlier, planning and land use control are often comprised of inherent conflicts – and the role of planning is arbitrate the range of values. Thus, obvious differences in common substantive elements such as local economic development verses environmental protection are arbitrated at the Local Council level and decisions are made (or not made) to resolve or mediate the conflict. Even within common elements of a land use plan, such as transportation, the goal conflicts often result in conflicting instrumental outcomes between public transport and automobile use. Within this arena, larger scale issues such as sustainability are often

placed aside, and the public interest is reinterpreted for shorter term goals. Thus, large scale, poorly defined (by local eyes) concepts such as global warming are marginalised to a minor role compared to objectives which are perceived to be a more immediate priority.

Davoudi (2013) summarises planning tools and resources under four generic categories: strategies and plans, regulatory measures, resource mobilisation, and collaborative practice. The realm of conflict is vast at this scale – as planning is often viewed as the basis to resolve conflict – ranging from competing values within community plans, development priorities, and funding priorities. As Davoudi (2013) notes, planning at this level is effective if it can achieve collaboration across other policy instruments.

Instrumental and implementation conflicts include diverging views of the appropriate implementation time frames, spatial scales, governance contexts and resources. Romero-Lankao (2012) for example, considers local concerns, leadership and institutional capacity, the autonomy, resources and decision making power of local authorities and the inertia of cultural preferences as factors in determining how climate policy is translated from rhetoric to implementation. Conflicts at this level can occur despite high level strategic policy agreement because there are vastly different methods of implementation and different factors that impact operations. The levels of governance often conflict; national, state, and local governments need to have converging agendas. Resources are also a significant area of potential goal conflict, such as both the allocation of administrative resources within planning authorities and the allocation of land according to specific policies.

6 CONCLUSION

The application of land use planning to adaptation strategies for climate change is complex. If land use planning is to be one of the mechanisms to implement climate change adaptation, then internal conflicts in the policy and implementation frameworks must be recognised. Without this acknowledgement and resolution of these goal conflicts – spatial planning will be ineffective as an implementation tool. Within this context 3 levels of conflict are identified: philosophical, policy, and instrumental/implementation. Each level is interrelated; certainly the philosophical basis of a policy impacts its implementation (for example, neoliberal market oriented approaches). If planning is to be effective as a platform to respond to climate change: (1) actual and potential goal conflicts need to be recognised and explored (2) land use planning needs to assume a communicative and participatory approach to negotiate and resolve goal conflicts at a local level to prevent paralysing knowledge controversies.

Planning tools based on climate science are critical resources in producing knowledge that can protect and help communities mitigate and adapt to climate change, but they will need to be implemented in such a way that involves close collaboration with affected parties in the community. In effect, the science behind spatial planning and other climate change tools needs to be 'democratised'. New forms of public engagement will be required, beyond the traditional one-way consultation involved in typical planning and policy development cycles (Healey, 2003; Fischer and Forrester, 1993). As Yeardley argues (1999: 863) in terms of climate models and planning tools, "…to build robust and legitimate models, public bodies will need to devise methods of consultation and participation not only when the model is running, but also in setting out the objectives and parameters of the model in its earliest stages". It is this kind of deliberative reasoning and network approach to governance and decision making that will be required to address goal conflicts and improve policy coherence between land-use planning, social policy and climate change.

Temporality of Physical and Political Liminal Spaces in the Urban Transformations of the Greater Paris

Federica Gatta

(Architect – PhD Student Urbanism/Urban Anthropology, Université Paris Ouest Nanterre la Défense – Laboratoire Architecture Ville Urbanisme Environnement UMR 7218 CNRS – Laboratoire Architecture Anthropologie, fed.gatta@gmail.com)

1 ABSTRACT

Since the last decade, the city of Paris underwent through an important urban renovation related to the process of metropolization called Greater Paris. This operation relies on two elements: (i) the redefinition of the relation between the central municipality and its periphery and (ii) the increase of the city's international competitiveness by creating new economic clusters and public transports. The northern east part of the city is one of the most emblematic areas of this political and spatial intervention, in the frame of a typical process of deindustrialization of historical popular districts. This area is today one of the largest metropolitan building sites in which all the temporalities of this long transformation process can be observed.

This article proposes a comparison among different kinds of "historicity systems" (Hartog, 2003) coexisting in this portion of the city. The meantime of the planning process will be considered as the fertile uncertain temporal space that creates new forms of power negotiations between the institutions and the civic society.

Which is the role of the inhabitants in the large scale development planning? Which are the new forms of urban conflict and negotiation?

Through the analysis of the "non-formal political actors" (Sassen, 2008) in the Parisian context, this paper will address the role of temporality in the planning process and the creation of new forms of urban engagement. From squats to community gardens, from participatory design processes to urban walks, the aim will be to describe which are the bottom-up practices and strategies that react or participate to the top-down projects. Those collective actions open the issue of the inhabitants' empowerment in the social and physical management of the public space and highlight the non-hierarchic relations between local actors and global politics at different scales. Through the analysis of conflictive discourses on the right to the city (Lefebvre 1968, Harvey 2008) in the French context, I aim to understand the new forms of urban development that are proposed by those new processes of negotiation.

Which is the role played by the image of a future project in the transformation of the city? Which is the temporality of the civic resilience?

2 THE TIME OF PLANNING

2.1 Present utopias

For Leon Battista Alberti, building was to be defined as a "body" made of "form" coming from "intelligence" and of "material" coming from the "nature". This assumption, that Françoise Choay calls "the axiom edifice-body" (Choay, 1980), is one of the most founding concepts of humanist architecture. Urbanism is a discipline deeply rooted in this tradition. It conceives the built environment not just as the reproduction of an organic body but, as a product of the man's "intelligence", a perfect and reproducible model of a body. According to Francesco Ventura, "utopia is constitutive of urbanism" (Ventura, 2006). In the utopia, as originally conceived by Thomas More, the model of space is intimately related to the model of society. Thereby the city is more than a single body, it is the expression of the union and relations of a community of perfect entities. It is upon this idea of the perfect society that the utopia builds a peculiar temporality. In order to design the idea of a perfect future as a skopós [1], as an aim to be reached in an unlimited time, the past has to become a disease to heal, an "imperfection that needs a radical correction" (Ventura, 2006). In this register, the future absorbs the present completely thus rendering it an irrelevant point of the tension towards the skopós. Likewise, the present and past societies need to be sacrificed to reach the never-coming utopia.

---

[1] In ancient Greek the word means target, goal. It defines a future that is searched and depicted starting from the analysis of the present conditions (Ventura, 2006).

However, the history of urbanism is not only made of utopias. I would like to consider here how the capitalist model of city is deeply based on the construction of a distorted utopian time. According to David Harvey, the capitalist urban model is meant to absorb the crisis of the surplus system (Harvey, 2012). In a moment in which surplus product cannot be absorbed and produce new surplus profit, urbanism comes in help by enlarging the scale of the city. This enlargement has two main goals: creating new infrastructures and proposing a new model of citizen. The first one responds to the need of new natural resources, labour forces and technology; the second provides the formation of new needs (consumptions) through the creation of a new way of life. This never ending process of market expansion projects the city in a continuous linear growth grounded on the imperative of technological and social innovation. This deletion of the past reproduces the same utopian idea of a society and a space that are stuck in a "messianic present" "anxious of predictions" (Hartog, 2003).

In European cities, the futurist attitude of the capitalist model finds today an evolution in terms of construction of time and creates new forms of presentism (Hartog, 2003). In the time of the crisis of the neo-liberal city – in which the future becomes "uncertain" and "threatening" (Hartog, 2003) – the present has to take the burden of the innovation and depict itself as an already-realized future. This is translated also in the tendency, produced by the media, to historicize the present and substitute the "presence" of the real human dialogue with the "present" of the image (Lefebvre, 1992). At the same time, the society is led to look at herself pretending to have an historical distance and hoping to embody all the possibilities of the future. In terms of urbanism the linear growth of the capitalist city has to be reinvented in a new form of accessible utopia. The future city is too uncertain to be depicted in a convincing skopós and in consequence becomes an image that needs to invade the present. In this sense, this image of the future city needs to be constantly reinvented and translated in order to become a consumer good. The idea of an accessible future is also modifying the place of the society concerned by the urban transformation. The "right to change the city" (Harvey, 2012) is translated in new forms of participation and governance that pretend to open the access to a more democratic control of the planning process. The civil society is then invited to "take part" of this present utopia.

2.2 The Greater Paris

Based on an ongoing research in urban anthropology, this article questions the relations between the official processes of urban development of Paris and the inhabitant's informal actions of space transformation in the popular districts invested by the renovation projects.

Paris faces, since the last ten years, a complete renovation of its urban structure that was explicitly compared by the former right wing president Nicolas Sarkozy, to the Haussmanian renovation projects. This operation is based on redefining of the relation between the central municipality and its periphery and on increasing the international competitiveness of the city through the creation of new economic clusters and public transports. Since the launch in 2007 of the international competition "Le Grand Pari(s) de l'agglomeration parisienne" – the great bet [2] of the Parisian agglomeration – this process adopts the name of Greater Paris. This competition invited ten famous international teams of architects to produce a future vision of Paris as a larger metropolis. The guiding principle was mainly the "post-Kyoto" sustainable development and the need of a more global international competitiveness of Paris. This competition started a process of redefinition of the city's limits carrying on the classical model of concentric expansion and definition of what should be "inside" and "outside" the territory (Sotgia, 2011). This process is translated in a project of a new circular subway defining at the same time the new limits of the city and the emplacement of new clusters of economic development. The result of this politics is also a debate on the governance of the city and the emersion of new political actors competing for the management of the metropolis [3].

This redefinition of the limits of the city started more locally in 2002 with the election of the socialist Bertrand Delanöe as mayor of Paris. One of his most important actions in terms of urban development is the

---

[2] The title is a play between the word bet, pari, and the name of the French capital.

[3] The municipality of Paris is really small (105 Km2) compared to the metropolitan area that affects the city (almost two thirds of the Île-de-France region, about 8.000 Km2). Nowadays there isn't an official government that manages the politics of the peripherals and the central municipalities. The most important emerging actor is the syndicate Paris Métropole that tries to work as coordination of the about 150 municipalities taking part to this association.

definition of eleven Greats Projects of Urban Renewal[4] implanted on the peripheral highroad, the boulevard périphérique[5], which corresponds to the limit of Paris. The goal of these projects is the "urban reinsertion" (TVK, 2008) of the boulevard. This domestication of the limit is meant as the symbolic start of a new dialogue between Paris and the surrounding municipalities.

Fig. 1: Image created by the architect Chrstian de Portzamparc for the international competition « Le Grans Pari de l'agglomeration parisienne » in 2007. This image has become an icon of the futuristic visions of the architects of the Greater Paris. (© Atelier Christian de Portzamparc)

To go back to the initial reflection on the future, it is clear we are in a classical model of capitalistic expansion of the city in search of new forms of economic competitiveness and producing new ways of life. But which is the model of society that is designed behind those actions? In other terms, this paper addresses the "historicity system" (Hartog, 2003) that those official projects produce, in comparison to the idea of future led by the inhabitants of the districts in renovation. What seems to be clear is that Paris is building a future based on a modernist idea of an ineluctable future of the expansion of the city. But, looking closer, those magnificent projects are far from being unavoidable as they seem to be. The budget of the new circular subway is of about 30 milliards of euro of which only 5 milliards will be given by the State. This gap produces a big margin of uncertainty on those projects that should be balanced by the valorisation of the urban areas surrounding the future stations of the metro. Looking at the eleven great areas of renovation of the périphérique, only about 19 % are being realized since 2002 and there is a margin of uncertainty on the possibility of realizing the remaining projects, mostly those envisaging a covering of the highroad. Some of those projects were in fact inserted in the areas for the candidacy to the Olympic Games that Paris tried last time in 2005, the hope was of course to realize them whit the income given by the international event.

This way, I underpin that those projects, which are strongly occupying the media since ten years, have also an influence that is completely virtual on the present of the city. Nevertheless, inhabitants look with strong concern to discourses that project the city to the horizon of the next thirty years and that are already defining who will be inside and who will be pushed outside the city.

Another important element highlighting how the actual project of renovation is inserted in the presentism of the neo-liberal European city model is the juridical and practical context of the "urban participation" in France. The process of citizens' participation to the urban projects is becoming a new important element of governance of the cities since the proclamation in 2000 of the law Solidarity and Urban Renewal that reshapes the frame of the city politics and defines the concertation [6] as a mandatory practice for the public projects. But participation, in official processes, is still reduced to information meetings or workshops that

---

[4] GPRU. Grands Projets de Renouvellement Urbain. http://www.paris.fr/politiques/vie-de-quartier/grand-projet-de-renouvellement-urbain-g-p-r-u/rub_6144_stand_612_port_13817

[5] The boulevard périphérique was built between 1960 and 1973 on the emplacement of the latest fortifications of Paris, the Thiers walls.

[6] Concertation is the French name for the institutional process of negotiation between different actors of a public project. Since the last ten years the word denotes principally the devices of information and participation of the inhabitants.

concern basically the architectural form of the projects and rarely his functional program. On the plan of the participation at a larger scale, the Parisian territory has recently tried to set up new forms of metropolitan concertation such as the public debate on the new metropolitan subway: this debate compared the project of the region with the one proposed by the state [7] and involved about 15000 participants in 55 meetings held in all the metropolis. But those remain as isolated events "which don't open a real debate articulating local and metropolitan issues" (Bacqué and Gauthier, 2011). We can also say that the format of those metropolitan meetings is based on a media model with showmen managing the debate and web-tv companies making the synthesis of the inhabitants' words. Looking to a series of devices which are recently used for the participation such as social networks and online forums that should "collect the words of inhabitants", we realize how this future that invades the present as an intrusive image don't produce a real dialogue between institutions and civil society. The words of people facing this far future, which is more concrete in terms of global economy than in terms of new ways of life, becomes a collection of atomized opinions that are impossible to translate in a collective voice. Those devices don't give in fact space to collective opinions or controversy actions but only to a series of individual conflictive stories. As a consequence, the discourses of the politicians can remain in the register of populism because their actions are not really questioned by the "inhabitants' words". In this sense we see how this fake accessibility of the future transformation of the city is only working as a form of virtual consensus within a society that still doesn't see clearly which is the social utopia that should follow through the urban projects.

3 THE TIMES OF TRANSFORMATION

3.1 Meantime and liminarity

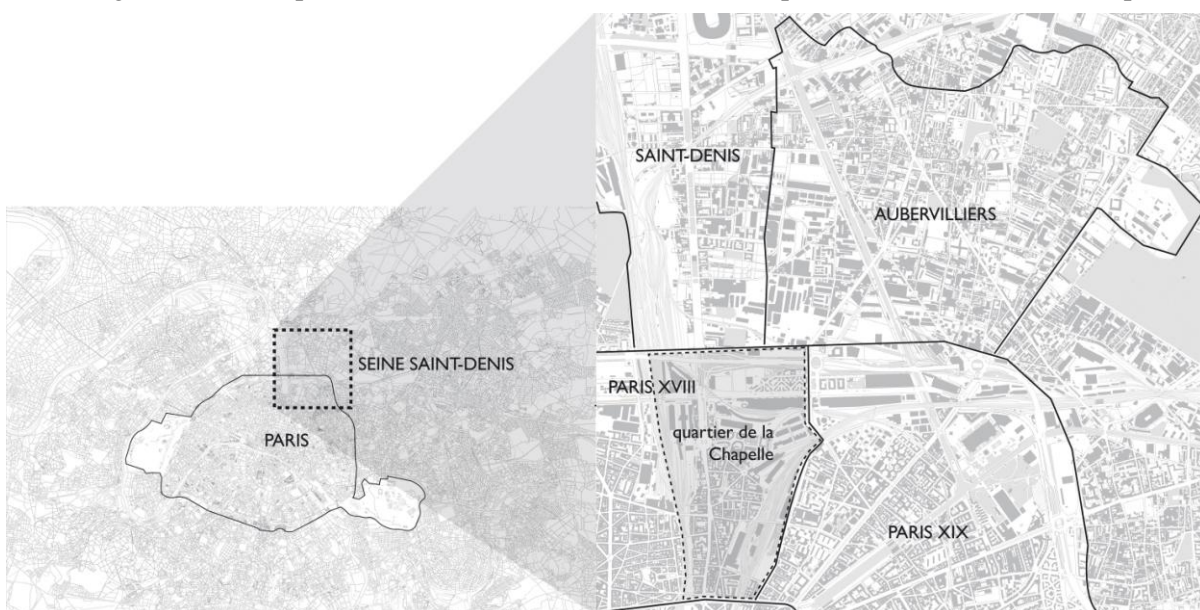
This current research's ethnographic entry is the limit of the northern east area of Paris. This is a classical frame of post-industrial city that is representing the new horizon of the metropolitan projects. What we find here is a context whose transformation is more and more related to a large scale with an over-planning and over-regulation structure conceived to build a global metropolitan strategy of action. Projects are based on the rehabilitation of "unsanitary" buildings, creation of new public transports and building of new housing and activities. This does not induce massive evictions and renovations, but more a slow process of gentrification in which sparse operations engendering population displacement are accompanied by massive rehabilitation of ex-industrial buildings. The northern east of Paris is an emblematic territory of this obliteration of the city's limits and of the research of a new metropolitan identity. At the same time this territory is increasingly attracting new citizen's actions that are linked not only to the local context of transformation but also to the global diffusion of alternative urban practices. The presence of urban interstices together with the process of renovation, seem to create the perfect frame for informal experiments.


Fig. 2: The Northern-East of Paris as framed by the research.

[7] The National Commission of Public Debate held those meetings between October 2010 and January 2011.

The fieldwork elements presented in this paper come from an approach based on a situational analysis applied to the context of an anthropology of the city (Agier, 2009), taking the space not only as the setting of social relations but as a product of a relational process. Several associations [8] working in the North-Eastern Paris, principally in the Chapelle district in the 18th arrondissement [9], have been approached since November 2011 in order to see and follow their social network and to analyse their discourses and repertoires of contention. This ongoing observation takes place basically in everyday and ritual situation, involving the internal organization, the building of consensual relations, the public performance and the collective action. The definition of ritual situations (Agier, 2009) is chosen in reference to the particular status of those actors which represents a sort of political and physical liminarity linked both to their ephemeral condition in terms of space and action and to their positioning regarding the institutions. An interesting argument to this liminarity is in part given by the different biographical trajectories observed in the interviewed associative actors: from professionalisation (for instance subjects starting their political career in the voluntary work), to redefinition of identity (retirees investing in new kind of activities or rediscovering a political activism), to the expression of an alternative political point of view (anarchist, self-management, radical ecology). Associations seem to serve as a kind of passage through different social position or as a "limbo" that permits unconventional social organizations. At the same time those actions are often taking place in the "lost spaces" of the city: abandoned plots or buildings that are waiting to be renovated that can be defined as a margin between the city and its future. This physical and political liminarity is also an expression of a more global phenomenon.

In the last twenty years, we can in fact observe a global proliferation of new kind of citizens' "non-formal" actions (Sassen, 2004) linked to a post-global and anti-liberal political vision. From the occupation of terrain vagues with ecological projects, to the new forms of urban art and artistic engagement in the popular district, to the different variations of sustainable tourism, we see spaces and practices that seem to propose a new management of the social conflict. In the Parisian region since the last ten years those initiatives are mushrooming in particular next to the "sensible" areas in renovation, i.e. the areas of the former industrial part of the city situated in the northern east. Nowadays we can count ninety urban gardens, twenty official artists squats, an increasing number of associations of urban walks (organised by independent architects or inhabitants), and at least four big areas of renovation in which inhabitants or collectives of architects are working for participatory processes.

In this sense we would like to highlight another important form of temporality of the city in transformation. If we consider the project not as a result but as a complex process opening a tension between the "field of experience" and the "horizon of expectation" (Hartog, 2003), we can consider it also as the in-between time that can give new meanings to the future visions of the city and to their relation with the society. The meantime of the project [10], if lived and filled of sense, is actually the time that permits the birth of new actors and of new power relations. The acceptance of this gap between the present and the future as a thick temporality can create a fertile state of uncertainty. We intend here uncertainty as a concept that can reveal all the possible solutions and open up fertile controversies (Callon, Lascoumes, Barthes, 2001). The hypothesis presented here is that the informal actions reveal the need of conceiving the urban transformation as a continuous uncertain process and not as an event that belongs to the future.

3.2 Times of informal actions

The analysis that we sketch here is not based on the difference between different kinds of associations working in the districts. Rather, I propose the idea that those actors constitute a complex system of interconnections that creates an homogeneous context regarding the urban transformation. It is not then the difference between the actions of a squat and of an urban garden that I will highlight, but more the circulation of practices between those places. This idea of an homogeneous system is particularly clear in the

---

[8] We use here the definition of association referring to the French context. In French culture those citizens' organizations represent one of the highest form of the civil society's right of expression. The so-called 1901 law defines the associations system through the right to civic organization and the non-profit activity contracts. In this flexible frame, the forms of associationism are quite diversified.

[9] The Chapelle district is a sort of triangle framed by the railroads of the East and North stations and by the boulevard périphérique.

[10] For the notion of meantime we refer to the researches of the Laboratoire Architecture Anthropologie of the School of Architecture of la Villette in Paris (www.laa.archi.fr).

Chapelle district in the 18th arrondissement. This district hosts a large number of associations that are linked to common interests and actions. In terms of urban transformation there are two big organizations that are extremely interesting.

The first one is an association working within the official concertation process, the Association for the Monitoring of Paris Nord-East Urban Development (ASA PNE18) [11]. The actions of this group of citizens started with the mobilization against a project of densification in the 1990s. After this experience they decided to become institutionally involved in the urban transformations of the Paris Nord-Est project, the biggest (200 hectares) of the eleven Great Project of Urban Renewal that touches this area of the périphérique highroad. At the present time they are involved in the official consultation committees. Their contribution includes the organization of public information meetings in the district and the participation to specific reunions with the architects and the institutional actors. In the ASAPNE18 the presence of architects and city planners, and the organisation of self-trainings are fundamental in order to "push" the limits of the institutional participation defined by the law. Moreover the association has the character of a coordination of different associations. What is important in their activities is not only the capacity of dealing with the most technical issues, but also their ability of being connected with both the political and the associative net of the district and of the city. In this sense it is evident how the role of this actors is not only of the defence of their own micro-local interest but it is a political action which goes beyond a NIMBY logic.

The second organization is the Collective of Chapelle Open Day (POLC) [12], a collective of three community gardens and three artistic squats that work as a federation. These associations organise festive weekends proposing a common program of artistic performances and concerts, based on an increasingly common model of the artists' open days in the eastern districts of Paris. The reasons that they give for the birth of this federation is the awareness that all the places were individually dealing with the same institutional process through negotiations and collaboration with public landowners and City Policy actors. As a reaction to the institutionalisation and social service demand [13] of the public powers, they claim for recognition of their precarious existence opposing their gradual space transformation to the renovation of the new development projects. The production of texts, graphic documents and exhibition of pictures showing the close relationship between urban development and ephemeral initiatives, becomes an information device that is exposed to inhabitants in order to draw the public attention to a larger spatial consciousness. This call for the public interest is not presented, then, as direct support of the single initiatives, but as a reflection to an alternative way of intervening on the deindustrialisation process.

This district is also the set of many urban walks organized by diverse actors [14], from independent inhabitants to architects that work for the metropolitan participatory actions. This practice can be seen as a symbolic valorisation of space through its physical crossing. It is based on the principle of visiting less known districts that are undergoing a process of urban transformation. The "tourists" usually meet the guide and follow an itinerary that is punctuated by a series of stops in specific places in order to discover some activities, projects or meet other inhabitants. The performance of those "situational sequences" (Palumbo, 2009) is meant to disclose the social life of the place or to explain its recent past and its near future. Unlike classical architectural sightseeing, which illustrates what is visible in urban space through a set of notions, the urban walks organized by the inhabitants want to reveal the invisible reality of the city through the concrete experience of social interactions.

---

[11] Association du Suivi de l'Aménagement Paris Nord-Est 18e (http://asa-pne.over-blog.com/). The objective of the association is the promotion of a participatory design process for the Paris Nord-Est project sector in the 18th arrondissement.

[12] Portes Ouvertes de La Chapelle. All the components of the collective are associations recently established in the district. "The Collectif Portes Ouvertes La Chapelle federates a group of associations concerned by urban transformation and renovation of the district. Their initiatives took root in inhabitants' life." (http://portesouverteslachapelle.blogspot.fr/).

[13] This demand is both defined by the informal negotiation for occupation and by the contractual definition of public founding given to the association that imposes the declaration of a public interest of the structure in the context of a "sensible district".

[14] One of the first and most known example of this practice is the one of the "Global Greeter Network" (http://www.globalgreeternetwork.info/) started in New York in 1998. The Parisian version of the movement is the "Parisien d'un Jour" (One day Parisian) association (http://www.parisiendunjour.fr/) promoted by the Municipality of Paris and the Parisian Tourist Office.

In the following passages I would like to question the different "historicity systems" that are acted by those practices and their relation to the official time of planning. In opening the reflection on those temporalities I will refer to what could be defined as "performed discourses", in the sense of narrations that come out mainly from the direct action.

3.2.1 Futures

Speaking of future we find two different ideas that coexist in the informal actions.

The first one is what could be seen as an apocalyptic and nostalgic future. This kind of vision is mostly related to the ecologist visions that can be shared by the actions of urban gardens and artists' squats, and that finds its roots in the precautionary principle of environmental movements. According to some of those discourses the "possible" future is seen as fearful because it is putting in danger the next generations through environmental problems. In reaction, this form of temporality is constructing an ideal future that evokes a mythic past in which the man was living in a greater balance with the nature. In some ways this future reproduces the idea of a present that has to be sacrificed for the wealth of a skopós. Those discourses are performed through urban agriculture, both in the sense of farming and in the sharing of ecological knowledge. The understood goal is that people must learn how to live in self-sufficiency and outside the capitalist production system.
Fig. 2: Quai Louis Blériot, Paris 1918 (source: www.paris1914.com). This image was sent in February 2013 on the mailing list of a community garden of the Chapelle district with the title: "With (just) a little bit of chance, this is what we're going to have". The utopia proposed is the return to a post-war condition in which urban land is exploited for feeding the population.

The second idea is the one of an imminent and pragmatic future. The action of visiting a building site with an urban walk or to claim for the needs of the present inhabitants in a project that will be built in thirty years, seem to be a desperate effort of translating the future of planning in a presence that will affect the life of the district tomorrow and not in dozens of years. The future here becomes less eschatological. The performed discourse is the one of a research of the physical traces of the announced future in order to understand it pragmatically. At the same time this action builds a temporality that works as a "counter-device" (Agamben,

2006) giving back the future to a real space of existence and claiming for taking in account its daily presence.

3.2.2 Pasts

The different ideas of the past can be also articulated in two categories.

On one hand we have a nostalgic past. This past is mostly set in urban walks, but is also linked to the actions of urban gardens. What we face is again the case of a mythic temporality linked to a past that is reinterpreted and exploited in order to construct a discourse on the present. We find here also a form of presentism that in facts uses the past in order to patromonialize a present time. The performed discourse is meant to insert the built and green environment in a larger national history and preserved as it is. Associations occupy and valorise the terrain vagues and the former industrial buildings claiming to the recognition of their value in terms of biodiversity or architectural quality. The space is then used as the main pretext to defend the social practice that it hosts. This can be also seen as a form of "moderate resistance" to the transformation that works on the same register of the official transformation because tends to use the same type of arguments in order to be recognised.
Fig. 3: Document produced by the ASA PNE18 (CEPA at that time) in December 2002 for a meeting with the municipality. The goal of the presentation was to convince the architects and politics to preserve an ancient industrial hall. The two slides question: "Then demolish? Or renovate? And how?" The image inside the second slide is taken by a magazine on renovations of industrial buildings and says: "To renovate at a small price". In order to contest the project of demolition the association shows a typical example of patrimonialization of an industrial hall transformed into a museum. (© Coordination Espace Pajol)

We can also talk of an anecdotic past that sets the space in a local or biographical chain of events. This temporality tries to inscribe the territory in a smaller and more controllable scale of comprehension. In reaction to the politic and economic forces, which act to link the territory to a global scale, the narrative related to a recent past gives the possibility to focus on the needs and wills of the people that are living the place in the actual present. This temporality can be set up by urban walks through the construction of biographical sequences in which the visitor is led to experience the daily path of its guide. A similar interpretation of the past can be found in the reconstruction of the history of projects made by the inhabitants during the participatory processes, or in the reconstructions of the ephemeral spaces' history in the district. In this sense the shift of point of view in the narration of the urban transformation can show how the space belongs to a plurality of temporalities.

3.2.3 Presents

The two last categories are based on rhythms that create two different articulations of the present.

One present can be the one of an intermittent but constant rhythm. This is specifically linked to the action of the ephemeral place as urban gardens and squats. Even in a context in which the municipality is in part institutionalizing those actions, the nomadic nature of some of these associations creates a form of constant presence within the city that escapes to a politics that would reduce them to a sort of short spectacular events in the future building sites of the cities. Some of the squats and urban gardens speak about a "nomadic strategy" that accepts to enter in negotiation with the municipality – that gives them a contract of temporary

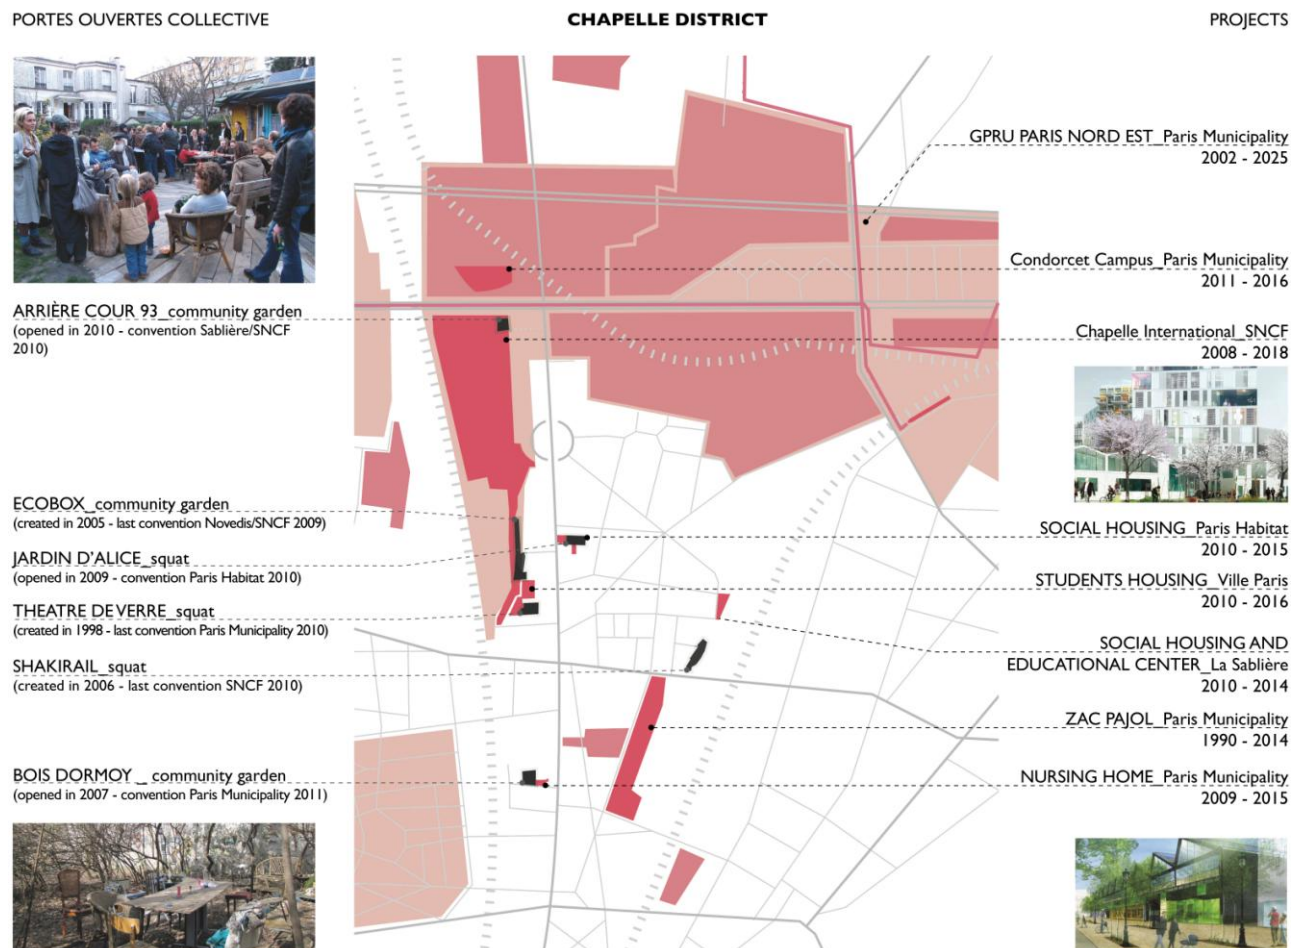
occupation – but tend to exist beyond the single place that is occupied. This means that an urban garden can exist since ten years having occupied three different plots and that an association of artist can squat at the same time different places and be ready to move to new ones in a short time. This behaviour builds a present that is at the same time precarious and reproducible. The present time then is uncertain in terms of space but not in terms of action. This resistance can create also interesting situation in which those associations are finally taking part to the official projects by partially participating to the design or management of new spaces.


Fig. 2: Relation between the urban projects and the ephemeral spaces in the Chapelle district. The author has assembled the document in March 2012 for the POLC collective. It indicates: on the right side, the duration of the projects and the name of the developers; and on the left side, the start of the ephemeral activities an their date of convention.

The last form of temporality is the one of a constant and persisting rhythm of present. This temporality is built mainly by the associations working in the participatory process. The fact of acting in the district since even twenty years on one or more projects permits to inscribe the actions of this association in a stable present legitimating their action in the concertation. This rhythm is not based on a tactic of reaction to the politics like the previous one but is rather building a strategy of the "presence". Their action is largely based on a form of insistence: claiming for having meetings with the municipality, asking a continuous control of the evolutions of a project, or simply being present in every possible occasion. This permits also the inscription of the future of the project in a present time in which a physical and political space has to be built in order to speak about its existence.

4   GIVING BACK SHAPE TO THE PRESENT

Evidently, these temporalities are not completely separated and can be combined and overlapped in a continuous process of transformation and composition of the different actions of the associations. This short review would like to highlight how this diversity of temporalities, even with its inner critical points, makes possible the construction of a deeper temporality of the projects.

In terms of political discourse, those actions don't really seem to question the official urban development, but propose, as evoked, more a kind of "soft subversion". Differently from the claims of the 1970s, we observe here a more strict negotiation with the political powers and a direct management and control of the public space. In order to do that, the discourses tend to reproduce the same strategies of the official powers instead of opening a direct conflict with it. If on one hand we could ask if the social conflict is still possible in a context in which the State is abandoning his role of public guarantor, on the other hand the sphere of public informal actions seem to take a new relevant role. What appears is how the action is building a new temporal vision of the urban development. It is precisely through the action that the different "historicity systems" construct a present that finds its independence and emerges again as a positive element. Those performed discourses reclaim then the central importance of the present in the progressive construction of the future.

In conclusion, I would like to underpin how the contribution of these informal actions, based on this capacity of giving complexity to the temporality of the project, opens the idea of a project as a continuous and uncertain process. More than on the form of the city – which is questioned only partially -, the real debate seems to shift on the processes of empowerment and on the governance procedures. This way, those actions are questioning the definition of the project through an idea of future that should not only be concretized in a building site, but rather becomes an open debate that should release the citizens' imaginary on the possible and desirable models of society. In this sense, to release the imaginary is precisely "to think about what it would take to live in a world in which everyone really did have the power to decide for themselves, individually and collectively, what sort of communities they wished to belong to and what sort of identities they wanted to take on" (Graeber, 2004). If, as sustained by Immanuel Kant, time always needs a symbolization through the space and remember us that we need the space in order to know our existence, we should also realize how the space always need to be inscribed in a multiplicity of times to be our place of existence.

The Beauty or the Beast? Can Illegal Housing Tackle the Problem of Social Integration and Social Housing?

Branislav Antonic, Biserka Mitrovic

(Assistant Professor Biserka Mitrović, MSc, MArch, Faculty of Architecture, University of Belgrade, Bulevar kralja Aleksandra 73/II, Belgrade, biserkamitrovic@gmail.com)

1 ABSTRACT

Serbia as a neighbouring EU country is, like some other countries, facing the problems of incoherent urban and regional development, of tackling the urban growth and of deficit of integrated urban strategies. On the other hand, specific problems of Serbia are related to the possibilities of integration of special socio-economic groups, such as low income citizens, refugees etc. Having this in mind, it is understandable that Serbia is coping with even bigger problem of affordable and social housing, which has become an emergency even in cities with a weak demographic growth in developed countries. The problem of the lack of adequate affordable housing and its capacity is often followed by the problem of real social integration of vulnerable social groups.

The pressure of these problems is more visible in Belgrade, Serbian capital since it deals with the demographic pressure and growth for a long time, and especially in past two decades. As a consequence of this pressure many previously agriculture areas at the fringes of the city have become illegal settlements.

Being a developing country severely hit by economic crisis in past few years, Serbia will not easily reform its housing policy and enable growth of the affordable housing which will meet demands. It is also not very likely to expect that the problem of illegal settlements will vanish or even lessen since the actual Serbian political framework is encouraging legalization process.

So what is to be done? Is it realistic to treat such big issues of urban development separately? Or maybe it is possible to change the prospective and try use problems in the way they partly solve each other?

This paper will enlighten the problem of illegal housing in unconventional way – by trying to understand the illegal settlements as areas of social/affordable housing and social integration. It will also discuss the possibilities of urban upgrading and regeneration of illegal settlements making them liveable places and areas which can be integrated into the Belgrade development.[1]

2 THE NEED FOR SOCIAL/AFFORDABLE HOUSING AND TACKLING URBAN GROWTH

Well-known statement is that appropriate housing is one of basic human rights (UN, 1948, art. 25th). It is usually interpreted as the affordability of decent and healthy homes. But the importance of appropriate housing as a human need is more complex issue today, since it also includes the questions of transport and public facilities as intermediate social needs (UN habitat, 2012, p. 33). Finally, housing is a good on the market, so the consequences of market trends are visible in patterns and conditions of housing. This is the reason why the integration of housing issue into wider spatial systems, such as cities and communities, is a necessity for urban development and growth.

Social (affordable, public, non-profit) housing is one of important ways to overcome the gap between social and economic aspect of housing. There are many definitions of all mentioned terms of the housing concept, depending on regional and historical conditions (UNECE, 2006, pp. 1-3), but the common ground for most of is the housing concept which is provided by government agencies or non-profit organizations for people on low and middle incomes or with particular needs. In continental Europe the term social housing is more familiar than other ones. This is also the main term in Serbian practice and legislature, although term affordable housing can be found in some new documents and policies, as well as in those in European Union – EU (Milić, 2006, p. 31). Because of this fact, this paper will use term social housing as the key term for this housing concept.

As it was previously specified, the concept of social housing has strong historical and regional context. Generally, social housing is more familiar to the countries with social capitalism than those with liberal capitalism. The best examples are "old" EU countries, especially those in Western and Northern Europe, where social housing has been especially developed since The Second World War, passing through several phases (UNECE, 2006, pp. 1-3). Firstly, Post-war social housing was built for growing population on public land with public money (Whitehead, 2010). Its main characteristics were cheap mass production and the building on "free land", usually on the outskirts of cities and towns, which produced "uniformization" and "ghettoization" of huge social housing areas during 60es and 70es. This was notably different from views of new generation of social housing occupants, who tended to be better educated, middle-income and less traditional in family issues.

These problems caused various new directions for social housing: from public building to public-private building corporations; from public ownership to several different ownership models, from new building to renewal and regeneration; from huge urban independent areas to small integrated quarters; from mass production to individualization and place-making; from low income persons to middle income ones; from nuclear families to different types of occupants (UNECE, 2006, pp. 1-3). There are also many regional and state-related differences and specificities. All these processes are flexible and never finished, so the field of social housing is still vivid and it represents a real support for permanent urban growth. Further impulse for these processes is the fact that the need for new housing has not decreased with well-known problem of aging population of EU in recent years. Relatively stable number of households, which are smaller and more heterogeneous, has given the new demand for various types of social housing (UNECE, 2010, p. 9). Finally, the model(s) of social housing in EU is used as a role-model for social housing policies and strategies all over the World.

Although the cities in developing countries face the similar problems about social housing concept and its realization, they also have to fight bigger problem than the cities in EU – taming the urban expansion, which is, in most cases happening out of the desired policies and plans. This is also the case with Belgrade, despite the fact that socio-economic path of Serbian capital was and still is different than of those in developing countries at other continents; nevertheless there are common effects and characteristics of spatial growth, with huge illegal settlements being most significant similarity. On the other hand, Belgrade's urban expansion has not much in common with the neighbouring EU countries' cities or even with ex-socialistic cities despite the geographical and historical link to them, with the exception of some Balkan cities.[2]

The magnitude of urban expansion is frightening when analysed through figures. According to the World Bank study (Shlomo, Civco at all, 2005.) cities in developing countries whose population is over 100,000 can be expected to triple their area, from 200,000 to 600,000 sq km until 2030. This means that every resident will convert, on average, about 500 sq m of non-urban to urban land.

---

[2] This standpoint is supported by Petrovic, M, claiming that the task of transforming from totalitarian to capitalist system stipulated post-socialistic cities of Europe to get some characteristics of American and even Third world cities, rather than of balanced models of EU cities (PETROVIC M.: The transformation of cities towards de-politization of urban issues, The Institute of Sociological Research, Belgrade, 2009., p. 251). Same author, going back to the question of ex-Yugoslav cities' unique characteristics and/or similarities with other post-socialist cities, emphasizes that (they) resemble them in the slow pace of post-socialist restructuring and establishment of new types of public control, and respective elements of the Third World development (PETROVIC, Mina: Cities after socialism as a research issue. Discussion papers (LSE – South East Europe series), DP34, Centre for the Study of Global Governance, London School of economics and political science, London, 2005., p. 20). Finally, M. Petrovic concludes: "The most likely outcome is that ex-Yugoslav cities will become unregulated capitalist cities with more or less evident elements of Third World cities" (PETROVIC, Mina: Cities after socialism as a research issue. Discussion papers (LSE – South East Europe series), DP34, Centre for the Study of Global Governance, London School of economics and political science, London, 2005., p. 20).

Region	Definition
East Asia (China, Philippines and Vietnam)	Areas subject to urban expansion on the edge of cities (often called "rural-urban" areas or "peri-urban" areas) and environmentally fragile urban areas (e.g. river banks, canal edges and flood plains), which are unstable and unfit for occupation and should be protected to provide ecological services to cities. Spatially, this definition encompasses primarily marginal land (unstable and unfit for occupation) and land in the periphery of urban areas.
Europe and Central Asia (Albania, Kyrgyz Republic)	De facto urban areas that largely remain classified as agricultural. Largely comprised of informal settlements, which are not recognized by municipal governments.
Latin America and Caribbean (Argentina)	A wide strip of land that is too expensive for rural uses and yet too distant for urban purposes.
Middle East and North Africa (Egypt)	Localities where the rural-urban transformation is taking place – those vast areas that surround cities which are neither strictly rural nor urban. The existence of a large and disproportionate peri-urban segment is a central feature of African cities.

Fig. 1: Definitions of Peri-Urban Areas across Regions (Source: World Bank, 2008)

In general, the space within metropolitan areas can be categorized into 3 main types (1) urban cores, including central business district and the rest of the inner city; (2) suburbs, usually subdivided into the inner and outer and usually driven by residential expansion; (3) peri-urban areas which may be driven by industrialization and or spill-over effects from the city itself, depending on structure of the urban economy. The most of the urban expansion of course affects zones 2 (partly) and 3.

Urban expansion is expressed in different spatial forms – contiguous, leapfrogging, 'necklace' corridors, continuous corridors, etc. These different forms affect the overall efficiency, especially energy efficiency of cities a great deal. The bulk of rapid urban growth in developing countries is taking place in peri-urban areas. In many poorer cities spatial forms are largely driven by the efforts of low income households to secure land that is affordable and in location that is reasonably close to the places of work, often in peri-urban slums and informal settlements. There is also a trend induced by local governments to relocate inner city slum/informal dwellers to the urban periphery.

The growth of peri-urban areas is caused by different reasons: from enveloping previously rural settlements, to migration from other parts of the country, process of gentrification and other land use changes in the city core etc. The characteristics of per urban areas are as follows:

- Low density, mostly unplanned development, lack of infrastructure, mixed use depending on the economy of the city, rural and agricultural enclaves.
- Economic status of peri-urban citizens may vary, from high-income gated communities to low income housing, industrial areas and finally informal settlements and slums.

Depending on the mix of land use (residential/commercial) and infrastructure quality, these areas can often be squatter settlements, informal land subdivisions, not complied with building codes and constructed on the inappropriate land (such as landslides, flood plains etc.). Low income households often locate in the urban fringe as it offers access to affordable land and housing with minimal standards. Peri-urban areas grow rapidly in Latin America, east and South Asia, though are also seen in other parts of the world, such as South Eastern Europe.

According to the manual: Sustainable Land Use Planning – Peri urban growth, World Bank Institute, 2012, key challenges in peri-urban growth management are:

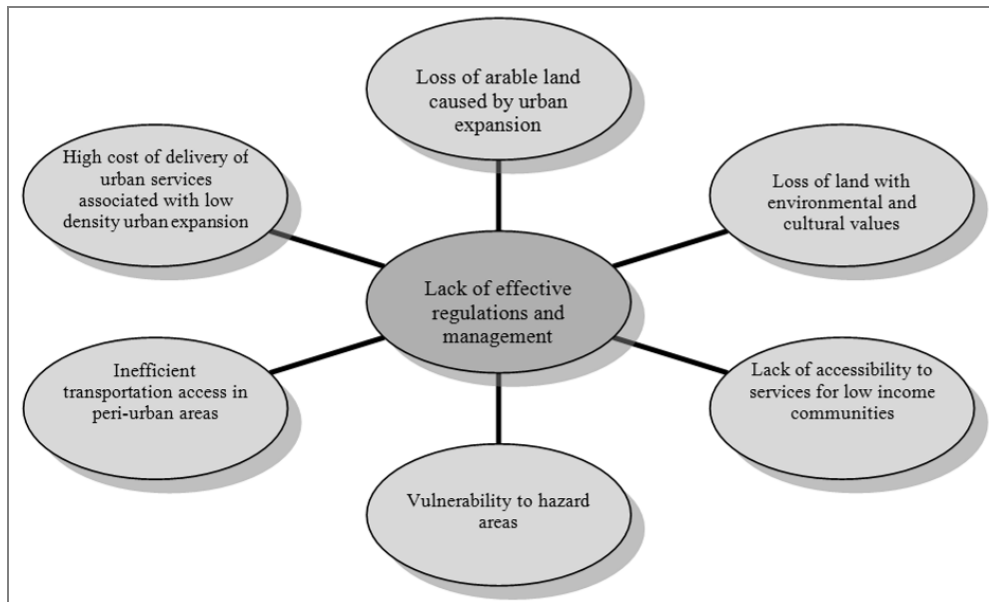
- Lack of effective regulations and management;
- Loss of arable land caused by urban expansion;
- Loss of land with environmental and cultural values;
- High cost of delivery of urban services associated with low density urban expansion;
- Inefficient transportation access in peri-urban areas;
- Lack of accessibility to services for low income communities in peri-urban areas;
- Vulnerability to hazard areas.


Fig. 3: Key Challenges in Peri-Urban Growth Management (Source: World Bank Institute, 2012)

Managing peri-urban growth and improving living conditions in peri-urban areas contribute to socioeconomic equity in the city as whole. The above mentioned document (World Bank Institute, 2012) names key interventions which include facilitating land tenure and management, increasing access to basic services which bring along environmental benefits, followed by service provision and regulatory coordination across jurisdictions. Cities in developing countries need to make realistic, minimal plans for urban expansion. The key areas for land use in those countries are: designation of adequate areas for accommodating projected expansion, investing in basic infrastructure to serve this expansion and protecting sensitive land from intrusion by new urban growth.

The discussion above undoubtedly shows the negative trends about land conversion and city growth globally and as a consequence, about the shrinking the agricultural and forest land while on the other side gives the possible directions for overcoming or lessening these negative impacts.

3 BELGRADE REGION DEVELOPMENT

3.1 Problems of incoherent urban and regional development, deficit of integrated urban strategies and tackling the urban growth in Belgrade

Belgrade, being by far the most vibrant city in Serbia over a long period, due to its diversity of economic activities, has been and still is a great demographic magnet. According to the official statistical data, 22.5 % of the country's population lives in the city, but unofficially there are more than 25 % of country population. Such trends have never been positive neither for Belgrade, making an enormous pressure about employment and housing, nor for the rest of Serbia, leaving many towns without adequate workforce and creating negative demographic situation. At the same time, Belgrade region has influenced greatly the development of other regions in the country, lessening the chances for balanced regional development.

Today, the economic profile of Belgrade is both oriented to the inner market as well as to the wider scene, aiming to be competitive in the country and region. Belgrade is defined as an organizational, administrative, service, educational, scientific and cultural centre. Among the most vibrant economic sectors of Belgrade core area is: construction industry, processing industry, wholesale centres, financial services and insurance companies and other business related activities. On the other hand, there are many insufficiently used possibilities, which are not adequately treated by most of actual plans, like development of tourism, culture and nodes, related to the position and intersection of European traffic corridors 7, 10 and 11.

Regional development of wider city area has never been actually balanced. Though Belgrade has adopted the Regional Psychical Plan (Town Planning Institute of Belgrade, 2004), as well as other relevant planning documents, such as: Master plan of Belgrade 2021 (Town Planning Institute of Belgrade, 2003), Belgrade Development Strategy (Town Planning Institute of Belgrade and PALGO Centre, 2011) and several sectorial strategies (Energetics Development Strategy, Tourism Development Strategy, Forestation Strategy, Retail

Development Strategy, Agriculture Development Strategy, Civil Society Support Strategy and others), unfortunately most of the development and especially peri-urban growth has already happened before and during the plan-making process. Moreover, the documents, though been made at almost the same period, did not acquire the substantial level of integration and coherence. Additionally, the instruments for the implementation and the institutional and procedural support of mentioned documents were not adequate so the real realization has failed.

Belgrade has got its Master plan after many decades so this document had a tough assignment to cover both strategic as well as regulatory elements of development. According to the Master plan of Belgrade 2021, there is strong orientation to foster touristic, cultural and business potential of Belgrade by development along riverfronts. Such very important ideas, though not new, required a detailed implementation covering and huge financial support which was not easy to enable in trying transitional and period of economic crisis. In the wider area, especially along main traffic corridors (such as highway) there is a great potential for development of creative economy – industrial eco parks, smart zones etc., but still there is no adequate strategy of corridors' tributary areas.

Though city development policy is not oriented and is not officially supporting the informal housing and economy, it is estimated that informal economy takes as much as 30 % of economic activities, mostly in the field of retail, services, catering, manufacture and even construction industry (supporting building of informal settlements). At the same time, informal housing takes almost 44 % of housing areas in Belgrade. Despite the fact there are perfect brownfield locations in wider centre of Belgrade with good spatial development chances, the city growth unwillingly turned to the agriculture land at the outskirts of the city.

Some of the main issues related to the land use and city growth in Belgrade are:

- Illegal and unplanned settlements, which have grown and spread intensively over the Belgrade territory during more than 2 decades, with the exception of historical centre of Belgrade;

- Generally insufficient and /or weak infrastructure equipment in metropolitan Belgrade area, with the exception of core area and New Belgrade; urgent problems for the city as whole are related to the waste disposal and treatment of wastewater;

- Unfinished and insufficient traffic network, mostly manifested in lack of transit roads, bridges and mass public transport;

- Inadequate use of the most attractive areas and locations in the city, especially in the river coastal areas;

- Unequally dispersed greenery and the lack of real green network;

- Chaotic growth along the main traffic corridors.

The problem of illegal and unplanned settlements in Belgrade region is strongly related to the other problems of city development, sometimes being a cause, but more often being a consequence of complexity of spatial, economic, social and political issues.

3.2 Characteristics of housing in Belgrade as a reflection of socio-economic transformations

The major influence of mentioned EU social housing concept is noticeable in Eastern and South-Eastern European countries which in this field face(d) many challenges. East European countries have been in the process of transition, as a fast and sudden transformation of one recognizable system to another one (Pickvance, 2002, p. 195) for more than 20 years. The process of transition was also related to the field of housing. The exclusive model of state-provided housing in socialistic system was dramatically transformed in market-oriented housing model. "In almost all post-socialist cities radical reforms of housing and urban policy are seen as a necessary step because of their economic inefficiency and social ineffectiveness" (Petrović, 2005, p. 7). Good example is the percentage of public-owned apartments in these countries, where previous exclusive model of housing has dwindled to negligible percent of housing (UNECE, 2010, p.13). The main result of the transition of housing sector in Eastern Europe is overall deterioration of housing condition in many urban areas (Vukov, 2008, p. 19).

Among several regional types of housing transition is "Ex-Yugoslavian type" (with the exception of Slovenia) (Petrović, 2005, p. 15). This type shares many characteristics with housing types of other Balkan

countries, such as: under-urbanization, self-help housing construction, common lack of infrastructure and amenities, the absence of "classical" social housing and other publicly supported measures in housing sector and the extreme confrontation "urban centre–periphery" (Tsenkova, 2005, pp. 115-123). Other characteristics of the type are connected to the postponed or "blocked" transformation during the wars in 1990s (Petrović, 2005, p. 16), which are connected to the problem of refuges and illegal housing construction.

Good example of "Ex-Yugoslavian type" is Serbia, where a radical turn-over from previous state-provided housing system to market-oriented one is also visible. Some local specificities are: complete privatization of the sector, lack of appropriate regulatory mechanisms and strategies, strong influence of refuges, housing construction as extraordinary profit, illegal practice in housing construction, degradation of old housing fund, weak mortgage system, etc. (Mojović, Čarnojević, Stanković, 2009, pp. 6-11). This is particularly evident in Belgrade, which being the capital city, played a leading role in the transformation and the introduction of new types of housing, such as social housing.

On the other hand, the introduction of real estate market in the 1990s, with the characteristics of those of capital cities, marked by extreme economic crises and high poverty of most of its inhabitants, had the negative effect on the city development. Public sector stopped investment in housing production and maintenance and the number of dwellings built per year dramatically declined (Vujovic and Petrovic 2007). Private investors have entered the process of housing production, but the crises of local planning institutions and state power pushed them to the illegal sphere. On the other hand, market prices of the housing in the city were too big for most citizens and new migrants to the city, economically exhausted by sanctions, inflation and unemployment. As a result, for many citizens and migrants of Belgrade the only chance for acquiring accommodation was private building of modest huts on the periphery of Belgrade (Zegarac 1999). The problem was severely aggravated by the influx of refugees from the other parts of the former Yugoslavia, when approximately 100.000 of them have settled in Belgrade (Hirt 2009). During the 90', the informal housing became a dominant form of housing development in Belgrade, ignoring the urban plans and legal frame. After 2000, political and other changes in Serbia resulted also in the expansion of building in Belgrade, bringing back the multi-family housing and construction of office buildings (Simeuncevic, Mitrovic at all, 2012). Within the total new building production, the amount of single-family housing has decreased, as well as the share of informal buildings.

3.3 Illegal settlements and housing in Belgrade

Since the overall study of the informal growth in Belgrade has never been made, there are no exact data about it, so the estimations vary. For example Janic (1998) estimated there were about 150.000 illegal housing units in Belgrade, while others say that only 20 % of the buildings in the peripheral areas were actually regulated by some urban plan (Djukic and Stupar 2009). Third approximation is based on the number of applications for the legalization – 147000 illegal buildings (Petovar 2005). We cannot take these numbers as final, since not all the owners of the informal housing applied for the legalization, while on the other hand the overall spatial analysis of the area and the approximate density will increase the figures for more than 25 %.

The largest informal housing settlements of Belgrade are situated at the North Eastern and Southern Belgrade outskirts, as well as on the left Danube river bank, expanding deeply to the north. There are other smaller settlements and scattered informal housing groups all over the city borders and within the city structure. In most settlements relatively convenient terrain for building prevails, with the exception of left Danube river bank. There is still a decent share of green areas. The concentration of buildings is the highest along the main traffic corridors. Dominant land use is for residential areas – approximately 90 % of total surface, but there is significant share of non-residential land use, such as retail, services and other commercial activities, mostly concentrated along the main traffic corridors. Traffic network is irregular and insufficient. Except the electrical network the infrastructure mostly does not exist. Some parts of the settlements are provided with water supply. Streets are narrow, without drainage and often are lined with large slope, so driving is difficult during winter period. There are almost no sidewalks for pedestrians. Since all kinds of transport overlap in a narrow corridor, safety is low. In the future, street regulation could be very difficult since it would cause massive demolishing of houses facing such streets in order to provide safe width of streets and sufficient place for infrastructure equipment.

One of the main problems about informal settlements' land use structure is lack of public spaces and services, such as schools, health and children day care facilities, which are a direct effect of illegal building process and absence of regulatory plans. Although the Institute of Urbanism Belgrade has started the draft version of regulatory solutions for whole Belgrade territory, including these areas, in 2010, it is not yet brought to public.

Urban structure of such housing areas is irregular and spontaneous. There is no firm urban matrix with defined size of blocks or parcels. Parcels are often irregular, not enabling good orientation and position of a house towards neighbouring houses. Therefore, privacy is often threatened since the space between houses is very narrow. Architectural design shows the spontaneous nature of building – houses are simply designed and in most cases without any particular characteristic of style. Decorations are rare and often inappropriately applied. The interior organization also lacks good architectural design but housing units are functional in its simplest meaning. Unfortunately, there are no reflections to the traditional Serbian housing.

There is a variety of social background of the informal housing dwellers. In the first group there are citizens of modest socio-economic background who have moved from other parts of the country in search for employment in Belgrade and they live and own smaller one-family units. Second group are refugees and people who have moved from other ex-Yugoslavian republics during civil war in 1990s and their economic status vary, so they live (and own) both in big houses – villas, as well as in smaller ones. Third group consists of residents – housing tenants of lower economic status who live in bigger houses, but rent the apartments, while the owners of these houses are of different background. Approximate socio economic structure of the population, given above, has significantly influenced the formation of settlements and size structure of the buildings.

Concluding, it is easy to say that instead of being respective residential area, with high quality of life, great green areas and good urban pattern with minimum of planning intervention, informal housing areas are mostly perceived as impersonal and disharmonized residential areas, being neither quite urban, nor rural settlements.

3.4 Possibilities of integration of special socio-economic groups (such as low income citizens, refugees)

As a result of the wars during the 90' in former Yugoslavia a large number of families had to leave their homes. Serbia has got the largest number of refugees in Europe – by 2008 there were 200.000 refugees, but other estimations say there were additional 220.000 refugees. Over past few years situation had changed for the better, but there is still a great number of refugees. One of the cities which have undertaken the most pressure of the new immigrants was Belgrade. Since Belgrade had not had ready building plots and building areas with completed infrastructure and traffic equipment, the city experienced an explosion of unplanned housing. In addition to this situation, the inhabitants of these illegally built areas in most cases did not have jobs and have been existentially threatened. Extremely difficult situation is in refugees' collective centres, where people live under very tough conditions – often whole family in the same room and with no sufficient sanitation. Most of the refugees' collective centres have been closed by 2012 but there is still significant number of it and they are problem for the inhabitants themselves, as well as for the local communities. On the wider territory of Belgrade there are still 17 informal and 7 formal refugees' collective centres, mostly located in several local communities: Palilula, Zemun, Rakovica, Zvezdara, Vozdovac, Cukarica, Grocka, Barajevo, Obrenovac. All mentioned kinds of settlements lack primary social infrastructure – above all there is lack of children day care facilities and older people nursing homes. There is also a lack of facilities for people with special needs, whose sharing in total population is greater than in other population groups because they had suffered stress and other specific health problems.

Besides refugees, who are the most important of targeted vulnerable groups for contemporary social housing in Serbia, there are several other socio-economic groups, who are seen as potential social housing users. Some of them are already included in programmes of social housing. This is in particular the case with Roma population, which is numerous in Serbian society (UNHS, 2008). The interest of researches about living conditions in Roma settlements and possibilities to their improvement are quite often and in focus of Serbian practice for a long time (Macura, Petovar, Vujović, 1997, p. 3). Other socio- economic groups are less pointed out.

Regardless of the above mentioned facts, it is interesting to notice the gap in perceiving the inclusion possibilities of these socio-economic groups by Serbian professionals, Serbian regulatory framework and

strategies, and foreign organizations, which are active in this sector in Serbia (for example, UN Habitat Serbia). Following table compares the similarities and differences in their views:

SOCIO-ECONOMIC GROUP	VIEW OF SERBIAN PROFESSIONALS[1]	VIEW OF SERBIAN REGULATORY FRAMEWORK AND STRATEGIES[2]	VIEW OF FOREIGN ORGANIZATIONS IN SERBIA[3]
Refugees	Very important group	Very important group	Very important group
Low income households	Very important group	Very important group	Very important group
Families with many children	Important group	Very important group	Less important group
Families with single parent	Important group	Important group	Less important group
Young families	Very important group	Important group	Important group
Single persons	Less important group	Less important group	Unimportant group
Older persons	Less important group	Important group	Unimportant group
Persons with special needs	Less important group	Very important group	Unimportant group
Ethnic minorities (*Roma*)	Important group	Very important group	Very important group
Students	Less important group	Unimportant group	Unimportant group
Seasonal workers	Less important group	Unimportant group	Unimportant group
Public sector employees	Less important group	Important group	Less important group
Comments: [1] Retrieved from: Milić, Vladimir: Urbanistički aspekti socijalnog stanovanja. Belgrade, 2006. [2] Retrieved from documents 1, 4, 5 and 6 in chapter 4.1 [3] Retrieved from documents 2 and 3 in chapter 4.1			

Table 1: Possibilities of inclusion of some socio-economic groups – the views of Serbian professionals, Serbian legislature and strategies of foreign-supported organizations in Serbia

In conclusion, it is inevitable to stress that comprehensive inclusion strategy of vulnerable social groups in Belgrade has not been made. The real challenge relates to the needed integration of social and spatial-psychical aspects of the problem of social housing.

4 THE POLICY OF SOCIAL HOUSING IN SERBIA AND EMERGENCY FOR AFFORDABLE AND SOCIAL HOUSING

4.1 Regulatory framework and policy of social and affordable housing in Serbia

Serbian regulatory framework and policy of social housing is relatively new and mainly without adequate „forerunners". The key documents of the framework are (by chronological order):

1. Housing Law (1992, amendments 1993-2012) is the oldest important document for the topic. It is one of relatively long-lasting legislative acts in Serbia. This is even more important if it is known that this law has "survived" ex-Yugoslavian wars, crisis, significant political turmoil and several national assembles. But, it has had 14 amendments, which indirectly have presented painful transition of Serbia in last two decades. This law is generally in sector of housing, so it regulates only key matters. The article No 2 is especially important for this topic, because it says that "State ... provides the conditions for the resolution of the housing needs of socially threatened persons" (PS, 1992-2012, Art. 2). But, crucial fact is that the law had been the only important act for the regulation of housing sector during long transitional period (1992-2006). Because of this it hasn't been "adequate to the conditions of market economy" and it had not enabled "resolution of housing needs of socially vulnerable groups" (Petovar, 2005[4], p. 15).

2. The Study of Housing Sector of Serbia (2006) was the first policy after overthrow of Milošević's authority. It is arranged as a review of legislative and other public actions in housing sector and it mainly deals with problems and understatements of previous period. Social housing sector is elaborated in one chapter. Special attention of the study is given to housing issues of the National strategy for refugees and displaced persons. This part presents various housing options with different building types, ownerships, kinds of construction and kinds of public support and is also connected to appropriate spatial distribution (UNECE/CHLM, 2006, pp. 58-59). This was certainly "refreshing" document for that period.

3. Publication "Four Strategic Themes of the Housing Policy in Serbia" (2006) is a document prepared by UN Habitat Serbia as a support for government institution and bodies. The field of social housing is directly

connected to Affordable rental housing, but its elements can as well be recognized in two other themes (informal settlements, inclusion of Roma population through housing). The main goal of this publication is defined set of recommendations for social/affordable housing development in Serbia and their connection to other housing problems, such are illegal settlements.

4. Social Housing Law (2009) is the most important legislative act in newer social housing practice in Serbia. The draft of the law was presented 2004, so Serbian society has waited for 6 years till it was adopted. The law especially deals with the issues of institutional context and financial aspect / ownership of social housing, giving several models. Other elements of social housing, particularly those related to spatial aspect, are not elaborated.

5. National Strategy of Social Housing (2012) is very new document, which is settled as en elaboration of Social Housing Law. Last part of the strategy proposes several models of social housing support, which are scarce in space-related instructions; they include basic standards of minimal space areas per occupants, but they do not include "urban dimension" (spatial distribution, typology, level of spatial intervention, links to land allocation, related public facilities and services, etc.).

6. Action Plan for Implementation of the Strategy (2012) is an addition to the strategy related to their implementation. It is more detailed document and it includes more spatial-related elements. Some terms and "word constructions" are interesting to debate for the purpose of this research. The usage of term стан (eng. housing unit, but also apartment) is by far more present than the usage of term кућа (eng. house, especially single-family house). The term кућа is only mentioned one time and connected to village areas, which are also mention only once. In accordance to expression of the action plan, it seems that dichotomy apartment building-single-family house is equalized with dichotomy urban-rural social housing. Besides, there are no actions aimed to improve urban context of socially supported housing (including any action targeting illegal settlements).

All listed documents guide to the conclusion that there are very few actions of spatial-related elements of social housing. Present actions are usually focused to basic architectural elements, without clear connection to "urban dimension". In some cases, they seem "narrowed" and even contradictory to rich contemporary EU practice. Then, although the current connotation of illegal settlements in Serbia is well-explained in most of the documents, distinct solutions for their improvement as a social housing action are not presented. Finally, in accordance with presented regulatory framework and policy in Serbia it is can be concluded that state institutions and bodies do not define strictly any model and/or building type of social housing as role-model for implementation "in situ".

4.2 Practice and typology of social and affordable housing in Serbia

In situation of newly introduced legislative and policy framework without strict directions and instructions practice is always trying to find other markers for undefined issues. Social housing sector in Serbia is not an exception, especially about the issues such as a typology, position in urban territory. The testing for the argument will be short analysis done in several cases of new social housing in Serbia, with the focus to Belgrade cases.

Dominant building type of new social housing is a building with numerous apartments. Programme propositions strictly specified this building type in many cases (UNHS, 2009, pp. 41-44). This type of construction was implemented even in urban quarters with predominant other type of housing – single-family housing. In the terms of social integration, this is even more illogical proposition, having in mind the social background of future dwellers – mostly refugees ((Vujošević, Žarković, 2009, pp. 21-22), who usually had lived in rural areas with low-density housing types. Partial exceptions are few cases with small buildings with several apartments, which are easily noticed and positively appraised by new dwellers (UNHS, 2009, pp. 50).

All social housing programmes were organized with cooperation of local authorities, who were responsible for adequate locations (Vujošević, Žarković, 2010, p. 24). One of the criteria was to choose locations that are public properties and it limited resources in Serbian towns. This occasion dictated many propositions for new projects. Majority of social housing projects are consequently smaller interventions (usually one building with yard) with random position in urban structure, which is sometimes with totally different typology.

Other actions in social housing sector were directed to the regeneration of existing social housing stock. They are usually directed to various types of structures (detached houses, houses in raw, transformation of collective refugee centres). Even though these cases were more similar to the Serbian context, they are named as "alternative housing solutions" (UNHS, 2009, pp. 61-62). The name can be understood indirectly as a negative or less-important connotation.

If all mentioned conclusions are put in the context of Belgrade as a capital, they become even more serious. All examples in Belgrade area are buildings with numerous apartments (according to the web site of The Society of Belgrade Architects) usually organized in huge urban blocks, provided by the city or state. These cases are often in more isolated positions (at edges of city) with weaker public transport and services. Because of that, they are completely related to older examples from the West, which have been "the personification of uniformization and "ghettoization". Therefore, their success is clearly doubtful.

4.3 Wider picture: Does the regulatory framework on planning and building in Serbia encourage illegal building?

Since 1996. there is continuity in regulatory framework in Serbia of encouraging informal sector. This is the statement many would argue about, but the fact is that several laws, appendixes and other regulation and legislative material have treated the informal/illegal sector without much success. The first document which has treated this issue was the appendix to then-in-force Planning law (1993.). The intention supposedly was to tame the illegal building by enabling the legalization of then-existed buildings built without permits or out of borders of actual plans, while future illegal building was strictly forbidden. After that, two Laws on planning and building came into force (2003 and 2009), both with several amendments and both, along with amendments, treated the illegal building again substantially in the same manner as the first one. All laws and regulation have emphasized the importance of placing the informal growth into legal framework and at the same time banned its future growth. While the intention was probably good, the measurements and instruments for its implementing were poor. Namely, the state and local governments and the administration did not have the capacity to support and realize such measures defined by law. The inspection bodies also suffered from the lack of capacity and other means of preventing new informal growth, while they were not quite empowered to implement the regulations by demolition of the illegal houses. As the illustration of the above said can serve the fact that less than 1 % of total number of illegal buildings in Serbia have been demolished. On the other hand, very well spread corruption was hand in hand with the informal sector supporting it, so the illegal settlements were flourishing and have expanded a great deal. As the consequence, many regulatory plans have been made with sole function to legalize the expanded informal settlements, instead of being the strategy for the future development.

Furthermore, the newly prepared amendments of the Law on planning and building (2013), which are adopted by the state Government but not yet adopted by the Assembly, propose that every building in Serbia, regardless of their ownership status should be noted by the cadastre (practically free of charge) and therefore would seem as building with building permits. While there are, beyond doubt, many positive effects of the proposed amendments it is important to emphasize the possibility of equalizing illegal and legal buildings as a negative effect in the context of this paper.

As the (theoretically, but not fully practically) rigid framework of banning illegal building sector does not work and the old policies seem to have failed, maybe it is the time to admit that changes in the attitude has to be made. All the above stressed leads us to conclusion that, instead of turning head off the fact that it is not possible to fully tame or prevent the illegal city growth, is not it better to embrace it and fully integrate into the planning frame and social housing policy and legislation?

5   CONCLUSION – THE ILLEGAL SETTLEMENTS AS AREAS OF SOCIAL/AFFORDABLE HOUSING AND SOCIAL INTEGRATION

The extensive discussion about the city growth, urban land management, informal settlements and housing sector made us question most of the conventional approaches to solving both the problem of illegal settlements and informal urban growth on one hand, and of the social housing in Belgrade on the other. The above mentioned sectorial policies and regulatory framework, as well as international strategies and instructions for overcoming the stressed problems of a contemporary city in developing countries seem to have been made to be implemented separately, not integrated with other aspects, problems and possible

solutions. Each trying to function on its own, they fail to acknowledge the 'bigger picture' and to 'think outside the box'. What we propose is the reviving of holistic approach by observing the problems overlapped in spatial, social, financial, environmental and other context.

In order to be able to do that, it is necessary to change the prospective and conventional way of thinking of the problem. First of all, instead of thinking of informal sector as of the outlaws and invisible, let us try to treat it as reality. The social structure of the inhabitants and owners of the informal housing sector leads us to conclusion that this form of habitat has certainly gained some qualifications of the social housing as well. Furthermore, the informal settlements and their inhabitants, by self-making process of their homes, have surely lessened the pressure of the population that would require a habitation in the field of social/affordable housing sector.

In order to make the idea more feasible, some future steps are proposed:

- The change in the perception of informal settlements as of undesirable, non-appropriate form of housing, far from legal framework and professional standards, that has only to be exterminated;

- The change in the social housing sector legislation as well as in the planning and building sector legislation in the way they become more comprehensive and integrative, embracing each other; furthermore, the legislative and regulatory framework of social housing should be more open to the public and private sector partnerships, as opposed to the actual practice of leaving it solely to the public sector; this could be the opening of the possibilities to include informal sector housing owners into the legal framework;

- The change in social housing typology so that it accepts and further develops other spatial and physical forms of social housing than it was the case in past, leading to greater diversification of types, including the transformed types of informal buildings;

- Acknowledging the values of the informal sector when possible, as opposed to the prevailing absolute criticism towards it; possible qualities of informal settlements, having in mind the spontaneously formed types in Belgrade, could be related to the relatively good quality of applied building materials in many cases, the size of the dwellings and its plots and most of all recognizing the amount of the greenery in the settlements. In order to recognize these values and of course for many other reasons, it is necessary to undertake a comprehensive research and study about the informal settlements and provide a reliable information data;

- Redefining the possibilities of upgrading the informal settlements so that they achieve newly defined standards of social/affordable housing.

- Other future steps and research required should refer to:

- Institutional support in the form of new body assigned to assist upgrading informal sector/settlements, providing adequate services, traffic and infrastructure network;

- Legislative support at local level and preferably also at state level when possible; since local government level is seen here as more willing to adjust in short time, a set of local measures and instruments to support urban upgrading of informal settlements are more likely to happen. This would include stimulations for houses and owners who invest an effort to meet social housing criteria, criteria of basic infrastructure equipment, energy efficiency, etc. The process should empower local tenant associations, neighbourhood organisations, builders from the informal sector, third sector social service providers (health, education, social provision, etc.) to improve existing settlements;

- Specific education process (e.g. short term courses) for local communities with the aim to train them to assist in implementation of this idea.

Bringing new ideas about working positively with existing informal settlements as a contribution to housing the local population instead of rejecting them or worse still trying to demolish such fixed capital investment, Belgrade could become a pilot area for experimenting with such alternative institutional arrangements and cooperative forms, supported by university research.

There should be a balance between formal and informal sector. The presence of informal sector might be stimulating and encouraging for formal sector, as opposed to the common and prevailing opinion that they

have to exclude each other. The treatment of informal sector should be related to the local characteristics and cultural and social background and other relevant aspects and fields. Cutting the informal growth in the surgery manner during the economic and transitional crisis is neither effective nor wise. It is not possible and not useful to define one pattern applicable all over the world, though there are similarities about informal sector worldwide. Though we are in the era of global economy and under the influence of global forces, it is local resilience that will make our cities survive.

The Challenge of Economic Regeneration in Small Urban Settlements of Greece

Despina Dimelli

(Associate Professor Despina Dimelli, National Technical University of Crete, Sarantaporou 6, dimelli@arch.tuc.gr)

1 ABSTRACT

Greece is a country that has been focusing its development in big urban centers. Almost all policies were based mainly on the development of Athens, Greece's capital and then in the other urban areas. This phenomenon was not random as after the Second World War intense population movements towards big cities with the simultaneous abandonment of the countryside were taking place. This mono-centric development continued in the next decades until in 1999 the first Regional Plan for Greece noted the need for a more balanced development where all county's parts would be equally developed. But this speculation did not manage to reverse the gigantism of the urban centers and the simultaneous population reduction in the small urban settlements.

The economic crisis that Greece today faces has caused many changes in the productive basis of the country so and in the areal distribution of its citizens. The tertiary sector that for the last years was the basis of employment is today descending while many Greeks "return" to more traditional occupations of the primary and the secondary sector. Unfortunately Planning could not predict these rapid changes. The settlements that until today were faced fragmentarily only in cases where they could be exploited for touristic reasons must again be seen under the new view and must be adjusted in the new needs that have resulted.

The current paper will focus on the Greek settlements of Greece, their population changes and their productive basis, while it will also investigate the parameters that affect their development. Finally after the investigation of the small mountainous settlements, it will propose ways for their optimum development and their adjustment in the new crisis needs so that they can be a part of the solution and so that finally the

2 THE SMALL SETTLEMENTS OF GREECE

The Greek territory has been developed for the past 200 years without planning. The industrialization, the immigration and the enlargement of the tertiary sector in the big cities have shaped different kinds of areas. The regions that are overpopulated and their urban centers are continuously expanding at the expense of agriculture and forest areas and the regions that lose their inhabitants while the productive sectors, in which their economy is based, are declining.

The geomorphology of Greece with its mountainous areas and its 227 inhabited, islands have led to its population's distribution in many different areas. The majority of the population lives in urban centers[1] where 35 % of the population is recorded, while the 491 small cities[2] assemble 36,4 % of the total Greek population (table 1).

Population	Number of settlements	% of the total population
More than 100.000	8	17,7
50.000 <population<100.000	28	17,3
10.000 <population<50.000	108	22,8
2.000 <population<10.000	383	13,6
Less than 2.000	10.011	28,6

Table 1: The distribution of the Greek population in different size areas.

The 10.011 small settlements (some representative cases of their size are shown Figures 1 &2),[3] that are recorded in the total Greek web, concentrate 28,6 %[4] of the total Greek population according to the census of 2001. A more detailed research, shows that most of these settlements (81 %) have less than 500 residents and they concentrate 44,7 % of the small settlements population, while the rest 1.939 settlements are inhabited by 1.731.103 people (Table 2). As these settlements are basic for the country's development it is essential that Regional Planning focuses on their particularities and on the factors that define their changes.

[2] with more than 2.000 inhabitants

[3] areas that are inhabited with less than 2.000 people

[4] 3.135.678 of 10.964.020 inhabitants

Fig.1 Moutsouna Settlement, Naxos, Fig.2 Faraklata settlement, Keffalonia

Small Settlements			
Population	Number of settlements	Average population	Total population
1500-2000 inhabitants	173	1.730	299.340
1000-1500 inhabitants	411	1.208	496.674
500-1000 inhabitants	1355	690	935.089
1-500 inhabitants	8.072	174	1.404.575

Table 2: The distribution of small settlements regarding their population

The allocation of these settlements in the Greek territory is shown in figure 3. The small settlements are allocated in the all Greek territory except the areas with high altitude.

From the investigation of the small settlements population changes, during the 1991-2001 decade, results that in 1991 3.083.415 inhabitants were living in small settlements, while in 2001 3.135.678 were recorded. So, small settlements population has increased. This increase is not uniformly distributed as in many small settlements the population has increased, while in others the inhabitants have moved, not to the urban centers where the population is also recorded decreased, but in other bigger settlements where the population oscillates between 2.000 and 10.000 inhabitants (figure 4). The factors that cause these population changes and accordingly their development possibilities are the subject of the current research as small settlements planning is necessary for the achievement of a successful regional development policy that aims in the survival of the small settlements via the improvement of the factors that will lead to their population's increase.

3   THE MUTATION OF GREECE'S PRODUCTIVE BASIS

From the declaration of the Greek state until today, the Greek space has been developed according to the existing social, political and economic changes. The Greek, initally rural areas, diachronically mutated to urban areas as big population movements took place with different intensity, according to each prepondarate conditions from the small settlements to the urban centers. The desire for a different life with better conditions in the city, that was combined with the abandonment of the primary sector and the dream for a better and a more comofortable life through the employment in the secondary and tertiary sector, that were rapidly developing in the urban centers, led to the movements towards the cities.

It is characteristic that [Kotzamanis, 2009: 8]:

"[…] during 1920-1940 the trend for urbanization was decreasing, (the urban population consisted the 33 % of the total recorded population), while during the Second World War and the Civil War this urbanization accelerated. So in 1950, 38 of the 100 Greece's residents were living in urban areas. In the next thirty years, Greece will be characterized by the internal and external migration and urbanization. […]".

So, although in 1853 the rural population was 79.4 % of the total recorded population, in 2001 the rural population occupied only 28,6 % of the total recorded population (Figure 5).

Today, as Greece faces the phenomenon of economic crisis, the recorded data show a "return" to more traditional productive sectors, as the tertiary and the construction sectors are facing huge problems (figure 6). The fact that the Government has decided to stop the gigantism of the public services and has reduced the

salaries of public employees has drifted all the other sectors, as trade, construction e.tc. On the contrary, the lack of vacancies in the tertiary sector and the cheaper way of living in the small settlements has led to the relocation from the urban areas to small settlements. But is Greece prepared for this new reverse phenomenon? The up to today formulated policies have been concentrated on development of urban areas, whereas small settlements were fragmentarily faced.

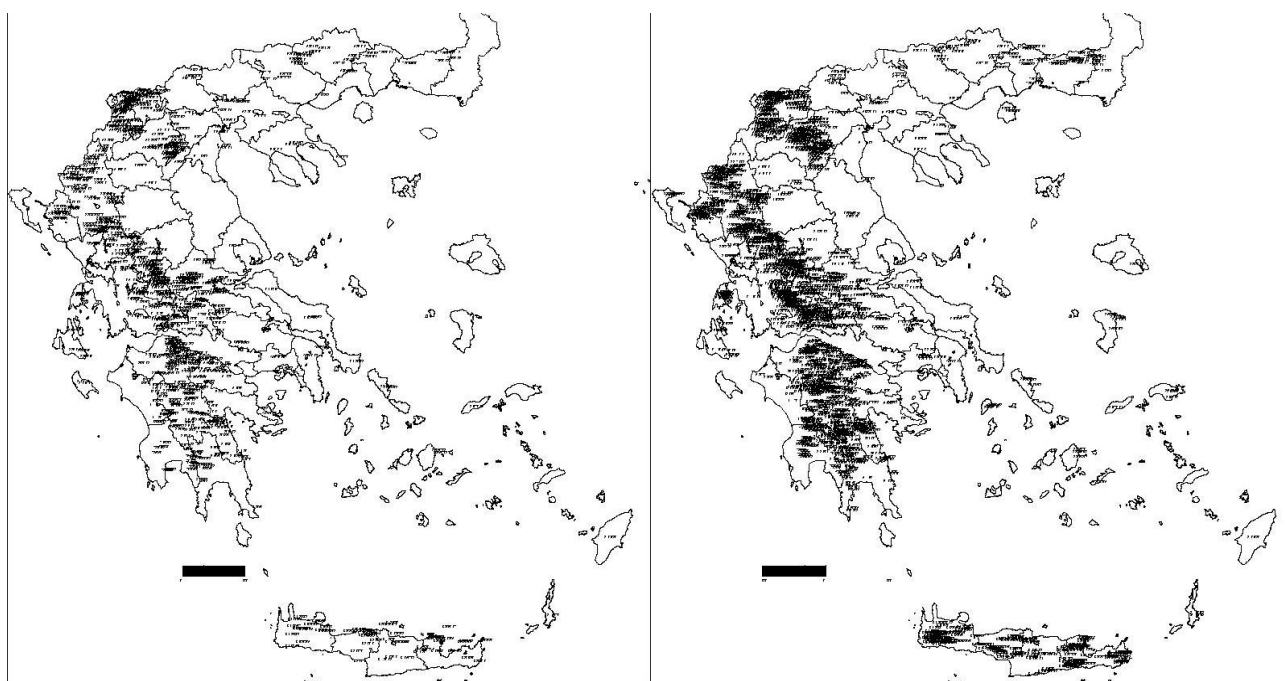

Fig. 4 . The population changes of the small settlements of Greece. Settlements with increased population (left), Settlements with reduced population (right).
Fig.5 The population of Greece according to its urbanization degree. (%)
Fig.6: Real value added in productive sectors of Greece.

4   THE EXISTING SPATIAL POLICIES FOR SMALL SETTLEMENTS PLANNING

In the existing National Regional Plan of Greece, the small settlements are mentioned in Article 9, that concerns the areal development of the mountainous, coastal, island, rural and border areas. This article defines, that the development of small settlements will be achieved via the development of their infrastructures and the improvement of their accessibility.It also mentions that there is a need for the formulation of a more detailed National Mountainous Plan, which since 2008 has not yet been legislated.

In the urban planning level the 2508 law that was legislated in 1997 was the first law that noted the need for planning that would cover not only urban areas but also non- urban areas. But although the total space is planned,only directions based on estimations of future development are given. A more detailed approach, based on more specific elements is not realised, so it seems that planning is only about the definition of the necessary infrastuctures.

The speculation that results, is if these formulations are enough for the solution of the small settlements problems, or if planning should include specific features that will result by the use of quantitative and qualitative indicators. These indicators will reveal their particularities and will eventually lead to specific policies that will contribute to their best development.

5 THE CASE STUDY: THE SMALL MOUNTAINUOUS SETTLEMENTS (S.M.S.) OF GREECE

As mountainous settlements, according the European directive, are defined the settlements that are allocated in areas with altitude higher than 800 meters. In Greece, 2.504 mountainuous settlements are recorded.

The population changes that have been recorded during the 1991-2001 decade, regarding the settlements altitude are shown in figure 7 and table 3.
Fig.7: The number of s.m.s concerning their altitude

Altitude (meters)	Population		
	2001	1991	Variation
800-850	27288	29067	-1779
850-900	31450	36565	-5115
900-950	17310	18995	-1685
950-1000	29024	30794	-1770
1000-1050	10142	12742	-2600
1050-1100	6091	6990	-899
1100-1150	45	33	12
1150-1200	9483	9641	-158
1200-1250	595	656	-61
1250-1300	119	143	-24
more than 1300	920	814	106
total	132.467	146.440	-13.973

Table 3: The s.m.s. population changes concerning their altitude.

The relation of the recorded population changes with the existing road axes is obvious, as mountainuous settlements that are distant from the national road network (figure 8) present bigger population reduction, compared with the corresponding that are adjacent to the national road network. The same phenomenon is faced in the small settlements that are close to urban centers. In this case,the population reduction that is recorded, is less intense compared with the settlements that are distant from the urban centers. So, it is concluded that the demographic changes are not affected only by the altitude in which a small settlement is allocated but they are also affected by factors as distance from urban areas, road network e.tc.

6 THE CHANGES OF THE S.M.S PRODUCTIVE STRUCTURE

The s.m.s. concentrate most of the functons that are taking place in urban areas with different ratio. The main sector that was recorded during the 1991 employment census, was agriculture and livestock which concentrated 30 % of the total recorded employment. The tertiary sector concentrated 22 %,while industrial and manufacture activities concentrated only 11 %. From the employment 2001 census resulted that the employment in agriculture was reduced in 22 % while the tertiary sector was increased to 36 % (figure 9).
Fig. 8 . The population changes of the small settlements of Greece and their relation with the main road network. Settlements with increased population (left), Settlements with reduced population (right).
Fig.9 The employment distribution for each productive sector in the mountainous settlements in 1991 and in 2001.

For the reveal of the structural productive changes of the s.m.s., the research will proceed to their classification with the use of Principal Components Analysis, that reveals the settlements groupings based on their common characteristics. The variables of the analysis will be the recorded changes of each productive sector for each s.m.s..

From the Analysis resulted that five groups of s.m.s. were revealed. The first group included settlements that had increased their employees in the tertiary sector while the rest four groups were shaped by s.m.s. where changes in the primary and the secondary sectors were recorded. The investigation of this s.m.s groupings allocation, shows that there has not been a specific region where certain groups are recorded but that all the different groups are dispersed all over the Greek territory.

7   PROSPECTS AND PROPOSALS FOR THE DEVELOPMENT OF S.M.S.

The s.m.s. are areally dispersed with problems of infrastructures and accesibility lack. The investigation of their population changes shows thet they are not disadvantageous areas as in many of them population increase has been recorded while the employment in their productive sectors has increased.

It is also remarkable that when the changes of employment are areally recorded, it seems that s.m.s. function suplementarily. It is concluded that they can function as areal cells networks that are functionally related.

So, planning of all levels should encourage activities that face survival problems with the establishment of motives and create the infrastructures needed for the coverage of the s.m.s. residents needs. Simultaneously, the road network improvement can meliorate accesssibility, as the roads condition is a factor that influences s.m.s. development.

The fact that also results is that s.m.s. cannot be fragmentarily faced as they are characterized by particularities that are not taken into consideration by the existing planning systems of spatial levels.

So,the creation of an observatory is proposed as all the changes and the specific characteristics should be recorded and special policies should be applied. This way, planning can create hierarchies, predict and encourage or discourage the parameters that can contribute to s.m.s. development through coordinated policies that will derive from all planning levels. This approach which will be flexibly adjusted can focus on every areas particularites and lead to the achievement of the s.m.s. best possible development.

Finally, it must be realised that today is more than ever imperative the need for a new planning approach, that will focus on all kinds of areas, as new needs have emerged.

1 BACKGROUND

Urban areas especially suffer from hot days because of the urban heat island effect. Heat periods have impacts on urban residents; in particular, the elderly group, above 65 years, is suffering from the impacts of heat stress. Studies about previous heat impacts have revealed that the morbidity and mortality rate of the elderly are increased during and post heat periods. This has been observed for several US-cities (Anderson & Bell, 2009; O'Neill et al., 2003), as well as for several European cities such as London (Hajat et al., 2002), Paris (Fouillet et al., 2008; Vandentorren et al., 2004) and Rome (Michelozzi et al., 2003). The heat wave in the summer of 2003 in Europe resulted in about 70.000 deaths (Robine et al., 2008). Regarding Vienna, similar impacts of heat waves have been noticed (Hutter et al., 2007, Moshammer et al., 2006).

It is projected that climate change will further increase heat waves in number, intensity and duration during the 21st century affecting most land areas (IPCC, 2007). There will be an increase in hot days with temperatures above 30°C and tropical nights (with temperatures not below 20°C) (Formayer et al., 2007/2008). The living conditions of the urban population will be negatively influenced particularly by long lasting and intensive heat waves.

As cities have a large and increasing elderly population and a high number of those living isolated in poor housing conditions, the issue becomes far more important in the near future in particular as more heat periods are predicted because of climate change (Hutter et al., 2011). Thus, the reduction of the vulnerability of elderly people is a prior aim for city administrations. One strategy in reducing heat stress impacts is changing residents' behaviour during heat waves. Unfortunately, knowledge on adaptive behaviour of the edlerly during heat waves is often lacking.

2 PROJECT OBJECTIVES

The aim of the 3-year STOPHOT-project is the reduction of the vulnerability of elderly people (> 65 years) living in cities (in this case Vienna) against urban heat. This study develops sustainable short- and long-term preventive measures for the built environment and green spaces, and measures encouraging proper behaviour of the elderly. It will have a specific focus on social meeting places, in- and outdoors, avoiding social isolation. This study appears to be the first comprehensive one in Austria, developing adaption measures in an inter- and transdisciplinary manner, reducing the vulnerability of elderly urban residents. It specifically investigates elderly awareness of heat risks, perception of heat stress and adaptive behavior avoiding heat impacts (Wanka et al., 2012). The empirical study will identify gaps between 1) actual and recommended behavior of the elderly and 2) proposed or existing stakeholder health-related strategies and efficacious measures recommended by the medical resp. public-health experts.

3 METHODS

Several partners from different working fields (health, planning, seniors, …) are part of this project (Figure 1). A mixed-methods design that combines both qualitative and quantitative methods is used to take into account the viewpoints of different disciplines and actors (Figure 2).
Fig. 1: STOPHOT-project team and partners

- Several types of urban study areas were selected. These types represent varying degrees of green spaces and socio-economical levels in and out of heat islands of Vienna. Older peoples' attitudes towards climate change, their awareness and perception of heat stress as well as their adaptive behaviour were investigated per study area type. Using a standard questionnaire, 400 subjects over the age of 65 were interrogated via anonymous telephone interviews in their private homes (in- and outside urban heat islands) in 2011. A telephone survey among younger persons for controlling age as major independent variable (n=200) was done. In addition, face-to-face interviews with elderly living in retirement and care homes in- and outside urban heat islands were carried out (n=200).

- Fifteen in-depth interviews with stakeholders from city planning, green space management, health care, retirement and care homes etc. were carried out between June and December 2011. The interviews focused on stakeholders' awareness, perception of climate change risks and their perceived relevance of heat impacts on elderly residents. It also provided an overview on the degree of stakeholders' activities reducing the vulnerability of the elderly. Using the free listing method adaption measures were collected. A inteview guide was developed, the interviews were recorded and transformed into text form and analysed using a qualitative content-analytical text analyses (Mayring, 2010), supported by ATLAS.ti software.

- Then the study identified the gaps between actual behaviour of elderly and recommended behaviour with respect to in- and outdoor activities and gaps between proposed or existing stakeholder strategies aimed at reducing the vulnerability of older people and efficacious measures from the medical point of view.

- First results were presented in stakeholder workshops and first sustainable management and planning measures for urban heat islands were developed.

- In the next step the elderly will evaluate developed adaption strategies and management measures. For this purpose, a survey among elderly living in urban heat island will be carried out using a stated preference model (discrete choice experiment; Louviere et al., 2000). With face-to-face interviews, the elderly (n=200) will be asked to evaluate alternative configurations of hypothetical/existing adaption measures which are defined as combinations of physical, social and managerial factors. To ease the evaluation of the heat avoiding scenarios visualization of scenarios will be provided, using digitally calibrated images, which strictly controls the variables under investigation (Arnberger & Eder, 2011a,b).

- These results will be presented in a second stakeholder workshop to refine management and planning measures.

4 RESULTS

4.1 Elderly's perception of and behaviour during heat waves

The survey among the elderly aimed to work out 1) whether elderly people perceive climate changes and rises in temperature, 2) how they react to it physically and mentally, and 3) how they adapt to these changes. An overview of the results is provided below.

Elderly people and climate change awareness

Half of the elderly respondents living at home and half of the elderly respondents living in retirement homes stated that they have experienced more hot days, hot nights and longer heat periods today than ten years ago. Accordingly, the vast majority perceived climate change to be a serious problem that might have catastrophic consequences. Retirement home inhabitants, persons with a higher educational status und persons living in areas with little green spaces were more aware of this problem. However, the majority of the elderly also stated that climate change will not affect themselves anymore because of their old age.

Heat stress and its effects on elderly people

Elderly people felt most comfortable at temperatures which range from 21°C to 25°C during the day and 18°C to 23°C during the night. Particularly among women, sensitivity to heat increased with age.

Heat primarily affected the elderly's energy balance. Reported heat impacts on physical wellbeing were fatigue and sleeping problems. On the one hand, heat caused senses of pleasure. While both older and younger people (18 to 55 years) frequently reported these symptoms, older people suffered more from heat stress. Risk groups, defined as people who suffer most from heat stress, comprised:

- younger people (18 to 55 years) with a low socio-economic status who live in socially disadvantaged areas
- older people (65 years and older) with a low socio-economic status, poor health condition, who tended to be socially isolated

The latter group was more likely to withdraw from the public life during hot periods. Those who didn't withdraw appeared to suffer from fewer heat induced ailments. Factors that increased the likeliness to stay at home were a disadvantaged neighborhood, dissatisfaction with and lack of social neighborhood networks and age discrimination in the residential area.
Fig. 3: Reported activities against heat stress (survey 2011)

Strategies to coping with heat stress

Altogether respondents felt well informed about the right behavior during a heat wave. Seniors living at home mentioned most frequently newspaper, television and radio as sources of information. In contrast, respondents living in retirement homes mentioned most frequently home management, doctors and care personnel as sources of information. This group perceived personal information as more helpful than media

Brigitte Allex, Arne Arnberger, Anna Wanka, Renate Eder, Hans-Peter Hutter, Michael Kundi, Peter Wallner, Franz Kolland, Beate Blättner, Henny Annette Grewe

information. The most common recommendation elderly people received from their doctor (especially those living in retirement homes) was to increase their liquid intake during a heat wave.

Seniors themselves claimed drinking as one of their most commonly deployed measure against heat stress. Other often mentioned measures were wearing lighter clothes, drawing the curtains, shifting their pysical activities to the morning or the evening hours and keeping the windows closed during the day. Elderly people reduced their activity level to a greater extend than younger people.

The majority of older people stayed in their apartment when it was hot. They perceived the home to be cooler than the outdoors. Those who went out, did less suffer from heat stress. They visited semi-public (gardens, inner yards) and public (parks, waters) areas. Older people showed a preference for parks and green spaces, while the younger ones favoured blue spaces.

4.2 Stakeholders' views on urban heat and the elderly

Stakeholders had different perceptions on the topic of urban heat and the elderly. Most experts were aware of climate change and heat waves, but most of them had not yet considered them with respect to the elderly. Whereas stakeholders from the field of "planning / green space" have already dealt with the topic heat and climate change (mostly at workshops/conferences), representatives of older people had only discussions on that topic with senior citizens, but no experiences at scientific level.

The experts were able to name a lot of measures to make the summer heat in the city bearable for the elderly. In total, 79 different measures were mentioned. On average one expert named 13 measures.

The measures stated most frequently were "sufficient drinking", "greening of roofs/facades/courtyards", "planting and preservation of trees/avenues", "keeping/including more green in the city" and "more drinking fountains in public spaces".

Depending on their discipline, the experts focussed on different measures. Representatives from the sector "planning / green spaces", for example, named many measures which were related to public (green) spaces, such as "ventilation of the city", "greening of roofs/facades/courtyards", "planting and preservation of trees and avenues". Representatives of the elderly as well as representatives from the health sector had their focus on individual measures such as "sufficient drinking", "right food", "appropriate clothes", "avoiding midday heat" etc.

Although the stakeholders were able to name a number of measures, only few measures have so far been implemented for the elderly in Vienna. The representatives from retirement homes mentioned the following measures which have already been implemented in their retirement homes: drinking fountains in the common areas, diet food on heat days and apartments with heat protection. The care station has been moved to the ground floor due to the summer heat. Furthermore, posters and billboards as well as announcements inform about heat waves and provide recommendations regarding proper behaviour.

In addition, the city of Vienna provides a heat wave warning system and a list of recommendations regarding proper behaviour, which has already been distributed to those elderly who live alone in private homes.

Experts differrently assessed the present risk of urban heat for older people living in private homes. Some experts thought that there is already a risk for elderly people, especially if there is no person who looks after them, others believed that the risk will significantly increase in the future. The risk of the elderly living in retirement homes was estimated to be as high as that of those living in private homes. Representatives of the elderly, though, regarded the risk level to be lower due to residential care in retirement homes.

5   CONCLUSION

The elderly are particularly vulnerable towards heat stress. With urban populations ageing, and urban temperatures rising, planning and design of urban areas must increasingly consider the interaction of social and climatic factors as an important part of becoming an age-friendly city.

However, many relevant stakeholders in Vienna did not feel any direct responsibility regarding the issue, only few measures have so far been implemented for the elderly in Vienna. Therefore, a responsible person and multidisciplinary collaboration between the different organisations and working groups are needed; at the moment, synergies seem to be missing.

Study results suggest that heat is essentially a social problem in three ways. First, people with a lower socio-economic status tend to live in disadvantaged areas, in which heat exposure and heat stress are increased by building density, building materials, lack of public and green spaces and other environmental and planning factors. Second, once exposed to heat, people with a lower socio-economic status suffer more from heat stress due to their generally poorer health (caused by bad living and working conditions as well as unhealthy lifestyles). Third, the study has provided new insights in how disadvantaged groups tends to deploy unfavourable coping strategies, like staying at home in a hot apartment.

Recommendations for concrete measures and activities reducing the vulnerabilitis of the elderly can be drawn from these conclusions. The measures have been discussed and evaluated by stakeholders of urban planning, senior and social work as well as climate research in the course of a World Café. STOPHOT recommendations for urban outdoor planning comprise for example:

Challenge	Description of Measures
Accessibility	Elderly friendly and climate adapted corridors to reach public and green spaces and parks For example: Green paths and corridors Accessible public toilets and information about where to find them
Mobility	Elderly friendly and climate adapted resting possibilities like mobile benches that can be moved to shadowy or sunny places (depending on the weather and season)
Privacy	Elderly people enjoy to be outside, yet they express a need for semi-public places and places in public space where they can withdraw and have a moment of quietness
Maintenance	Provision of infrastructure (e.g. benches in green spaces) is not sufficient, it must be maintained. Urban planners should cooperate with local initiatives, NGOs and organisations offering leisure activities for older – and younger – people.

Heat has to be seen as an environmental factor which is not natural and unchangeable, but as part of social inequalities that can be balanced. Resilience and individual coping strategies have to be supported by community-planning initiatives (e.g. green corridors, community gardening).

The Heart of the City from a Socio Cultural Perspective

Heba Safey Eldeen

(Associate Professor of Architecture, Misr International Univsersity, 11841 Cairo, heba.safieldin@miuegypt.edu.eg)

1 ABSTRACT

Ontological city planning theories suggest that the definition and location of the city heart (AKA CBD and City Center) is the geographically centered, economically based, and activity vibrant spot of the city. In Cairo, the heart has applied this actuality since its foundation in 969 AD, and has moved or transformed and changed size and location with every major shift in Cairo's planning milestones. However, January 2011 revolution in Egypt has identified a new parameter to the theory of the deteriorated heart; suggesting a new hypothesis: "the heart of the city is related to socio-cultural attributes rather than to the physical planning measures". Incidents of the revolution and its consequences and aftereffects are changing both the society and the urbanism at a fast pace. The question in debate here is: How can urban planning improve Cairo's resilience to political and social changes caused by the upheaval era we are living in? How can we make use of this transitional period towards an urban democracy of our victorious city?

The paper at hand aims at answering the preceding questions. It aims at introducing a differentiation between the CBD and the heart of the city as well as proposes some recommendations for its public spaces development. Its methodology is based on a review of the concept of the heart through a chronological review of the case of Cairo. Arguing the validity of the theory, the paper moves to showcasing the urban status of its major public spaces that are used as revolution and demonstration "hearts". Discussion of the cases is expected to shed light on some basic considerations needed to react to our fast changing City.

2 INTRODUCTION

While cities continue to grow, real knowledge of their evolution is tied with the study of social science. For the complexity of the urban life can never be explained without a complete analysis of the economic and social processes. This is our duty if we are to regulate the physical world. Works of Marx, Simmel, Freud, Weber and Wagner emphasized the preceding ideas since the first quarter of the twentieth century. In the last quarter of the century, Peter Hall and McLoughlin accentuated on the urge of a different kind of knowledge in order to accommodate the design of cities, and to improve the lives of their people. Zukin points to the significance of culture in the creation of urban forms, while Boyer explains that the production of built environment is part of the material production of society (Boyer, 1984). Moholy-Nagy wrote that cities, like men, are embodiments of the past, and mirages of unfulfilled dreams. They thrive on economy and waste, on exploitation and charity, on the initiative of the ego and the solidarity of the group. They stagnate and ultimately die under imposed standardization, homogenized equality, renewing themselves unit by unit in a slow time bound metabolic process. Society is therefor the determining factor in urbanization (Nagy, M. 1968).

We must return then to the economic and political, cultural and social contexts as pillars of the spatial morphology and building typology of the city. The city thus, is a text that can be read as a system of differences or fragments that bear a loose or indeterminate relation to each other. Since these texts are all constructions following certain laws, then they can also be deconstructed and therefore understood (Cuthbert, 2006). Indeed many cosmopolitan cities have undergone cultural and urban transformations, however, and despite any development or move of the CBD, there is always a constant fact; which is the urban essence of its heart. Along the history of Cairo, the heart has moved or transformed and changed size and location with every major shift in the city's planning milestones. From the old gated Fatimid city center, to the Ottoman center, to the Khedivial "West El Balad" (downtown) for over a century regarded as "Paris of the East" or the "Golden Age", to its fractioning to Heliopolis in the East and to Mohandessin in the West, and then out of the city fringes: to New Cairo and to 6th of October city as multinational business hubs with a change from the boulevards to the campus form. The original city has become a multiple city, and so its center was divided. Along with the journeys, an immigration of city dwellers with every political regime has led to decentralization and a defragmentation of the CBD to new downtowns as a natural consequence formulating an urban enigma. Each and every newer center always attracted the top of the Cairene social pyramid class, leaving the older heart to lower societal classes to enjoy the left overs of buildings and public spaces. However, the Cairo phenomenon I would like to highlight here is the revivification of the old Khedivial

downtown with January 25the revolution in 2011, introducing a knot in the urban logic. For in the large square that has long belittled into a central geographical node, since its fragmentation in the eighties (more than a quarter of a century ago) has accommodated millions of Egyptians for an uninterrupted 18 days with a continuum todate. Tahrir square (epic of the Khedivial downtown) and its surroundings has overnight been transformed into the heart of the country- not only Cairo; an Agora, a hide park speakers' corner and a sit-in as well as a camping site, in addition to Egypt's ultimate demonstration center. Every one was welcomed in the square; politicians, intelligencia, students, families, elite, scientists, officials, the urban poor and even criminals, homeless and street children. A new hypothesis can now be debated, that is: the CBD might be the geographical and economic center of a city, but the heart is related to socio-cultural attributes rather than to the physical measures.

3   A CHRONOLOGICAL REVIEW

Literature defines the CBD or the Central Business District as the focal point of a city. It is the commercial, office, retail, and cultural center and usually is the center point for transportation networks. Usually typified by a concentration of retail and office buildings. Also called a central activities district, is the commercial and often geographic heart of a city, also referred to "downtown" or "city center" (Gosling, D. & Maitland B. 1984).

The term "city place" is similar to CBD serving the same purpose for the city, and both are marked by a higher-than-usual urban density as well as often having the tallest buildings in a city. City center differs from downtown in that the latter can be geographically located anywhere in a city, while a city center is generally located near the geographic heart of the city. London arguably has three city centers; the City of London, the medieval City of Westminster and the transformed Docklands area. Mexico City also has more than one city center: Centro Histórico, the colonial; Paseo de la Reforma – Polanco the mid-late 20th century CBD, and Santa Fe, the new CBD. In Taipei, Taiwan, the area around its main railway station is regarded as the historic city center while the Xinyi Planned Area located to the east of the said railway station is the current CBD of Taipei and not only is it considered the financial district of Taipei, but it is arguably the premier shopping area in Taipei and Taipei's most modern cosmopolitan district. Taipei 101, Taipei's tallest building and currently the world's second tallest habitable skyscraper, is located in Xinyi Planned Area (Curthbert A.R. 2000, Mumphord, Kostof, S. 1993).

The shape and type of a CBD or downtown almost always closely reflect the city's history. Cities with maximum building height restrictions often have a separate historic section quite apart from the financial and administrative district. In cities that grew up suddenly and more recently such as those in the western half of North America, a single central area will often contain all the tallest buildings. It has been said that downtowns (as understood in North America) are therefore a separate phenomenon. Central Business Districts usually have very small resident populations. For example, the population of the City of London declined from over 200,000 in the year 1700 to less than 10,000 today. In some instances, however (and particularly in large Australian and Canadian cities), CBD populations are increasing as younger professional and business workers move into city center apartments (Mumford 1966).

A chronological review illustrates how the CBD was initiated as the market square in ancient cities. On market days, farmers, merchants and consumers would gather in the center of the city to exchange, buy, and sell goods. This ancient market is the forerunner to the CBD. The basic ancient Roman plan consisted of a central forum with city services, surrounded by a compact, rectilinear grid of streets. To reduce travel times, two diagonal streets crossed the square grid, passing through the central square. Many European towns preserve the remains of these schemes. Later, Renaissance and Baroque were featured by one city type which for a century and a half: the „star-shaped city", with radial streets extend outward from a defined center of military, communal or spiritual power.

As cities grew and developed, CBD's became fixed location where retail and commerce took place. Typically at or near the oldest part of the city and is often near a major transportation route that provided the site for the city's location, such as a river, railroad, or highway, a center of finance and control or government as well as office space. In the early 1900s, European and American cities had CBD's that featured primarily retail and commercial cores. In the mid-20th century, the CBD expanded to include office space and commercial businesses while retail took a back seat. The growth of the skyscraper occurred in CBD's, making them more and more dense. In recent decades, the combination of residential expansions and

development of shopping malls as entertainment centers have given the CBD new life. One can now find, in addition to housing, mega-malls, theaters, museums, and stadiums. Pedestrian malls are also common nowadays in an effort to make the CBD a 24-hour a day destination. The CBD is often far more populated during the day than at night as relatively few workers live there and most do commute to their jobs around. By the beginning of the 21st century, the CBD had become a diverse region of the metropolitan area and included residential, retail, commercial, universities, entertainment, government, financial institutions, medical centers, and culture. Lawyers, doctors, academics, government officials and bureaucrats, entertainers, directors and financiers are often located at workplaces or institutions in the CBD (Kostof, S. 1993).

In 1933, the German geographer Walter Christaller has developed the "central place theory", defining the central place, as it exists primarily to provide goods and services to its surrounding population. An attempt was to explain the reasons behind the distribution patterns, size and number of cities and towns around the world. Doing so, he attempted to provide a framework by which those areas can be studied both for historic reasons and for the locational patterns of areas today. Christaller further tested the theory in Southern Germany and came to the conclusion that people gather together in cities to share goods and ideas and that they exist for purely economic reasons (Christaller 1933). In 1954, German economist August Losch modified Christaller's central place theory creating an ideal consumer landscape. Both Losch's and Christaller's ideas are essential to studying the location of retail in urban areas today. This model is shown all over the world, from rural areas of England to the United States' Midwest or Alaska with the many small communities that are served by larger towns, cities, and regional capitals (Losch, A. 1954)

Back to the CBD, where the highest land value and the most valuable real estate in the city; core of the metropolitan area, would typically home to one of the city's tallest and most valuable skyscrapers. On the other hand, the convergence of road networks in the CBD often creates overwhelming traffic jams as commuters from the suburbs attempt to converge on the CBD in the morning and return home at the end of the workday. In recent decades, edge cities have begun to develop as suburban CBD's in major metropolitan areas. In some instances, these edge cities have become a larger magnet to the metropolitan area than the original CBD.

From retrospection, literature planning classics have identified the heart as the core of the city. In its "The Heart of the City: Towards the Humanization of Urban Life", the Congrès Internationaux d'Architecture Moderne (CIAM) has identified the heart as 'the core' as 'an element that made the city a city as opposed to an aggregate of individuals' (Sigfried Giedion), as 'the meeting place of the arts' (Le Corbusier), as 'the repository of the community's collective memory' (J.M. Richards) as 'natural expression of contemplation, quite enjoyment of body and spirit' (Ernesto N. Rogers), as 'background for spontaneity and feeling of processional development' (Philip Johnson) and as 'expression of the collective mind and spirit of the community' (Jaqueline Tyrwhitt). Team X has further developed the concept of the heart in the 1950's (Geddes, P. 1949)

4 THE CAIRO PHENOMENON

Along ist history, Cairo has been and still is a challenge to the study of urban design. For its socio- cultural attributes were and still are in continuous transformation. Since its construction in 969 AD, its occupation by Fatimids (969-1171), then Ayubids (1171-1250), then Memluks (Baharis 1250-1382, Burjis 1382-1517), then Othomans (1517-1798), then Mohamed Aly, and his ancestors who drifted Cairo's culture and urbanism towards the French, the Italian and then the English (1805-1952). A disperse and liberalization of culture for one and a half century were abruptly suppressed by the nationalization policy (1961) after the July 1952 revolution, shifting culture and urbanism towards socialism/collectivism. Then Cairo's culture and urbanism were turned head over heals overnight with the open-door policies (1974). A loss of stability was a prologue for the privatization that accompanied the globalization with its underlying aspects of trans-bordered economics and media rebellion accentuated the multi-layered and accumulative ad-hoc's of Cairo's cultural identity and urbanism over the last thirty years. Tracking the changes on the map reveal that perception of its CBD is always associated by a socio-cultural change, rather than economic measures (Safey Eldeen, H. 2008). The mile stones can be identified in four milestones: 1. Before Mohamed Aly (969-1805), 2. Khedivial Cairo and the Belle Epoch (1863-1952), 3. Post 1952-Revoltion, and 4. Cairo Today

Before and during the reign of Mohamed Aly, the unique urban fabric of Historic Cairo was a reflection of its social structure (Bianca, 2004). The heart was al-Mu'izz Lidin Illah Street – the Qasaba (Spine) of Fatimid Cairo, rooted in the principle of symbiotic interaction between the members of its community. The street, over one thousands years old and one kilometre long with dominant markets – besides residential – of specialised crafts and small trades of jewellery, copper, leather, clothes, herbs and other specialized goods and crafts. Each activity was located in a specific section of the street, along the different historic periods of the Fatimids, Ayyubids, Mamluks and Ottomans. User groups were well-to-do residents and merchants who have been replaced by a poorer working class community and a wave of emigrants from different Egyptian cities. Originally designed for pedestrians, horses and cattle, the narrow and sinuous street has been transformed into an over-populated typical residential/commercial activities in slow replacements of ist authentic nature as the medieval local heart and market due to the change in demographic characteristics of its users (Abdel Hady, A., Nachar, E., & Safey Eldeen, H. 2011).

With the Haussmannian Cairo Project (Paris of the East) 1863-1907 witnessed a new down town when foreigners and élite began to invest heavily. Grand palaces and beautiful European style buildings were erected, outstanding squares were designed. French architects, assisted by Italian contractors and designers undertook the building of a pleasant mix of Neo-Classic, Art-Déco, Art-Nouveau, Baroque and a little later, Neo-Islamic styles (Mintti, 1999 & Hawas, 2002). Along its "Belle Epoque", banks, insurance companies and wealthy individuals invested in blocks of flats. The very luxurious apartment buildings were then rented out as offices or private dwellings to a cosmopolitan élite careful to preserve the buildings in excellent shape. Later in the 1930's, downtown tenants abandoned their less fashionable address and transformed their flats into well-appointed offices for their own use or as an investment. Elegant boutiques provided shade with their colourful awnings to a selective clientele who preferred shopping in Cairo rather than in any European capital. Physicians, dentists, lawyers and accountants vied for clinics and offices in such prestigious surroundings. The metro project that has started in 1905 to link the capital downtown with the new suburb of Heliopolis has expanded to reach and link most of the city's districts. The increase in using motor private and transportation vehicles and the introduction of the bus as public transportation in 1935 in the newly paved urban roads have resulted in the expansion and maturity of the suburbs (Heliopolis 1905, Maadi and Hadaek El Qubba 1908, Dokki 1922). New urban suburbs were planned on modern aspects of urban design: Al Awkaf city, Mokkattam, New Helwan, and Nasr City. The older districts have also swelled and increased in number of their inhabitants. Each district was significant for its urban character and identity, reflecting its user groups' cultural and socioeconomic features and sometimes nationalities or ethnicities (Safey Eldeen, H. 2010).

It is hypothesized that the beginning of the urban change in Cairo goes back to the late forties of the twentieth century. After WWII, an inflation of the land values and building costs as well as the wages of craftsmanship took place. Internal immigration constituted a housing problem for the middle and low classes. The poor districts went from pathetic to miserable. For the first time in Egypt, cemeteries acted as housing areas. The number of Cairene inhabitants doubled in only ten years (1939-1949). Cairo remained attractive until the mid century with the break of the 1952 revolution. Afterwards, the exodus of the foreign community hit hard at Cairo downown. Its activities diminished, its boutiques no longer attracted the élite and its apartments were taken over by a social mobility that accompanied the nationalisation and centralisation. The user groups, the land uses, and the urban fabrics have changed. Shops changed ownership and indulged their own decorating schemes. Negligence in laws and regulations enforcement helped establishing commercial buildings into the neighbourhood, regardless of any aesthetic measures or considerations of the historic values of the buildings (Al-Ahram weekly, 2001). Parking problems, together with car exhaust fumes added to a misuse and a lack of maintenance of buildings and pavements. Decades of neglect by downtown landlords and tenants, precipitated by the migration of the expatriate community, and the succeeding departure of the upper classes, have left the ornate splendor of its lavish edifices mired in decay. Negligent enforcement of laws and regulations gave way to the entry of commercial establishments into the neighborhood, mostly with no regard to maintaining aesthetic harmony or preserving the historic buildings (Abdel Hady, A., Nachar, E., and Safey Eldeen, H. 2011).

5 CAIRO'S URBAN ENIGMA'S REFLECTION ON THE CBD

With the 1960 nationalization policy (laying hands on private projects), a centralization process has resulted in an unpredictable enlargement of the city master plan. Accompanied by a socioeconomic change of the Cairenes; a claim of eradication of the socioeconomic buffers has resulted in an allocation of the elite, and an advancement of the middle and lower middle classes, causing unsteadiness in the demographic map of Cairo. Rural immigrants, poor, and youngsters and unqualified class extensively worked in the capital, living on the margins and the peripherals of the city, composing the early urban slums and squatter settlements. After the 1967 Arab-Israeli war, the same inflation of WWII was repeated. However, the results were more intense because of the migration of the canal cities habitants during the war. The new regime of the open-door policy that has started after the 1973 victory has shifted the administrative orientation towards capitalism. Coinciding with the exploration of oil in the gulf countries has resulted in a new reconstruction of the social classes and urban configuration of the city. A shift in the formulation of the middle class was witnessed. Neaveau-riche constituted a new social class, which has contributed to a new urban irrelevancy in the new districts and suburbs with their comeback from oil countries for homing upgrade. Apart, was a vast investment movement empowered by the political decision, contributing to a tremendous inflation and the emergence of new residential districts with new housing cultures. In the eighties, the gaps between socio-economic groups have widened and the demographic structure has mingled. The housing projects could not cope with the pace of the housing need, leading to an entire urban deterioration allover the city. The squatter settlements then were estimated as an 85 % of the entire housing in Cairo. Blocks of flats were erected in place of private villas, or adjacent to villas in place of the gardens were sold. Cairene urban status was then described as spontaneous or "improvised" or "ad-hoc". A quick deterioration has spanned along the original older districts of the city because of over population, and lack of maintenance and renewal projects (Safey Eldeen, H. 2008).

In the early nineties, and after the political regime shifted its economy towards the privatization, the investment sector has swept like a flood, building its own residential compounds outside the borders of the city. Creating opportunities for the building sector to flourish and the demand of the out-side-the city new residential compounds to increase, creating a new inflation in the land prices, building costs and craftsmanship wages. From retrospection, the demand for houses for the poor classes became merely a need for shelter, which has resulted in the swelling of the older squatter settlements and the development of newer ones. The "modern" districts can be described as repellent, due to the urban mismanagement, defiance of laws and legislations and the defacement of urban standards (Sims, 2011).

During the last two decades, the desert land around Cairo has shown dramatic changes in its physical, cultural and social features. Starting as opportunities of desert land reclamations for the agricultural projects, the foundation of the ring road and several road conjunctions attracted many investors who started new housing projects hence, establishing new communities for upper middle class families, together with some educational, cultural, medical and commercial facilities (GOPP 1993). Those new communities are profit oriented and determined by land developers. Accordingly, a considerable portion of the socially higher population living in nearby overcrowded Cairo districts chose to move seeking a better quality of life in those new communities. In turn, this move imposed the extensive use of cars for long distances commuting to and from the city, with a limited availability of public transportation (Abdel-Hadi & Elazhary 2009). In 2008, Greater Cairo Region was expanded to include two more newly developed governorates, Helwan to the east and 6th of October to the southwest.

It is evident that the Khedivial downtown of the twenty first millennium Cairo has followed the ontological city planning theories suggest that the location of the city heart is the geographically centered, economically based, and activity vibrant spot of the city. The new CBD/City Center (or as we call: the downtown) it always attracted the top of the social pyramid class, leaving the old heart to lower societal classes to enjoy the left overs of buildings and public spaces. The entire downtown has witnessed the actual departure of head quarters, large shopping chains and hotels and A-class entertainment facilities. With every fracture or departure of the CBD, a rehabilitation of the user-groups is associated. Several studies, documentaries and even movies have tackled the issue of the deterioration of the urbanism of down town and the rehabilitation of its user-groups (ya'kubian building, banat west elbalad, and others). From a personal perspective, the area for us was avoided even for a pass by. Relying on the ring road, or hanged bridges penetrating Cairo, we-inhabitants of the fringes, visit downtown when it is extremely urgent. A trip that is always accompanied by

nostalgia for the days bygone and a dream of preservation of a suppressed genuine urban essence that most of the younger generations cannot perceive.

6   AL TAHRIR SQUARE IN REVOLT

Tahrir Square or "Liberation Square" is „the heart of the heart" the major public square in Downtown Cairo. The square was originally called "Ismailia Square", after the 19th-century ruler Khedive Ismail, who commissioned the new downtown Hausmannean 'Paris on the Nile' or 'Paris of the East' design. After the Egyptian Revolution of 1919 the square became widely known as "Tahrir" Square. However the square was not officially renamed until the Egyptian Revolution of 1952, which changed Egypt from a kingdom into a republic. In 2011, the square was a focal point for the Egyptian Revolution. At the centre of the Square is a large and busy traffic circle. On the northeast side is a plaza with a statue of nationalist hero Omar Makram, and beyond is the his Mosque. The square is the northern terminus of the historic Qasr al-Ayni Street, the western terminus of Talaat Harb Street, and via Qasr al-Nil Street crossing its southern portion it has direct access to the Qasr al-Nil Bridge crossing the nearby Nile River. The area around Tahrir Square includes the Egyptian Museum, the former National Democratic Party (NDP) headquarters building, the Mogamma governmental building, the Headquarters of the Arab League building, the Nile Hotel, Kasr El Dobara Evangelical Church and the original campus of the American University in Cairo. The Metro serves Tahrir Square with the Sadat Station, which is the downtown junction of the system's two lines, linking to Giza, Maadi, Helwan, and other districts and suburbs of Greater Cairo. Its underground access viaducts provide the safest routes for pedestrians crossing the broad roads of the heavily trafficked square.

Like any city geographical and large sized center. Tahrir Square has been the traditional site for numerous major protests and demonstrations; 1977 Egyptian Bread Riots, and March 2003 protest against the War in Iraq. On Tuesday, 25 January 2011, millions of protesters from a variety of socio-economic and religious backgrounds demanded the overthrow of the regime of President Hosni Mubarak. The uprising took place in Cairo, Alexandria, Suez as well as in other cities in Egypt, following the Tunisian revolution. Three days later (Jan 28th) "Friday of Anger" protests began. Millions demonstrated in Cairo and other Egyptian cities after the Friday prayers. Later that night clashes broke out in Tahrir Square between revolutionaries and pro-Mubarak demonstrators, leading to the injury of several and the death of some. A curfew was declared, but was widely ignored as the flow of defiant protesters to Tahrir Square continued throughout the night. On February 2nd, 2011, violence escalated as waves of Mubarak supporters met anti-government protesters, and some rode on camels and horses into the Square, wielding swords and sticks. During the 18-days-revolution; every one was there in the square; politicians, intelligencia, students, families, elite, scientists, officials, the urban poor and even criminals, homeless and street children. World media and global names on regular basis to join the protestors. Despite Mubarak's resignation on February 11th, thousands of protests have continued to gather and reside in Tahrir square. Although many pledged they would continue protesting until all the demands had been met. Since then- for more than two years, numerous "titled" Fridays demonstrations were held with demands or protests. From time to time police forces attempted to forcibly clear the square using tear gas, beating and shooting demonstrators, but protesters soon returned in more than twice their original numbers, and every now and then fierce fighting breaks out and continues through days and nights.

Eventually, with the continuum of Tahrir square occupation by camping protestors, and with the rate of violence increasing, the entrances and exists have been closed by concrete walls and up to date, turning the life of residents of the quarters to a night mare. More violence from the police and the army against the protestors and street gangs has intrigued a new type of demonstrations thus igniting the dreadful incidents of Mohamed Mahmoud and the Parliament Streets. Two more extremely drastic events in the Egyptian Contemporary history. More pessimestic environmental behaviour is witnessed and range fron vandalism and violation of buildings, streets and public spaces. More drastic attitude has started in the sexual harassments and the frequent rape cases in addition to the pick pocketing and robbery, and the street fights that have become recurrent incidents in the Cairene street lately! The square and the adjacent streets have been then transformed into a shelter for the homeless, which threatens the residents and the users of the areas. Some accuse the reminiscent individuals of the former regime to make people against the revolution.

If Tahrir square has become the icon of the revolution and reflection/indication of the political and social changes in Egypt along two years. Evidently, small hearts have appeared have been characterized by cultural/social/behavioral features according the nature of their location and the background and orientations

of the residents of theirs, or because of the acitivies and land use. The node of Mostafa Mahmoud in Mohandesin Area that has been founded and flourished in the eighties after the open-door policies and categorized as "rich" was an icon of the "anti-revolution" party. Abbaseya square was for the support of the army (Abbaseya is an old district from the late 19th century that has transformed from an elite district to a popular crowded and congested district since the mid twentieth century. Roxy square in Heliopolis residents are the elite of the second half of the twentieth century, now recognized as the icon of the "couch-potato" party, or the group of Egyptians that silently and remotely watch what is going on. And the auto-strade street, particularly at the unknown soldier memorial area is recognized by those supporting the late General Omar Soliman and Lieutenant General Ahmed Shafik (the last two men of the former regime that played roles part in after the revolution drama). Then, later in December 2012 Heliopolis has witnessed a union between the tahrir revolutionists and the Heliopolis revolutionist in front of the El-Eth'adeya palace accentuating on the collaboration between more parties against the ruling of the moslem brotherhood presidemt Morsy residing in the palace. Then it became a battle field, and the Tahrir cycle of events started all over again, this time in Heliopolis.

The fact is that political analysis goes beyond the scope of this paper, however, the 2011 revolution and beyond have shed light on the following four political/socio-behavioal/urban observations:

Rejuvination of the so long denied CBD of Cairo, and transforming it to the „center of the nation". During the 18-days revolution. This suggests the need of people for a common public urban space that would act as the social heart of the city where people can gather in large groups, uncategorized or classified by social/economic/cultural or religious measures-determinants so they can express themselves and renew their sense of belonging to the country. No matter how a city might swell in size or expand haphazardly out of ist peripherals, have as new CBD's as ist districts expand, yet, the classic heart would always be the refernce point where poeple will return to, despite of socio-economico or cultural differences.

The second observation pertains to the fragmentaion of the old heart to more recent hearts- as in the cases of Heliopolis, Muhandesin, Nasr City etc. has proved to be an urban phenomenon. This phenomenon is witnessed in the categorization of the demonstrations all around Cairo for their own reasons, expressing different political views and beliefs.

The margenalized, so long denied urban poor, who have been long supressed and underexpressed, deprived of any appropriate human built environemtnet and were underspoken, strive to experess themselves and announce their presence and their volume within the Cairene society (more than 65 % oft Cairo residents are urban poor according to several sources). Their message is that they are here to stay. Carrying some behaviors from their districts of origin- probably the informal areas and stress to the heart of the city right after the revolution and then to the fragmentted hearts where the demonstrations have moved to.

The fourth observation is the newly emerged street visual and performing arts; street journalism, graffiti, street troops, experimental plays, and others. Raising some doubts about where were those youth before the revolution? Didn't they have youth centers, clubs to perform and demonstrate such skills and talent shows? Was there urban suppression for some sectors of the society accompanying the political oppression that has found its way just like a jack –in-a-box after the revolution? Is there a relationship between a political dictatorship and urban dictatorship? Evoking an inquiry about the existence of adequate social places in the city to incube such cultural and entertainment cultural activities.

Day after day and month after the other more observations are detected. An unaccepted street behaviour has become dominant between both the youth and the adults as well. It has spanned to rign over personal, professional, and public interactions between many of the Egyptian youth and has accordingly changed the conception of use of open spaces and public areas in Cairo and other several major Egyptian cities.

7 DISCUSSION AND CONCLUSION

May be this previous section has relied more on personal observations and interpretations than on action-research investigation, However. They provoke several questions:

- Does politics influence socio-urban change?

Yes, and the review of the Cairine heart reveals the fact that politics dictates how a certain group/community live and therefor shape their districts, physically and conceptually.

- Can the design of the urban public spaces change with the change of the socio-cultural composition of residents in a district /area?

Yes, as every group of residents require some physical-tangible features for their conceptual-non-tangible vision, beliefs, requirements and aspirations, as seen in the transformations of the hearts reviewed along the paper.

- Did what happen of a change in attitude and behavior in the Egyptian conserved society has anything to do with a change of meaning and conceptualization of public spaces, squares and streets from merely physical paths and nodes to areas of human and social groups interaction?

Yes, what we saw of the newly emerged activities in the heart of the city and its major square "Tahrir" affirms the fact that we are in real need for the application of urban sociology and socio-behavioral studies in the planning, design and development of cities and districts

- Does what this paper tackle really calls for a redefinition of the heart of the city, detached from the definition of the CBD and totally detached from the city planning theories?

Yes, we are in urgent need of a socio cultural definition the proposes a new urban role of the vibrant areas inside the city and in need of methodic approaches for its urban design.

To conclude, and along the paper, theoretical foundation of the city heart, center and CBD was reviewed. Then, emphasis was given to the heart of Cairo; since its foundation, to its development, to its several migrations, proving that there is a difference between the CBD and the heart. After its migration to newer modern and contemporary districts, Down Town Cairo is NOT the CBD any more. Jan 2011 revolution is a milestone in the transformation of the heart of Cairo, transforming it to the heart of the nation after its decline and migration to remote hearts for more than a quarter of a century. The revolution has rejuvenated it as a heart repository of the community's collective memory (as described by J.M. Richards), an expression of the collective mind and spirit by the community (as described by Jaqueline Tywhitt). This phenomenon has rung a bell for "democratic urban areas" in the city that satisfy the sociocultural needs of the city dwellers, and not only the physical standardized measures. More, and as Le Curbosier has identified the heart of the city as "the meeting place for the hearts", it is evident that the young artists found no better place to revolt for their buried talents except by the "art demonstrations" in Tahrir. It is also worth mentioning that renowned artist, singers, poets and others, also perform in the square, accentuating on the notion that Tahrir and the Kedivial heart have been rejuvenated as an "art heart". I also believe what happens around me of a change in society and its shifting from a conserved, ethically driven society to a daring-bold attitude since the revolution and until now is a major socio-behavioral change that has to be dealt with from an urban perspective, if we believe that urbanism is a formula equivalent to [user*place*time]. I'm also convinced that we are in an urgent need that the city planning and city design sciences should include cultural and social aspects and measures, and not only engineering ones.

And finally, I leave the ending of the paper open for discussion and debate…

The Identity of Place ... and Memory of Time ... Define Space-Time of Human Architecture

Mohammed Qasim Abdul Ghafoor Al Ani

(Dr. Mohammed Qasim Abdul Ghafoor Al Ani, Nahrain University – College of Engineering – Architectural Department; Baghdad, Iraq; mohammedkassim4-66@yahoo.com)

1 ABSTRACT

Problems of modernization and authentication in contemporary architectural experiments in the world and Arabic-Islamic countries, and manifestations of alienation in contemporary urbanism and debate among many intellectuals architectural theses. As these problems were raised in numerous conferences and symposiums which tried to shed light on the impact of new sciences and culture on heritage and urban civilization. As other, Arabic arts and Islamic architecture came under successive waves of Western cultural interruption and progress of scientific theories in the twentieth and twenty one centuries. It also changed the architecture features and urbanism, cross-cultural trend was cut with the past intellectual creations, informative literature, art and architecture.

The identity of the place is one of the important vocabulary which linking human, architecture with built environment containing it, so the strength and the weakness of the link generated by several elements, discussed several theories and intellectual urban studies through physic sciences ,psychology, sociology, and poetic of space studies where the spirit and Genius Loci of space emerge throw places, as viable place had physical and metaphysical characters effected and affected with human impact manufacturer and inhabitant.

Returning to the city and their connotations and links to the urban environment of the Arabic Islamic city in old era, and in the European medieval cities, where (human enclosure, the stimulus of streets and open spaces with response of memories, sensations and feelings), make the place an integral part of city life and their inhabitants, by overlapping times and products within masses and spaces of the city.

At present the sense of city components are less than past, and weakened its association with city spaces, and more weakness is the new design for the architecture of the city in particular within the city centre.

The place is not abstract location but real things component, possesses by material, moral entity, pro forma, sensory properties and symbolism give specific environmental identification, which are the essence of the place. The strongest place emerge when connecting time to space (space-time as in Relativity theory) in documenting events.

The architecture one of documenting events make place is a product of many forces including social, natural, historical and a spatial property create human environment satisfactory (including event in Folding Architecture), and that's what we see in some European experiences in preserving historical city centers such as (Venice, Prague, Rome, ...Etc) using laws and legislation concerning conservation strategies like (Venice Charter, Washington Charter, Zimbabwe Charter, Nara document of authenticity...Etc) and other conservation methods that can be adopted in the heritage of Arabic-Islamic cities, which give continuity of Identity of places, to connect ancient civilizations places with current time.

2 INTRODUCTION

Architecture is a thing of art, a phenomenon of the emotions, lying outside questions of construction and beyond them. The purpose of construction is to make things hold together; of architecture to move us. Architectural emotion exists when the work rings within us in tune with a universe whose laws we obey, recognize and respect. When certain harmonies have been attained, the work captures us. Architecture is a matter of "harmonies," it is a "pure creation of the spirit." Le Corbusier. (Vogler, 2006, p. 8)

In the few past decades, many cities are losing their characters and getting more and more ambiguous. As planners began to pay more attention on the categories of beauty and function, they failed to catch the essence and the humanity of place. Also, many traditional sites and heritages are destroyed which make cities lose the continuity and identification. While people call those as "loss of place", the research wants to avoid the losing and rebuilding our living places, so should first understand from the concept of "existence". And according to this, the research could catch the essence of place which exists in the locality.

The research also describes the progress that has been made recently in correspondences between apparently different theories of physics. These correspondences are a strong indication that there is a complete unified

theory of physics, but they also suggest that it may not be possible to express this theory in a single fundamental formulation. (Hawking, 2001, P. 1). Einstein's General Theory of Relativity seems to offer the possibility that we could create and maintain wormholes, little tubes that connect different regions of space-time.

Human experience of physical space and places is a complex phenomenon that includes architectural and sensorial, as well as more social and interpersonal dimensions. The research investigate theoretical insights from computing research and environmental psychology on space and place to determine the different dimensions of the experience of physical space. The research indicates dimensions that encompass the different ways of apprehending our environment, as well as the emotional relationships develop toward it, through personal and interpersonal experiences-in-place. Theoretical science and technology should be examined in terms of its potentiality for supporting rich experiences of and in physical space. Assuming that the identified dimensions can serve as basis for the development tools to be used in that perspective.

Sociological studies sensitive to the issue of place. So, How do spaces come to be places, and how do places come to be the way they are, and how do places matter for social practices and historical change? The research discusses how to make a harmonious place with nature, keeping the spirit of place which we call "Genius Loci", and using phenomenological analysis to understand the meaning of place through its structure. Symbolization and concretion are also discussed as they are used to transform nature to architecture; orientation and identification are used to prove the existence (Yiran, 2009, p. 2). This research also connects place to man's image with social and cultural aspects, and seeks a way to keep continuity in history. Therefore a humanistic place should have agreements with essence of place, human demand, and historic continuity.

The research concludes by providing glimpses of what awaits us in the 21st century. So work represent the cultural and social contexts as well as natural environment. this should be a way for contemporary planners and architects to understand humanity and harmony of place.

3   MEMORY OF TIME

Every civilization has been fascinated by notions of Space (the Heavens) and Time (the Beginning, the Change and the End). The space had three dimensional continuum which envelops us. Also time as flowing serenely, all by itself, unaffected by forces in the physical universe. Together, they provide a stage on which the drama of interactions unfolds. The actors are everything else in the universe. (Ashtekar, 2005).

3.1 From antiquity to Einstein

Early Muslim philosopher Al-Kindi (Alkindus), and Muslim theologian Al-Ghazali (Algazel), used logical arguments against an infinite past, being the "argument from the impossibility of the existence of an actual infinite", (Al Jabri, 2002, p. 280-284)

On the other hand, there existed a school of thought that differed with Al-Ghazali and Al-Razi and other intellectuals of that period. The pioneer of that school of thought was the philosopher Ibn-Rushd (1126-1198 AD), known in the Western culture as Averros. Many historians argued that the writings of the philosopher Ibn-Rushd had a major effect on the development of the Western philosophy from the 13th century AD onwards and its struggle for the differentiation between philosophy and theology. However, the Ibn-Rushd school of thought (Averros) acts as an example of the containment process that was evident throughout the development of Arab/Islamic philosophy and ways of thinking. (Al-Hokail, 2004, P 8)

In the early 11th century, the Muslim physicist Ibn al-Haytham (Alhazen) discussed space perception and its epistemological implications in his Book of Optics (1021). His experimental proof of the intromission model of vision led to changes in the understanding of the visual perception of space, contrary to the previous emission theory of vision supported by Euclid and Ptolemy. In "tying the visual perception of space to prior bodily experience, al-Haytham unequivocally rejected the intuitiveness of spatial perception and, therefore, the autonomy of vision. Without tangible notions of distance and size for correlation, sight can tell us next to nothing about such things." (Al Jabri, 2002, p. 344-350)

In modern terms one can say that in Aristotle's paradigm, there was absolute time, absolute space and an absolute rest frame, provided by earth. This was the reigning world-view, Isaac Newton was exposed to, as a student at Cambridge in the years 1661-65. Twenty years later, Newton toppled this centuries old dogma.

Through his Principia, first published in 1686, he provided a new paradigm. Time was sill represented by a 1-dimensional continuum and was absolute, the same for all observers. All simultaneous events constituted the 3-dimensional spatial continuum. But there was no absolute rest frame. Galilean relativity was made mathematically precise and all inertial observers were put on the same physical footing. The Principia also shattered Aristotelian orthodoxy by abolishing the distinction between heaven and earth. (Ashtekar, 2005)

Both Aristotle and Newton believed in absolute time. That is, they believed that one could unambiguously measure the interval of time between two events, and that this time would be the same whoever measured it, provided they used a good clock. (Hawking, 2001, ch. 2, P. 2) Time was completely separate from and independent of space.

An absolute speed blatantly contradicted Galilean relativity, a cornerstone on which the Newtonian model of space-time rested. By then most physicists had developed deep trust in the Newtonian world and therefore concluded that Maxwell's equations can only hold in a specific reference frame, called the ether. But by doing so, they reverted back to the Aristotelian view that Nature specifies an absolute rest frame. A state of confusion remained for some 50 years. (Ashtekar, 2005).

3.2 Human build architecture in order to achieve civilization

The concept of space and time connect with civilization, this relationship emerge through outlook absolute terms flowing space / time in each asset. In the theory of relativity emerge association between space / time, one depends on the other (Einstein). But after the relativity, the relationship between space and time seem more complex for more than one direction, and isn't separated from the event.

3.3 Relativity Theory (Einstein)

At the beginning of the 20th century, Einstein revolutionized the notions of space and time, first through special relativity and then, a decade later, through general relativity. Conceptual ideas underlying general relativity are explained and its physical ramifications summarized in general terms, without recourse to advanced mathematics. This theory is perhaps the most sublime creation of the human mind. Nonetheless, it has become increasingly clear that it too has serious limitations which can be overcome only through another dramatic revision of our notions of space and time. (Ashtekar, 2005)

Einstein's theory of relativity, which showed the interconnection between time, space and matter, exposed the limitations of Newtonian- Cartesian physics, even though Einstein himself remained a recalcitrant Cartesian as his historic debate with Bohr in the 1920s demonstrated.

3.3.1   Spacial theory of Relativity 1905

Einstein's theory based on the idea that the laws of science should be the same for all observers, no matter how they are moving, in the absence of gravitational phenomena. (Hawking, 2001, ch. 10, P. 5). Time lost its absolute standing. Only the 4-dimensional space-time continuum had an absolute meaning. Space-time distances between events are well defined but time intervals or spatial distances between them depend on the state of motion of the observer, i.e., of the choice of a reference frame. The new paradigm came with dramatic predictions that were hard to swallow. (Ashtekar, 2005).

3.3.2   General theory of Relativity 1916

In this theory, space and time fuse to form a 4-dimensional continuum. The geometry of this continuum is curved and the amount of curvature in a region encodes the strength of the gravitational field there. Space-time is not an inert entity. It acts on matter and can be acted upon. (Ashtekar, 2005). Einstein's general theory of relativity, on its own, predicted that space-time began at the big bang singularity and would come to an end either at the big crunch singularity (if the whole universe re collapsed), or at a singularity inside a black hole (if a local region, such as a star, were to collapse). (Hawking, 2001, ch. 8, P. 7).

3.4 Spacetime

In physics, spacetime is any mathematical model that combines space and time into a single continuum. Spacetime is usually interpreted with space as existing in three dimensions and time playing the role of a fourth dimension that is of a different sort from the spatial dimensions. From a Euclidean space perspective,

the universe has three dimensions of space and one of time. By combining space and time into a single manifold, physicists have significantly simplified a large number of physical theories.

In non-relativistic classical mechanics, the use of Euclidean space instead of spacetime is appropriate, as time is treated as universal and constant, being independent of the state of motion of an observer. In relativistic contexts, time cannot be separated from the three dimensions of space, because the observed rate at which time passes for an object depends on the object's velocity relative to the observer and also on the strength of gravitational fields, which can slow the passage of time. We can only say that Euclidean geometry deals with things called "straight lines," to each of which is ascribed the property of being uniquely determined by two points situated on it. (Einstein, 1920, p. 2)

Since space-time is also omnipresent and the same for all physical systems, Einstein was led to regard gravity not as a force but a manifestation of space-time geometry. Space-time of general relativity is supple and can be visualized as a rubber sheet, bent by massive bodies. (Ashtekar, 2005). This latter statement need not of necessity hold a priori; it is not contained in the conceptions of "motion" and "reference body" and derivable from them; only experience can decide as to its correctness or incorrectness. (Einstein, 1920, p. 71)

In accordance with the special theory of relativity, certain co-ordinate systems are given preference for the description of the four-dimensional, space-time continuum. We called these "Galilean co-ordinate systems." For these systems, the four co-ordinates x, y, z, t, which determine an event or—in other words —a point of the four-dimensional continuum, are defined physically in a simple manner. (Eins

-                              -   Which had spatial dimension: Any of the three dimensions that are space like – that is, any except the time dimension. (Hawking, 2001, ch. 10, P. 5). The fundamental postulate of the theory of relativity, as it was called, was that the laws of science should be the same for all freely moving observers, no matter what their speed. This was true for Newton's laws of motion, but now the idea was extended to include Maxwell's theory and the speed of light. (Hawking, 2001, ch. 2, P. 2)

In other words, the theory of relativity put an end to the idea of absolute time! It appeared that each observer must have his own measure of time, as recorded by a clock carried with him, and that identical clocks carried by different observers would not necessarily agree. (Hawking, 2001, ch. 2, P. 3). We were able to make use of space-time co-ordinates which allowed of a simple and direct physical interpretation, and which, can be regarded as four-dimensional Cartesian co-ordinates. This was possible on the basis of the law of the constancy of the velocity of light. But according to the general theory of relativity cannot retain this law. (Einstein, 1920, p. 111).

3.5 Sigfried Giedion's "Space, Time and Architecture"

The perspective was invented in the Renaissance period, around the fifteenth century –firstly used in a drawing by Masaccio, then adapted to architecture by Brunelleschi, and written down by Alberti. Almost five centuries later a new space conception – space-time as Giedion calls- was invented and appeared in the works of cubists. Both conceptions simultaneously grew with the developments in physics and brought about 74 revolutionary changes in art and architecture to their period and the following periods. (Giedion, 1971, p. 42). The terraces in the Piazza Del Popolo designed by Valadier in Rome (Fig. 1) –showing the hovering effect with the change in the horizontal and vertical surfaces. (Giedion, 1971, p. 153)

In addition, Giedion construes Cubism and Futurism in a way that they dwelled their arguments on one of the constituent facts –a new space conception- and helped the fact to progress. The last three constituent facts seem to be far from a direct contact with artistic production; they rather are the consequences of the developments in industry and technology in the nineteenth century, in which the spirit of the age was revealed from the sphere of thinking, but not from the sphere of feeling. (Giedion, 1971, p. 13-14)

The American architect Frank Lloyd Wright exposed the plain wall and the human-nature relationship more easily than his colleagues. (Giedion, 1971, p. 396-400). Architecture strongly influenced by that era these concepts, either through analogy or cognitive theme of architectural subject, specially mechanics waveform, that clear in the work of Wright, which called for organic forms refer to the origin of nature through mechanics waveform, and can be seen in the Guggenheim museum project in New York 1943-1959 (Fig. 2), with spiral form like wave which gave another dimension to the architectural form. Waves and twisted forms

influenced by nature, variable interaction with any object exists and private changing waves in nonlinear layer are important and ubiquitous presence of space – time for each one of them in nature.

Constituent facts should and could only be scrutinized within the framework of dialectic materialism in consideration of the content and the approach towards. This suggestion and the involvement of Space, Time and Architecture with dialectic materialism will be discussed. (Giedion, 1971, p. 400)

In order to produce a new tradition, Giedion asserts, introducing new methods has a vital importance. For Giedion, who did not believe in the notion of style, sought for another explanation to elucidate the discrepancies among the taste of different periods, acknowledging the reader as "… the links and associations between periods –the constituent facts- are more important to us than self-enclosed entities such as styles." (Giedion, 1971, p. 21) He found the remedy in asserting the constituent and transitory facts, under the very pioneering of the spirit of the age –namely, Zeitgeist-, which he became devoted to while he was writing his dissertation under the supervision of Wölfflin. (Boring, 1955, p. 2).

3.6 Zeitgeist

The term Zeitgeist was –most probably- first used by Goethe in 1827, which is very much involved with the concept of the spirit of time, the spirit of the age, namely the Zeitgeist. Everything happens for a reason, and it happens because the spirit of the age permits it to be. The formation of the constituent facts, and later their reawakening are in fact the consequences of the spirit of the age. (Boring, 1955, p. 102)

The spirit of the age is responsible for the construction of the interrelationships among various fields, such as science –including physics, mathematics, technology, philosophy, art, architecture, town planning, and naturally, history. Most evidently, "a common spirit" can be recognized in Baroque period, as Giedion puts forth. The simplest example Giedion gives about one of the circumstances that the spirit of the age gives rise to be how the development in mathematics and physics in Baroque period – the discovery of integral calculus- found its counterpart in the space conception of Baroque art and architecture as the impression of infinity. (Boring, 1955, p. 109). On the other hand, whilst the mathematician Herman Minkowski was working on the proof of a fourth dimension, the artists in various parts of Europe as being either cubist or futurist were developing the space-time notion in their works. (Boring, 1955, p. 14). For Giedion, these facts are all because of the existence of a spirit that runs through the age, and that affects the outcomes of the age. Throughout the book, that spirit is also referred to "the universal laws of Nature", that within the twentieth century, both modern art and modern science have found the common and parallel results by following the intuitions of the artists and scientists. (Boring, 1955, p. 460-461)

The most important aspect of the spirit of the age can be accepted as the demonstrability of the close relationship among new materials, new methods and the human needs. Along with some other protagonists of the era, Le Corbusier was the perfect model, who achieved to build relationships such as the one between ferroconcrete construction and the human needs. (Giedion, 1971, p. 542) (Fig. 3)

That Giedion"s Space, Time and Architecture was "more ambitious in its scope" than the other early historians of the Modern Movement because of the fact that went back further as to Rome of Pope Sixtus V (Fig. 4), and including the technical developments as well as urban planning. (Giedion, 1982, p. 82). However, forget to mention that he posited the developments in modern physics and mathematics in a more important level than the social change, which showed his strong formalist attitude. Giedion mentions, the immense developments in science in the nineteenth century could catch the spirit of the age, whilst the architecture could not.

4   THE IDENTITY OF PLACE

Architecture is the style of human life, therefore it is a tool to be our identities and our differences, and framing our knowledge of the world. Architectural Identity is one of the phenomena of public identity of the communities. The privacy defined in architecture, as reality containing qualities core. Architecture is actually within the dimensions of time, space and the impact of humanitarian axis (community / civilization) and clarified as a reflection of the life of society as evolved and reached a positive phase.

4.1 Space & Place

In popular discourse, space and place are often regarded as synonymous with terms including region, area and landscape. However, these twin terms have provided the building blocks of an intellectual and disciplinary enterprise that stretches back many centuries. Yet, as Livingstone intimates, the theoretical specification of space and place has remained a matter of some dispute, being transformed as new ways of 'thinking' have developed. Likewise, until the 1970s, most human researchers considered space to be a neutral container, a blank canvas that is filled in by human activity.

This work alerted researchers to the sensual, aesthetic and emotional dimensions of space. The humanistic tradition that these thinkers developed conceptualized place as subjectively defined. As such, what constituted a place was seen to be largely individualistic. Although attachments and meanings were often shared. Simply put, a place meant different things to different people.

4.1.1 Space

Space is a central concept in architecture, used in the form of absolute, relative and relational (cognitive) space (Table 1):

- Absolute space is an understanding of space as a distinct, physical and imminently real or empirical entity. Traditional regional studies the empirical entities, dependencies or vertical connections between humanity and the environment within the 'container space' of a particular region.

- Relative space has the location of, and distance between, different phenomena (horizontal connections) as the focus of architecture inquiry. Distance as measured in terms of transport costs, travel time and the mileage within a network, as well perceived distance, is given explanatory power. (Holt, 1999, p. 216-227).

- The meaning of relational (cognitive) space is that space and place are intrinsic parts of our being in the world – defined and measured in terms of the nature and degree of people's values, feelings, beliefs, and perceptions about locations, districts, and regions. Relate to other people and the physical environment. Thus relational space is consciously or unconsciously embedded in our intentions and actions. (Knox, 2004, p. 505).

4.1.2 Place

Space is organized into places often thought of as bounded settings in which social relations and identity are constituted. Such places may be officially recognized perceptual entities or more informally organized sites of intersecting social relations, meanings and collective memory. The concept of place, the uniqueness of particular places and place-based identities are hotly contested concepts in the contemporary context of increasing globalization and the perceived threat of placelessness.

Place was seen by positivists as more subjectively defined, existential and particular, while space was thought to be more universal, more abstract phenomenon, subject to scientific law. The humanistic concept of place, largely drawn from phenomenology, was concerned with individuals' attachments to particular places and the symbolic quality of popular concepts of place which link events, attitudes, and places and create a fused whole. It was concerned with meaning and contrasted the experienced richness of the idea of place with the detached sterility of the concept of space. Idea is that place is an emotional bounded area, often the dwelling-place, to which an individual or a group has a strong emotional relationship. People can even derive their personal identity from it. So Place is a portion of urban space, sometimes defined as 'territories of meaning' (Holt, 1999, p. 224)

Outside this place starts the immeasurable space, of which the individual or group has some knowledge but does not feel at home at or have any affectionate feelings towards. The way in which people identify with a place is very different from individual to individual. Humanistic studies show that people alternately associated place with safety and security (feeling at home) but also to imprisonment and isolation. The place where one lives, with its social pressure, and forced solidarity, can be perceived as suffocating. Space compared to the latter can be perceived as free and dissolute. In such a situation the dangers and threats of an unknown space are not so important.

4.2 Transformation from space to place

Environmental character is created by the relationship between things. Norberg-Schulz emphasized phenomenology, which he called "return to things" in his book Genius Loci to explain place. What factors make up a place? For example, location, landscape, climate, seasons, day-night, livings, buildings, even human activities. Generally, the research can classify them as natural things and man-made things.

These can be further subdivided as "objects", "temporal field", "spatial field". While Norberg-Schulz liked to classify them as "thing", "order" and "time", there is an easy way which is to put "time" into "order", so that "thing" and "order" could be two classifications. "Thing" contains natural things such as landscape, life-form, man-made things like building, city, human behavior. These all have their special characters and have certain contact with each other. "Order", we can understand through explaining "X axis", "Y axis" and "Z axis". Place is a structured space with the given character, cardinal points is the main orientation and identification of one place, we can call it "X axis", then, the hosts of heaven-the sun, the moon and stars, and the change of sky, can call it "Y axis". Basically, cardinal points and hosts of heaven could be collectively called "cosmic order", in a few words, earth and sky. Finally, time, which gives place continuity and variability could be thought as the variable of cosmic order, so it can be seen as "Z axis" which makes space from a plane to be stereoscopic. (Yiran, 2009, p. 7)

The interaction between space and place here is a crucial one. Equally vital is that while we must distinguish between these different realms if we are to apprehend place construction and transformation, we must simultaneously capture how they are in fact forged together in a dialectical unity. When dimensions are understood as mere components of the grid system, rather than physical attributes of space, it is easier to understand the alternate dimensional views as being simply the result of coordinate transformations.

Places are worked by people: we make places and probably invest as much effort in making the supposedly pristine places of Nature as in cities or buildings. Social processes (difference, power, inequality, collective action) happen through the material forms that we design, build, use, and protest. (Gieryn, 2000, p. 465). Norberg-Schulz (1980) pointed out: "'Thing' and 'character' are dimensions of the earth, whereas 'order' and 'light' are determined by the sky. Time, finally, is the dimension of constancy and change, and makes space and character parts of a living reality…" Therefore place exists between earth and sky, and living with time. (Yiran, 2009, p. 8).

4.2.1   Design space and create place

There are many different between space and place such as:

- Place is not space—which is more properly conceived as abstract geometries (distance, direction, size, shape, volume) detached from material form and cultural interpretation as thoughts of Hillier & Hanson 1984. Space is what place becomes when the unique gathering of things, meanings, and values are sucked out.

- Place is space filled up by people, practices, objects, and representations. In particular, place should not be confused with the use of architecture metaphors (boundaries, territories) that define conceptual or analytical spaces. (Table 1)

- Place is not just a setting, backdrop, stage, or context for something else that becomes the focus of sociological attention, nor is it a proxy for demographic, structural, economic, or behavior variables.

- Place is not merely a setting or backdrop, but an agentic player in the game—a force with detectable and independent effects on social life. place becomes a stand-in for clusters of variables located in spaces chosen for their analytic utility but generally denuded of architecture, landscape, and actors' own narrations. (Gieryn, 2000, p.466-467)

So we cannot understand social life without understanding the arrangements of particular social actor's in particular social times and places… Social facts are located. (Logan, 2011). Place stands in a recursive relation to other social and cultural entities: places are made through human practices and institutions even as they help to make those practices and institutions. Place mediates social life; it is something more than just another independent variable. (Gieryn, 2000, p.468)

A spot in the universe, with a gathering of physical stuff there, becomes a place only when it ensconces history or utopia, danger or security, identity or memory. In spite of its relatively enduring and imposing

materiality, the meaning or value of the same place is labile—flexible in the hands of different people or cultures, malleable over time, and inevitably contested. (Gieryn, 2000, p. 465). Place should not be confused with the use of cognitive maps (boundaries, territories) such as Jean Piaget Schemas that define conceptual and analytical spaces.

4.2.2 Active Place

A concrete term for environment is place. It is common usage to say that acts and occurrences take place. When things have characters and build the environment with phenomena, we call it "place". The meaning of phenomenon is revealed by "taking place", any tiny movement or happening make place to be lively and active, and under these circumstances, place does make sense. The research can also see it from the phrase "take place", it means something or some acts happening; the occurrence would "take" in certain "place", it cannot occurred without "place", the same, "place" is based on these occurrences. (Yiran, 2009, p. 6)

Therefore, place is a totality made up of certain things with their active characters and special atmospheres. No two such places are the same. Every place has its own attribute, or we can call it "environmental character". The character of place is presented by characters of the parts, which explained the "atmosphere" of things, or a "total phenomenon". (Yiran, 2009, p. 7).

4.3 Identity

The forces of new technologies, globalization and 'time-space-compression' have sought to represent localized identities as historical, regressive characteristics, and have worked to undermine the old allegiances of place and community. But the burgeoning of identity politics, and now nationalism, reveal a clear resistance to such universal strategies. If places are no longer the clear supports of our identity, they nonetheless play a potentially important part in the symbolic and physical dimension of our identifications. It is not spaces which ground identifications, but places!

National Identity refers to a group of people who share particular historical-cultural characteristics or imagine themselves to do so. Nationality refers to the condition of belonging to a nation. At its most basic, nationality can be seen as a mechanism of social classification. There are two components of national identity, according to Verdery:

- Collective identity which refers to national characteristics and so-called national traits and may include such things as language and style of dress. This is an identity which is shared by the members of the national community.

- National identity is the individual member's sense of self as a national. An individual's feeling and self-identification as 'Iraqi', 'Italy', 'Dutch', 'German' or 'French' is an important component in their self-perception. It refers to a feeling of belonging to a nation.

Therefore national identity as composed of five key elements:

- Psychological: consciousness of forming a community.

- Cultural: sharing a common culture.

- Territorial: attachment to a clearly demarcated territory.

- Historical: possessing a common past.

- Political: claiming the right to rule itself.

Obviously these five characteristics are closely interlinked. Within this milieu elements such as language, religion and social mores may take on particular significance. Many nations are seen to possess their own language, while in some the majority of members adhere to a particular religion. In these cases language or religion may be the key defining the characteristic of the nation. National identity is not some much a rational thing; as it is an emotional thing, it is hard measuring this objectively. A nation is more a mental construct than a concrete reality. Identity can be defined as the sense that people make of themselves through their subjective feelings based on their everyday experiences and wider social relations. (Knox, 2004, p. 508)

So, identity seeks in the similarities that gather a group of communities with similar characteristics (relations, elements), (Genotype, Phenotype). While Privacy seeking in differences that characterize a society has an identity, from other communities that have or may not have the identity itself, at the same time to achieve

privacy must be achieved similarity between (relations and elements) in the properties that varies the society from other communities that have or may not have the identity itself. (Al Jabri, 2002, p. 346)

To achieve the identity and privacy in the architecture of human societies it represents the idea of the bind everything followed to achieve differentiation, particularly with respect to its past, present and future with its ties to the temporal and spatial. Temporal relations are most relevant to the privacy of the place, and a sense of identity, as can be achieved acting time in architecture by translating temporal structures to spatial properties. (Schulz, 1980, p.54) Space is created for the temporal sequence of sensations, and the time is enriched through experience space. (Lynch, 1972, p.76-77).

5 THE GENIUS LOCI OF SPACE

The term genius loci were used in the ancient world to underline the idea that every place has its own character. (Verschuure, 2009). In Roman mythology a Genius loci was the protective spirit of a place. In contemporary usage, "genius loci" usually refers to a location's distinctive atmosphere, or a "spirit of place". The concept of "genius loci" has been discussed in modern architecture, but still is much underestimated. When it comes to extreme environment, the situation is even worse. The problem of sensory deprivation in extreme environments should even result in putting more emphasis on the concept of genius loci. An important part of the 'spirits' of a place is the environmental energies. In space habitats the 'Life Support System' becomes an intrinsic part of the 'atmosphere' of the habitat. On Earth, the use of these energies, not only to make buildings self-sufficient, should enhance the quality of the architecture and our built environment. Humans differently than the other entities of life on our planet are capable to force large scale devastative change on the environment. The need to save our environment for future generations is one of the greatest challenges that humankind must address today. (Vogler, 2006, p. 2)

About a design theory on the Genius of the Place 'To build, to plant, whatever you intend, To rear the Column, or the Arch to bend, In all, let Nature never be forgot. Consult the genius of the place in all.' (Verschuure, 2009). Nowadays, many architects base their work to this line. Although new designs in urban design or urban planning are necessary, the spirit of the place should be respected.

5.1 Spirit of the Place

In 1980 the term Genius loci was used again in the book of the Norwegian architect Christian Norberg-Schulz (Genius Loci- Toward a Phenomenology in Architecture), where he stated that 'every place is a space with its own character'. He stressed that this line is still valid for many new designs. By respecting the 'local spirit' a counter movement could be set in to the unheimich feeling Modernistic architecture can give. (Verschuure, 2009). But what elements are we talking about in the genius loci?

The research study the Genius Loci by Norberg-Schulz, Where He made lots of great arguments in this book, about "thing", "existential space", "natural and man-made place" and also his explaining of "Genius Loci" which applied to Rome, Prague, and Khartoum (Yiran, 2009, p. 3) (Fig. 4).

5.2 Create Place

Human culture is very strongly linked to places. Indeed, the inseparableness of the human being and the world, at least from the human being's point of view, has been one of the main discussions of philosophy. In Being and Time, Heidegger (1962) argued that, in conventional philosophy and psychology, the relationship between person and world has been reduced to either an idealist or realist perspective. In an idealist view, the world is a function of a person who acts on the world through consciousness and, therefore, actively knows and shapes his or her world. In contrast, a realist view sees the person as a function of the world in that the world acts on the person and he or she reacts. Heidegger claimed that both perspectives are out of touch with the nature of human life because they assume a separation and directional relationship between person and world that does not exist in the world of actual lived experience. (Vogler, 2006, p. 8)

Architecture has an eminent role as a key interface and definition of our being-in-the-world. Where natural environment is more and more lost, architecture takes a key role in creating places and in the best case a 'genius loci'. With the dawn of rationalism, this spiritual meaning of a place has been more and more negated. The modern movement in architecture tried to analyses the site based on scientific parameters and their optimization like sun angles and circulation distances. The fast growth of cities in the last century,

which is still continuing today, and the application of the ‚modern formula' quickly resulted in sterile and faceless neighborhoods.

6 EVENT COVERING SPACE-TIME

The term spacetime has taken on a generalized meaning beyond treating spacetime events with the normal 3+1 dimensions. It is really the combination of space and time. Other proposed spacetime theories include additional dimensions—normally spatial but there exist some speculative theories that include additional temporal dimensions and even some that include dimensions that are neither temporal nor spatial (e.g. superspace).

6.1 Event in scientific theories

In cosmology, the concept of spacetime combines space and time to a single abstract universe. Mathematically it is a manifold consisting of "events" which are described by some type of coordinate system. Typically three spatial dimensions (length, width, height), and one temporal dimension (time) are required. Dimensions are independent components of a coordinate grid needed to locate a point in a certain defined "space". For example, on the globe the latitude and longitude are two independent coordinates which together uniquely determine a location. In spacetime, a coordinate grid that spans the 3+1 dimensions locates events (rather than just points in space), time is added as another dimension to the coordinate grid. This way the coordinates specify where and when events occur.

The theory of relativity does, however, force us to change fundamentally our ideas of space and time. We must accept that time is not completely separate from and independent of space, but is combined with it to form an object called space-time. (Hawking, 2001, ch. 2, P. 4). Similarly, the light spreading out from an event forms a (three-dimensional) cone in (the four-dimensional) space-time. This cone is called the future light cone of the event. In the same way we can draw another cone, called the past light cone, which is the set of events from which a pulse of light is able to reach the given event (Hawking, 2001, ch. 2, P. 7) (Fig. 5).

The special theory of relativity was very successful in explaining that the speed of light appears the same to all observers. (Hawking, 2001, ch. 2, P. 10). The situation, however, is quite different in the general theory of relativity. Space and time are now dynamic quantities: when a body moves, or a force acts, it affects the curvature of space and time – and in turn the structure of space-time affects the way in which bodies move and forces act. Space and time not only affect but also are affected by everything that happens in the universe. Just as one cannot talk about events in the universe without the notions of space and time, so in general relativity it became meaningless to talk about space and time outside the limits of the universe. In the following decades this new understanding of space and time was to revolutionize our view of the universe. The old idea of an essentially unchanging universe that could have existed, and could continue to exist, forever was replaced by the notion of a dynamic, expanding universe that seemed to have begun a finite time ago, and that might end at a finite time in the future. (Hawking, 2001, ch. 2, P. 11).

6.2 Event in Folding Architecture

Folding is a transformation technique using in Digital signal processing architecture implementation for minimizing the number of functional blocks in synthesizing Digital signal processing architecture. Folding was first developed by Keshab K Parhi and his students in 1992. Its concept is contrary to unfolding. Folding transforms and operation from a unit-time processing to N unit-times processing where N is called folding factor. Thus, in N unit-times, a functional block in transformed system could be reused to perform N operations in original system. While the folding transformation reduces the number of functional units in the architecture, it needs more memory element to store the temporary data.

Folding is the art of seeing something invisible. Something that does not exist now. So, the fold represent space, mass at one time. The idea of folding is a time- event, when place left it is Spatial Situation. The place is temporal and spatial boundaries, and became non place and non time (timeless), and fold trying to restore time and space. So, The fabric of space-time is ruptured. Continuum physics rooted in this fabric stops. But the quantum threads are still meaningful. (Ashtekar, 2005).

6.3 The User as part of Places

The position of space in-between implies a middle location between two events and opposed spaces, the first space of origin or departure to the second space of arrival.(Luz, 2004, p. 155). The aim is to shift from the previous spatial narratives of preset planning into a more social-based approach, which identifies the user as the creative element in the construction of the transient situation. Contrarily to fixed spatial syntax analyses, recent studies sustain that the user is the most productive element and thus the co-author or co-producer of our production of spaces and places. Based on the user's capability to adapt to different situations, spatial behavior should be considered as an invariant variable, open to chance rather fixed in predictions. (Luz, 2004, p. 158)

A design possibility, By embracing the recent reclaims of urban space and street movements, the design of place-making should adopt new 'techniques' and methodologies for urban exploration based on everyday occupying practices. This entire urban buzz means that city dwellers are reclaiming their 'place in space'. they are moving away from the fixed preconceived idea of the Greek agora and the public life confined to the city central squares of political, economical and social powers. (Luz, 2004, p. 159) the opportunity provided by the spaces of transition, the leftover places and other uncertainty spaces suggests the development of new 'clever' designs, where experiencing the urban space could be more than seeing or passing by, but instead occupying, co-producing, touching, tasting and listening to different textures and sounds. (Luz, 2004, p. 159).

6.4 The Transformation

Transition is a change of state; a change from one thing to another, 'a passing or passage from one condition, action, or (rarely) place, to another; change;' 'the passage from an earlier to a later stage of development or formation;' 'a style of intermediate or mixed character'. While Transformation is a change of state, a more whole and complete change than in transition. 'The action of changing in form, shape, or appearance; metamorphosis;' 'a complete change in character, condition, etc.;' In physics 'Change of form of a substance from solid to liquid, from liquid or solid to gaseous, or the reverse' (Repenning, 2003, p. 12)

In this system, any one of the events along it, the program is dominant over the character of any one single space. The transformational sequence is based on rules and discrete architectural elements. Passage through this sequence becomes its own theoretical object. The process must become the result, with the sum of transformations being at least as powerful as the ultimate transformation. Transformational devices, or rules of transformation, include compression, rotation, insertion, and transference. They may show "particular sets of variations, multiplications, fusions, repetitions, substitutions, metamorphoses, anamorphoses, dissolutions."

These intermediate stages apply to each phase of separation, transition, and reincorporation. That is, a transformation is a more intricate journey than a here-and there set of steps. A transformation is a progression and the importance is the actual occurrence of the evolution. (Repenning, 2003, p. 20).

6.4.1 Transformation from space to event

The space between spaces and the time between times exhibits a distinct energy. Characterizing this energy of transition is essential to creating powerful and compelling spaces whose integral focus is transition. These spaces include Churches, Theaters, Museums, Transportation Facilities, Parks, Health Care Facilities, Educational Facilities, (Repenning, 2003, p. 9)

An event is something that happens at a particular point in space and at a particular time. So, one can specify it by four numbers or coordinates. (Hawking, 2001, ch. 2, P. 5). So, Ritual is A sequence of events, or states, specifically arranged to bring about a realized transformation; as standard cultural or religious observance (Repenning, 2003, p. 12). Also the historical experiences produce the autonomous culture of any human group. These historical experiences are called traditions and they constitute the heritage of any cultural grouping. (Al-Hokail, 2004. P 10).

In "Sequences," architect and theorist Bernard Tschumi categorizes sequences themselves into three groups:

- The transformational sequence is a device or procedure used for laying out spaces.
- The spatial sequence is the method of grouping the spaces and is founded on typological precedents and their morphological variations.

- The programmatic sequence is the usage and the occurrence of events planned for the spaces.

Tschumi views ritual as a framework held in place by its spatial and event sequences as in the La Villette Park in Paris (Fig. 6). For Tschumi, ritual calls for a highly structured program that orders movements, events, and spaces into a progression. Design connected to ritual sequence disregards the significance of the individual steps in the journey. (Repenning, 2003, p. 46).

"The linearity of sequences orders events, movements, and spaces into a single progression that either combines or parallels divergent concerns." Not all architecture is linear or made of clearly-defined parts. Some fragmentary experiences without beginnings or ends, produce a jumble, where meaning is derived from the order of experience, rather than from the composition as a whole. Order of experience refers to time, chronology, and repetition. (Repenning, 2003, p. 48)

Tschumi states explicitly, "A ritual implies a near-frozen relationship between space and event. It institutes a new order against the disorder it aims to avoid. When it becomes necessary to mediate the tension between events and spaces and fix it by custom, then no single fragment must escape attention. Nothing strange or unexpected must happen. Control must be absolute." (Repenning, 2003, p. 49).

6.4.2 Transformation from place to context

In urban studies, the liminal space is a major characteristic of the city. The term of 'cyberspace' was coined by cyberpunk writer William Gibson and used for the first time in his story "Burning Chrome" (1982). The principle of cyberspace is similar to Michel Foucault's heterotopias. The terms, concepts, notions and theories that reflect on this composite and indistinct spatiality of the contemporary world proliferate. (Bădulescu, 2011)

New perceptions of space are reflected in such conceptual perspectives as Foucault's 'heterotopias,' Which is refers to spaces of otherness, and are neither here nor there, simultaneously physical and mental. The French philosopher distinguishes between utopias, which are sites with no real place, and heterotopias, which are places absolutely different from all the sites that they reflect and speak about. However, between utopias and heterotopias there is what Foucault calls "a sort of mixed, joint experience," which is the mirror. (Bădulescu, 2011)

The globalization effected by the internet is a new major source of dynamism. In the first place, it reorders and compresses time and space. Secondly, communications and information technology facilitate action at a distance and are deeply bound up with the intensification of globalization. Instantaneous global electronic communication has profoundly altered the relationships of reciprocity and interdependency: we now live in a 'global society' in which we can no longer avoid other individuals and alternative ways of life. New communication networks increase the possibility of global scrutiny and global visibility, and also the possibility of mutual interrogation. We no longer merely exist 'side by side' with other cultures and other people but interact with them in many different and ever-changing ways. However, contemporary globalization raises feelings of anxiety and frustration. As global communication networks reorder time and space, they also facilitate shifts in the global flows of symbolic goods and in the concentrations of symbolic power. Given the complexity of the structured character and patterns of transmission, it is unlikely that our understanding of these features will ever be more than partial. (Bădulescu, 2011)

Ritual as a model displays the period of liminality as a critical phase for transformation and renewal. Additionally, activities and policies within the period of liminality are distinct from regular experiences and time constraints of customary society. (Repenning, 2003, p. 18) and looks like zeitgeist.

The reuse of buildings, urban structures or landscape architectural plans will be important in new design strategies in the 21st century. To understand architectural design, landscape architectural or urban designs, not only the plan or design itself should be examined, but also the surrounding or the context should be taken into account. And how the design is anchored to its context- to the genius loci?

Nowadays, rapid urbanization is swallowing the surrounding of these buildings. Understanding the context or the spirit of the place and the way the design was anchored to the location of these buildings will help to maintain or give a direction to reuse it, without harming the original design and giving room to new developments. (Verschuure, 2009)

In this time of growing globalization, greater movement of people, urban planners and architects seem to make more and more the same sort of plans, not taking in the specifics of the community, city or landscape they were made for. This can be seen in the objects of building itself, but also in the way a design is placed in its surroundings. The specifics of the surrounding, the context of architectural, urban or landscape architectural designs, is not always taken into account. This leads to uniformity of new plans and loss of identity, but also to designs not being anchored to the context they were made for. Especially for existing buildings and monument, this leads to unwanted situations. A building or structure is not a stand-alone element, but it is anchored to other buildings, structures or to the underlying landscape, which forms the context of the design. To add new developments to existing designs, the specific characteristics and the context should be examined, according to (Venice Charter, Washington Charter, Zimbabwe Charter, Nara document of authenticity...Etc). These specific characteristics determine the identity of the area & era – such as the genius loci of Rome (Fig. 4).

7 CONCLUSION

- Architecture influenced by new open philosophy of science and new sciences, beside positive achievement from these effects, but it spawned some of the negatives in the emergence of new intellectual references instead of human reference, which led to the violation of human rights and their associated relationships with the surrounding urban environment.

- The research indicates that architecture had many dimensions beside the normal 3 (space) +1(time) there are many additional dimensions like (Emotional, Spirit, Genius loci, Zeitgeist, Events, Intuition and Prediction).

- Sense of place not belonging to a certain architectural trends, or a specific environment, but emerges from the background of simple living for a long time as a liaison to the social interactions around the fixed parameters of significant importance to the occupants.

- When we combine quantum mechanics with general relativity, there seems to be a new possibility that did not arise before: that space and time together might form a finite, four-dimensional space without singularities or boundaries, like the surface of the folding architecture but with more dimensions.

- The modern movement in architecture tried to analyses the site based on scientific parameters. The fast growth of cities in the last century, which is still continuing today, and the application of the 'modern formula' quickly resulted in sterile and faceless neighborhoods.

- In place the research finds a rational way to integrate nature, human and continuity where man can lives harmoniously, humanly and poetically. So, to solve the problems of modern cities including Arab- Islamic cities, the environmental issues may at least bring people closer to live more in harmony with their natural environment.

- There are divisions of the elements of place with "space", "time" and "order", the structure of place could be seen as enclosure, expansion, foci, axis, boundary and domain while Kevin Lynch pointed them to five elements: paths, edges, districts, nodes and landmarks, and added later identity, structure, and meaning. These elements give the identity of the city.

- Norberg-Schulz make little attention on human's aspects and influence to nature made his theory trend to environmental determinism, while Kevin Lynch used man's subjective mental image of the city (mental map), and Jean Piaget use Schemas as (cognitive maps).

- To design something new is probably an approach to generate new meaningful places. Places are complex systems and we are still very weak in understanding and dealing with complex systems and their phenomena.

- Any object, event, situation or experience, there are a phenomenology of (light, color, architecture, place, home, travel, seeing, learning, change, relationship, economy, sociability) and so forth. All of these things are phenomena because human beings can experience, encounter, or live through them in some way.

- The design of place-making should adopt new 'techniques' and methodologies for urban exploration based on everyday occupying practices.

- Not all architecture is linear system or made of clearly-defined parts. Some are non linearity systems according fragmentary experiences without beginnings or ends; produce a jumble, where meaning is derived from the order of experience, rather than from the composition as a whole. Order of experience refers to time, chronology, and repetition.

- For plazas of the city, how can the genius loci – the spirit of place – been found and created today? The architect has to take into account the multitude of these phenomena to be able to create architecture with meaning. Architecture can neither be only an aesthetical exercise nor a technological construction to be able to create genius loci'.

- Nowadays in many cities especially Arab – Islamic cities, rapid urbanization is swallowing the surrounding of the historical and heritage buildings. Understanding the context or the spirit of the place and the way of design was anchored to the location of these buildings will help to maintain or give a direction to reuse it, without harming the original design.

- To add new developments to existing designs, the specific characteristics and the context should be examined, according to (Venice Charter, Washington Charter, Zimbabwe Charter, Nara document of authenticity...Etc). These specific characteristics determine the identity of the area & era- such as the genius loci of Rome.

- The research vision for future, that building should be one system within the natural environment and context. The research believe that designs with limited resources in extreme environments leads to a much higher respect of nature and the human being and thus is generating a strong drive to improve life on Earth. About a design theory on the Genius of the Place, let Nature never be forgot, and the spirit of the place should be respected.

The Multidimensionality of Contemporary Urban Spaces – Implications for Design

Cecilia Scoppetta

(Cecilia Scoppetta, PhD. Sapienza University of Rome)

1 ABSTRACT

The paper is aimed at highlighting the spatial outcomes of structural changes occurred in world societies/economies, with the shift from the production of "tangible" to "intangible" goods, and the spread of the technical-economic information paradigm that is strictly connected to the globalisation process.

Such transformations seem to require an interpretative shift in the ways in which urban spaces are usually conceptualised and perceived. Moving from the more fruitful concept of multidimensionality of urban spaces, the paper suggests that (material) sites can be thought as the spatialisation of digital (immaterial) dynamics. Conceptualising urban public spaces along these lines creates both theoretical and operational openings that mean rethinking traditional approaches in designing public urban spaces.

2 TOWARDS NEW DESCRIPTIONS/INTERPRETATIONS (PROJECTS)

Since the early-Eighties, with the sh ift from a Fordist to a post-Fordist production (from "tangible" to "intangible" goods), we have witnessed a profound structural change of economies/societies. As it is well-known, this has meant market internationalisation, multi-nationalisation of productions, and increasing mobility of capitals, services and competences aimed at innovation. But, mostly, the techno-economic paradigm focused on information constitutes the main presupposition of such a relevant shift. In fact, even for the obvious «assonances» (Goodwin, 1984) with the results of scientific and technological evolution of the «network society» (Castells, 1996), during the Nineties a powerful network metaphor has become a «hegemonic image to which re-led the understanding/interpretation (planning) of contemporary complexity (city/territory/society)» (Scoppetta, 2009).

Effects of such shift on cities and metropolitan areas have been extensively studied, and they were often interpreted as the result of a particular issue related to globalisation, i.e. neo-liberal policies that were developed in order to support the wide reconversion process of economies/cities/territories/societies that started with the global crisis of the Seventies, when the new competitive scenario began to loom on the horizon.

Instead, what still remains too scarcely examined is the issue concerning the effects of digitalisation on the urban space: we have an interesting research field here, to be studied not only in analytical and descriptive terms, but also from the more operative view-point of planning and design.

Difficulties related to a fully understanding of the real impact of digitalisation on the urban space seem to concern two main interpretative errors (Latour, 1991a; Avgerou et al., 2004; Graham & Marvin, 2001). The first one tends to confinate the analysis within an strictly technological reading of the digital dimension, moving from the assumption that an innovative technology can be simply intended as a mere replacement of the slower and less effective previous one. The second error, instead, consists of a persistent dependence from analytic categories used within the highly different historical (and spatial) conditions of the pre-digital age.

Both readings, however, are guided by the idea of a substantial separation and independence between the intangible dimension of technology and the tangible reality of cities, so that a possible more complex interpretation that considers the inter-relations between material and immaterial (space and cyberspace) remains largely unquestioned. It is plain, indeed, that a large part of what happens into the cyberspace is deeply influenced by material practices, imaginaries, social and economic relations occurring in the material space. In other words, what the two above-mentioned readings tend to ignore is that an essential implication of globalisation consists of an increasing digitalisation of the urban dimension. This highlights the limits of a mere topographical representation, and forces us to rethink our traditional interpretative categories and operative tools (Scoppetta, 2011).

The matter in hand does not consists of a certain resemblance between virtual and real spaces (or between virtual spaces and the imaginary of real urban spaces) in the sense highlighted by Ursula von Petz [1]: «In the Seattle EMP […] Museum you can travel into a virtual plaza of a Spanish or South America small historic town, where people sing and dance joyously and integrate you seemingly into their happy street life. A deception. […] the environment of the virtual event is an invented historic site in the taste of CokaColaLand […] and not at all a futuristic spacelab or skyshuttle. Is it our restricted fantasy that prevents us to simulate some future images? Do we want to assure ourselves of the familiar past on our way into the new?».

The question rather is to highlight the emerging of a new multidimensional nature of urban space, i.e.: the co-existence of an immaterial component that is incorporated into the material, and cannot be intended as separated from the materiality of places. The limits of a topographical description/interpretation precisely lies into the incapacity to capture such multidimensionality through traditional categories that are still based on a rigid and unfruitful separation of material and immaterial.

3 THEORETICAL IMPLICATIONS OF TAKING MULTIDIMENSIONALITY AS A BASIC FEATURE OF PLACES

3.1 Co-existence of global and local dimension

A first important implication of the proposed approach concerns technical-disciplinary issues, and it is related to an interpretation of urban space aimed at overcoming the dichotomy between local and global. In fact, the main part of what we perceive as local in the reality can be rather interpreted as a micro-environment having a global span given because of its high or low degree of inter-connection. In this sense, each object that can be mapped as a place through a topographical description of its materiality is (can be) also a part of a long-range reverberation.

This is the case of the inseparability between international finance (an highly digitalised and immaterial global activity) and (very material and local) real estate, which can be interpreted (Sassen, 2008) as emblematic of both the multidimensional nature of contemporary urban space and the inadequacy of traditional interpretations and models.

Phenomena related to immigration in our post-industrial cities, with its internet point and money-transfer services (Hannerz, 1997), show us, however, the ways in which what we have always thought as "places" can really be nothing but single elements of wider territorial systems as they support larger networks and diasporas (Tarrius, 1992). Although unperceiveble according to logics that do not consider such further amplified dimension, in planning terms such "places" can be interpreted as "centralities" in all respects, and they end up to (informally) modify the "functioning" of that place within the city. Assuming the multidimensionality of urban spaces could allow us to better and more precisely understanding the disperse circulatory nature of contemporary territory (Tarrius, 1992) in order to elaborate effective urban policies answering the needs due to the relevant changes given by such new constantly re-territorialising plurality.

Furthermore, what we have traditionally interpreted and perceived in planning terms as a "centrality" (i.e.: a place of concentration high-level functions, as in the case of CBD) can be no more simply associated to a geographical centre with a specific physical shape (a concentration of office buildings and skyscrapers into the inner city): business activities, in fact, may have a disperse physical shape (Marcuse & van Kempen, 2000; Graham & Marvin, 2001; Scott, 2001). Evidences are given by the fact that the (concentrated) CBD in Chicago and the (disperse) Sylicon Valley share the same functions within the world digitalised economy, but their geographical shapes are deeply different.

And, however, evidences of such compenetration of material and immaterial, places and flows, real and digital come from the contemporary territorial (and institutional-political) rescaling, on which a vast literature exists (among the others: Sum, 1999; Taylor et al., 2002; Barry & Slater, 2002; Ferguson & Jones, 2002; Brenner, 2004; Olesen, 2005; Miller, 2009; on the European case, see: Berezin, 2003; Brenner, 2003; Gualini & Woltjer, 2004; Scoppetta, 2012d; 2012e) and highlights the destabilisation of older hierarchies,although such new organisations and formations do not replace them at all, but rather tend to emerge alongside them.

---

[1] Lecture at the 4th Biennial "Culture of the city – transformations generating new opportunities" (Rotterdam, Sept. 20-22, 2001).

In the Italian case the proposed multidimensional interpretation has found full citizenship at the regional scale, resulting in the effective image of the «multi-layer territory-network» [2], which refers to flows of goods and people, but also of knowledge, capitals, innovation and ideas that are conveyed through social and digital networks.

Therefore, what is questioned here is how this view can be taken at a closer scale for the interpretation, planning and design of urban public space.

3.2 Political implications

A second relevant implication concerns the sphere of values to which the project of urban public space is to be referred, and this clearly is an implication of political nature. In fact, the acknowledgement of the new multidimensionality of places includes the possibility that some elements of the urban topography can be understood as the spatialisation of global and essentially digital dynamics. The political dimension of the issue precisely lies in the nature of such global digital dynamics.

This results in two different possible directions of investigation: the first one moves from the assumption that such dynamics are essentially market-oriented, since several studies (Sum, 1999; Urry, 2000; Brenner, 1998; 2004; 2009; Magnusson, 2009) have highlighted the ways in which the contemporary rescaling tends to cut across institutional dimension of territories through policies such as deregulation and privatisation, with consequences related to the privatisation of urban public spaces, social exclusion, segregation, spatial control, and so on.

The second, instead, moves from the observation of the increasing use of digital modes by social movements and political activists that, traditionally, are strictly linked to the immobility of local dimension. Think of networks of environmentalists that are interconnected through the web and that insert their specific local territorialised instances within broader de-territorialised global circuits (Cleaver, 1998; Mele, 1999; Donk et al., 2005; Garrett, 2006). In this sense, the emphasis on the multidimensional nature of places means highlighting a renewed relevance of social and political movements in the construction of urban space. And, moreover, as in the case of international finance, the immaterial dimension of inter-connections does not seem to be able to leave out of consideration the materiality of the city (rather than the national level) as the main space of political action (Torres et al., 1999; Lovink & Riemenes, 2002).

In this sense, the digitalisation of global finance has led Greece to a semi-bankrupt, just like the mobile synergy of SMS, alternative websites (such as Athens Independent Media Centre), different social applications – such as blogs of occupied universities, Twitter and other micro-blogs, Facebook and further networking sites (see: Milioni, 2009) – have played a relevant role as useful tools of communication and information exchange (text photos, videos) for individuals, affinity groups, collectivities and associations during the recent (2009 and 2012) struggles in Athens.

What is to be highlighted here is the way in which what started as a social conflict, due to the economic crisis combined with major cases of government corruption, has then evolved to a multifarious and inventive reclaim of city public space, so that we may say that urban space and its uses have become one of the stakes of the conflict, and the latter has ended by actively transforming such spaces, since new more or less temporary forms of spatiality have emerged in terms of both concrete arrangements of physical elements and ways to perform them, and they represent the ways people who participate tend to imagine spaces that will house the life they fight for.

Thus, in such molecular more or less temporarily re-appropriated free areas of otherness – which, however, can be defined by a recognisable perimeter (e.g.: in the case of Exarchia neighbourhood, where a large parking lot was transformed to an urban park through both open design meetings and online discussion and negotiations) – can be conceptualised, according to de Certeau (1984), as «a migrational, or metaphorical, city slips into the clear text of the planned and readable city», in which innovative social practices can be experienced: affordable food products bought directly from the farmers are now provided by the self-organised "potato movement", and non-monetary local exchange systems and time-banks are practiced (Dalakoglou, 2012).

---

[2] As defined by the research study SIU-MIT/DiCoTer (2006) "L'armatura territoriale e insediativa del territorio italiano al 2020. Principi, scenari, obiettivi" (coordinators: A.Clementi, G.Dematteis, P.Palermo). See also: Scoppetta, 2012b.

Thus, especially this second direction of investigation may lead to more fruitful outcomes in terms of planning and design, while the first one seems to be more interesting in descriptive and interpretative terms, as it can offer useful insights into otherwise invisible inter-relations between different places.

4 POTENTIALS IN TERMS OF URBAN PLANNING AND DESIGN

In the light of the previously highlighted theoretical implications, three different modes of inter-relation between the material and immaterial dimension are examined here as well as the related planning and design approaches.

4.1 Control of urban flows

A first one refers to experiences based on the potential of typical ITC real-time representations, an effective tool for mirroring an "object" – the city – which is characterised by multiplicity and movement. The privileged technology, in this case, is the mobile phone and GPS, whose users are unwitting drawers of thematic maps with space and time coordinates.

The purpose of such real-time maps – which require the construction of a platform for collecting and exchanging data – concerns the control and management of specific phenomena, such as traffic or concentrations related to particolar events. In other words, such typology can be use for controlling and managing the unpredictable «hypermobility» (Gillespie & Richardson, 2000) of contemporary urbanity, also given by the result of the individualisation of working arrangements that has produced new «nomadic workers» (Castells, 2001; Prato & Trivero, 1985) with their «office on the run» (Thrift, 1996).

Obviously, this typology of interaction between material and immaterial dimension can be used within traditional top-down planning and decision-making, since participation is anaware. Furthermore, it is to be highlighted that a "dark side" exists: it concerns the potential of controlling spaces (and also people).

An example is given by the Real Time Rome project [3], in which aggregated data from the use of mobile phones are interpolated with traffic informations. What results is a representation of the (otherwise elusive) "urban ubiquity" deriving from an "hybrid" inter-connection between people, places, and technological infrastructures, between "static" and "fluid" urban elements. Fluidity is given by the time coordinate, which allows to represent, for example, the daily rhythms of a certain neighbourhood, or if the organisation of public transport effectively mirrors and answers the real dynamics of movement and/or concentration as well as the behaviours of specific groups (e.g.: tourists) or of the "urban organism" as a whole during a special event. Especially in the latter case, beyond representing and individuating the places in which people was concentrated, the map based on the use of mobile phones in different moments of the final match of the FIFA World Cup in 2006 returned phases and trends of collective enthusiasm, i.e.: it was able to represent the different intensities of (collective) emotion.

4.2 Community-building

The second typology of inter-relationship between material and immaterial space is linked to the spread of social softwares and the related virtual communities (Schuler, 1996), i.e.: groups that differ from the traditional ones for both the lack of face-to-face contact and the use of technology as preferred tool.

This has resulted in the interpretation of virtual "places" as public space in all respects, since they can be re-led to the Harvey's definition of space (2000) as «predominantly social construction» as well as the Lefebvre's well-known dialectical triad of the «production» of urban space (1974) – material space, representation of space, spaces of representation – according to which space can be interpreted as a tangible place of experience, as a conceptualised mental space, and as an interiorly lived space through emotions, desires, imagination, and memory.

A further example is given by the Lynch's study (1960) on the imageability of the city and the ways in which people, through their informal understanding, thought about its structure in terms of their own movements and opportunity to act: the Boston he describes is not a city made by grids and precise measures, but it rather is a loosely defined region, which is made by paths, landmarks, and networks.

[3] The project is one of the implementations of the "WikyCity Project", developed at the SENSEable City Laboratory of the Massachussetts Institute of Technology. See: http://senseable.mit.edu/wikicity

In general, the design approach based on the typology of inter-relation of social softwares seems to be particularly fruitful as it can be referred to an idea of public space as a «construct» – in the sense used by Pasqui (2001) – or, better, as «activated construct», following an interesting definition of "context" formulated by Weik (1969), which, in turn, refers to Giddens (1984).

In particular, two different design levels can be individuated within this second typology of inter-relationship between material/immaterial, and they are aimed at translating the interaction in more or less transformative consequences about a place (about its distinctive meaning).

In both design levels the characteristic element consists of the existence of an identitary link between the virtual community and a specific place (Hampton, 2002; Scoppetta, 2009), and the latter may be the daily living environment of the components of the community, e.g.: their neighbourhood (Hampton, 2007). In this sense, the first level of the interaction consists of the fact that the construction of the virtual community moves from a map which is shared online. The emphasis is not so much on the ability to reproduce specific real places in the virtual space by replicating them (e.g.: through the use of 3D technology [4]), but it rather concerns the possibility of using the potential, given by the interactions and feedbacks of social softwares (such as Facebook, My Space, and so on) in the construction of social capital (Hampton & Wellman, 2003).

Such virtual maps, therefore, consist of representations that are collectively constructed online and that represent places that are understood as subjectively experienced, perceived, desired, i.e.: by including the "thickness" of a narration, or of a spatial practice.

A second level of interaction may be linked to cooperative needs of mutual exchange [5] or – being constructed around specific problems or claims also expressing a certain degree of potential design – can result in participative planning processes (Apostol et al., 2008). These are experiences that can be re-connected to the Lynch's «good city form» (1981) or, more generally, to the mainstream of community planning, or, with reference to the Italian context, to the «identitary maps» of the "territorialist school" (see: Magnaghi, 1990; 1998; 2000), which are aimed at creating synergies between "expert" and «local knowledge» (Geertz, 1993; see also: Scoppetta, 2012a).

The most trivial variant of such approach is the "institutional", which becomes merely passive especially when is intended as (uni-laterally) "communicative", since it is too often aimed at seeking consensus around essentially top-down decision-making processes in which participation mainly tends to be seen as «exit» (as in the case of audit or similars) and not as «voice» (Hirshmann, 1970).

4.3 Post-representational maps

A third mode of inter-relationship between real and virtual space includes a series of experiments that focuses not so much on community-building, but rather on the unexpected emerging of a place to which further temporary meanings are given thanks to their "construction" through an online interaction. This is the case of the so-called "flash mobs" that consist of the sudden and temporary concentration in a public space of a large number of people, which is activated through a flow of communications via web or via mobile phones, in order to play an unusual or extraordinary action, and then to disperse. Examples are given by experiences such as Meetup [6], in which a virtual community, which is established moving from a shared interest (and not from a place), meet or organise an event into a real place.

Such experiences clearly refer to the Situationists' practice whose aim was to reinvent everyday life in urban space by constructing situation which disrupted the ordinary and the normal in order to jolt people out of their customary ways of thinking and acting (see: Debord, 1994). By using the dérive (i.e.: the urban flow of act and encounters) and détournement (i.e.: re-routing of events and images), Situationists developed a number of experimental techniques stressing the relationship between events, the environment, and its participant.

Unlike the previously mentioned typology, what prevails is an occasional and temporary character as well as the lack of any identitary link between the virtual community and the real place. Thus, while the previously

---

[4] An example in this sense is given by Twinity, in which the avatar of the online community move within a virtual representation of certain places oft he city of Berlin. See: Twinity on-line community (http://www.twinity.com/).

[5] This is the case of i-neighbors on-line community (http://www.i-neighbors.org) or Peuplade on-line community (http://www.peuplade.fr/).

[6] See: Meetup on-line community (http://www.meetup.com/).

described mode can be considered as an expression of instances and needs of the Castell's «space of places» (1996), the latter rather seems to refer to a «spaces of flows». Not surprisingly, frequently the relationship between virtual and real does not occur with reference to a single site, but rather to a network of places as well as the spatial experience that is played does not tend to be linked to the daily lived neighbourhood dimension, since it rather consists of crossing (and so linking together) different spaces as a discovery/invention of innovative territorial values and meanings.

It is not a coincidence, therefore, that the design dimension tends to be expressed through a map, and the latter may be intended as a post-representational map (Kitchin & Dodge, 2007; Kitchin et al., 2009) that is not assumed to be mirror of the world (it does not describe and explain it), but rather to produce (to re-create) it by making propositions, so that it is about «the construction of meaning as a basis for action»(Wood & Fels, 2008). Since they are socially constructed (Harley, 1989) – and, as such, «dialogic, polyphonic and multivocal» (Pickles, 2004): the writing the heterogeneity of (collective and individual) "histories" and narrations onto the multiplicity of contemporary urban geographies – such maps can also be intended as a set of social practices and, therefore, they as «mobile subjects» (Del Casino & Hanna, 2005) in a constant state of becoming. The digital de-materialised component provide these post-representational maps of a sort of instantaneous connective echoes that amplifying the organised event.

Not infrequently, the emphasis is on spatial experience as an artistic practice, which often explicitly refers to a wide range of creative streams: from the happening to the Situationists' psycogeographical actions; from the theatrical post-avant-garde to the cyber-performance. But it is worth noting that such mode of material/immaterial inter-relationship is not always associated with a specific design intent: the latter can consist only of attracting, even if for a short time, the collective attention on a particular place. Even in this case (even if in a different way), the main goal seems to be the construction of social capital as a prerequisite for the transformation/invention of one or more places by highlighting the potential of social creativity and self-organisation (Portugali, 2000). Such scope is pursued not so much through the strengthening of the ties of belonging, but rather through mainly playful interactions as well as by the use of the wide range of available technologies (social softwares, blogs, videos, twitter, and so on) and cross-media platforms (web, mobile, etc.).

5 MAIN CONCLUSIVE FINDINGS

Conceptual implications of taking the multidimensional nature of urban spaces, and the different ways in which such multivalency is expressed highlight the shift in understanding the meaning of contemporary design. The latter, in fact, can no longer be simply intended as configurative of spaces, but rather as an interactive and hybrid device, which is able to accommodate the categories of both the social and the natural (Latour, 1999), and to generate not necessarily predictable processes through the establishment and widening of an always changing network of interconnections between subjects/objects/discourses (Latour, 1991b; Akrich & Latour, 1992), who interpret the transformation/invention of a space as an opportunity for the mise-en-scéne of its own instances (Scoppetta, 2012c).

The Planning of Peri-Urban Agricultural Areas: the Case of "L'Horta de València"

José Luis Miralles i Garcia

(Professor of Urban and Regional Planning, Universitat Politècnica de València, c/ Camí de Vera s/n, 46022-València (Spain), jlmirall@urb.upv.es)

1 ABSTRACT

València is a city in the spanish mediterranean sea. Is the capital of Valencia's region. The peri-urban territory of Valencia is an agricultural land with higth productivity. This land is in production since the medieval age through an irrigation system of Arab origin. The "water court", with probable Arabic origin, dispensing with words (not write) justice among irrigators all Thursdays at gate Cathedral. The historical agricultural land had a surface of 10.000 ha of which 5.000 ha have been built. There are also another 10.000 ha of agricultural land of high quality. So this space has an important potential agricultural, cultural, económic, as landscape, historical, as a natural resource, ... All included in the metropolitan area of Valencia.

Since 1946 there have been several experiences and attempts for planning and management this space. Usually as passive planning. After the European Landscape Convention (Florence, 2000) changes the way for approach the problem. Now we have a perspective as a landscape product of human interaction. With this new perspectiva is realized the Territorial Plan of Action for the Protection of L'Horta.

However, the plan done, now completely finished but not approved, has not been able to overcome the contradictions and conflicts of uses for this peri-urban area.

Particularly, the Valencian society lives today the economic consequeces of the housing bubble crack. But this society (particularly public autoritys) expect another housing boubble and does not perceives the environmental bubble (consumption continued each year more natural resources than those produced by ecosystems in the same year).

This paper reflects on the approach of a new paradigm for planning and land management to prevent new bubbles and their consequences.

2 PERIURBAN AGRICULTURAL SPACE OF "L'HORTA DE VALENCIA"

2.1 Characteristics

L'Horta de Valencia is a unique landscape. It is located in the suburban environment of Valencia metropolitan area. Valencia is a city in the Spanish Mediterranean. Its origin is Roman. The Spanish Mediterranean coast, in general, is mountainous but Valencia is located in a flood plain along the river Turia. This has enabled the agricultural use of the land by irrigation.

About 30 km south of the mouth of the Turia river, Júcar river flows into the sea. Both rivers share therefore floodplain. Originally, this plain had numerous wetlands. Throughout the centuries have dried all that existed in the environment of Valencia city except Albufera lagoon.

Today, in the wetlands around the Albufera lagoon, rice is grown, and the rest of the plain vegetables and citrus fruits are grown. The whole plain is irrigated. Not precisely known but it seems that the origins of the irrigation network are Arabs.[1] The historic irrigation network has 7 channels that take water from the River Turia.

The long history of Valencian irrigation has generated a powerful agricultural and water culture whose main symbol is the Water Court (possible arab origin). The Court dispenses justice every Thursday at the door of the Cathedral even today. It deals with the problems of irrigation farmers. All processes are exclusively oral and judgments are met by the verbal agreement of farmers who submit to the court.

The historic vegetables garden came to occupy an area of about 10,000 ha. which, at present, approximately half are maintained (Biot, 1998). But also in the metropolitan area of Valencia are another 10,000 ha of high quality agricultural areas cultivated mainly with orange (Antolín et alt, 1998) .

---

[1] Differents Muslims governments of Valencia occur in the period from 711 to 1238 years.

The first report of Dobris European Environment Agency (EEA, 1995) made an approach to European landscapes and identified only 6 places with landscape garden. Two of them in Spain, the orchards of Valencia and Murcia.

The agricultural land of L'Horta de València has special values as cultural heritage, historical heritage, anthropic landscape and for its heritage architectural and hydraulic work. And also, of course, for its agricultural economic activity (Miralles, 2012).

2.2 Transformation process

For a long time, the growth of the city of Valencia and its urban environment has been limited. Until 1960 the city of Valencia grows in the expansion of the historic walled city. The expansion area is developed following the Valencia Expansion Project. Thus, until 1960 remains almost the entire historic huerta of Valencia.

Fig. 1: Detail of Valencia and surroundings in 1944. Historical National Topographic Map of Spain, 1:50,000 original scales.

From 1960 began the first real estate expansive cycle in Spain and Valencia. In Spain and Valencia have been three periods of urban expansion: 1960-1972, 1985-1991 and 1997-2008. he three correspond to three real estate expansive cycles associated with real estate bubbles (Miralles, 2011).

Urbanization produced during successive booms housing bubbles have been very intense in Spain and, particularly, in the Valencia region. It has also been particularly strong in the third period of expansion (Miralles, 2009).

	1990	2000	2006*
Urban fabric	61.670	79.612	85.696
Industrial, commercial and transport units	10.696	18.897	22.988
Artificial non-agricultural vegetated areas	1.303	3.881	4.327
Sum (ha)	73.670	102.390	113.011
% surface areas of Com.Val.	3,17	4,40	4,86

Table 1: Artificial surface in Valencia region according CORINE database (Miralles, 2009).

In the third period begins to offer up to 180 Euros per square meter of land protected not urban developable of periurban Huerta of Valencia. Exactly protected land, with the expectation that the administration will change the urban plan to remove protection and allow its construction. These facts show that the land market to build is not efficient to optimize the uses of land in the territory.

New urban fabric in VALENCIA PROVINCE	Period, 1990-2000 (ha)	Period, 2000-2006 (ha)	Total surface (ha)
Coastal zone	2.630,62	2.115,48	4.746,10
Pre-coastal zone	5.161,90	4.099,04	9.260,94
Interior zone	2.557,44	1.631,67	4.189,11

Table 2: Rural land transformed in urban fabric in Valencia Province, 1990-2000-2006 (Miralles et alt, 2012).

Obviously, the price reaches the land for building is purely speculative and turn is generated as a result of speculative selling price reaches the price of housing. In this situation, the extra profits are not produced by the construction and sale of homes but by the change in land value.

In all three periods housing bubble, the expectation of business by changing land use has promoted a tendency to sprawl supported in new transport infrastructure. The process is similar to that occurred elsewhere but in each case with their own local characteristics. This alters substantially the landscape and generates margins urban or peri-urban areas with a specific problem (Magoni, 2012). In any case, the land transformation process is virtually irreversible and this forces us to rethink intervention in these spaces (Treu, 2012).

Fig. 2: Urban fabric in metropolitan area of València in 2011. Generalitat Valenciana, SIOSE geodatabase (GVA, 2011)

So, the process of transforming this periurban agricultural space shows a set of contradictions. It irreversibly destroys a natural resource, agricultural land, to create city. But the city is created by a speculative expectation and not the result of an objective demand of urban activity. Now there are many houses without a market and urbanized areas without buildings.

Urbanization processes in Spain, are planned. Local government approved urban plans that establish areas to urbanize and conditions. Governments administration has short-term objectives. Urbanization generate income for the local administration during the construction phase. Therefore, during the decision-making process are not considered long term consequences. Paradoxically, today foodstuffs are the first export concept of the Valencian economy.

3 PROTECTION PLAN OF "L'HORTA DE VALÈNCIA"

3.1 Historical attempts for planning and management of the vegetable garden

The first planning of Valencia metropolitan area is produced by the Plan General de Ordenación Urbana de Valencia y su Cintura (Urban Plan of Valencia and around) approved in 1946. At this time, the Spanish economy operates in autarky regime with the dictator Franco. So, it follows the general approach of reserving most productive agricultural land for food production. For the Valencia metropolitan area, the

urban growth in the plan focuses on central area and the west where there are no productive agricultural lands.

Fig. 3: General Urban Plan of València and Around, 1946. Historical Cartography.

In 1957 the Turia River overflows and produces a great flood causing serious damage. To prevent further similar disasters, decides to build a new river channel with sufficient capacity. The layout of the new channel runs through the south. This changes the territorial structure and motivates the metropolitan plan amendment.

So the Plan General de Valencia y su comarca adaptado a la solución Sur (General Urban Plan of Valencia and the surrounding area adapted to South solution) is approved in 1966.

At this time, Spain is in first expansive economic cycle and first real estate bobble. So, the agricultural activity is considered as an activity of underdeveloped countries and socially undesirable. Gradually, the children of farmers engaged in other economic activities in the sectors of industry, services or construction.

The urban plan of 1966 according to the value system of the time, committed to a great urban development with big symbolic projects. Especially big traffic infrastructure designed for a massive use of private vehicles. Agricultural land is considered to spaces for transform by processes of urban speculation.

In 1978 is approved the new democratic Spanish constitution and legislative powers in urban planning and land passed to the new regional governments. In 1988 is approved a new metropolitan plan, the Normas de Coordinación Metropolitana del Area Metropolitana de Valencia (Coordination Metropolitan Rules for Metropolitan Area of Valencia). This is a new metropolitan plan for establish land reservation for: infrastructures (especially transport), regional public facilities and protected areas. According this plan, an important part of agricultural land is protected but not everything. These metropolitan rules are implemented by Consell Metropolità de L'Horta (L'Horta Metropolitan Council).

The conflict of interest between the Metropolitan Council (which advocates a global vision and makes decisions that limit the ability of decision municipalities) and municipalities (who want freedom of choice to develop their land according to their particular interests) is finally resolved with the disappearance of Metropolitan Council and the metropolitan rules in 1999. So, since 1999, the municipalities of metropolitan area of Valencia define uses of their land by its own urban plan, tutoring with the regional administration but without a regional framework plan.

All such plans are static plans. That is, all of them down rules to possible uses but none provides initiatives for improving the design of the spaces, particularly for the active promotion and improvement of agricultural land.

3.2 The last attempt: regional action plan for the protection of L'Horta de València

Approximately in 1970 the first citizen movements arise in favour of protecting the agricultural space of L'Horta and against urbanization of agricultural land to residential areas and infrastructure. These citizen movements have been active, with greater or lesser intensity, to the present.

In 2000 he presented a popular legislative initiative in Valencia Parliament for protecting agricultural land of L'Horta. The initiative collected 113,000 signatures but was rejected. From these facts, successive governments have made efforts to recognize values of Valencia agricultural land of L'Horta. Actually initiatives have been a public acknowledgment of their values but no effective protection.

Fig. 4: Promoters of the popular legislative initiative for the protection of L'Horta in act of delivery of the signatures collected.

In 2004 is approved the Regional Planning and Landscape Protection Act. This law establishes the development of a Territorial Action Plan for the Protection of L'Horta. The work to drafting the plan began about 2006. In 2007, Regional Government assumed direct drafting the plan. In early 2011 completed the drafting of the plan. The plan is available in www.cma.gva.es (Plan de Acción Territorial de Protección de La Huerta de Valencia). Currently the plan is not yet approved.

For the preparation of the plan were made very rigorous and comprehensive analysis of the situation of the agricultural landscape of L'Horta. We also performed a very thorough process of public participation (July to December, 2008) which included public appreciation of the landscape of L'Horta. Therefore, the development of the plan has been a remarkable effort. Also conducted several "working groups" of experts on different realities of agricultural land: irrigation, agricultural economics, transport infrastructure, rural-urban relationship, sociological perception, stakeholders,

Fig. 5: Image of L'Horta, 2004. Picture of author.

The drafting team believes that the planning of this space cannot be reduced to a "passive" planning. That is, a geographical planning of uses and territorial rules for permitted uses. L'Horta landscape is a living landscape product of human labour. Thus, it is necessary to promote economic activities that produce the landscape. And we need a landscape management system that allows the collection of revenue to invest in promotion of the landscape. These ideas already point in the text of the popular initiative legislative for the protection of L'Horta.

This entire means that besides a regional planning, other plans are required to promote socioeconomic activities in the landscape of L'Horta and also laws to implement a management system of that landscape. So the intervention in the landscape of L'Horta arises in three axes:

- Regional planning: Territorial Action Plan for protection L'Horta de Valencia
- Complementary socioeconomics plans
- Complementary instruments

3.2.1 Territorial Action Plan for protection L'Horta de Valencia

This plan is designed as a conventional regional plan but with special attention to the landscape. In particular:

- Infrastructures
- Urban border
- Cultural, hydraulic and architectural heritages
- Visual landscape
- Amenities and facilities

The plan includes a prospective part where are planned projects and actions to promote activities.

3.2.2 Complementary socioeconomics plans

In addition on the regional plan are considered necessary:

- Agricultural plan: for to optimize the agricultural production and to promote ecological agricultural production.
- Irrigation modernization plan: usually agricultural land is irrigated by sheet of water and is possible improving irrigation systems to prevent losses and save on water consumption.
- Plan for rural tourism and recreational uses: the landscape of L'Horta within the metropolitan area of Valencia has a good tourism potential but it necessary to compatible with agricultural activities.

3.2.3 Complementary instruments

Many planned actions to improve the landscape or promoting activities need investment. You need an entity manager with ability to earn income from economic activities in L'Horta and invest in improvements such income. Only by law you can improve a specific management system for this space.

3.2.4 Methodology

The methodology for the elaboration of the plan is divided into three phases:

Phase 1:

- Identify the most valuable landscapes and spaces of connection between them
- Identify the major conflicts that threaten the preservation
- Identify change predictions in urban plans and programs

Phase 2:

- Identify quality objectives, level of protection and public use for different landscape units

Phase 3: Actions for

- Protect and connect most valuable landscapes

- Define sustainable systems for management and financing agricultural activity
- Integrate infrastructure and urban border in agricultural landscape
- Protecting and valuing cultural, visual and environmental heritages
- Valuing L'Horta for recreational and cultural public use

Fig. 6: Zoning proposal in Territorial Action Plan for protection of L'Horta (GVA, 2011)

3.2.5 Final proposal

From all this comprehensive approach, finally only regional plan was developed in full but not yet approved. During the execution of the work, the administration has made many public statements in favour of the preservation and promotion of the symbolic space of L'Horta. But it has resulted in any positive action to solve problems.

4 CONFLICTS AND CONTRADICTIONS

After the experience created by this case, one wonders why it has not been successful protection and maintenance of the historic agricultural land of Valencian huerta. On the one hand there are professional and technical capacity to address the problems and propose solutions for the future. hus, the cause of failure in conservation policy L'Horta be sought primarily in management, not in planning.

Moreover, agricultural space of L'Horta is not a particular case or local. Rather, it is a paradigmatic management case of natural assets necessary for the future in a society that is playing its own existence.

In fact there are three contradictions, unresolved, which impede progress in the efficient management of natural resources.

First, the sustainability management. Society tends to give priority to the immediate benefit and punishes the governors who demand current sacrifices for future benefits. This dominant social value is generating environmental bubble.

Second, the ownership of land for building prevents the maintenance soil as a natural resource. Particularly in situations of speculative value of land to build, such land acquire prices so high that no one dares to stop construction. Although it is irrational and generate misery in the future.

Third, the government of the territory is not adapted to the current needs of sustainability. Territorial administration do not have appropriate tools to ensure environmental and economic sustainability of the activities.

4.1 The environmental bubble: the contradiction between sustainability and immediate individual interest

Since 1998, the World Wildlife Fund publishes the Living Planet Report. The last report is in 2012. According these reports, since 1975 approximately, the ecological footprint of all planet activities is larger than the planet's surface that produces environmental goods flows consumed by society. So, the planet's Natural Capital decreases each year. The natural resource consumption and pollutant emission current is possible because it is being consumed each year a portion of the stock of such resources.

So, for a long time, economic activity is based on unsustainable consumption of natural resources. In other words, it is generating an ecological bubble: the current consumption level is at the expense of lower future consumption possibilities. But people do not want to renounce their current consumption or their current income level. As time goes on, the situation will become increasingly unsustainable.

It is clear that to achieve a sustainable situation, should be kept the natural resource stock (and if possible increase it) to ensure the flow of natural goods consumed (and if possible increase it).

In case of L'Horta, we must be this agricultural landscape as natural resources. But stakeholders want immediately incomes by land speculation (so agricultural land destruction).

In agricultural periurban areas we have two major issues for sustainability: urban sprawl and farmland deficit.

4.1.1 Energy deficit and urban sprawl

In Spain, and particularly in Valencia, all urban development is planned. But stakeholders prefer urban development (short-term income) to agricultural land maintenance (short-term low income but long-term activity). So we have in metropolitan area of Valencia an urban sprawl planned. Urban sprawl produces very inefficient energy consumption.

From this point of view should concentrate urban growth compactly on the land without value as a natural resource (en the case of Valencia, in the west).

4.1.2 Farmland deficit

It is known shortage of arable land on the planet. This produces food speculation and land hoarding by some countries (to ensure availability of food).

From this point of view, must maintain highly productive agricultural land and urban growth divert to other places.

4.2 Reviewing theory property: the building land market is not efficient to optimize the location of uses in the territory

The theories of Adam Smith on land ownership focus on farming. Defend the property to convert the farmers in direct beneficiary as a result of their own efforts. In fact, agricultural land is a product of farmer labour.

But the builder does not need the ground but underground. The constructor destroys and removes the ground to cement his work/built on the basement.

The underground is a natural good. Nobody has made the underground. Nobody has made underground. Therefore no one should pay anything for a good that nobody has produced. The price of underground is only a speculative price. If we pay for the underground, pay someone to do nothing and, consequently, discourages productive economy. So the underground should be public.

The value of land for building, or underground, in free market depends on the expectation value of the intended uses. Its value is absolutely independent of the economically optimal use for each area of the

territory. Thus the land market to build does not optimize land use, nor does it create a competitive economic activity. In contrast, generates irreversible destruction of natural resources, urban sprawl and increased costs of constructing and maintaining the networks of urban services.

This approach involves linking the building usufruct of the surface; compensate the landowner for its rural value and efficient administration in the management of natural resources for the future.

4.3 Reviewing the governance of the territory

Valencia's case shows the need to review the organization of the administration. Historically governance is seen as a representative of the people. May be more appropriate at present conceive the ruler as an administrator hired by the people to administer public affairs (state budget, property, assets, natural resources, ...), an administrator that must account for its management.

One of its functions should be the maintenance of the natural resources in the territory that may be needed in the future.

This approach is particularly important in the field of local administration. Spanish municipalities have their origin in the Roman administration (between 200 BC and 400 AD). An important part of their characteristics are maintained today. It is an organization designed for colonization of new territories. But today our country is fully occupied and the problems and the tools available are substantially another.

In addition, natural resources, agricultural lands and landscapes should form networks to maintain the connection between ecosystems. This new network we call green infrastructure.

4.3.1   From roman municipality to e-governance

Initially municipalities were created to administer the territory when transport systems were based on walking, the horse and carriage. The city was a perfectly bounded space and outer space was completely rural.

From 1900 he popularized the use of the car then urban living space extends diffusely. With the expansion of the Internet, vital urban space becomes a space without limits. The functional boundaries of cities gradually disappear. Increasingly, cities function in network.

The network of personal relations overlaps the network of personal relations by transport which, in turn, overlaps the network of relationships through internet.

The municipality as an organization that manages all public services in limited physical space has become obsolete. For some services still needed direct relationships, to other geographical scope more efficient is the region and other can be managed by internet.

So it's necessary reviewing the organization of public administration. Its necessary rethink the functions of public administration, to include between its functions the guarantee of sustainability in land use and equip it to accomplish its function.

If a significant part of the revenues of the municipalities, as in Valencia, comes from urban development and land speculation, it will never be possible to rationalize land use with sustainability criteria.

4.3.2   Green infrastructure in the territory of the networks

In the territory of the networks it's necessary to guarantee a new network: the green infrastructure. The green infrastructure should consist of the territorial spaces that contribute to the ecological footprint (which I prefer to describe as ecological larder because they are spaces that nurture society of environmental goods) connected by ecological corridors to keep the connection between ecosystems.

Besides, public administration must be prepared to ensure the maintenance of such spaces. Creating a Natural Capital Bank (an environment power) may be an option. This bank operates under the principle of "political protection and technical safekeeping". That is, the legislature decided to protect spaces so justified. Once an area has been protected, the safekeeping corresponds to the Natural Capital Bank (independent of political power) and you cannot remove the protection.

4.3.3 The CAP towards 2020

At the moment, it is in process the new Common Agricultural Policy (EC, 2010). The base document, The CAP towards 2020: Meeting the food, natural resources and territorial challenges of the future, structure the new policy around three strategic aims: food security; quality, value and diversity of food; and employment.

These strategies involve changes in food security, environment and climate change and territorial balance.

Particularly, the new CAP includes what "The active management of natural resources by farming is one important tool to maintain the rural landscape". And, according EU 2020 Strategy, "Targeting support exclusively to active farmers and remunerating the collective services they provide to society... ".

All these approaches are according with objectives for maintain the periurban agricultural areas as L'Horta de València.

But finally, the success of this new policy is strongly conditioned by the management system for application the European funds and efficiency of public institutions responsible for its implementation. For example, no sense in applying EU aid for maintenance farmland when no safeguards to protect such spaces against its urban development in the future. To avoid these situations can be useful contracts for land stewardship.

5 CONCLUSION

The agricultural land of L'Horta de Valencia is a particular landscape with high value environmental, economic and as heritage. Also it is a symbol of natural resources that its necessary to maintenance for the futur.

Although their values are recognized by the Valencian society for a long time, yet the regional government has not been able to establish an effective system for protection and management.

It is a paradigmatic case of inability to solve problems of sustainability in metropolitan area. To progressively correcting environmental bubble it is necessary to solve the contradiction between sustainability and immediate individual interest.

The building land market is not efficient to optimize the location of uses in the territory. So its necessary reviewing theory property to achieve sustainable progress.

Finally its necessary reviewing the system of governance of territory for to adapt public administration to new functions (garantee of sustainability) with new tools (e-governance) in the territory of networks.

The new European CAP can help make changes if appropriate tools are implemented.

1 ABSTRACT

In spite of a strong tradition in spatial planning and ambitions to create compact cities, most rural-urban fringes in the Netherlands have seen substantial urbanization in recent decades. Urban expansions at the rural-urban fringe have formed complex hybrid landscapes consisting of residential areas, commercial zones, agricultural land, recreational functions and natural areas. These hybrid landscapes are characterized by great diversity in size, density, form and composition. Moreover, the urban developments in the rural-urban fringe take divergent forms in different urbanized regions. This paper analyses recent developments and urbanization patterns at the rural-urban fringe in the Netherlands. In some regions the urbanization is rather compact and concentric, whereas other regions show dispersed and polycentric morphological patterns. Paradoxically, at the local level, urban compaction policy seems quite successful, whereas at the regional level, local developments add up to traditionally unwanted urban development patterns. Moreover, the ongoing urbanization at the rural-urban fringe has been entailing many spatial, environmental, financial and social problems. Therefore, recent suburbanization and uncertainties concerning future spatial developments at the urban fringe raise some complex policy and design issues on the local, regional and national scale. At the national level, an important question is how increasing dispersed urbanization will affect the most urbanized regions in the Netherlands, in terms of both the economic performance of cities and the efficient use of existing infrastructure. At the regional level, there is a need for urbanization strategies that transcend municipal boundaries. At the local level, developing and deploying inventive urban (re-)design strategies to improve the spatial and functional quality of the rural-urban fringe are a challenge for local authorities and urban planners. Important design tasks are to create areas with combined functions, to improve connections between separated functions and to upgrade the identity of places at the fringe.

2 INTRODUCTION

The Netherlands has a distinct and internationally much acclaimed tradition of spatial planning on the national, regional and municipal level. In a context of limited space, challenges of water management and a strong demographic and economic growth, Dutch planners and policy makers have strived for compact and well organised forms of urbanization since the 1950s. Nevertheless, most rural-urban fringes in the Netherlands have seen substantial changes in land-use in recent decades. Large-scale residential areas and recreational parks were developed. Furthermore, a considerable number of commercial areas, office parks and retail centres were constructed in the surroundings of cities, mostly on locations in the vicinity of motorways. In general, the urban fringe, as in many other countries (see Bryant et al. 1982, Audirac 1999, Gallent et al. 2006), is characterized by a large degree of spatial and functional heterogeneity. At the rural-urban fringe, new urban expansions emerge next to established areas, large-scale developments next to small-scale locations and urban functions next to rural functions. Formerly agricultural and natural areas around villages and cities have slowly transformed in into a complex and hybrid landscape with a combination of rural and urban functions. Compared to other countries, most of the urban developments at the rural-urban fringe in the Netherlands take place nearby existing cities. Therefore we define the rural-urban fringe as a rather narrow area (approximately 2 kilometres) between the city and the countryside. This area is like a shell around the existing urban area and follows its irregular contours. In other countries, such as the United States and Canada, definitions of the rural-urban fringe in metropolitan areas often describe much larger areas, in some cases up to 50 kilometres.

2.1 Research questions

This paper addresses four main questions: What types of urban developments can be distinguished at the rural-urban fringe in the Netherlands? What are the morphological structures of recent urban developments

on the regional scale? How do the urban developments relate to policy ambitions to keep urban areas compact? And finally, what are future challenges for policy makers and urban planners concerning urban developments at the rural-urban fringe?

In the first part of the paper we will briefly describe the main drivers of urban deconcentration and related environmental, social and spatial effects. Subsequently, we will give a short overview of the history of relevant spatial policy in the Netherlands. In the following section, we will introduce seven significant types of urban developments at the rural-urban fringe and analyse three regions showing different patterns of urbanization. Finally, we will summarize the most important findings and conclude with identifying challenges for policy makers and urban planners on the local, regional and national scale.

2.2 Drivers of urban developments at the rural-urban fringe

In the past decades urban developments at the rural-urban fringe have accelerated in response to growing welfare, global economic forces, improved transportation links and enhanced personal mobility. This has made it possible to live and work increasingly farther away from city centres, while retaining all the advantages of central city location. In Europe today, even where there is little or no population pressure, a variety of factors are still driving urban deconcentration. Suburban residential, recreational and commercial developments are attractive for people, companies and municipalities for many reasons. Residential projects on suburban locations offer affordable houses with gardens, that are especially attractive for families with children. For companies, initial investment costs for suburban real estate locations are relatively low compared to inner city locations. Moreover, locations at the urban fringe offer good accessibility, especially for motorized vehicles. Furthermore, suburban developments have been an important source of income for municipalities and project developers in the past decades. The development of new commercial areas enabled municipalities to attract new companies and employment, and project developers could earn money with land transactions and the development of residential and business projects. On the regional and national level, the government has been facilitating these developments by financing the road, rail and public infrastructure serving new locations at the rural-urban fringe.

2.3 Effects of urban deconcentration

As described above, urban developments at the rural-urban fringe have economic benefits and offer space for commercial, residential and recreational functions. However, urban deconcentration causes a number of negative environmental, social and spatial effects. There is a general consensus that dispersed urban developments have been putting pressure on the environment. Due to the larger area consumed by suburban neighbourhoods compared to inner-city neighbourhoods, more farmland and wildlife habitats are displaced per resident (Benfield et al. 1999). Furthermore, international studies show that suburban residents generate more per capita pollution and carbon emissions than their urban counterparts because their increased personal mobility and a higher car dependency (Fuller and Crawford 2011). In the Netherlands, suburban residential areas have a relatively high density compared to other countries. Nevertheless, car-ownership and traveling distances are higher compared to inner-city neighbourhoods (Snellen et al. 2005). Next to environmental issues, suburban developments have other costs. For example, the cost of providing and maintaining streets, utilities, and other public facilities to suburban communities is significantly higher than for high-density residences in a city. Urban sprawl also separates classes of people. According to Dam et al. (2010) suburban residential developments increase segregation by income and ethnical background. Moreover, suburban developments can have significant negative impacts on neighbourhood vitality and the accessibility of the recreational land surrounding urban areas. From a more qualitative point of view, the loss of open landscapes and the lessening contrast between city and countryside are negative effects of suburbanization. Next to that, the urban fringe is frequently cut through by infrastructural bundles that create spatial barriers, resulting in spatial fragmentation. As a result, many areas at the urban rural-fringe are perceived as cluttered (Veeneklaas et al. 2006).

2.4 Current transitions and future expectations

At the present time, the rural-urban fringes in the Netherlands still have a predominantly green character (MNP 2007, Vreke et al. 2007, Piek and De Niet 2010). However, due to the developments mentioned above, urbanization is increasing rapidly. At the rural-urban fringe, various land-use functions fight over the scarce amount of space. Natural and agricultural areas have lost space to benefit the urban functions of

housing, employment and recreation. It is expected that pressure at the rural-urban fringe will remain strong in the future (Ritsema van Eck et al. 2009). Moreover, the recent liberalization and decentralization of the spatial policy in the Netherlands is expected to accelerate the shift towards the rural-urban fringe, and to make regional differences even bigger since more responsibility concerning spatial planning is given to regional and local authorities (PBL 2011). Additionally, the current financial and real estate crisis has brought an end to the large-scale and top-down planning approach that has dominated urban developments in the Netherlands in the past decades. In this context it will be necessary to take a closer look at small-scale and organic approaches to transform and develop urban areas (Buitelaar et al. 2012 and Tennekes and Harbers 2012). Considering the ongoing pressure at the urban fringe, recent changes in spatial planning policy, and ambitions to create more sustainable urban areas in the future (European Commission 2011), planning and (re-)designing areas at the rural-urban fringe is a significant challenge for policy makers and urban planners.

3 TAMING URBANIZATION: SPATIAL POLICY IN THE NETHERLANDS

In the Netherlands, the national spatial policy has had great influence at the urban developments in the country. To get a better understanding of urban – and suburban – spatial morphology it is important to have a look at the history of national spatial policy and leading concepts of spatial planning. Since more than sixty years Dutch planners and policy makers have strived for compact forms of urbanization. The aim was to keep the existing cities compact in order to avoid extensive and uncontrolled urban sprawl. In various Dutch national spatial policy documents different strategies to achieve compact urban developments have taken a prominent position (Nabielek et al. 2012). In the following passages the most important concepts and strategies are briefly described.

3.1 Buffer zones

Already in the years following the Second World War, planners and policy makers feared that cities would grow towards each other, leaving little green space in-between. Therefore, protected buffer zones were introduced in the First National Policy Document on Spatial Planning (1960). These buffer zones restricted urban developments in these zones. The first two buffer zones were located between Amsterdam and Haarlem (Spaarnwoude) en between Rotterdam and Delft (Midden-Delfland). Over the following 50 years the strategy of 'green' restriction zones was extended and further elaborated.

3.2 Clustered dispersal

Moreover, the Second and Third National Policy Document on Spatial Planning (VROM 1966 and 1978) introduced the concept of 'clustered dispersal' and 'growth centres'. This concept was guided by the idea to limit new urban expansion at the urban fringe by creating new towns that were located at a distance of 10 to 30 kilometres to the bigger cities. Some of these new settlements were completely new (e.g. Almere to the northeast of Amsterdam) and others were linked to existing small towns or villages (e.g. Zoetermeer to east of The Hague).

3.3 Compact city

In the beginning of the 1980s, the concept of 'clustered dispersal' became more and more criticised, as the new towns were dominated by a residential character and showed a lack of urban qualities, such as density, cultural diversity and mixed functions. Furthermore, the big cities like Amsterdam and Rotterdam were faced with population decline and growing socio-economic problems. The reaction to this was a re-orientation on the existing big cities that was framed by the concept of the 'compact city'. In this concept the focus shifted from urban expansion to revitalizing and densifying existing urban areas. The aim was to limit new urban suburbanization on the urban fringe. The Forth National Policy Document on Spatial Planning (VROM 1988) was based on the concept of the 'compact city'.

However, this document should not stop suburbanization. In the following period large-scale suburban neighbourhoods (so-called Vinex-locations) were planned as part of the supplement to the Forth National Policy Document on Spatial Planning (VROM 1991). These residential neighbourhoods were precisely planned in a top-down manner with relatively high densities and good access to public transport. Nevertheless, the sheer scale of developments led to massive urbanization in some parts of the rural-urban fringe, especially in the Randstad. As a consequence, the population of inner city areas should continue to

decline (Nabielek 2011). Moreover, the economy was growing strongly and municipalities were developing new commercial zones at the fringes of their cities. However, it is remarkable that large out-of-town shopping malls could be avoided due to a very restrictive policy concerning retail developments.

In the following National Policy Document on Spatial Planning, the so-called 'Nota Ruimte' (VROM 2004) the focus shifted towards urban networks and urban developments on the regional scale. This document set specific goals for so-called 'concentration areas' around greater urban conurbations and 'urban densification' in existing urban areas. Furthermore, valuable green areas were protected by national buffer zones, a national ecological network (EHS) and national parks. However, this document also left more space to local authorities and the private sector to develop residential and commercial areas.

3.4 Liberalization and Decentralization

The most recent National Policy Document on Spatial Planning SVIR (I&M 2012) strongly focuses on economic growth and large-scale infrastructural investments. Spatial planning is decentralized to regional and local authorities and national planning strategies, such as the national buffer zones, the national ecological network, urban concentration and densification, have been abolished. Therefore, it can be expected that the decentralization of the spatial policy will accelerate urban developments at the rural-urban fringe.

4 SPATIAL DEVELOPMENTS ON THE RURAL-URBAN FRINGE IN THE RECENT PAST

The previous paragraphs have described drivers of urbanization on the periphery of cities in the context of spatial policy in the Netherlands. This paragraph will provide an insight into quantitative and qualitative aspects of the developments at the rural-urban fringe. We used two approaches to the urban fringe: a strictly delineated definition to facilitate calculations based on GIS analyses and a looser approach to facilitate qualitative analyses of urbanization patterns in the region surrounding the city. In the qualitative analysis, we will describe seven types of urban developments in closer detail. Before turning to the morphological particularities, however, we will present the results of our quantitative analysis of the rural-urban fringe that maps out important land-use changes in the Netherlands.

4.1 Quantitative analysis

In the quantitative analysis we have made a distinction between existing urban area, rural-urban fringe and countryside. For this distinction we have used the definition of Hamers et al. (2009). This definition assumes that the size of the urban fringe depends on the size of the urban area: the larger the existing urban area, the broader the urban fringe becomes. In this quantitative approach, the broadest urban fringe in the Netherlands (for the urban area Amsterdam–Zaandam) is 2 kilometres wide; the narrowest urban fringe is only a few hundred metres wide. While Lucas and Van Oort (1993) used a relatively traditional concentric shell model, Hamers et al. (2009) also took explicit account of urbanization near motorway slip roads, both in the immediate vicinity of cities (circles with a radius of 1800 m) and at larger distances (circles with a radius of 900 m). Finally, the dynamics of the urban fringe are important. Due to the expansion of the urban area, the urban fringe has shifted outwards through the years. During the 1996–2003 measurement period, the urban fringe made up 14 % of the land area of the Netherlands, compared with 9 % in the existing urban area and 77 % in the countryside.

To analyse the spatial developments, we used a GIS analysis of the land-use statistics from Statistics Netherlands (Bodemstatistiek, CBS) to compare the developments in housing, commerce, recreation and nature in the three areas mentioned above, for the period 1996–2003. This comparison showed that by far the majority of developments in housing, commerce and recreation took place at the rural-urban fringe (see Figure 1). For housing, the development per square kilometre at the rural-urban fringe was over 5 times greater than that within the urban area and nearly 14 times greater than in the countryside. For commercial developments, the area at the urban fringe expanded eightfold compared with the rural-urban area and became 12 times larger than in the countryside. The area of recreation also increased the most in the rural-urban fringe: per square kilometre with nearly 6.5 times that of the countryside. In the city, recreational areas actually decreased. The increase in land use for housing, employment and recreation at the rural-urban fringe took place at the expense of space for nature and especially agriculture.
Fig. 1: Land-use changes in the Netherlands 1996-2003

4.2 Qualitative analysis: seven types of urban developments at the rural-urban fringe

Figures alone offer an insufficient basis for urbanization policy for the rural-urban fringe. For this purpose, qualitative insight into the spatial developments is also required. Which types of land-use functions seek the urban fringe, and which spatial patterns are created as a result? Before we show spatial patterns on the regional scale in the following paragraph, we present seven types of urban developments in greater detail that are specific for the recent past (see Figure 2): large-scale residential areas (Vinex-locations), small-scale residential areas, commercial areas, peripheral office parks and retail centres, recreational areas and shadowland (in-between areas). We have selected and analysed these types based on field research and literature studies. In the qualitative analysis we have studied urban developments in a larger area than the strictly delineated zone of the quantitative analysis discussed above.

4.2.1 Large-scale residential areas

Housing is one of the most dominant urban functions in the rural-urban fringe. The residential areas that are built in the recent past are primarily the large-scale suburban neighbourhoods that were planned as part of the supplement to the Fourth Policy Document on Spatial Planning (VROM 1991). Some of these neighbourhoods are planned for more than 30.000 inhabitants. These neighbourhoods can either create a new ´edge´ of existing concentric cities or have such an independent position in the urban network that they serve as new centres of a polycentric urban region (Lörzing et al. 2006, Boeijenga and Mensink 2008). A concentration of large-scale residential areas can be found in and around the four largest cities in the Randstad: Amsterdam, Utrecht, The Hague and Rotterdam. Examples of such residential areas are the neighbourhoods Ypenburg (close to The Hague), Carnisselande (close to Rotterdam), Leidsche Rijn (close to Utrecht) en Almere Buiten (close to Almere).

Although there is in general a wide variety of housing typologies and styles, these so-called Vinex-locations recently are criticized for their monofunctionality and inflexibility concerning the future urban transformation task. The large housing stock, that is developed at the same time, could also become obsolete (and thus a major transformation task) in the same period of time. Furthermore, not all areas are provided with good public transport connections and are mainly designed for motorized vehicles.

4.2.2 Small-scale residential areas

Small-scale residential developments lay scattered in the urban fringe, mostly in the vicinity of small villages and cities. They can predominantly be found in more rural areas, such as the Groningen region. Common examples of these kinds of residential areas are small neighbourhoods with detached houses. More particular

examples of these residential developments are ´exclusive´ residential neighbourhoods that are designed for certain target groups, often higher-income earners. They are characterized by clear boundaries towards their surroundings and distinctive (themed) architecture (Nabielek 2009). In some cases the residential function is a combination with recreational functions (e.g. golf course, harbour).

Although there is a growing number of residential neighbourhoods with an enclosed character in the Netherlands (Hamers et al. 2007), compared to gated communities in the United States or South America, the scale of the developments is much smaller and the gradation of enclosure relatively soft (e.g. by stretches of water). Nevertheless, these developments are examples for an increasing trend in the housing market that leads to increasing segregation by income and ethnical backgrounds.

4.2.3   Commercial areas

Next to housing areas, there is a noticeable large area for commercial purposes. Between 2000 and 2006, the total urban area has been growing with approximately 150 km² and a large part of it (60 km²) has been developed for commercial use Ritsema van Eck et al. (2009). In the area of employment, it is traditionally the nuisance-causing businesses (noise, stench) that are located at the urban fringe. However, many other types of businesses have also found their way here, especially those that need a relatively large amount of space and that must be accessible by vehicle. Many business estates have been developed in the in the immediate vicinity of motorway junctions and exits. They often fill up the leftover areas between the motorway and housing areas. In some areas, however, commercial parks are located at a larger distance of existing urbanized areas, for example the area of Schiphol airport. The extend and type of the development has led to severe critic of the Dutch society. On the regional scale, there are complaints about the ´filling up´ of open spaces (mostly along infrastructure) and the lessening contrast between city and countryside. On the local scale, business estates are characterized by a very functional design and lack basic urban or architectural qualities (Van der Gaag 2004). Furthermore, business estates without a connection to public transport that are designed for vehicles have a negative impact on the environment as they increase pollution and carbon emissions. Another problem is the growing number of decaying business estates with vacant plots and buildings.

4.2.4   Office parks

In recent years, there has been a strong growth of office parks at the rural-urban fringe in the Netherlands. Headquarters of national and international companies used to be located in the city centre but today one can find them increasingly on the urban fringe of big and medium-sized cities and along motorways (Hamers & Nabielek 2006). Statistically, office parks often belong to the category ´business estates´, but spatially their dynamic development and architectural layout is different. Between 2000 and 2006, the number of peripheral office clusters has been increasing significantly in comparison with other employment areas, namely with 26 per cent compared to 3, 5 per cent of all employment areas. In a spatial sense, the total surface area of office parks is relatively small. Office parks have, however, usually are eye-catching structures with high-rise buildings that are visible from far away. Some office parks are carefully designed in relation to their surroundings including a park-like setting that is accessible for the public. Examples are the office park Papendorp at the motorway junction Oudenrijn (Utrecht) or De Hoef at the motorway junction Hoevelaken (Amersfoort).

Currently, there is a record of vacant office space in the Netherlands. In 2012, more that 7 million m2 of office space was vacant, that is almost 15 per cent of the total amount of office space in the Netherlands. New peripheral office parks contribute to the high vacancy rate because they attract firms that are already settled in office buildings elsewhere in the Netherlands. Furthermore, office parks are primarily designed for car access and therefore foster commuting. They therefore entail a negative impact on the environment in general and in particular on their surrounding (noise, pollution).

Large-scale residential areas (Vinex-locations)

Small-scale residential areas

Commercial areas

Office parks

Retail centres

Recreational areas

Shadowland (in-between areas)

Fig. 2: Seven types of urban developments at the rural-urban fringe

4.2.5 Retail centres

The development of commerce near motorways on the urban fringe is especially apparent: commerce on the urban fringe as a whole has already grown much more than in the cities, but at motorway locations, the development is even greater. There has been a particularly striking increase in the number of large garden centres and in furniture centres in existing and new out-of-town retail centres such as 'factory outlets centres' and 'retail parks' (Hamers and Nabielek 2006). However, compared to other European countries, it is remarkable that large out-of-town shopping malls could be avoided due to a very restrictive policy concerning retail developments.

In general, retail areas have a very functional layout. In most of the cases, the public space is poorly designed and dominated by parking spaces. Like business and office parks, they put pressure on the environment by

contributing to the increase of car traffic. Furthermore, peripheral retail centres can have a negative effect on the existing retail structure in, for example, inner city locations. Therefore, the matter of new peripheral retail centre is highly political. In 2009, a referendum of the population of the city of Tilburg has stopped the development of a large shopping mall on the northern edge of the city.

4.2.6 Recreational areas

As stated previously, the area for housing and employment at the urban fringe has increased the most. In addition, the area for recreation is also growing. Recreational land use can have both a 'red/urban' and a 'green/rural' character. There is a difference between buildings or structures with a recreational function (indoor) and outside areas with a recreational function (outdoor). Examples of the first group are ski halls, thermal baths, mega cinemas and examples of the second group are sports grounds, allotment gardens, natural areas and parks. Indoor-facilities are mostly located in the vicinity of motorways and are equipped with larger parking areas as they sometimes have high concentrations of visitors. In the category of outdoor-facilities, the growing number of larger peripheral golf courses is particularly striking. Between 1998 and 2006 the total area of golf courses has increased from 1.300 to 7.300 hectare (Schuit et al. 2008). A third important category is the clustering of vacation homes, mostly concentrated in recreation parks.

The footprint of indoor recreational facilities is much smaller than outdoor recreational functions. However, large-scale and 'stony' buildings and complexes, such as large indoor playgrounds built in open areas, can negatively affect the original landscape around the city. Other developments are more compatible with the landscape, such as the construction of bicycle paths. Another problematic issue is the construction of so-called vacation villages – a cluster of vacation houses – because they contribute to the urbanization of rural areas.

4.2.7 Shadowland (areas in-between)

In-between areas are characterised by administrative and spatial fragmentation. In many cases, large-scale infrastructure is cutting through these areas and new, established, small and large functions lay like randomly distributed in the area. This so-called ´Shadowland´ can be often found in the urban fringe. It is characterised by the coexistence of different functions that have little in common (Frijters et al. 2004). Shadowland has an organic, unplanned layout and the quality of public space is mostly poor. Shadow land is therefore often perceived as ´untidy´. On the other hand, these areas offer opportunities for small-scale local activities for which there is currently little space in the inner city such as artist ateliers, allotment gardens and sport fields. In recent years, however, many Shadowland areas have been transformed into (among others) business parks or commercial areas.

The usual way to transform Shadowland is mostly by demolition and new building. In doing so, however, local activities that may have a positive effect on the area in the long term are banished. A more sustainable way to transform Shadowland could be to strengthen the local identity and landscape qualities and to improve (public) transport connections.

5 REGIONAL COMPARISON

In this part of the paper, we will analyse the morphological patterns of recent urban developments on the rural-urban fringe in three Dutch regions: The Amsterdam region, the Rotterdam-The Hague region and the Groningen region. These three regions were selected because they show different types of urban regions. The Amsterdam region is an example of a monocentric city region in which smaller cities are clustered around a dominant city. The Rotterdam-The Hague region has a polycentric structure with to big cities of more or less the same size. Finally, the Groningen region is an example of a monocentric medium sized city in a rural region. On the regional scale we can get an impression of the scale, location and spatial patterns of urbanization at the rural-urban fringes. On the maps we can distinguish where the urban expansions are compact and where they show a dispersed structure.
Fig. 3: Urban developments 1989-2003 in the Amsterdam region

5.1 Amsterdam region

With its monocentric structure, the city of Amsterdam is a typical example of a compact European city. Together with the surrounding smaller cities, it forms a polycentric region in which Amsterdam clearly takes a central and dominant position. The map of the region (see figure 2) shows that there have been very few urban expansions on the fringe of the city in the past 20 years. The map shows that Amsterdam is surrounded by green buffer zones that have successfully protected these areas from suburbanization. Furthermore, in the south of Amsterdam, the airport and the related noise contour has limited possibilities for residential expansions areas. In the surroundings of the airport, however, the map shows a strong dynamic of new business locations.

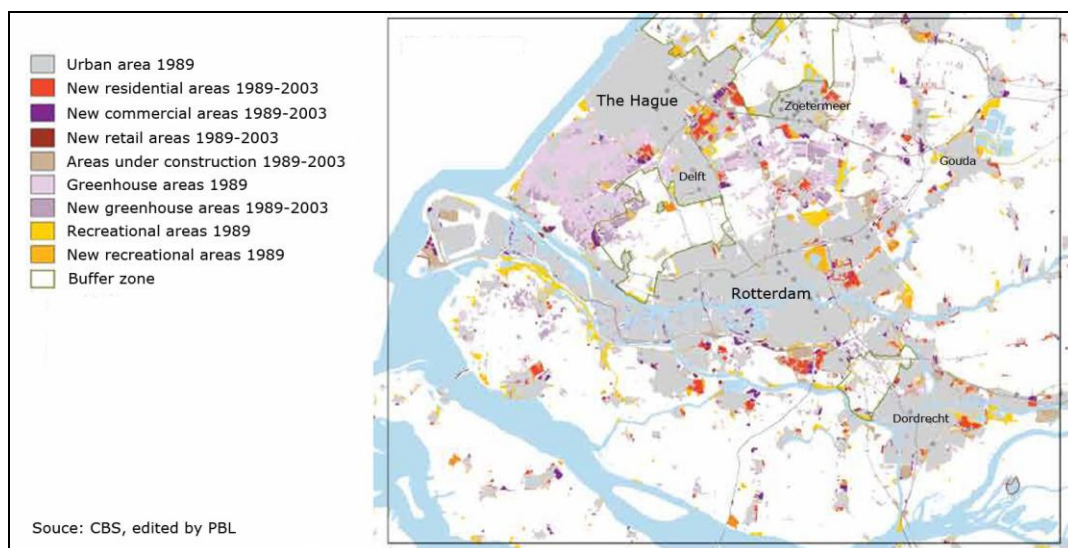
Looking at the urban developments in the Amsterdam region, it can be argued that the developments are in line with the national concentration policy. The city has very much kept its compact character and the green buffer zones have protected Amsterdam from growing together with neighbouring cities. However, the smaller cities in the surrounding, such as Haarlem, Hoofddorp and Almere, show much larger suburban developments. Because the city of Amsterdam could not expand on its edges, these expansions have shifted towards locations at a greater distance of the city. In the southwest of the Amsterdam region we can see that a ring of continuous urbanization emerging between smaller cities. Moreover, decentral locations in the regions, such as large-scale expansion areas around the newtown of Almere (more than 30 kilometres away from Amsterdam), have put serious pressure on the road system in the Amsterdam region. If we look at the urban developments at the rural-urban fringe on the local and on the regional level, we can conclude that the concentration policy has had positive as well as negative effects on the region.


Fig. 4: Urban developments 1989-2003 in the Rotterdam-The Hague region

5.2 Rotterdam-The Hague region

The Rotterdam-The Hague region can be described as a polycentric urban region with two big cities. With 600.000 inhabitants Rotterdam is slightly bigger than The Hague (500.000 inhabitants). Smaller cities in this region are Delft, Zoetermeer, Gouda and Dordrecht. Furthermore, the region is characterized by large areas of greenhouses for the production of vegetables. The map of urban developments in the region (see Figure 4) shows there has been almost no urbanization between Rotterdam and Delft. In this area, the open landscape has been protected by the national buffer zone of Midden-Delfland that has been established in 1960. However, there have been strong urban dynamics in the area between Rotterdam, Zoetermeer and The Hague. The urban developments are a combination of residential and commercial (mostly greenhouses) functions. In these areas, a new local railwayline has been established in to connect Rotterdam with The Hague. New residential neighbourhoods were constructed along this line. This has led to a fragmented, spread out morphological pattern that is quite unsusual in the Netherlands. Furthermore, we can see a number of new large-scale residential areas in the Rotterdam-The Hague region. These areas are located at the urban fringe of the cities. In Rotterdam and The Hague, these large 'Vinex-locations' were built on the 'other' side of the motorway. In these cases, the motorway forms a strong spatial barrier in the urban structure.

5.3 Groningen region

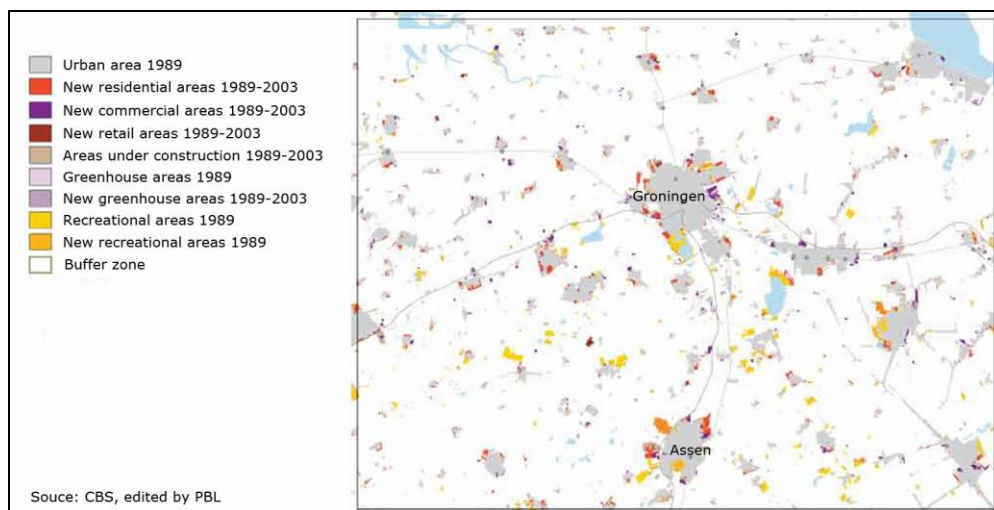
The city of Groningen has, like the city of Amsterdam, a monocentric structure. The urban expansions on the urban fringes in the period between 1989 and 2003 in the Groningen region (see figure 5) are comparably modest and mainly concentrated around Groningen and surrounding small towns. The majority of peripheral developments are new residential neighbourhoods that are situated concentrically around the historic towns, directly next to established urban areas. However, the small town Assen seemed to have faced a relatively strong growth in the recent past. In comparison the size of the existing town, the new development areas on the western and northern side of Assen are relatively large; on the western side, over the A28 motorway, there is a new residential area (Kloosterveen) and a large golf course. In the east of Assen, the National Landscape Drentsche Aa has prevented urban expansions.


Fig. 5: Urban developments 1989-2003 in the Groningen region

6   CONCLUSIONS

Looking at the urban developments in the Netherlands in recent years, we can question how they relate to the aim of keeping urban structures compact. We can observe a strong shift towards a highly urbanized rural-urban fringe. In general, we can observe that new suburban residential areas are rather compact and are located close to cities, whereas new commercial and recreational areas show a more fragmented pattern. Paradoxically, at the local level, urban compaction policy seems quite successful, whereas at the regional level, local developments add up to traditionally unwanted urban development patterns. The maps in this paper show that diverse local expansions can result in contiguous urbanized regions. Moreover, we can see

significant regional differences. In more rural areas, such as the Groningen region, the new urbanization shows a very compact structure. However, in regions with a more polycentric urban structure, such as the Rotterdam-The Hague region, we can see that spaces between cities and villages have been filled up with new urban developments that show a much more fragmented morphological character.

With an outlook on future spatial planning tasks at the rural-urban fringe, it will be important to anticipate on regional differences due to specific regional developments and conditions. For example, the expected spatial need for housing and employment in the north and the south of the country is expected to be much lower than in the Randstad. Therefore, generic planning concepts appear to be inadequate for steering urbanization in the desired direction. The recent liberalization and decentralization of spatial policy in the Netherlands is in line with this observation. However, it can be expected that the liberalization will strengthen the trend of an increasingly dispersed urbanization and will make regional differences even bigger. In this context, re-designing existing suburban areas and planning new developments on the rural-urban fringe raises some complex policy and design issues on the local, regional and national scale.

6.1 Challenges on the local scale

The qualitative analysis and the maps in this paper show that many recently developed urban areas at the rural-urban fringe are characterized by function separation and single functionality. As a result, from a morphological perspective, the urban fringe clearly differs from inner-city locations, where, for example, housing and businesses are mixed together within the same area much more frequently. At the urban fringe, there are many new areas with divergent functions located next to each other as distinct spatial entities. In many cases these entities are separated by infrastructural bundles (often large-scale) that create spatial barriers, resulting in spatial fragmentation. In addition, the barrier effect of infrastructure (together with aspects such as large business estates) limits the possibilities of urban residents to reach the countryside easily, for example, for recreation.

Considering ambitions to create more sustainable and more liveable urban areas in the future, it is an important challenge to improve the quality of existing and new areas at the rural-urban fringe. In many urbanized regions in the Netherlands, urban, recreational and natural programmes will occur in combination in the future, which is a challenge not only for regional and local planning but also for local design. Therefore, local authorities, urban planners and architects should pay attention to developments at the rural-urban fringe and come up with strategies to create multi-functional areas with shared facilities, to improve connections between separated functions and to upgrade the identity of places on the fringe by, for example, supporting small-scale local activities that have a positive influence on their environment. Concerning commercial functions attracting many visitors, such as retail centres and recreational areas, a relevant task is to improve the quality of the public space in such areas. Finally, in times of decentralization and financial crisis it will be necessary to have a closer look on inventive small-scale and bottom-up strategies to enhance the quality of areas at the rural-urban fringe.

6.2 Challenges on the regional level

Within the region, parties must take account of differing urban, recreational and environmental tasks for each municipality. For example, one centre can be faced with severe green restrictions, while another can accommodate urban expansion more easily. To acquire a sharper image of the specific planning and design tasks, the spatial needs, together with the conditions for urbanization and the policy and nuisance restrictions, will have to be mapped out region by region. If a region wants to deal with problems as successfully as possible and take advantage of opportunities where possible, then planning will require cooperation at a regional scale. It is advisable to develop an urbanization strategy for the rural-urban fringe that transcends municipal boundaries, that focuses on the regional interest and that provides room for sub-regional differences. Within such frameworks, integral regional development projects can then be implemented at a lower scale. Although transcending municipal boundaries has, in the past, proven to be a formidable challenge (competition still seems to be more widespread than collaboration), experience with such an approach is currently being gained in various regions of the Netherlands, in terms of long-term strategic planning and (temporary) changing governance alliances.

6.3 Challenges on the national level

An important question is how increasing dispersed urbanization will affect the most urbanized regions in the Netherlands, in terms of both the economic performance of cities and the efficient use of existing infrastructure that are important policy objectives of the national government. For instance, whereas urban growth can lead to the desired agglomeration effects, increased urban sprawl can negatively affect various aspects of the environment and the quality of living (which is a basis for an attractive business climate). One way or another, a balance will have to be struck between a certain 'critical urban mass' that is needed to reach agglomeration effects and some form of urban containment that will guarantee desired levels of quality of living (e.g. clean air, proximity of natural areas). The outcome will differ from region to region, depending on the amount of space needed for urban land use as well as regional decisions on where exactly urban development will be allowed to take place: within existing urban areas, at the urban fringe or further out. In a quantitative sense alone, urban planning will be an enormous task (especially in the Randstad). Moreover, in the light of issues such as the loss of open landscapes, the lessening contrast between city and countryside and poor accessibility of the recreational land surrounding urban areas, there is an additional qualitative task that should not be underestimated. To face this challenge successfully, the urban fringe requires special attention. Sector-based policy for housing, employment, infrastructure, recreation and nature will remain necessary, but an integral spatial policy is also required where the possibilities and limitations are viewed in relation to each other, transcending the boundaries between policy dossiers.

The Slums Affect the Future of the Metropolis

Sonia Pintus

(Sonia Pintus , PhD in Land Engineering, Department of Civil and Environmental Engineering and Architecture – DICAAR, University of Cagliari, Sardinia, Italy, soniapintus@unica.it)

1   ABSTRACT

This work is part of a research in progress: in particular it is aimed to tackle the problem of uncontrolled city growth. Urban sprawl has recently become a critical issue not only from the spatial point of view, but also for overcrowding.

The main objective of this study is to point out the need for a proper planning of the largest urban areas in the world by means of a strategic project. Also, the need for a functional organization of the so-called slums is worth considering.

Slums are usually left out from the well-organized urban system. Although they can easily be identified within the city, they are not formally recognized from the perspective of soil occupation and the related social issues.

In the light of this, planners are increasingly given important responsibilities as well as a set of different tasks. In fact, besides the multi-disciplinary approach, they should deepen the correlation between space and the population.

The explosion of megacities, along with the prospect of further settlements in the world, involve a mixture of people, cultures, religions, education, interests, and technologies which undermine the traditional planning methodologies. In fact, this situation affects the functional integration and the development of a participatory process.

This research in progress would provide new methods and new models so as to analyze the phenomenon, both large-scale and the small-scale aspects.

2   MIGRATION TO THE CITY

2.1 Population growth

The world population is rising very fast, in fact, now about half live in urban centres. Census data in 2010 indicate that cities are home to 3.5 billion people, which is 50.5 percent of the world. The growth of cities is one of the most significant phenomena of our time. Most of this massive urban growth will take place in Asia, Latin America and Africa. The total population presents one overall measure of the potential impact of the country in the world and within its territory. In general the movement of large masses of the population is determined by the hope of improving their living conditions.

This rapid and massive urbanization poses serious problems for countries in the developing world that need to find means and policies to provide essential services to their growing populations. „When cities fail to satisfy these basic needs, it creates areas known as slums, which usually lack drinking water, safe sanitation, durable living space, or the safety of a lease" (Worldwatch Institute, 2012).

Migration in the cities poses complex problems with regard to the management and governance of urban areas in fact the rate of growth in demand for goods and services will become much higher than that expressed by the capacity of government and response from the authorities.

The result of this differences will be the rapid expansion of slums that are the most obvious expression of urban poverty.

2.2 Slum's space

„Probably in the world there are more than two thousand slums with a population living there that ranges from some hundreds to more than one million" (Davis, 2006).

The comparison between the most recurring settlement typologies points out the lack of an organic pattern and technically functional to the settlement. The layer building in following times takes to the occupation of all the available spaces, without any distance, heights, road space regulation, and the environment safeguard.

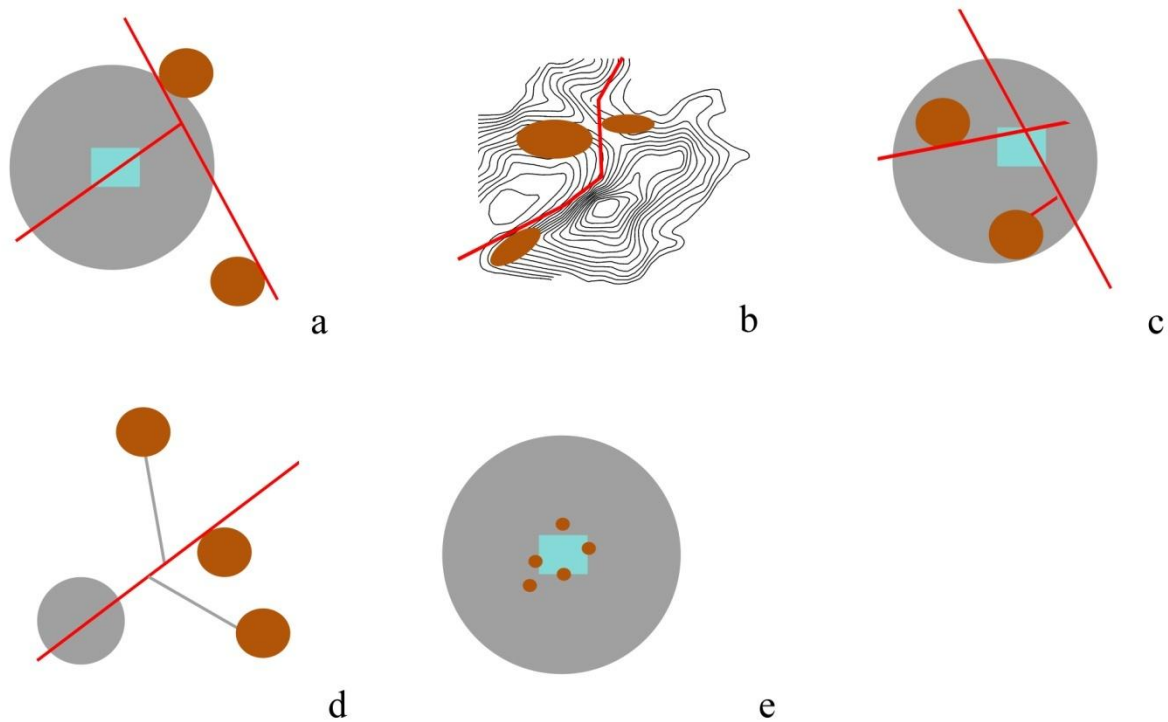
A first reading of the settlement pattern in relation to the city leads to the following graphic synthesis (Fig.1):


Fig. 1: Graphic synthesis of the types of slum

Peripheral slums (Fig.1.a): they take a side position compared to the urban centre, they are often next to a road infrastructure linking to a financial and productive centre of the city.

Hillside slums (Fig.1.b): are characterized by the precariousness of the training site. Generally these are the surroundings of the steep hills (for example favela of Rochina a Rio de Janeiro), alluvial soils, overall areas with a high risk of natural disasters.

Inner city slum (Fig.1.c): they are located in the empty spaces of the existing urban structure (for example Dharavi slum in India) or they are incorporated in the city process of expansion.

Satellite slum in the wide area (Fig.1.d):they are far away from the city (for example, refugee camps) next to a main road or to secondary roads linking to the urban centre.

Gentrification (Fig.1.e): they are typical suburbs and urban centres areas. They are characterized by a cycle "degradation – requalification, and they are used alternately by the immigrant population and high-income population.

In "Planet of slums" Mike Davis represents the comparable models of rational choice that can be found in all cities (Table 1). He identifies a number of specific types of ownership and settlement and also he said: the table below is „an analytic simplification useful to set a global comparability, but it does not take into consideration locally important characters".

Table 1: Typology of slum (Source: Davis, 2006)

It is difficult to take an action for a reconversion apt to guarantee the minimum civil living standards, without a strong action able to dimension the population density and the use of soil for public and collective aims. If the conditions to move outside the slum part of the overcrowded inhabitants do not come up, it will be easy to think about the only option of widen the building action areas. It is probably also one of the reasons why the slums do not come into the strategic projects of great areas. Those projects that should express a strategic vision of the metropolis and a sustainable mission of the territory infrastructure, supported by a financial policy of public intervention.

3 TWO EXAMPLES OF REFERENCE: DHARAVI (MUMBAI) AND ROCHINA (RIO DE JANEIRO)

To get a first evaluation of the relationships on the wealth status of the population, it is indicating a data that compares the recorded urban population with that one which we assume to be informally settled in the slums.

(Table 2). Two significant examples that are examined here are: the case of Dharavi slum in Mumbai and the case of favela Rochina in Brazil. The two examples are not comparable to each other in terms of differences for the population structure, types of urbanization and cultural factors but they have also analogies in the economic aspects, settlement growth, poverty, humiliation, degradation. However, there are differences on the typological profile: settlements, or favelas, in Brazil are made of masonry, with much better anthropological and relationship-wise factors; however, in India slums are constructed with metal and recycled materials. Even the actions and the state hand that point to give answers to the seriousness of the problem are different. The efforts, even if just occasional, like those taken or taking place at the moment in the Rochina's favela, are characterised by the goal to project proposals that will allow to improve the environment quality without great changings of the settlement, but especially to give a positive hope to the inhabitants. It is as well important to point out that in India there is a common policy to accept the state of things as they are to enjoy "the induced effects", in a relationship cost and benefit between city and slum; in Brazil the state of things is different under this aspect because the contest exploitation is less clear.

Country	• Urban population (thousand)[1]	Percentage living in slums (%)	Slum population (thousand)	Year
India	341247	32,1	109540	2007
Brazil	163462	28,0	45769	2007

1 United Nations Department of Economic and Social Affairs Population Division – World Urbanization Prospects: The 2007 Revision

3.1 The case of Dharavi in Mumbai (India)

India is an ancient nation and more than a billion people live there, one sixth of the world population. Mumbai, also known as the "city of dreams" is the financial heart of the country. The mirage of wealth caused a population explosion: in ten years the population increased from 9 to 14 million people. This has led to an overcrowding of colossal proportions and to the creation of one of the Asian largest slums: Dharavi (Fig. 2). Mumbai suffers from one of the most desperate urban poverty than any other part of the earth.

„The reality is that over one half of Mumbai's population live in conditions of abject poverty, squalor and deprivation (...) the poor live in overcrowded slums and hutments, on pavements, along railway tracks, beside pipelines, under bridges, on ill craned marshlands and in other vacant spaces available to them. Although not strictly categorized as "slums", many others live in relatively old and dilapidated single room tenement chawls (..) The slums and hutments are located in highly polluted and unhealthy environments as a result of proximity to industrial emissions and effluents, and/or from poorer sewage, drainage and irregular garbage clearance" (Byrne, 2001).

Fig. 2: Slum of Dharavi in Mumbai (India) (Source: http://news.bbc.co.uk).

In the slum of Dharavi a million people live in less than two square kilometres. The state capital of Maharashtra, in the south west, is both an economic centre and the poorest place in the entire India. In the eighteenth century, Dharavi was a fishermen's island and slum, it subsequently emerged from the mud without any planning and infrastructure. Although it is impossible to live there, it still is a place full of life. Among the slum and narrow constraints there is a „ city within a city". Inside Dharavi, divided into sectors, in fact, work activities such as: plastic recycling, metal processing, textile take place. These activities made the slum community economically independent. „India is full of human energy and talents which could be positively gathered without too much bureaucracy, (Gleaser, 2011).

3.2 The case of favelas in Rio de Janeiro (Brasile)

„Brazil presents a very contradictory image to the outside world. The seductive face of Brazil is represented by its music, soap operas, football, innovative cities like Curitiba, and, of course, the delirious aphrodisia of Carnival. However, Brazil is also the daily violence of its cities and the misery of its countryside. It has the world's highest national ratio of socioeconomic inequality" (Davis and Monk, 2007).

Rio de Janeiro is one of the biggest cities in the world and there are more than 600 favelas, most of them are in the north and west parts of the urban centre. In the south, on the contrary, it is located what is considered by most the biggest bidonville of Brazil and of Latin America in general, Rochina's favela. It is a detached administrative region which stretches for 1,44 square kilometres. It arose at the beginning of the thirties, at first it was made of a few wood or recovered materials huts, basic facilities, like water and electricity were illegal. Nowadays, however, most of the buildings are built with bricks. Just like in many other favelas the

inhabitants live from informal productive activities, with a high unemployment rate that is one of the highest in the country. In addition to that the same inhabitants suffer a condition of discrimination and isolation.

In Rio de Janeiro there have been several attempts to improve the favelas: projects to make better housing conditions, to redevelop the landscape, services and networks (Fig. 3).

Fig. 3: Project of Arch. Frederic Druot to the favela of Rochina (Rio de Janeiro).

Starting from a precise diagnosis of the urban organisation and of the existing buildings, the project recommended by the Architect Federic Druot, aims at transforming and adapting a situation of fragility by rebuilding the existing precarious housing.

The objective is: to offer smarter, brighter, more comfortable surfaces providing the housing of basic services.

4 CRITICAL ECONOMIC AND PARADOXES

4.1 Cultural factors: indicators of perspectives and integration

„The fastest and most dramatic process of urbanisation in history takes place in the marginal areas, illegal settlements and slums of the metropolitan areas of the developing countries. Because of globalization and of the unequal development million of people are forced to live in a physical and social misery that is reaching a point of idealogic disaster" (Schmidt, 1998).

The traditional planning must take into consideration the consequences of the metropolis expansion and of the perspectives that come from further settlement aggregations. They take place through a mixture of different populations, cultures, religions and technologies. The possibilities of creating a condition of functional integration and of a shared development seem to be rare. In its historic evolution, the city tries to keep in itself all its qualities by defending its own social and economic features. This is the reason why mass immigration is seen as a threat for the cultural identity of the consolidated groups and a factor of pollution of the reached quality of life. The difficult relationship between residents and immigrants has a negative effect on the city organisation. Informal settlement, or slum, suffers discrimination between the welfare state and poverty. The social and cultural contradictions are due to an uncontrolled growth and they appear also in the building typologies and in the urban pattern.

4.2 Determinants economic factors: GDP

„A nation's GDP (Table 3) rates is the sum value of all goods and services produced in the country. This is the measure most economists prefer when looking at per-capita welfare and when comparing living conditions or use of resources across countries" (IndexMundi, 2010).

„Cities are the motors of economic growth and social development; they claimed the industrial and commercial development around the world" (Dogan – Kasarda, 1988), where new forms of activities and economic organization evolve and acquire a greater value. Metropolis are, therefore, responsible of a significative portion of the Gross National Product and the main sources of development opportunities. Although the metropolis economic development is linked to the informal economy, which grows through the companies working there, in part or totally, out of the legal system, ignoring any health, environment and labour security regulations.

The informal employment is a widespread phenomenon, especially in development countries where growth is strong for the presence of immigrants. They are the poorest part of the society and they accept extreme working conditions. The levels of informality vary from country to country: in Brazil, for example, „informal economy accounts for 40 % of the national GDP (compared to 13 % in China and 23 % in India)" (McKinsey Quarterly, 2011). The size of these realities is incredible. Often activities which characterize the informal market are: recycling plastic, manufacturing, ceramics.

The informal sector generates many micro companies almost always strictly connected to the productive cicle of the great companies which are part of the productive system projected into the local market and above all on the international one.

„In the developing countries the high weigh of the informal work reduces their capacity of gaining benefits from an opening to trade and it creates poverty traps for those working temporarily" (ILO, 2009).

Even though trade contributes to the world's growth and development, it does not take to better working conditions. In order to create new quality working positions, the opening of trade should necessarily come together with national appropriate policies. It is, therefore, particularly evident because, in a time of crisis like the present, thousands of workers have found a place in the informal economy.

Country	GDP (Gross Domestic Product) (Billion $)	Year
India	4,515	2011
Mumbai	**209**	2008
Brazil	2,324	2011
Rio de Janeiro[2]	**96**	2011

Table 3: Gross Domestic Product (GDP) (Source: CIA World Factbook, 2012)

4.2.1 The Gini index for inequality

One of the largest impacts of the economic crisis are social inequalities. These last can be measured by the Gini coefficient, which measures the deviation from the wealth (or consume) among people inside a country, through a value equal to 0, which represents the absolute equality, and a value equal to 100 which defines the absolute inequality (Table 4).

Country	Gini Index	Year
India	36,8	2005
Brazil	59,3	2009

Table 4: Gini Index (Source: World Bank, 2011)

A social policy in Brazil has had a significant impact on the reduction of inequalities in the country. Strong changings have taken place, particularly during the eight years of Lula's presidency (2002 – 2010) Who, for the first time has included the poor people in the economy, leading the country to a strong lowering of the poverty rates. Furthermore, this changing is connected to the supported development plans. Among which

---

2 http://www.ibge.gov.br

Borsa Familia: a benefit given to mothers exclusively supplied with the guarantee of a regular school attendance of their children. The strong changings, which are taking place in the country take it to be an important symbol of an attempted development which aims at cancelling poverty and reduce inequalities. .

4.3 Slum productivity

The informal economy will be a permanent character of the metropolis economy in the near future, as strictly connected to the massive arrival of immigrants. Paradoxically the breaking of the balance between city and slum could lead to a lowering of GDP and to the unemployment of the slum workers.

„In 2007, the Ministry of Finance, the Government of India, constituted a High Powered Expert Committee to examine various aspects of making Mumbai an International Financial Centre. GDP in Mumbai (estimated in PPP terms) was $209 billion in 2008 that makes GDP per capita at $10,800" .

The incidence of the city on the country's GDP is 4.63 %.

„Mumbai needs to become the first world city that can attract the brightest minds of the world by being an attractive place to live, work and play" (High Powered Expert Committee on Making Mumbai an International Financial Centre, 2007).

In Dharavi is case, it is clear how it can be convenient to keep a mass of "precarious balances", in a reality of social and structural contrasts rather than running the risk of the same metropolis "medium term" breakdown. In an international competitiveness environment if the game rules between the established city and the slum's system, in some way egoistically efficient, were modified.

5 CONCLUSION

Either from an architectural or urban point of view, it is taking place a deep historical changing „an overcrowded city can survive in two different ways either new building areas are created or new ways of using the existing ones are invented" (Mehta, 2006).

The urban area organization should take into account the political, social, economical and infrastructural elements which, through a difficult mediation path of interests at stake, which are the core of the strategic urban planning. This is a task that the central and municipal governments bring forward even though they are aware of the more and more sudden changing of indicators and of coordinates to which refer. Taking also into consideration the fact that, the will to increase the effect of the development indicators, in order to improve the collocation in a world context, is so strong to become a priority in the urban and social choices.

On the basis of the work done so far, the research aims at improving the knowledge between the urban methodologies and of the urban sociology to evaluate if it does exist coherence between the settlement models and the land policies able to face the slum topic. In particular they want to understand to what extent the general planning models (linked to the American city) can still be effective for the problems solution and to redefine the indicators between land and population, between cubic meters and rooms, between services and community needs. Furthermore, it aims at finding the most suitable solutions according to the political and regulations situation (democratic, participating, representative democratic, oligarchic, monarchist, authoritarian) with the land potential.

1 ABSTRACT

One of the most important aspects of sustainable planning today is sustainable land use and managing city growth. Urban sprawls, regardless of reasons causing their spread, are considered as one of the biggest problems in the development of cities in developing countries.

Belgrade has been and is witnessing a wide spread illegal housing and settlements in its suburban areas during a long period. This paper will explore the genesis and growth of illegal settlements in Serbian capital, with the aim to present the specificity of informal housing areas, to give general recommendations for its improvement and to offer a possible approach for taming its further growth.

Starting points are the analysis, typology, spatial distribution and overall impact of illegal housing settlements in Belgrade territory on one hand, while on the other hand the theoretical background, related to the sustainable urban growth and sustainable urban land use will be presented.

Furthermore, the paper refers to the methodological framework given as the choice of aspects that should be treated in the process of integration of illegal settlements, while regulatory framework will point out the issues related to the shaping of settlements as liveable places. Conclusion remarks will emphasize the benefits and constraints of the chosen path for the integration process. [1]

2 ON CHALLENGES FOR DEVELOPING COUNTRY CITY, SUSTAINABLE LAND USE AND CITY GROWTH

Though the theoretical framework of sustainability concept is well known, it is significant to emphasize the importance of the issues especially addressing developing countries. According to the latest Global Report on Human Settlements prepared by UN-HABITAT, entitled Planning Sustainable Cities (2009: xxii-xxiii), there are five current and future global urban challenges, namely: demographic, environmental, economic, social-spatial and institutional. Many argue that 21st century urban planning must take place with a full understanding of these factors and emerging forces leading to new spatial configurations.

Alarming demographic challenges refer to the global trends of world. About a sixth of the world's population now lives in slums, with projections suggesting this number could double to two billion over next 20 years (UNDP-HABITAT, 2003). In 2008, over half of the world's population lived in urban areas and this proportion is projected to rise to 70 % by 2050, with almost all of this growth confined to the developing world. The annual urban population increase in developing regions is anticipated to rise to 53 million (2 %), compared to a mere 3 million (0.49 %) in developed regions. The principal problem associated with demographic trends in developing world is frequent inability of governments to provide adequate infrastructure, institutional support and public services, as well as (most critically) to generate sufficient revenues to fund these needs.

The most significant environmental challenge confronted to the cities globally is climate change, with the poorest being the most vulnerable to this threat. As recent Global Report on Human Settlements (UNDP – HABITAT, 2009: xxii) explains, high urban land and housing costs are pushing the poorest population into areas that are prone to flooding, landslides and other natural disasters, especially slums and other informal settlements. This exposure is considered only partly due to natural forces, since it can be avoided or greatly minimized by improved urban development and land use planning.

Another significant challenge is the environmental impact of the world's excessive dependence upon fossil fuels, particularly in urban areas for daily domestic use, industry, construction and especially for transportation. Dramatically increased motorization in the developing world has fuelled a form of low-

---

density development associated with urban sprawl. Since urban areas are predicted to occupy only 1.1 % of the earth's land surface in 2030, and given that urban regions may consume between 5-7 % of the total arable land by 2030, another principal problem is the forecasted aggregate loss of arable land providing important recreational and environmental services for urban communities.

The Global Report on Human Settlements (UNDP-HABITAT, 2009: 31) suggests that the recent global economic recession had a number of important economic implications for urban areas in the developing world and beyond. These include (a) general shrinkage of economic growth, leading to less funding being available for urban development and capital projects, especially for poorer developing economies; (b) higher levels of unemployment; (c) an increase in poverty levels following the rise in unemployment, which, if compounded by anticipated food price hikes and increased energy costs, will contribute to greater income inequalities and subsequent increased social and political instabilities.

Local and global forces of all kinds (economic, technological, political etc.) in recent decades have shaped urban areas in such way that spatial forms have tended toward increased fragmentation, separation and specialized functions as a result of economic drivers of change that typically lie outside the control of local government (UNDP-HABITAT, 2009: xxiii). This is especially the case in cities in the developed world, but increasingly so in developing world as well. Cities with increasing differences between high-income and lower-income areas are common in developing countries, with at one extreme, high-income gated communities being developed and, at the other extreme, enclaves of poverty and ethnic communities emerging. An additional phenomenon in developing country cities is the expansion of informal (often illegal) communities, many of them being slums, both within the city and on the urban periphery in locations that lack the most basic infrastructure, and where land prices and rents are, as a consequence, very low and more affordable to the lower-income population.

The last, but not the least on this list is institutional challenges. The responsibility of undertaking and delivering urban planning is traditionally associated with the public sector, both within the developed and the developing world. The institutions to which these planning responsibilities are typically assigned have long been under-resourced and are therefore problematic in the developing world. Urban planning has often been seen as unaffordable (and therefore unrealistic) and an obstacle to economic development and market freedom, sparking, among other things, a distrust of public sector master planning, as opposed to private sector. According to the recent Global Report on Human Settlements (UNDP-HABITAT, 2009), significant transformations in local government have recently taken place, much of them influenced by globalization. That had led to the urban political system evolving from 'government' to governance'. As the wider economic role of urban centres and their governments has drifted from geographically bounded administrative roles, the need to rescale the city-region level and introduce multilevel and collaborative governance has become increasingly apparent in many parts of the world. Another global trend has been in the area of participation. Communities have become increasingly unwilling to accept passively the planning decisions of politicians and technocrats that affect their living environments. However, within the cities in both developed and developing countries, "delivering consensus" is becoming more difficult, as societal divisions have been increasing, partly as a result of international migration and the growth of ethnic minority groups in cities, and partly because of growing income and employment inequalities that have intersected with ethnicity and identity in various ways.

Bearing all above in mind, the World Bank has recently launched the Urban and Local Government Strategy (World Bank Institute, 2012), which advocates a new paradigm aimed at harnessing urbanization for growth and poverty reduction. It states that cities, if well managed, are desirable assets to economic growth and governments must plan and act in the interests of their communities. The Strategy unfolds along several lines considered critical for cities and local governments in decade ahead, namely:

- City management, finance and governance, focusing on core elements of the city system;
- Urban poverty and slums – making pro-poor policies as priority in cities;
- Enabling urban economic growth;
- Urban planning, land and housing, encouraging progressive land and housing markets;
- Promoting a safe and sustainable urban environment, having in mind climate change and disaster management;

- Efforts to integrate the "green" and "brown" agendas;

- Effectively linking urban land use planning, urban development and infrastructure planning;

- Undertaking planning in peri-urban areas and at the regional level, particularly in the case of regional metropolitan areas and megacities.

According to the global organizations such as UN HABITAT, UNDP and World Bank, development priorities of the developing country cities must be:

- Minimizing urban sprawl and developing more compact cities served by public transport;

- Reliable infrastructure and services, including water supply, waste management, transport and communications, energy supply;

- Affordable access to land or premises in appropriate locations with secure tenure;

- A healthy educated workforce with appropriate skills;

- An enforceable legal system that ensures competition, accountability and property rights;

- Appropriate and adequately resourced regulatory framework which defines and enforces non disciplinary, locally appropriate minimum standards for provision of safe and healthy workplaces and places to live;

- Promoting equal access to services and fair and equitable provision of services;

- Advancing social integration by prohibiting discrimination and offering opportunities and physical space to encourage positive interactions;

- Assuring gender and disability sensitive planning and management;

- Political will and support in the delivery of sustainable visions, transparent administrative structures and processes and adequate and sustained institutional capacities;

- Relevant and effective regulations for the sustained management and revenue generation of urban development services.

Urban land use planning, as important component of urban planning can contribute significantly in addressing the major urban challenges discussed if led by well-informed policies based on sustainable development principles and supported by well thought out and managed follow-up actions and investments. As it is well-known, urban land use planning is based on premise that city areas have land use functions, which are typically undertaken by city authorities who apply enablement and intervention measures targeted at different types of activities the land areas accommodate, attract and generate.

Some most significant issues of the role of land use planning in addressing urban challenges are below:

- Compact urban form, which is important in reducing urban energy consumption, particularly through density and transportation efficiency; subsequently, compact urban form also reduces almost all negative emissions and saves the time and money (by reducing travel costs and congestion, increasing work efficiency, etc.). There is also a strong bond between urban form, climate change and pollution.

- Land use can help in risk assessment and reduce vulnerabity of city structure by channelling growth away from potential natural hazard areas, such as slides, coastal areas subject to sea rise etc.

- Efficient land use can help preventing disease spread, due to more efficient traffic and adequate infrastructure, above all good water supply and sewage system.

- Land use related to the city economy: Infrastructure costs per housing or work unit are much lower if urban construction land is used efficiently and benefits are associated with the density, degree of contiguity and nodality (Asian Development Bank, 2005). On the other hand, economic productivity can be facilitated through cluster development (localization, agglomeration of activities and logistics process).

- Efficient land use prevents over-consumption of agricultural land and natural environment, subsequently increasing the agricultural production and the quality of environment (e.g. by preserving forest areas).

- Spatially efficient cities can deliver affordable housing, accessible to working places, education facilities and places for leisure, and it is important for low-income city population.
- Effective land use management ensures security and social mixing and benefits to the urban poor.
- Land use planning can contribute to the local culture by maintaining the cultural landscape. Moreover, it can be important tool in enhancing cultural development through providing the space for cultural exchange, such as vibrant city centres.

At the end of discussion about sustainable urban land use, it is necessary to emphasize that land use is regarded more as a product than as a driver of economic performance. A city's function and the level of economic development play a very important role in determining the city form. The level of the overall functional development and diversification of the city and its socio-economic environment also determine land use.

The role of urban use planning, as it was stressed out above, has a leading role in taming the city growth and managing the appropriate economy of city construction land and it can help a lot in dealing with problems of informal and illegal settlements and their integration in regulated city structure.

3 ILLEGAL HOUSING AND SETTLEMENTS IN BELGRADE

3.1 General characteristics of Belgrade development

Belgrade, the capital of Serbia, is defined as an organizational, administrative, service, educational, scientific and cultural centre. Among the most vibrant economic sectors of Belgrade core area is: construction industry, processing industry, wholesale centres, as well as financial services and insurance companies and other business related activities. The economic profile of Belgrade is both oriented to the inner market as well as to the wider scene, aiming to be competitive in the country and region. Being by far the most vibrant city in Serbia over a long period, due to its diversity of economic activities, Belgrade has been and still is a great demographic magnet. According to the official statistical data, 22.5 % of the country's population lives in the city, but unofficially there are more than 25 % of country population. Such trends have never been positive neither for Belgrade, making an enormous pressure about employment and housing, nor for the rest of Serbia, leaving many towns without adequate workforce and creating negative demographic situation.

According to the Master plan of Belgrade 2021, the future of Belgrade development is oriented to fostering touristic, cultural and business potential of Belgrade by development along riverfronts. In the wider area, especially along main traffic corridors (such as highway) there is a great potential for development of creative economy – industrial eco parks, smart zones etc. Still, there are many insufficiently used possibilities, like development of tourism, culture and nodes, related to the position and intersection of European traffic corridors 7, 10 and 11.

Though city development policy is not oriented to and is not officially supporting the informal housing and economy, it is estimated that informal economy takes as much as 30 % of economic activities, mostly in the field of retail, services, catering, manufacture and even construction industry (supporting building of informal settlements). At the same time, informal housing takes almost 44 % of housing areas in Belgrade. Despite the fact, there are perfect brownfield locations in wider centre of Belgrade, (such as location Ada Huja), with good spatial development chances, the city growth unwillingly turned to the agriculture land at the outskirts of the city.

Some of the main issues related to the land use and city growth in Belgrade are:

- Illegal and unplanned settlements, which have grown and spread intensively over the Belgrade territory during more than 2 decades, with the exception of historical centre of Belgrade;
- Generally insufficient and /or weak infrastructure equipment in metropolitan Belgrade area, with the exception of core area and New Belgrade; urgent problems for the city as whole are related to the waste disposal and treatment of wastewater;
- Unfinished and insufficient traffic network, mostly manifested in lack of transit roads, bridges and mass public transport;

- Inadequate use of the most attractive areas and locations in the city, especially in the river coastal areas;
- Unequally dispersed greenery and the lack of real green network;
- Chaotic growth along the main traffic corridors.

The problem of Illegal and unplanned settlements in Belgrade region is strongly related to the other problems of city development, sometimes being a cause, but more often being a consequence of complexity of spatial, economic, social and political issues.

3.2 Belgrade illegal settlements – genesis, growth, characteristics and specificities

Although the genesis and growth of illegal settlements in Belgrade have been researched a great deal, it is not possible to form a unanimous opinion about its genesis and growth. Many authors (Hirt, 2009, Petovar, 2005, etc.) claim that the most important illegal growth in Belgrade happened during the 90s, though it goes way back to the 80', even 70', when one of the largest informal settlements in the Europe, Kaludjerica (at the North eastern periphery of the city) by that time started its expansion. The causes for the initiation of the informal growth of the city as well as its further unexpected spread and forming many settlements at Belgrade outskirts are different and are related to the specific socio political context.

The very start of the informal settlements in Belgrade, according to our research, happened during the socialistic period, in late 70' and continued in 80'. The mentioned demographic pressure on Belgrade, as the capital of former Yugoslavia, was enormous. As Mihaljevic pointed out (Mihaljevic, 1992), there was a process of "Belgradization" going on in Serbia and wider. Since the politics supported the idea of concentration and centralization of industrial, business, administrative and other activities, Belgrade had to cope with a great deal of new citizens. At one point, Belgrade took as much as 27 % of total population in Serbia. Having that in mind, it is in a way understandable that the city and its institutions could not enable decent habitation for such great number of people in short time. Great share of the new population have resolved their housing problems by getting an apartment in typical socialistic multi-family units in New Belgrade and other new settlements out of the city core. But also a great deal of new workforce was still in urgent search for place to live, so the pressure on the outskirts of Belgrade has begun, in the new form and typology of private, mostly one-family houses. During the 90's, the transition brought about fundamental changes in the sphere of housing ownership and planning regulation, encouraging private ownership, as well as the real estate market. Furthermore, the 90's was marked by extreme economic crises and high poverty of most of its inhabitants and had the negative effect on the city development (Simeuncevic, Mitrovic at all, 2012). Public sector stopped investment in housing production and maintenance, so the number of dwellings built per year dramatically declined (Vujovic, Petrovic, 2007). On the other hand, market prices of the housing in the city were too big for most citizens and new migrants to the city, economically exhausted by sanctions, inflation and unemployment. As a result, for many Belgrade's citizens and migrants the only chance for acquiring accommodation was private building of modest huts on the periphery of Belgrade (Zegarac, 1999).

The further demographic growth of Belgrade (from 1.4 to 1.6 million of inhabitants, according to the Statistical Office of the Republic of Serbia, 2002, unofficially even to 2 million), has induced the informal sprawl of Belgrade. There was a great deal of illegal construction on agricultural land on the fringes of the city, as well as in the areas inside city borders on the urban construction land designated for public use. Although the overall metropolitan area of the city has remained mostly the same, the percentage of non-built land (agricultural land, green and protected areas) has drastically decreased (Simeuncevic, Mitrovic at all, 2012). The problem was severely aggravated by the influx of approximately 200.000 refugees from the other parts of the former Yugoslavia who have settled in Belgrade. The informal and illegal construction became dominant form of housing development in Belgrade city, ignoring the urban plans and legal frame. After 2000, the share of single-family housing building decreased compared to the total number of new housing, but the informal one-family housing still remains significant.

Since the overall study of the informal growth in Belgrade has never been made, there are no exact data about it, so the estimations vary. For example Janic (1998) estimated there were about 150.000 illegal housing units in Belgrade, while others say that only 20 % of the buildings in the peripheral areas were actually regulated by some urban plan (Djukic, Stupar, 2009). Third approximation is based on the number

of applications for the legalization – 147000 illegal buildings (Petovar, 2005). We cannot take these numbers as final, since not all the owners of the informal housing applied for the legalization, while on the other hand the overall spatial analysis of the area and the approximate density increases the figures for more than 25 %.

The largest informal housing settlements of Belgrade are situated at the North Eastern and Southern Belgrade outskirts, as well as on the left Danube riverbank, expanding deeply to the north. There are other smaller settlements and scattered informal housing groups all over the city borders and within the city structure. In most settlements relatively convenient terrain for building prevails, with the exception of left Danube river bank. There is still a decent share of green areas. The concentration of buildings is the highest along the main traffic corridors. Dominant land use is for residential areas – approximately 90 % of total surface, but there is significant share of non-residential land use, such as retail, services and other commercial activities, mostly concentrated along the main traffic corridors. Traffic network is irregular and insufficient. Except the electrical network the infrastructure mostly does not exist. Some parts of the settlements are provided with water supply. Streets are narrow, without drainage and often are lined with large slope, so driving is difficult during winter period. There are almost no sidewalks for pedestrians. Since all kinds of transport overlap in a narrow corridor, safety is low. In the future, street regulation could be very difficult since it would cause massive demolishing of houses facing such streets in order to provide safe width of streets and sufficient place for infrastructure equipment.

One of the main problems about informal settlements' land use structure is lack of public spaces and services, such as schools, health and children day care facilities, which are a direct effect of illegal building process and absence of regulatory plans. Although the Town Planning Institute of Belgrade has started the draft version of regulatory solutions for whole Belgrade territory including these areas in 2011, it is not yet brought to public.

Urban structure of such housing areas is irregular and spontaneous. There is no firm urban matrix with defined size of blocks or parcels. Parcels are often irregular and of insufficient size, not enabling good orientation and position of a house towards neighbouring houses. Therefore, privacy is often threatened since the space between houses is very narrow. Architectural design shows the spontaneous nature of building – houses are simply designed and in most cases without any particular characteristic of style. Decorations are rare and often inappropriately applied. The interior organization also lacks good architectural design but housing units are functional in its simplest meaning. Unfortunately, there are no reflections to the traditional Serbian housing.

There is a variety of social background of the informal housing dwellers. In the first group there are citizens of modest socio-economic background who have moved from other parts of the country in search for employment in Belgrade and they live and own smaller one-family units. Second group are refugees and people who have moved from other ex-Yugoslavian republics during civil war in 1990s and their economic status vary, so they live both in big houses – villas, as well as in smaller ones. Third group consists of residents – housing tenants of lower economic status who live in bigger houses, but rent the apartments, while the owners of these houses are of different background. Approximate socio economic structure of the population, given above, has significantly influenced the formation of settlements and size structure of the buildings.

Concluding, it is easy to say that instead of being respective residential area, with high quality of life, great green areas and good urban pattern with minimum of planning intervention, informal housing areas are mostly perceived as impersonal and disharmonized residential area, being neither quite urban, nor rural settlements.

3.3 Typology and spatial distribution

As it was mentioned earlier, informal settlements occupy 44 % of total housing area in Belgrade, according to the research of authors of the paper (2012) [2].

Surface	Share in housing areas in Belgrade	Share in Belgrade Master plan for 2021.
5,521 ha	43.9 % of total housing areas (12,575 ha)	7.1 % of total surface treated by MP (77,602 ha)

---

[2] Research is done as a part of research project "Research and systematization of housing development in Serbia, in the context of globalization and European integrations, with the aim of housing quality and standard improvement" (TR 036034), financed by Ministry of education and science of Serbia.

Table 1: Share of informal settlements in total Belgrade territory

Belgrade informal settlements show great diversity in size, urban structure, quality of buildings, as well as in social and economic structure of its inhabitants and ownership. Even their legal status differs – some have grown completely spontaneously, while the others have continued some form of urban regulation of the surrounding. Form and structure of illegal housing often reflects the lack of proper urban and architectural design. Illegal housing does not care much about the neighbourhood – there is rare or no adjustment to the position of other buildings, public space or traffic and infrastructure corridors.

Spatial distribution is relatively even in the sense that, except for the city core and New Belgrade, every other part of the city has some kind of informal settlement. Total number of settlements is not defined, but the authors estimate there are 29 settlements of different size, position, spatial-physical characteristics and other specificities. The picture shows the spatial distribution on the territory of Belgrade Master plan for 2021 (Town Planning Institute of Belgrade, 2003), which is done before the plan was adopted (approximately in 2002).
Fig. 1: Distribution of informal settlements in Belgrade, according to Belgrade Master Plan 2021. (Dark areas present informal settlements)

Probably the most appropriate term for these settlements is 'informal', rather than 'illegal', as the houses mostly have their house number and address, land ownership, streets with solid cover, water supply electricity. They mostly lack sewage and drainage system, building permit and proper entry to the lot. Public transport is also a significant problem, especially to children and elder population.

Apart from above analysed settlements, there are 120 small Roma settlements with much less quality of life, houses that can hardly be classified as solid, mostly without any infrastructure. Social integration of these settlements is difficult but some improvements have been made lately.

The table shows the variety of settlements, their position in the city structure and main characteristics:

Name	Position	Main characteristics
1. Borča (approx.2/3)	Northern	Plain terrain, stable, high level of ground waters; street matrix partly formed and regulated, one-family housing, mixed with partly regulated legal multi-family housing settlement
2. Krnjača	Northern, by Danube left bank	Plain terrain, very high level of ground waters, street matrix partly formed, one-family housing, mixed with industry, retail and other commercial activities
3 Višnjica and Višnjička banja (approx.1/2)	North, by Danube right bank	Hilly, slope, very unstable, irregular streets and matrix, one-family housing, mixed with regulated legal multi-family housing settlement
4. Karaburma (partly)	North-eastern, close to the wider continually built Bg area	Hilly, slope, slightly unstable, street matrix partly formed and regulated, mixed with regulated legal multi-family housing
5. Mirijevo (approx.1/2)	Eastern, close to the wider continually built Bg area	Hilly, by and on afforested area, street matrix partly formed and regulated, mixed with regulated legal multi-family housing
6. Mali Mokri Lug	East-South-eastern, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed
7. Kaluđerica (approx.1/2)	East-South-eastern, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed, but mostly irregular, largest settlement, partly, mixed with retail, services and other commercial activities
8. Leštane (approx.1/2)	East-South-eastern	Hilly, stable, one-family housing, street matrix partly formed but mostly irregular, mixed with retail and services
9. Vinča (major part)	Eastern, by Danube right bank	Plain, high level of ground waters, one-family housing, street matrix partly formed, mixed with retail and services
10. Boleč (approx.1/2)	East-South-eastern	Mostly plain, street matrix partly formed, one-family housing, mixed with retail and services
11. Veliki Mokri Lug	South-eastern,	Hilly, stable, one-family housing, street matrix partly formed but mostly irregular
12. Settlement between the highway and Medaković 3	South-eastern, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed but mostly irregular, mixed with regulated legal multi-family housing
13. Padina	South-South-eastern, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed but mostly irregular
14. Kumodraž	South-South-eastern	Hilly, stable, one-family housing, street matrix partly formed
15. Jajinci	Southern	Hilly, stable, one-family housing, street matrix partly formed but mostly irregular
16. Trošarina (partly)	Southern, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed
17. Kanarevo brdo (partly)	Southern, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed, mixed with regulated legal multi-family housing
18. Miljakovac 3	Southern, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed but mostly irregular, by and on afforested area, mixed with regulated legal multi-family housing
19. Manastirska šuma	Southern, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed but mostly irregular, by and on afforested area
20. Resnik (partly)	Southern	Hilly, stable, one-family housing, street matrix partly formed but mostly irregular, by afforested area
21. Kneževac (major part)	Southern, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed, mixed with regulated legal multi-family housing and industry
22. Makiš	South-western, close to the wider continually built Bg area, Sava river right bank	Plain, one-family housing, street matrix partly formed but mostly irregular
23. Železnik (outskirts)	South-South-western, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed, mixed with regulated legal multi-family housing and industry
24. Bele vode	South-South-western, close to the wider continually built Bg area	Hilly, stable, one-family housing, street matrix partly formed, mixed with regulated legal one-family housing
25. Staro sajmište	Western, close to New Bg core area	Plain terrain, stable, high level of ground waters; street matrix partly formed
26. Ledine	West-North-western	Plain terrain, stable, one-family housing, street matrix partly formed
27. Altina	North-western	Plain terrain, stable, one-family housing, street matrix partly formed but mostly irregular
28. Zemun (partly)	North-western, Zemun core area	Plain terrain, stable, one-family housing, street matrix partly formed
29. Batajnica (outskirts)	North-western	Plain terrain, stable, one-family housing, street matrix partly formed

Table 2: Illegal settlements on the territory of Belgrade

4 GENERAL RECOMENDATIONS FOR THE IMPROVEMENT OF INFORMAL SETTLEMENTS AND WAYS TO TAME ITS FURTHER GROWTH

Recommendations and suggestions for improvement of informal urban areas in Belgrade reflect the idea of comprehensive approach to the solution, realistic according to habitants and economic conditions of city:

- Adopting the set of special laws and regulations referring the urban planning aspect of these settlements and including urban upgrading principles and indicators. They would enable the infrastructure and traffic equipment of the most of the illegal buildings and settlements with

minimum of investment. The regulations would also refer to the lower standards and 'softer' criteria than the ones defined for the rest of the city territory.

- Intensifying the production of urban land use plans for these parts of the territory, which will be the legal basis for the construction of necessary transportation, including public transport, utility and social infrastructure. The appropriate timing for making plans as well as fast implementation is crucial for the process of 'taming' the illegal – informal settlements. Planning action should quickly respond to the building initiatives, no matter if they are legal or illegal (World Bank Institute 2012).

- Definition of special fiscal instruments exclusively for these city areas, so that the citizens can do their commitments according to their realistic economic possibilities (e.g. lower payments for the use of urban construction land and infrastructure).

- Intensifying the displacement of areas with low sanitation conditions and which cannot be upgraded. (Some of them are even a threat for health conditions and social safety). It is also necessary to provide areas for displacement in urban land use plans, as well as the areas where these citizens could organize some of the economic activities that will enable them economic survival and social integration.

- In the context of climate changes, it is necessary to plan public facilities, which would provide the shelter for the most threatened groups of people, such as refugees.

- Having in mind that settlements lack social infrastructure, especially education facilities, it is necessary to enable the introduction of additional lines of public transportation or school buses that would allow children a relatively quick and safe access to schools. In this regard, it is necessary that regulatory plans provide for adequate street widths for the movement of school buses. As for the day care facilities for children, is necessary to foster building of affordable private units, since there is no chance to provide public construction land in already dense built informal areas.

- Planning the sports and recreation facilities and areas, as well as other public places, meeting the social and other needs of youth and children. The implementation should involve facilities in private sector, as well as public private partnership in this field.

- Finally, the most important recommendation refers to the set of future actions for planners and city government: a/defining the city border in order to prevent further re-use of agricultural land out of the city territory; b/fast planning action (regulatory plans) with the aim to provide planned areas for further residential needs of the city within the city border; c/preservation and acquisition such planned areas for traffic and infrastructure equipment, using the model of public and private partnership.

5 CONCLUDING REMARKS

Informal settlements in Belgrade, a city in developing country can be understood though the power/failure of public sector, legislative framework, economic conditions (Huchzermeyer and al. 2006) and institutional capacity, as well as through the complex socio-political conditions. Taming the informal city growth of Belgrade requires different approach.

In the context of sustainable urban planning it is important to emphasize mutual dependence between land use and growth of the city on one hand, and ecological, social and economic development on the other. In the case of Belgrade, its correlation is even more obvious since the spatial consequences of imbalanced 3E are more than visible. The urban planning should focus to be strategic rather than comprehensive, flexible rather than end-state orientated, action and implementation oriented, stakeholder and community driven rather than expert driven. It also has to be reflective of emerging concerns and focused on the outcomes, which are locally sensitive and dependent upon stakeholders.

Wise governance instead of governing as a way of implementing institutional sustainability will result in balanced land use planning and inner city growth, replacing the practice of spreading and widening the city territory.

1 ABSTRACT[1]

The focus of the paper is on the relation between a traditional and a modern concept of street design and regulation, which have been overlapping and upgrading/degrading for decades.

The case of the Boulevard of Jurija Gagarina in New Belgrade will be used as an interesting example of a street constructed during the 1960s. The original modernist idea, reflecting the socio-economic background of the socialist epoch, is still recognizable in impressive prefabricated housing blocks, shaped according to the ideas of the Athens charter and the Modernist movement. The street, originally planed as an important transit artery with surrounding housing and green areas, started to transform its landscape during the period of transition (1990s). The position, available empty space and already provided infrastructure have directed a new tide of changes, attracting attention of city authorities, investors and entrepreneurs. The intensity of activities has increased, new office/commercial/housing units were constructed, but all these transformations have not been supported by the planning concepts which would improve the overall condition and quality of life in this area. Driven by the logic of economic efficiency and profit, the transformation of the Boulevard of Jurija Gagarina has also tackled the sensitive issues of spatial organization, social cohesion, redefined urban needs and questionable sustainability.

Therefore, the paper will discuss recent changes and trends which opened some new questions of urban durability, modernity, efficiency and environmental awareness, simultaneously emphasizing a need for an integral approach, adjusted to a new dynamic and multiplying demands of/for the future.

2 INTRODUCTION

New Belgrade, a unique urban entity designed and developed in the ex-Yugoslav capital after the WWII, has been a focus of attention of numerous professionals and researchers since its construction (Backovic, 2009; Blagojevic, 2007; Eric, 2009; Milakovic, Vukmirovic, 2011; Perovic, 1985; Waley, 2011; etc). Built between two historical cores – Belgrade and Zemun, the area was not spontaneously developed as an extension of the urban fabric. Instead, it was supposed to be an example of a total design and a radically different approach which reflected the power of the state and its new ideology. Conceived as a symbol and a spatial manifestation of a young, progressive and multicultural society, New Belgrade occupied the left bank of the river Sava, enabling the expansion of Belgrade on an empty terrain which was not burdened by any mental or physical heritage. The principles of continuous development of the (traditional) city were substituted by the ideas of the Modern movement, but the development and transformations of its structure have been influenced by a complexity and specificity of the general social, political and economic background, confirming the ambivalent character of the Yugoslav society and responding to changes and challenges generated by transition and globalization.

The case of the Boulevard of Jurija Gagarina represents a good example of shifts and turbulences on all levels of Yugoslav/Serbian society, a testimony of planning ideas, efforts and failures, but also an expression of urban vibrancy, dynamism and uncontrolled forces which could be identified in a contemporary city.

3 SHAPING A MODERN(IST) FRAMEWORK

Designed under the strong influence of CIAM and the Modern movement, the original streetscape of New Belgrade followed the principles of the Athens Charter. Consequently, the traditional development of street space was 'strictly prohibited', continuously built facades of street corridors were avoided, and open mega-

---

blocks with free-standing structures and a lot of 'sun, space and greenery' were promoted. This approach changed the basic, traditional morphology and the size/scale of urban blocks and streets, focusing on car-oriented transport. Pedestrian spaces were situated inside blocks, as separated public zones, enabling free movement and recreation of inhabitants.

However, the change of ideological circumstances has influenced significant transformations of the urbanscape of New Belgrade, implanting additional features into purified modernist pattern. Nowadays, we can identify four street forms defined by the level of dependence/correlation between blocks (buildings) and street regulation – (1) building structures perpendicular to a street creating a rhythm with deep penetration of vistas in the block, (2) structures parallel to a street, with large sidewalks and green pathways between buildings and streets, (3) individual, dominant structures built on the corners of blocks and (4) 'meander' structures in the central part of a block creating a dynamic secondary routes for pedestrian movement.

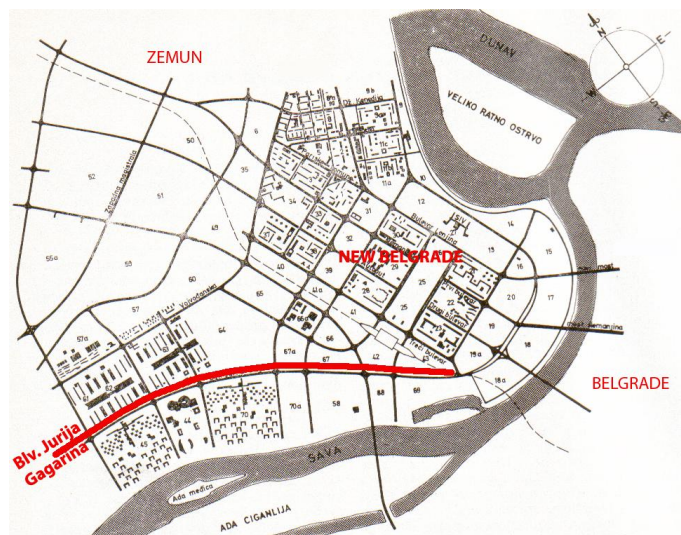
The example of the Boulevard of Jurija Gagarina represents a specific area of New Belgrade which was designed according to the official plans. However, its development was shaped by conflicting social, political and economic interests. Since New Belgrade occupies the central position of Belgrade, the area around the Boulevard was initially planned as a mostly industrial area, only partially habitable (Урбанистички завод ИОНО града Београда, 1951). However, subsequent amendments from 1965 changed the original idea imposing completely residential development (Figure 1). The main artery – the Boulevard of Jurija Gagarina, has become the backbone of the area, which consists of several types of open blocks.


Fig. 1: The position of New Belgrade between two historical cores – Belgrade and Zemun. Red line marks the Boulevard of Jurija Gagarina in a zone initially planned for industry, but transformed to a residential area.

Initially, blocks 45 and 70 were the only residential blocks in New Belgrade placed on the river bank, while Block 44, located between them, was built in the 1980's. [2] Both blocks have identical spatial organization, with two types of elements/buildings positioned (and copied) in a park setting. The part of the block toward the river consists of lower residential buildings (up to 4 storeys) in the shape of a horseshoe, while the other part, next to the Boulevard, is composed of orthogonal, freestanding solitaires (up to 15 storeys). The structures are grouped in four zones, with two main pedestrian passages in between – a promenade parallel to the river and the second one, perpendicular, with clustered services, education facilities (primary school and kindergarten) and a local community center. These additional activities and their structures create a central space, as a focus of social life and interaction. The size of each block is 800x800m, while car accessibility to buildings and parking spaces is provided by few internal streets/blind alleys (Figure 2).

---

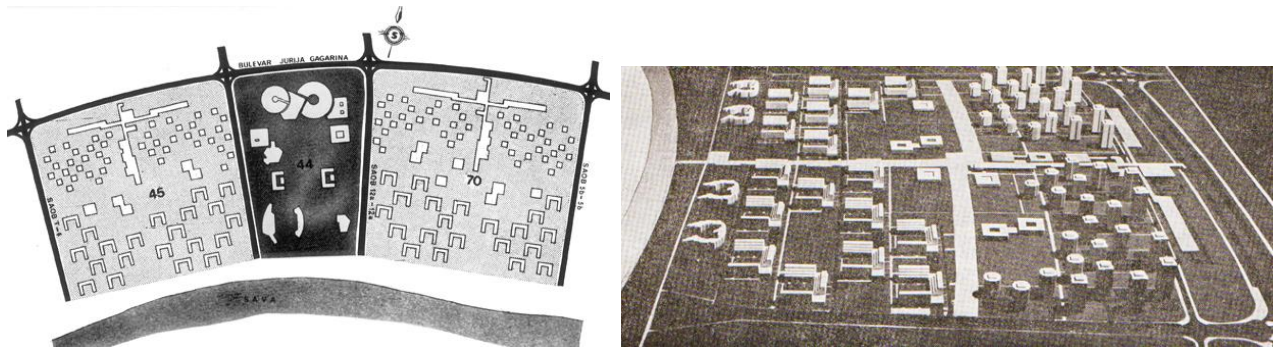
[2] Competition for these blocks was announced in 1965. The award-winning work is from Slovenia, authors Ivan Tepeš and Velimir Gradelj.


Fig. 2: Initially planned structures along the Boulevard of Jurija Gagrina – (left) the model of block 45; (right) the plan of the south part of the street (blocks 45, 70 and 44).

Blocks 61, 62, 63 and 64 have a different composition, but they are all designed in the same manner. [3] The basic urban concept represents a symmetrical macro-composition, consisting of two regular series of residential buildings, linked by the axis where the center is planned. The height of buildings decreases from the axis to the Boulevard of Jurija Gagarina.

All four blocks have a strict segregation of vehicular and pedestrian traffic – the first one is planned on the ground level, while pedestrian movement is placed above, integrating public/free space with access to residential structures. The connection between the axial center and buildings via passages was also planned, creating micro-ambiances as public spaces for social interaction (Figure 3).
Fig. 3: The initially planned structures along the Boulevard of Jurija Gagarina: (left) blocks 61 and 62 – plan, (right) typical block.

Since it was envisioned as a transit route, the Boulevard of Jurija Gagarina is wide 60 metres, with 6 car-lanes, 2 tram-lanes and large green buffer zones between roadway and buildings (Figure 4). However, since this area remained on the outskirts of the city, with prevailing residential activities and without construction activities around/at the end of the street, it actually acts as a highly frequent access road to existing residential buildings.

Fig. 4: The Boulevard of Jurija Gagarina before the transformation.

---

[3] The competition was announced in 1971. The winning proposal was designed by Darko Marusic, Milenija Marusic and Milan Miodragovic.

From the environmental point of view, the concept was made to fulfill main needs of comfort for the residents. By decreasing the building height towards the river, the majority of apartments are facing the south, and the basic laws of insulation and ventilation are met. From an economic aspect, the realization of this comprehensive project was possible only by industrial type of construction, i.e. prefabricated buildings. Within the socialist system, which existed before the 1980s, the state was the only and principal investor.

4 FACING THE TURBULENCES

The beginning of the 1980s was marked by the crisis of economy which also influenced the efficiency of the Yugoslav self-management socialism. Changed conditions and general instability of the system and society also triggered a number of other processes which finally led to the disintegration of Yugoslavia in 1991. Simultaneously, the economy started its shift to an open market, introducing privatization, decentralization and deregulation. Urban planning lost its centralized character causing a hyper production of detailed plans by different offices, without the influence of the Town Planning Institute of Belgrade. New architectural and planning paradigms were embraced by the professionals inclined to post-modern flows, while modernist models lost their importance in a changed socio-economic context (Vujošević, 2004).

Local authorities ignored previous models of development, refusing to define long-term strategies and visions. They mostly accepted and followed ad-hoc decisions enabling uncontrolled commercialization of urban space. The architectural and planning profession lost its significance affecting a degradation of urban environment with increased social and spatial segregation (Petrović, 2009). Consequently, during the last decade of the 20th century, the process of transition was visible in urban planning as a unique paradox – decisions were actually centralized, but their implementation (and legitimacy) was achieved by a number of decentralized decisions from various actors/participants in a planning process. This situation created a fertile ground for different malversations and uncontrolled private accumulation while the importance of public good was neglected (Vujošević, 2004). Therefore, urban planning represented an uncoordinated set of fragmented interventions, 'justified' by the lack of funds, regulations, tools for implementation and, above all, well-defined, comprehensive development concepts. The contradictions of the new system were reflected in architecture as well, shaping a new landscape for transitional flows.

New Belgrade, as a valuable and well-positioned urban resource, became one of the targets which attracted attention of numerous investors. Offering empty (unused) spaces and well-developed infrastructure it gradually reshaped its socialist image and generated a new identity. The urban tissue was invaded by new activities and structures which were not in accordance with the original concept, but in spite of its inconsistent, hybrid style, this part of Belgrade increased its significance and value (Petovar, 1989). The morphology of New Belgrade was changed, the inherited modernist legacy was negated but the current situation confirms the transformation potential of the space, as well as its flexibility for the future economic, social and spatial challenges.

Streets of New Belgrade changed their physiognomy too. The Boulevard of Jurija Gagarina was no longer considered a transit street, but as a social arena, which needed a formal and functional continuity. The construction of new buildings started during 1980s, when first small-scale shopping malls appeared along the street, in the former green areas. However, the significant transformation started after 2000, when foreign investments were intensified and a number of European and global corporations arrived to Serbian market. New Belgrade was recognized as a perfect site for business, services, exclusive residential buildings and – new shopping malls.

Introduction of a postmodern paradigm launched a different design concept which promoted a traditional model of street. However, a gap between planning profession and economy produced a specific scenery which followed the original plan from 1965 but adjusted to new regulations and indicators generated from contemporary trends and economic turbulences. Therefore, the Boulevard of Jurija Gagarina was gradually transformed into a compact urban tissue, with high density and decreased green areas/open spaces. These changes do not represent the outcome of planning visions, strategies and procedures which should improve a general environmental quality (Bajic Brkovic, 2009). Instead, they are a consequence of different investments which used the flexibility (i.e. insufficient determination) of the uncompleted modernist framework.

5 OVERLAPPING THE PATTERNS

The present constellation of power, interests and needs in the Boulevard of Jurija Gagairna mirrors 'the crisis of non-concept'. The new development is clearly visible along the street and the open spaces of housing blocks are occupied by the commercial drive of private capital, expanding its boundaries into the public areas (Figure 5). Demarcation lines are set between physical structures that represent two epochs creating a distorted image of this area. It is nowadays full of contradictions, which coexist and overlap, creating a surreal environment (Stupar, 2006).

The streetscape of the Boulevard of Jurija Gagarina has changed its density, function and overall narrative which had been visible for almost half a century. In search for a new continuity, its empty land has been filled with buildings which created a scenery for a traditional urban streets, but without any pattern or organized scheme it is hard to achieve a unity of architectural expression (Milakovic and Vukmirovic, 2011). Furthermore, there are several problems which could be identified in the main aspects of urban life – (1) physical – referring to spatial and functional organization; (2) social – implying a different use of space and the attitude of users toward change, and (3) economic – related to the validity of new structures and a balanced development.

Fig. 5: The Boulevard of Jurija Gagarina after the transformation.

In terms of physical environment, the construction of new buildings mainly threatened both the public space along the Boulevard and the space inside blocks. The current and planned construction activities are already beyond originally proposed capacities, while the new high rise buildings do not respect original rules of positioning, orientation, vertical regulation and environmentally responsible morphing. The level of comfort and the ecological quality of urban life is decreased. Meanwhile, the higher density of inhabitants and users caused a significant increase of the number of cars which made the existing parking capacities insufficient. Consequently, the open public spaces and pedestrian areas have been used as informal parking spaces which – to a certain extent – have even been legalized.

From a social perspective, the main problem is related to the altered use of open public spaces where we can identify a clash of two opposing concepts – the modernist model, which promotes the internal space of a block as a gathering place suitable for contacts, relaxation and recreation, and the post-modern model, which underlines the importance of a street for public life. The opinions of users are also divided – for some of them the usurpation of public space and a conflict between old and new structures only degrades physical, social and environmental quality of the space, while other users support introduction of new structures and activities which would complement already existing residential character of the area. In spite of this ambivalent perception of the space, the general opinion is positive because both groups appreciate a new daily dynamic which enables a simultaneous functioning of both spatial elements – blocks and streets.

The sustainability of the Boulevard and its surrounding area is also questionable. The intensification of activities has increased employment possibilities and enabled higher dynamic of economy and market, but the introduced activities are not evenly distributed and they still do not provide a satisfactory balance and a variety of services. Consequently, some office and commercial spaces remain without tenants which only confirms the lack of spatial and economic strategies which would stabilise supply and demand.

Finally, the factors of environmental quality and energy efficiency are mostly neglected which represents a serious warning and a problem for all users and space-consumers. Obviously, the ad-hoc shaping of a space does not consider problems generated by climate changes, which is also a result of low environmental consciousness. Therefore, the imperative of the future development of the Boulevard of Jurija Gagarina

should be adjustment to current climate conditions and global environmental trends, which is – again – a mission achievable only via comprehensive strategic plans and actions. In the meantime, ad-hoc approach could be used for environmental vibrancy as well, especially for the application of various biophilic elements which increase a general environmental quality and create new competitive advantages for this area.

6 CONCLUSION

The transformation of the Boulevard of Jurija Gagarina has been the metaphor of discontinuity and a materialization of all turmoils which ex-Yugoslav and Serbian society have faced since the 1990s. The overlapping concepts, unsynchrnonized actions and conflicting interest have shaped the morphology of this space, creating a confusing urbanscape and a distorted image of anticipated modernity. Disregarding original ideas and urban regulation, but benefiting from their generous spatial formations and available empty space, the latest phase of aggressive and often uncontrolled urban intensification has also brought an unexpected vibrancy to previously dormant residential area. However, the newly created urbo-economic system is not a stable one and it needs a proper tuning to contextual changes which should guarantee its long-term sustainability.

During the last two decades, the flexibility of the 'modernist' space has been brutally tested and – confirmed, but the accumulated problems and actual local and global challenges demand immediate, resolute and forward looking strategies and actions. Therefore, the future of New Belgrade, its mega-blocks and boulevards, should be defined in a well-balanced framework able to provide enough environmental and social benefits for different categories of residents and users, while remaining a hot-spot for all contemporary, innovative and creative impulses able to ensure its further 'modernity'.

1 ABSTRACT

Landscape and open space is where "cultural history and architectural practice" (Meyer 1997: 73) meet. Hence they are an expression of the culture and society of their time. Yet the meanings of each period overlap and are expressed in different ways. Since the 1962 recommendation of UNESCO in Paris (UNESCO 1962), a change in the definition of monument-related spaces and objects has intervened, a shift in focus from the created object to the significance of the location (BURRA Charter 1999). The question if this present meaning, encompassing all levels, can be exploited for tourist concepts is currently being evaluated on the basis of four case studies in the EU-funded CultTour project (CultTour 2012).

This paper describes the "attractive" — in the actual sense — features beyond the superficial, visible susceptibility to conservation that distinguish open spaces and which of these features can be integrated into a tourism master plan for the city and region. Furthermore, we will investigate how these hidden characteristics can be communicated and made visible in an imaginative, exciting way. This requires in the first place, a thematic framework to which other gardens, open spaces and objects can be added and visited as part of a theme route. But the focus will also be on the type of communication by which history and folklore can be perceived and passed on. Eyal Weizman, an English architectural forensic claims that such sites create their own stories; that it was only a matter of finding the right translation. (Weizmann 2012: 9). Thus the aim is "to shape perception that makes a difference between raw matter and landscape". (Shama 1995: 10)

In order to determine and analyse the open spaces, we resorted to historical research, landscape architectural surveying and graphic analysis, video analysis and an indexed analysis of interviews. The properties were analysed from a qualitative perspective.

This article will focus on the analytical methods, the allocation of the properties resulting from the qualitative analysis and on the various levels of meaning of the open spaces. This represents a partial result of the research project.

2 INTRODUCTION

This paper presents initial results from the project co-financed by the European Union: "CultTour: (garden) heritage as focal points for sustainable tourism". In this research project, open spaces and gardens in South East Europe were examined in regard to their cultural significance and combined at a later stage to establish themed routes for tourism purposes. The starting point are four pilot sites which were explored by an international team consisting of landscape architects and tourism experts. At all four sites, Alexandroupoli (Greece), Veliko Tarnovo (Bulgaria), Avrig (Romania) and Taranto (Italy), abundant traces of intensive change throughout history are found.

According to Elizabeth Meyer, landscape and open spaces are generally of a cultural heritage value which interacts with sculpted reality (Meyer 1997: 73). This interaction is not restricted in time to a certain period; rather it creates at any time sculpted spaces with multifaceted meanings. Landscape architecture and garden design fit into this overall context. "Landscape architecture as such is a rather hybrid than binary activity." (Meyer 1997: 50). 'Binary thinking', in other words, the polarity between historically relevant and historically irrelevant events impedes understanding the complexity of open spaces. In the context of the project we therefore argue that a touristically attractive cultural heritage site is not restricted to the marketing of a distinct space but also a way of communicating information and of perceiving geographic places.

The basic objective of the spatial analysis is to define the characteristic features of the open space, to assess the potential of the open space and the interpretation of the open space from the perspective of the project 'CultTour' – seeing garden and open space culture as the motor for sustainable tourism development.

Therefore, quite generally, correlations must be established from the facts to see and understand the open space in its historical, spatial and social context. Hence the view to the outside is not only essential and substantial for the purposes of monument conservation; the environment also acts as an integrative component of the site on the inside (Böhme 1996).

Fig. 1 SEE Programme Area

3 THE MEANING OF THE SITE

The various layers of meaning of an open space have been elaborated repeatedly in academic writings, while emphasising the role of the perceiving persons. (Schama 1995; Meyer 2008 and 1997; Treib 1995 et al.). Marc Treib, for example, has pointed out the meaning of the cultural background of the designers as well as of the users: "[M]eaning condenses at the intersection of people and place, and not alone in the form the designer's idea takes. Thus design can be perceived as a semi-permeable layer between 'intended perception' and 'perceived intention' in times of growing social differentiation." (Treib 1995). This approach makes it possible to create a nexus between the intention behind the historical design and its current use and function.

The project is at the fault line between the perception of open space and the cultural garden heritage of South East Europe. The focus is on four countries whose cultural garden heritage is perceived very differently by local experts and is known to a varying degree. The majority of the involved project partners had a conventional picture of historically valuable open space in mind, focusing on garden heritage sites to the exclusion of other types of open spaces, in particular public space. Yet the four pilot sites show how important these open spaces are in the daily life of the locations concerned. Thus the focus spanned from heritage significance to open space usage. Accordingly, it was necessary from the outset to explore the pilot sites in different ways and to reflect their perception from different positions. Recording methods such as landscape architectural surveys, expert interviews and cartographic, photographic and video recordings were used in addition to background research on the sites. Nowadays, the sites meet vital open space functions; as a result, their historical meaning is less obvious than their everyday use. The sites are rooted in different landscape contexts. Three spaces are integrated into an urban space, while the fourth one forms part of a rural environment. Moreover, they are in different states of maintenance. The question if and how they should and could be earmarked for conservationist renewal is not answered uniformly by the partners in the project. On the one hand, historical revival is proposed — for example, in the case of the former baroque palace gardens of Brukenthal in Avrig where baroque festivals take place— while in other cases, minor superficial changes — as in the urban green belt in Veliko Tarnovo — suffice.

The survey of the open spaces serves to explore the meaning of individual elements, spatial situations and narratives. These meanings may serve as the basis for means to integrate them into tourist concepts. To obtain information beyond the physical space, questions relating to the genesis of the site, its current function and meaning, the specificity of the location in the context of the landscape as well to the future projects of persons responsible were explored.

These issues cover the essential objectives of the project. In a second step, the levels of meaning were abstracted from the analysis and reviewed to determine how they might fit into tourist concepts.

4 METHODS

The methods presented here show several approaches an open space inventory. They are chosen to provide mulitlayered results for a twofold of recommendations and implementations. On the one hand they deliver a basis for practical measures to maintain the heritage value and at the same time safeguarding the actual usage. On the other hand they are a basis to develop touristic models and tools for re-utilisation of garden and open space heritage sites in South East Europe. The collection of data (survey) covers spatial, structural, plant and historical traces and uses. It consists of historical research, qualitative expert interviews as well as empirical field research. To analyse the surveys from a multi-layered perspective, data were generated on the one hand in different ways, going beyond the traditional surveying in the form entering data in existing maps. On the other hand, the data were analysed with different qualitative and experimental methods based on language, drawings and moving images.

The expert interviews consisted mostly of partially structured guideline interviews that were analysed qualitatively. The partial structure left room for additional emerging questions. This additional scope resulted in new perspectives and made it possible to spontaneously respond to and deal with specific situations. For the purposes of the analysis, the transcribed texts were encoded by assigning the contents to theme field. This procedure permits a qualitative comparison. Experts were dealing with regulations for protection and management and development of garden and open space heritage sites. The results of the interviews give insight into the existing framework and make it possible to formulate recommendations for structural changes.

The elements and conditions in the sites were recorded in simple, schematic drawings. Steenbergen (2008) describes graphic reproduction as copying. The abstraction during the process of transfer represents an interpretation step. Thus the situation is abstracted and filtered, revealing eventually that which is perceived to be the essential. In doing so, perception and selection are open to interpretation.

The transfer of site features into simple maps is similar to mapping. Compared to a conventional survey, a reduction takes place in this case, which results in the remaining features becoming more clearly visible. A weighing takes place, and correlations become evident.

The video analysis is based on the method developed by Christoph Girot with four different recording techniques each. The four variants are: long video sequences, slow walks, shooting in quick passing and recordings altered by editing or trick manipulations. (Girot 2010). Video analysis is understood to be the experimental part of the assessment of the site, which is influenced by the existing situation and the events taking place there. Statements are made, which can be related to the overall effect, the activities and sequence of spaces. By using video analysis spatial transitions are clearly displayed. By lining up the single video-stills of the states of transition the theatrical composition of site is traceable and communicable.

Historical research is carried out by studying the literary sources, historical maps and photographs, engravings, postcards, letters and paintings. In this way, through the collection, presentation and juxtaposition of the documents and contents it is possible to arrive at the genesis of the sites.

The empirical research provides a comprehensive understanding of the site. The abiotic and biotic properties of the site itself are examined and described as well as its integration into the adjacent, urban and regional surroundings. The functions and uses in interaction with the historical features reveal the specific character and context of the garden or open space.

5 EMPIRICAL EVIDENCE

The pilot sites provided the empirical data. The results of research, observation, interviews and surveys make it possible to interpret the layers of meaning of the sites.

The following section will illustrate by way of example how the different layers of meaning of the park of the Villa Peripato in the Apulian city of Taranto on the Ionian Sea were determined.

5.1 Levels of meaning – Components of a cultural change in meaning

5.1.1 Archaeological component

Archaeological finds are tangible legacies of people. Their reconstruction can manifest the cultural significance of a site. A. Ressa, the conservation officer of the city of Taranto, draws attention to these

hidden historical witnesses in the interview: A. RESSA: "Villa Peripato is a very important site, not only for the vegetable species in the garden or for the design of the garden which is typical for the 19th century. Not only for these cultural reasons, but also because Villa Peripato develops on a certain height (altitude level), on a higher part. This means that below Villa Peripato there are many levels of historic findings. There are a lot of archaeological findings. It is a very important archaeological site because of its height".

These specific archaeological findings emerged when the foundations for an annex to the open-air theatre built in 2004 were excavated. First scientific photographs of the excavations were taken, but then the places of discovery were filled again, ostensibly for a lack of funds to properly process and professionally display them. Another important consideration may have been that using parts of the garden site for an open-air theatre may have appeared more attractive than presenting an archaeological site. Anyway, it is part of the aim of project to make these distant historical artefacts accessible for presentation purposes and for the status of the site as a historical garden heritage. The lower-lying layers of the areas of the archaeological finds illustrate one of the layers of meaning of the park. It is hidden, yet known and thus part of the narrative of the location.

This level can be marketed for tourist purposes through the existing images of the historical mosaics.

Fig. 2: The excavation site before the construction of a toilet facility for the open-air theatre

5.1.2 Spiritual component

In the 13th century, a convent was built next to the garden of the Villa Peripato. Historian Cosimo D'Angela reported about it in the expert interview: "So, in the 13th century the Prince of Taranto wanted to create a convent in that area, dedicated to St Antonie. Since it is a higher part in the city, this area was called the posilipo, which is another area in Naples which means 'the higher part'. (...) The archbishop of the town built a private part here at the higher part of the town. During the construction of his house, the remains of Greek findings were found. Next to the Greek theatre, there was a temple of Dionysus. We have some draft about this discovering, that states the present of the temple and the Greek theatre. These drawings were made by a French traveller. They are available at a French bibliotheca, Paris. They have been published. The entire remains of Greek findings have been sold to King Gustav of Denmark, and they are in Copenhagen."

Christian religious buildings were often built on the sites of ancient Roman or Greek temples. Thus the Villa Peripato has always been a place of superior religious significance and forms part of a historical spiritual meaning for hundreds of years. The convent can be integrated into a tourist concept.

5.1.3 Social and economic components

For users, the meaning of the park has continuously changed. The conservation officer, Ressa, explains the atmosphere of the original garden of the villa. "Villa Peripato, like all other Villas of the cities, was like a dream (paradiso) at the beginning." When it was created in the 18th century by Beaumont Bonelli, it was an expression, typical of that time, of the eternal longing for paradise.

In the 19th century, when it was given the appearance that is still visible in part today, the Villa Peripato was also an important and regular meeting point for the wealthy middle class. The garden offered space for social interaction, as in a society salon, and was the platform for discussing economic and business matters, as A. Ressa explains in the interview: "The characteristic of Villa Peripato is based on a different way of life imposed by the middle class at that time. New interests, new way of life, new life in the city and so on (...). While at the beginning it was the meeting point of the middle class, it was a respectable place in a certain

way. Generally only middle class people went here. Here the cultural and economic life of the city was decided." According to Ressa, the garden changed once again after the period of industrialisation:"During the past [centuries, note of the author], the population grew, but the middle class got fewer. For this reason, the role of Villa Peripato has changed. Then, around 1950/1960 the situation changed because the middle class became fewer and Villa Peripato started to be used also by other social classes. Villa Peripato was more and more used by poorer people. In this way the idea of Villa Peripato changed. Since there was this contrast between the old city and the new city with Villa Peripato with all the green, from a cultural point of view, poorer people considered Villa Peripato as a beauty-farm, because of the presence of all the plants and so on. It was a healthy place. Their children were playing in the garden. In this way, it was difficult to control Villa Peripato. People started to make damages. There was vandalism and so on. Rich people did not feel safe anymore. For this reason they decided to close Villa Peripato"

The historical analysis and the analysis of use by means of mapping result in a spatial overlapping of several eras: According to historical sources, the large rondel was already created before the World War II (cf. the plan from the period of 1915 to 1925), but the American occupying forces turned it into a skating rink, according to historian D'Angela. Today, the rondel is mainly a very popular meeting point for adolescents and young adults. In winter it is used as an ice-skating rink. Thus the rondel, which was only added at a late stage to the development of the garden, became an important garden element dating from a later period than its establishment due to the new forms of usage. Through the available and actual types of usage, these time shifts can also be experienced by outside visitors.
Fig. 5: Plan around 1915/25

5.1.4 Design component – exemplified by the context of the surroundings

In spatial analysis, the open space is examined beyond its boundaries in the context of its surroundings. The open space is part of a larger (urban) landscape. The spatial analysis illustrates the actual integration and location of the site in this landscape, the visual connections that result from it and the spatial effects created from the outside. The analytical method of copying reveals the distinctive position of the open space on the terrain edge to the bay.

Fig. 3: Highlighting the terrain edge by copying

This makes it possible to highlight the significance of the open space of the Villa Peripato for the recognition value of the more recent historic city centre of Taranto.

Historical research has revealed that park was initially designed (around 1860) as a belvedere/viewpoint. It overlooked the "Mar Piccolo", the bay to the north-east. There were probably two terraces, at least one of which can still be seen on a historical photograph (cf. Fig. 4).

Fig. 4: Terrace overlooking Mar Piccolo, probably around 1930.

The spatial analysis shows that the present high plant density at the terrain edge forms a very distinctive, closed spatial boundary. The alley along the lookout area passes along a green wall, instead of the historical canopy for enjoying the view. The interaction with the lake created by the viewpoint was turned into a border zone. This offers individual user groups the advantage of being able to extract themselves from social control.

5.1.5   Atmospheric component – exemplified by historical fragments and retreats

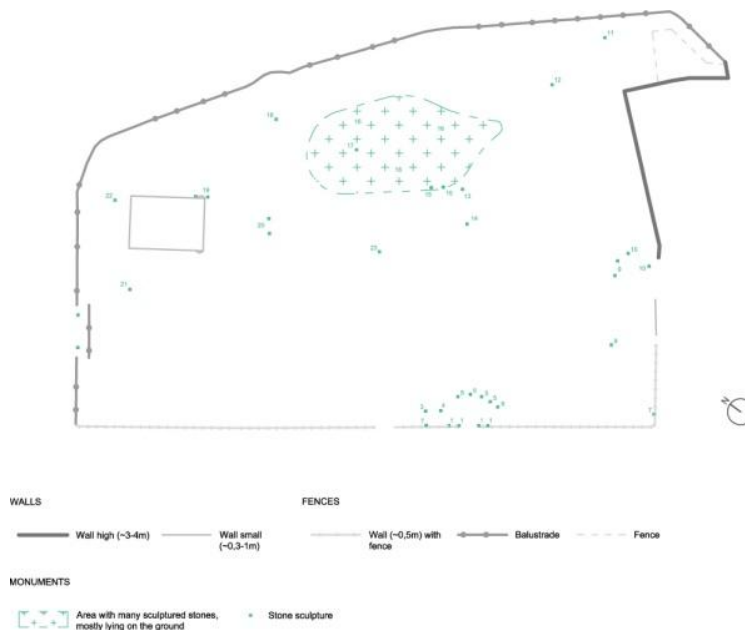
Through the analytical method of mapping it became apparent that a significant number of landscape architecture traces and historical garden remains can still be found in a particular section of the park.


Fig. 6: Walls, fences, monuments of the Villa Peripato

5.1.6   Components of movements and atmospheres – video recordings

A relatively new method of analysing open spaces is the viewing and interpretation of video recording taken in the field. The analytical observation of the site using this experimental method of analysis has revealed an additional layer of meaning of this specific section of the garden of the Villa Peripato. This can be seen from the video analysis as used in the project:

With this method a retrospective impact on the analysis method embarked on before could be discerned. Prior to the first on-site video recordings, the following methical foundations for the video shooting were

prepared: The video shootings were to be carried out in four different modes (long video sequences, video sequences taken during a slow walk, recordings shot in quick passing and recordings altered by editing or trick shots), based on "The Margins of Vision" by Christoph Girot (Girot 2010). Despite this classification of the recordings, the subjective perspective of the person who holds the camera remains: "Video is a modern instrument, which appears as an automatic and detached view in peoples´ lives. But do not forget that there is still a subject behind the camera. In simple terms: it is hand made!" (Girot 2010). That much was clear already before the start of the shooting. Yet once in the field, it became obvious that strict adherence to the four recording modes would prevent addressing the actual and specific characteristics of the site. This is evidenced by the results of the video recording methods at the four pilot sites:

The camera meanders through the park of Villa Peripato in Taranto on an unstructured, random route, similar to a walk. Yet the walking trail is not lost in thought, it takes numerous side glances into hidden niches and discrete corners of the park. The recorded version created on site symbolises the substantial heterogeneity of the site. It stands for looking and searching, getting lost, getting back on track and immersing oneself in this space.

In the Italian "Giardino Publico" of the Villa Peripatothe experimental analysis process using video footage has shown that the specific section of the park where numerous historical fragments are located is precisely the section which has a very withdrawn, remote character with an intimate atmosphere. Hence, a future presentation of the testimony to the historical significance of the park could be realised in this section of the site, since it also offers the opportunity for an unobstructed pursuit of the tracks of the cultural heritage.

Fig. 7: Video still: Historical fragment in the remote section of the park of the Villa Peripato

6 CONCLUSION

The analyses of the layers of meaning of the site presented here are based on conventional site survey methods and are purposely expanded with experimental methods. It is clear that such a mix of methods provides results on different levels. For tourist concepts, these specific results may contain direct information and proposals for action, such as visualisation of the historical mosaic. At the same time, it becomes clear that the interpretation of the entire culture heritage meaning cannot be done without blending and overlapping these results. For a comprehensive communication with visitors, separate narratives can be combined into new tales, as exemplified by the rondel of the Villa Peripato. At the moment when these different levels of interaction come together, the open space under review develops into an independent phenomenon that is hidden from superficial glances, arousing curiosity and stimulating imagination. However, further research into the relevance of the open space for the surrounding urban structure and its society resulting in profound overall narratives were only possible in conjunction with site-related insights. This is true especially if the tourist concepts are based on routes still to be established. Thus the surrounding location is not only to be understood — according to Marc Treib — as an "intersection of people and place", but also as part of the site's historical, spatial and socio-cultural context. Thus the shift from a created object to the meaning of the site (BURRA Charter 1999), as it is reflected in the current discussion of the cultural heritage, is taken into account.

These layered meanings will result in specific touristic products for the sites in order to show their touristic value as an example for the SEE region.

Transnational Planning Support by the European Geodata Infrastructure INSPIRE

Joachim Benner, Karl-Heinz Häfele, Andreas Geiger

1 ABSTRACT

In the INSPIRE initiative of the European Union a common spatial data infrastructure is being developed, which in a few years will support the Europe-wide, standardised access to spatial data from different thematic areas. In this context, a special activity is the specification of various data exchange formats, based on the OGC standard GML. Though INSPIRE primarily aims at environmentally relevant data, many of the themes are also relevant for spatial and urban planning. In this context, the paper presents the two INSPIRE data formats for "Buildings" and "Planned Land Use".

2 INTRODUCTION

In the INSPIRE (Infrastructure for Spatial Information in the European Community) initiative (EU 2007), a pan-European spatial data infrastructure is being developed. In a few years the service-based access on geodata from different functional areas will be possible. This not only comprises visualisation services like Web Map Service (WMS), the pan European exchange of geographic vector data via Web Feature Services (WFS) or Download Services shall be possible as well. For this purpose, standardised data exchange formats based on Geography Markup Language (GML 3.2.1) are being developed for a number of thematic areas.

Though INSPIRE primarily aims at the environmental area, this development is also highly relevant for supporting transnational urban planning or spatial planning. Spatially related planning in any case needs a suited representation of the actual state. For this, it is not sufficient only to provide a suited visualisation model, an automatic interpretation of the data in simulation or analysis tools should also be possible. The semantically enriched, two- or three-dimensional INSPIRE data model for buildings (INSPIRE BU) facilitates the trans-border exchange of information on a city's building stock. It is expected that such data in future will be an important basis for computer based, spatially related planning processes.

The INSPIRE data format for the planned land use (INSPIRE PLU) aims at representing the results of planning processes in Europe-wide standardised, semantically enriched data format. It is intended that this format facilitates different governmental levels. The range of the supported planning instruments goes from Construction Plans at the development area level (i.e. a few km2), over Zoning Plans at the area of a municipality or a group of municipalities (i.e. several hundreds of km2), up to Structure Plans at regional, state or country level (i.e. several thousands of km2).

The paper first of all will give an overview of history, actual status and time schedule of the INSPIRE initiative. Afterword, the main emphasis will be placed on presenting and discussing the two data formats INSPIRE BU and INSPIRE PLU. The structure of the data models will be presented, and the spectrum of the considered planning-relevant data is discussed. In this context, a number of Europe-wide standardised classification schemata for, e. g. land use categories are of special importance. Finally, the relation of the INSPIRE data formats to comparable international standards (CityGML) or German national standards (XPlanGML) is addressed.

3 THE EUROPEAN INITIATIVE INSPIRE

The European initiative INSPIRE aims "at the establishment of the Infrastructure for Spatial Information in the European Community (...) for the purposes of Community environmental policies and policies or activities which may have an impact on the environment" (EU 2007). This European directive, which meanwhile has been adopted as national legislation in all European Community (EC) Member States, lists 34 relevant thematic fields, segmented into three packages (Annex I – Annex III). Legal basis for the initiative, ensuring that the spatial data infrastructures of the Member States are compatible and usable in a community and trans boundary context, are five Implementing Rules in the areas:

- Metadata – Description of data and services;
- Data Specification – Interoperability of spatial data sets and services;
- Network Services – Specification of performance criteria for download, discovery, transformation and view services;
- Data and Service Sharing – Regulations on access to spatial data sets and services;
- Monitoring and Reporting – Definition of indicators for quality management of spatial data and services, and specification of common provisions for monitoring and reporting.

Though the development of the Implementing Rules is not yet finished, it is obvious that many areas of public administration are affected by INSPIRE. The INSPIRE directive does not require collecting new spatial data, but under special conditions spatial data have to be delivered "INSPIRE-conform" in future. These conditions are: The data are available in digital form, a national law imposes the responsibility of a public authority to collect and distribute the data, and the data can be assigned to one of the relevant thematic areas. This especially means that the specified visualisation and download services have to be supported, and that the data must be delivered in the corresponding data format.

Standardised data formats for the Europe-wide, interoperable exchange of spatial data are being developed for all INSPIRE themes. The formats for the 9 themes in Annex I have already been published at the end of 2010, and the development of the remaining data specifications for Annex II and Annex III is nearly finished. It is expected that the corresponding Implementing Rules will be adopted in October 2013. Based on this decision, the following roadmap for the implementation of INSPIRE in the Member States can be expected:

- From October 2015, all spatial data sets affected by INSPIRE, which have been created or significantly changed after adoption of the Implementing Rules, must be facilitated INSPIRE-conform.
- From October 2020, all spatial data sets affected by INSPIRE have to be facilitated INSPIRE-conform.

The implementation of the INSPIRE directive will surely have a strong impact on the activities of public authorities in Europe, and it will cause high personal and financial efforts. On the other hand, the possibility for a Europe wide, interoperable access to spatial data provides a high potential for improved or even new public services, especially in the area of trans-border urban or spatial planning. The spatial data infrastructure which will be available in a couple of years potentially can be used for several purposes in spatially related planning processes:

- Provision of restrictions or constraints influencing the planning process. This thematic area is e.g. tackled by the INSPIRE topics "Natural Risks Zones" (INSPIRE-NZ 2012), "Elevation" (INSPIRE-EL 2012) and "Protected Sites" (INSPIRE-PS 2009).
- Provision of data on the actual state of the build-up environment. This thematic area is supported by the INSPIRE topics "Buildings" (INSPIRE-BU 2012), "Transport Networks" (INSPIRE-TN 2009) and "Production and Industrial Facilities" (INSPIRE-PF 2012).
- Provision of spatially related planning documents and corresponding cartographic representations, which is supported by the INSPIRE topic "Planned Land Use" (INSPIRE-PLU 2012).

The paper is focusing on the two thematic areas Buildings (chapter 5) and Planned Land Use (chapter 6). The central goal is to present the two corresponding data formats, in order to show which planning relevant information in future is provided by the European spatial data infrastructure.

4   COMMON PROPERTIES OF THE INSPIRE DATA FORMATS

It was a central goal of INSPIRE that the data formats cannot only be used stand-alone, also a problem-suited combination must be possible. Furthermore, in order to facilitate implementation, a common basic structure for all data formats is intended. Therefore, all data models are specified as conceptual models in form of UML class diagrams, based on a common Generic Conceptual Model (INSPIRE-GEN 2012). This generic model itself is based on the family 191xx of ISO norms.

From the conceptual models, encodings in form of XML-schemata are automatically generated using common encoding rules (INSPIRE-Encoding 2012). These rules internally use the GML 3.2 (OGC 2007) and GML 3.3 (OGC 2012) encoding rules for the UML to XML-Schema transformation, and define a few INSPIRE specific rules. The latter mainly concerns the classification of attributes as "mandatory", "optional" and "voidable". While a mandatory attribute must be specified and an optional one may be specified or not, a "voidable" attribute is a mixture of both. Normally, voidable attributes must be specified at least once, but if the corresponding information is not available or unknown, the value may remain empty, but the reason for this has to be stated explicitly.

5   THE INSPIRE DATA FORMAT FOR BUILDINGS

In the INSPIRE specification, buildings are defined as "constructions above and/or underground which are intended or used for the shelter of humans, animals, things, the production of economic goods or the delivery of services and that refer to any structure permanently constructed or erected on its site" (INSPIRE-BU 2012). The specification mentions a number of important use-cases which were considered during the development process. Among these are statistics and census, safety (natural risks, human risks, rescue management), environment (air, noise or soil pollution, energy efficiency, preservation of national heritage), and infrastructure planning or management. A building may be composed of building parts, defined as "a sub-division of a building that might be considered itself as a building" (INSPIRE-BU 2012). Because the modelling of building and building part is identical, only the term "building" is used subsequently.

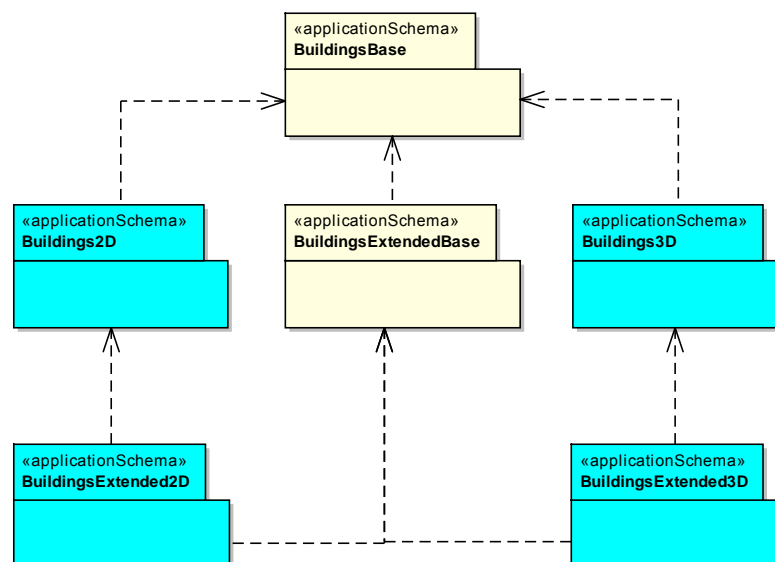
The INSPIRE BU format can be used with four different profiles, whose dependencies are shown in Figure 1


Figure 1: Profiles of the INSPIRE BU data format

The two core profiles (Building2D and Building3D) represent buildings with a reduced set of (normally optional) semantic attributes, which are provided by the (abstract) schema BuildingBase. The following information can be expressed:

- Classification of status (e.g. "functional" or "planned"), nature (e.g. "castle", "church" or "stadium") and current use of a building;

- Important dates in the building's life cycle: Date of construction, of last renovation and of demolition;

- Elevation of the building relative to a well-defined surface (e.g. geoid or water level);

- Height of the building, defined as difference between a well-defined lower reference (e.g. ground level) and a well-defined upper reference (e.g. top of construction);

- Name of the building;

- Information on the building structure: Number of storeys above ground, number of dwellings and number of building units.

The Building2D profile geometrically represents a building as 2D or 2,5D surface (see fig. 2a). A mandatory attribute specifies which element of the building (e.g. "above ground envelope" or "roof edge") was captured by the surface. The Building3D profile additionally supports a 3D representation of the building's exterior shell in three different Levels of Detail (LOD) (see fig. 2b). The INSPIRE specification uses the LOD concept of CityGML (CityGML 2012), which means that LOD1 represents the vertical extrusion of a horizontal surface, LOD2 a geometrically generalised representation, and LOD3 a geometrically exact representation.

In the profiles BuildingExtended2D and BuildingExtended3D, both based on the abstract schema BuildingExtendedBase, the corresponding core profiles are semantically enriched. The profiles support the representation of an OtherConstruction, which is defined as "self-standing construction not fulfilling the definition of a building". Additional attributes are provided, regarding

- the connection of the building to public infrastructure (gas, water, electricity, sewage);

- information on the building's energy performance and installed heating system;

- cadastral information (e.g. address or parcel);

- material information;

- detailed information on the storey structure above and below ground, including data on storey height, floor and window area, and the number of dwellings belonging to a storey;

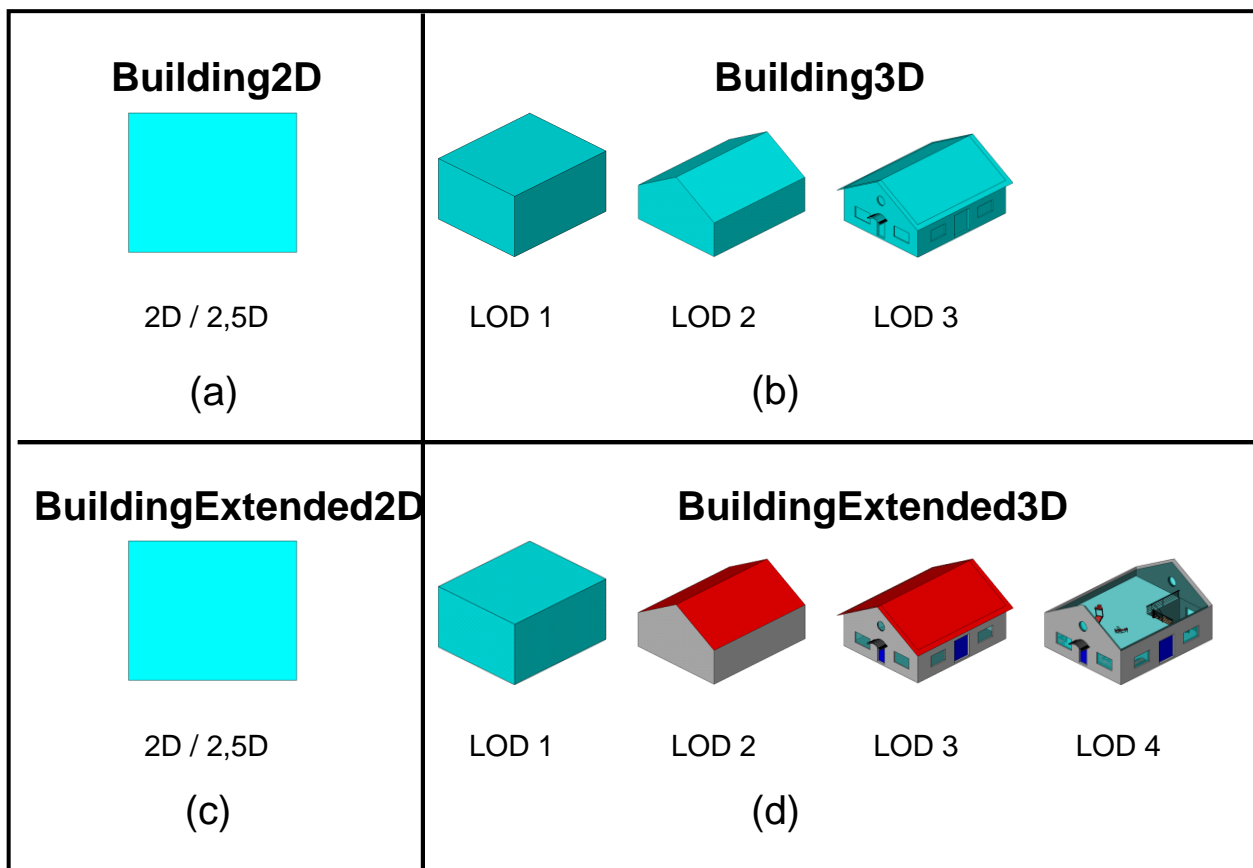
- real estate information (official area and value).


Figure 2: Representation of a building in the four INSPIRE BU profiles

Apart from the extended set of attributes, the representation of buildings in the profiles Building2D and BuildingExtended2D do not differ (see fig. 2a and 2c). This is not the case for the 3D profiles. The BuildingExtended3D profile (see fig. 2d) comprises the whole CityGML Building module and therefore provides, in addition to a purely geometric representation in four different LODs, classes for a semantic classification of the building's exterior shell by BoundarySurfaces. This means that every part of the

geometry is classified as RoofSurface (building roof), WallSurface (building facade), GroundSurface (building ground plate), OuterFloorSurface (part of the exterior shell with orientation pointing upwards) OuterCeilingSurface (part of the exterior shell with orientation pointing downwards) or ClosureSurface (virtual surface used for closing buildings which are not totally enclosed). Furthermore, external constructions or external devices attached to the building may be represented as Installation. In LOD3 or LOD4, BoundarySurfaces may refer to Openings representing doors and windows. In LOD4, also a geometrically and semantically representation of the building's interior structure is possible.

6   THE INSPIRE DATA FORMAT FOR LAND USE

In the relevant EC directive INSPIRE PLU, Land Use is defined as "Territory characterised according to its current and future planned functional dimension or socio-economic purpose (e.g. residential, industrial, commercial, agricultural, forestry, recreational)" (INSPIRE-PLU 2012). Land Use is split up into two different types: Existing Land Use, which objectively depicts the use and functions of a territory as it has been and effectively still is in real life, and Planned Land Use (PLU), which corresponds to spatial plans, defined by spatial planning authorities, depicting the possible utilization of the land in the future (INSPIRE-PLU 2012).

The scope of the INSPIRE PLU specification is giving the exact spatial dimension of all the elements a spatial plan is composed of. Spatial planning is performed at several governmental levels and the cartographic expression of the regulation differs in its graphical expression as well as the concepts that are represented. The specification distinguishes between three different types of plans (INSPIRE-PLU 2012):

- Structure Plans at a level of a wide area (several thousands of km², i.e. a country, a state, or a region), which outline the spatial structures and development in pursuance of spatial planning goals.

- Zoning Plans at a level of a municipality or a group of municipalities (i.e. several hundred of km²) cartographically representing the zoning and supplementary regulations (such as easements). Zoning refers to a partition where the planned land use is depicted. Supplementary regulations overlap the zoning where it exists and provide additional information and/or limitations to the development of the area.

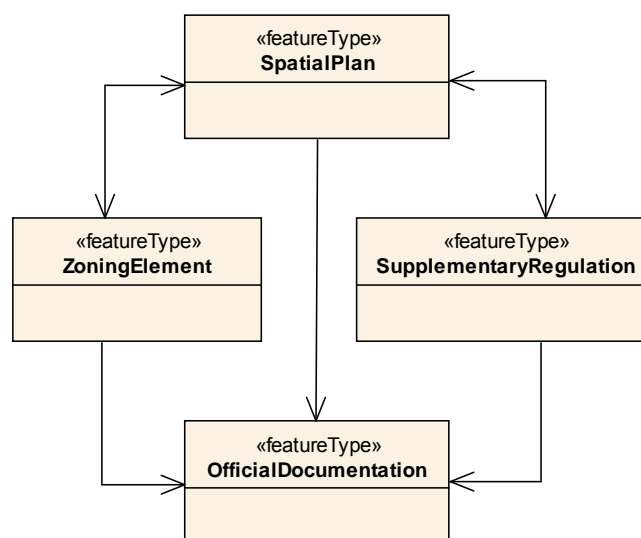
- Construction Plans at a development area level (i.e. few km²) cartographically representing the actual geographical objects that will be created such as building, parking lots, gardens.


Figure 3: Basic structure of the INSPIRE PLU data model

The basic structure (without attributes) of the INSPIRE PLU data model is shown in figure 3. There are four different feature types: SpatialPlan representing a spatial plan as a whole; ZoningElements representing planning elements of the zoning layer; SupplementaryRegulation for additional planning elements overlapping the zoning layer, and OfficialDocumentation representing documents or raster images, assigned to the plan as a whole or to single elements.

6.1 Representation of a Spatial Plan – SpatialPlan

A mandatory attribute of the class SpatialPlan is the surface geometry, outlining where the planning document is valid. Additionally, every planning document must have a unique identification, an official name or title, a classification to which level of the public administration it belongs (infraLocal, local, supraLocal, infraRegional, regional, supraRegional, national)), and a classification of the plan type according to national legislation. If available, additional information can be given: Temporal restrictions on the legal validity of the plan, an indication of the status of the planning process (adoption, elaboration, legalForce, or obsolete), a reference to the background map that has been used for construction the plan, and important dates during the process of establishing the plan.

6.2 Representation of zoning objects – ZoningElement

The class ZoningElement represents elements of the zoning-layer, which specify a unique dominant land use for all parts of the planning region. The elements therefore must have a geometrical representation by one or more non overlapping surfaces. For classifying the dominant land use, two schemata represented as hierarchical CodeLists are used: The Europe-wide standardised "Hierarchical INSPIRE Land Use Classification System" (HILUCS), and additionally an EC Member State specific classification schema (LandUseClassificationValue). Additional attributes of class ZoningElement indicate, whether the regulation is legally binding or not, and support the formulation of numerical values or texts, explicitly restricting the indicated land use. By this, e.g. a maximal value for the floor space ratio or a certain roof type may be stipulated.

The HILUCS schema is one of the standard's central components, being used for existing as well as planned land use. It has a hierarchical structure with 98 entries on maximum three levels of hierarchy. Due to the definition of "Land Use", mostly economic classification criteria are used. The first level contains the six categories

- Primary Production: Agriculture, forestry, production of raw materials;
- Secondary Production: Manufacturing industry;
- Tertiary Production: Services, including culture, recreation and sports;
- Transport Networks, Logistics and Utilities;
- Residential Use;
- Other Use, including economically unused land and water areas.

On the next two levels of hierarchy, these categories are refined. As an example, urban parks or other areas used for recreation purposes have to be assigned to the Tertiary Production area, sub-category Culture, Entertainment and Recreation Services, and sub-sub-category Open Air Recreational Areas.

For the HILUCS-classification of zoning information, there are multiple possibilities:

- The specification of one or more HILUCS-values without priority or weighting;
- The specification of several values with specified priorities;
- The specification of several values with quantitative weighting.

The specification states that always the most detailed classification or classifications, which are consistent with the intended land use, must be used.

6.3 Representation of additional information and limitations: SupplementaryRegulation

Any other spatially related content of the plan not belonging to the zoning layer is represented as SupplementaryRegulation. The attributes of this class mostly correspond to ZoningElement attributes. In particular, there are two hierarchically structured classification schemata for the semantic meaning of a SupplementaryRegulation: A Europe-wide standardised schema (SupplementrayRegulationValue), and a specific schema for every EC Member State (SpecificSupplementaryRegulationValue). Geometrically, a SupplementaryRegulation may be represented by points, lines or surfaces either.

In comparison to HILUCS, the SupplementaryRegulationValue schema is more complex and contains 159 categories on 4 levels of hierarchy. The top-most categories differentiate regulation into the themes

- Impact on environment;

- Risk exposure (natural and technological risk areas);

- Heritage protection;

- General interest (this category e. g. comprises easements);

- Land property right (restriction on the usage rights of land property owners);

- Regulations on buildings (restrictions on position, orientation and size of buildings);

- Local, regional, state development policies;

- Social health choices;

- Regulated activities (permitted, restricted and prohibited activities);

- Other supplementary regulations.

6.4 Representation of additional documents and raster images: OfficialDocumentation

As only class of the INSPIRE PLU data model, OfficialDocumentation has no explicit spatial relationship. It is used for assigning textually formulated regulations, raster images, official documents, or legal texts to a plan (SpatialPlan) or to specific elements of a plan (ZoningElement, SupplementaryRegulation).

7   GENERATION OF INSPIRE PLU ON BASE OF THE GERMAN STANDARD XPLANUNG

In the project XPlanung (Benner et al. 2007), the GML-based standard XPlanGML (Benner et al. 2010) has been developed, supporting the exchange of planning documents like Bebauungsplan (BPlan), Flächennutzungsplan (FPlan) or Regionalplan (RPlan), based on German national legislation (BauGB, BauNVO, ROG). On national level, XPlanGML thus supports the same type of information as INSPIRE PLU on European level. Implementation and usage of XPlanung are under way (Krause 2010) and on the technical level there are strong similarities between both standards. Therefore, it is obvious to use XPlanung for the implementation of the INSPIRE directive.

Spatial planning documents are generated with many different software systems. An effective way for producing INSPIRE-conform versions of spatial planning documents is to proceed in two steps (fig. 4): First to produce a XPlanGML version of the plan, which is automatically transformed into INSPIRE PLU in a second step. In order to proceed in this manner, transformation rules between XPlanGML and INSPIRE PLU need to be defined, ensuring that a valid, INSPIRE-conform data can be generated, representing the central content of the plan.

Figure 4: Automatic transformation of spatial plans into the INSPIRE PLU format

It turned out that the transformation XPlanGML ☐ INSPIRE PLU is principally possible, and that the major part of the national planning information can also be expressed in the European data format, but the transformation rules are quite complex (Benner 2013). Figure 5 shows as example the zoning plan (FPlan) of Hamburg visualised on basis of an XPlanGML and an INSPIRE PLU model with nearly identical content. The cartographic representation of the XPlanGML model is based on the German Planzeichenverordnung, for the INSPIRE model the portrayal rules of the specification (INSPIRE PLU, 2012) were used.

However, not in any case the total content of a BPlan or FPlan can be transformed. Exceptions are restrictions on the height of buildings, which need a precise definition of the lower reference (e.g. ground surface) and upper reference (e.g. ridge height). This specification is not possible with the INSPIRE PLU

syntax. For all XPlanGML Presentations Objects, supporting a problem suited, automated visualisation of a spatial plan, there also exist no counterpart in INSPIRE.

A major deficit of the INSPIRE PLU format is the fact that it does not support any relations between different SpatialPlan objects. XPlanGML supports such relations with the special semantic meaning, that a certain plan modifies, eventually only partial, another plan. This allows keeping the spatial plan and subsequently occurring modifications to be hold in separate data sets, which is common practice in German planning authorities. However, because the INSPIRE data format does not support this feature, for an INSPIRE-conform deliverable the different plan need to be integrated in one XPlanGML data set.

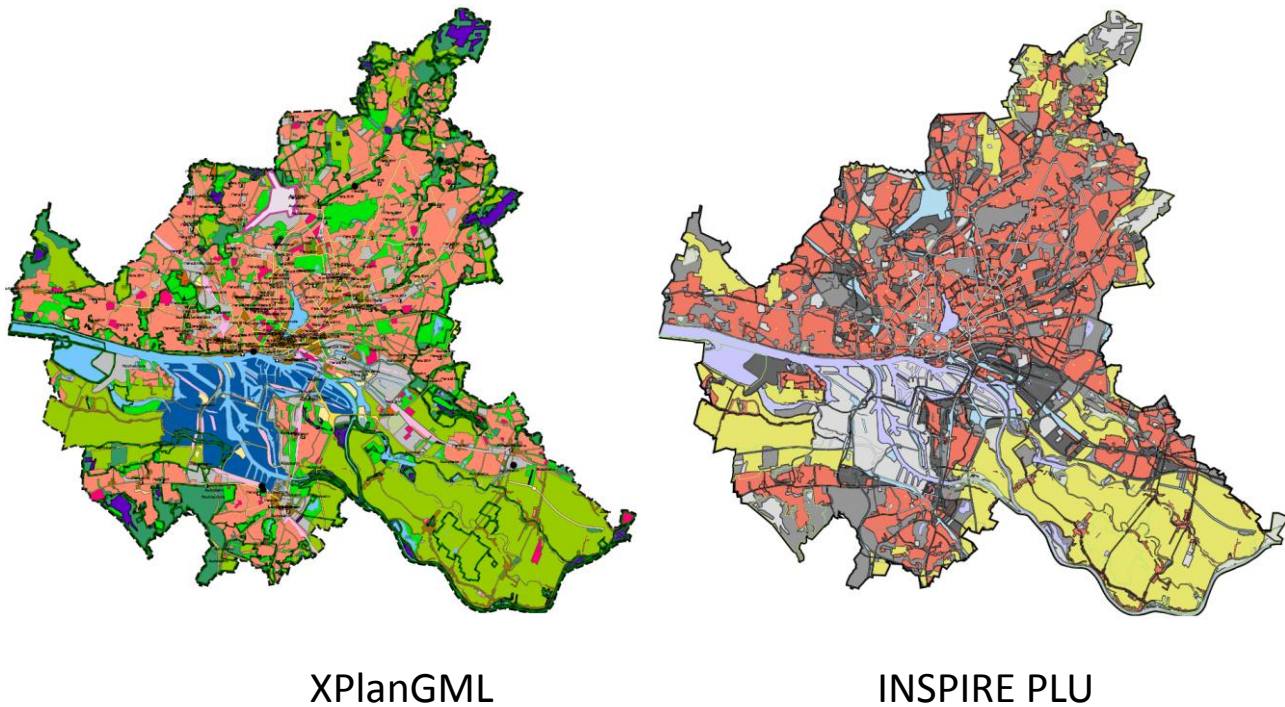

Figure 5: FPlan of Hamburg in XPlanGML and INSPIRE PLU format

8   SUMMARY AND OUTLOOK

In the INSPIRE initiative, the development of a trans-European Spatial Date Infrastructure is under way. In a few years, the Europe-wide access on spatial data from different thematic areas via standardised Internet services shall be possible, as well as the interoperable data exchange based on standardised exchange formats. Many of the thematic areas falling under the scope of INSPIRE are relevant for urban planning and should in future be used to support transnational planning activities.

During the last years, 34 different data exchange formats have been developed. Two of these, the INSPIRE data formats for modelling buildings (INSPIRE BU) and planned land use (INSPIRE PLU) were presented in the paper. The INSPIRE BU data supports four profiles with strongly varying functionality. The differences on the one hand affect the geometrical representation (two- or three dimensional), and of the other hand the amount of semantic information a building may contain. The profiles allowing a three dimensional geometrical representation of the building's geometry use central concepts of the international standard CityGML, e. g. the LOD concept or the classification of different parts of the building's exterior shell as thematic BoundarySurfaces. The main differences between the European and the international standard are that INSPIRE BU supports more non-geometrical, semantic attributes and explicit 2D geometry.

The INSPIRE data format for planned land use (INSPIRE PLU) is designed to support spatial planning documents of various governmental levels. The data format represents a spatial plan as a whole, two different types of spatially related elements of a plan (zoning elements and supplementary regulations), and elements like textually formulated regulations, raster images or legislation texts without explicit spatial representation. Central instruments for specifying the intended land use are four different classification schemata represented as hierarchical CodeLists. Two of them, the "Hierarchical Land Use Classification System" (HILUCS) for zoning elements and the "SupplementaryRegulationValue" system for

supplementary regulations are Europe-wide standardised and centrally managed by the EC. As not every speciality of national planning law can be expressed with these schemata, two Member State specific schemata (LandUseClassificationValue for zoning elements and SpecificSupplementaryRegulationValue for supplementary regulations) are provided. Every regulation in a spatial plan may optionally use these schemata, in addition to the mandatory classification due to the central schemata.

The paper finally illustrated the relation of the INSPIRE PLU data format with the German national standard XPlanGML. It turned out that rules can be specified; enabling an automatic transformation of most parts of XPlanGML represented plans to INSPIRE PLU. Some concepts of XPlanGML like explicit data supporting plan visualisation have no counterpart in the INSPIRE format, the corresponding information therefore will not be available on the European level. This causes problems in the context of modifying plans. The German planning legislation and the XPlanGML standard allow that a basic plan and subsequent modifications of this plan can be stored and exchanged as separate data sets. Because the INSPIRE PLU format has no concept for this, an integration of basic plan and modifications needs to be performed prior to the XPlanGML to INSPIRE PLU transformation.

It is expected that the specification of all INSPIRE data formats will be finalised soon, and that the corresponding Implementing Rules, defining the Europe-wide legal basis for the activities, will be adopted in the second half of 2013. For the actual implementation and usage of the Spatial Data Infrastructure, still a lot of work has to be done on European as well as national level. So, registry services supporting the different CodeLists need to be implemented on European and national level. A lot of EC Member State specific CodeLists still have to be specified, and transformation rules defining the mapping between exiting standards like CityGML and XPlanGML and the INSPIRE standards need to be defined.

Urban Coastal Environment and Management Policies in Attica

Minas Angelidis, Agisilaos Economou

(Professor, National Technical University of Athens (N.T.U.A.), Patision 42¸10682, Athens, Greece Email: angelidi@central.ntua.gr)
(PhD National, Technical University of Athens (N.T.U.A), Nikaias 18,17122, Athens, Greece, Email: aghs@mail.ntua.gr)

1 ABSTRACT

Nowadays, the coastal area of the Attica region faces many problems that degrade natural resources and the quality of life of the residents. In addressing these problems, the European Union has issued several directives and guidelines for actions taken at a local and regional level.

The research refers to the urban sprawl of cities on the coastal environment and its repercussions. Specifically it focuses on the problems of coastal cities as well as the policies that have been implemented to address these problems by taking into account the directives of the European Union.

To carry out the research, land use plans, legislation for regulations land use, statistical data and existing surveys, are used. Also a research in situ and a method of personal interviews with the persons who are responsible for dealing with the problems that coastal municipalities are facing and the policies which have been implemented in order to face them, took place.

The research showed that the coastal area of the Region of Attica has a great economic and environmental significance for enhancing the quality of life for residents. The degradation of natural resources is continuing, despite the policies that have been implemented up-to now. Thus, the search for new policies and measures as well as the active participation of citizens for an integrated management of the coastal urban environment are necessary.

2 INTRODUCTION

Nowadays, the proportion of European citizens that live in urban areas stands at 80 % and most of it is concentrated in the coastal area (CEC, 2004). Coastal cities face many environmental problems that degrade the natural and cultural resources, having as a result serious repercussions on quality of life and the sustainability of these areas.

According to the Sixth Action Programme for the environment, the main issue concerning urban areas were the management of the urban environment, sustainable transport, construction and urban planning and harmonization of different policies in accordance to the instructions of the European Union (EC, 2007).

Additionally, the Seventh Programme proposes the research for the urban environment to focus on innovative urban management, reconstruction of the human environment, promotion of cultural heritage, environmental risk assessment, energy efficiency, renewable energy, safety and protection.

Urban areas are currently called upon to play an important role in reducing greenhouse gas emissions and adapting to that decrease. The basic guidelines involve sustainable use of natural resources, waste production prevention, recycling waste, saving energy, using renewable energy sources, proper land-use planning, at protection of soil, water, air end other (CEC, 1997).

Also, urban areas play an important role in achieving the objectives of the EU strategy for sustainable development and are both economic drivers and areas where entrepreneurship and investments take place.

Regarding coastal urban development, the European Union is pointing out that: (OJE, 2009).

- The distribution of land uses in the coastal zone should be balanced and the unnecessary and the excessive concentration of urban development should be avoided.

- Priority should be given to public services and activities that require immediate proximity to the sea.

- The development of spatial plans and programs that cover the urban development and socio-economic activities as well as and other relevant sectoral policies should be secured.

- The linear extension of urban development should be limited and a new transport infrastructure along the coast should be created.

Taking the above into account, the present work refers to a research in coastal urban areas. As a case study the coastal urban area of Athens is selected. The problems which this particular area presents, the policies

that have been implemented until today, as well as the measures that have been taken for protection and its upgrading were investigated.

3 METHODOLOGY

To complete our study, legislation for regulations land use, statistical data and existing surveys and land use plans, are used. The study is based on a survey in situ and a series of personal interviews with officers of the municipality who are responsible for dealing with the problems that coastal municipalities are facing and the policies which have been implemented in order to face them, took place. Also, a geographic information systems (GIS) is used.

4 THE COASTAL REGION OF ATTICA

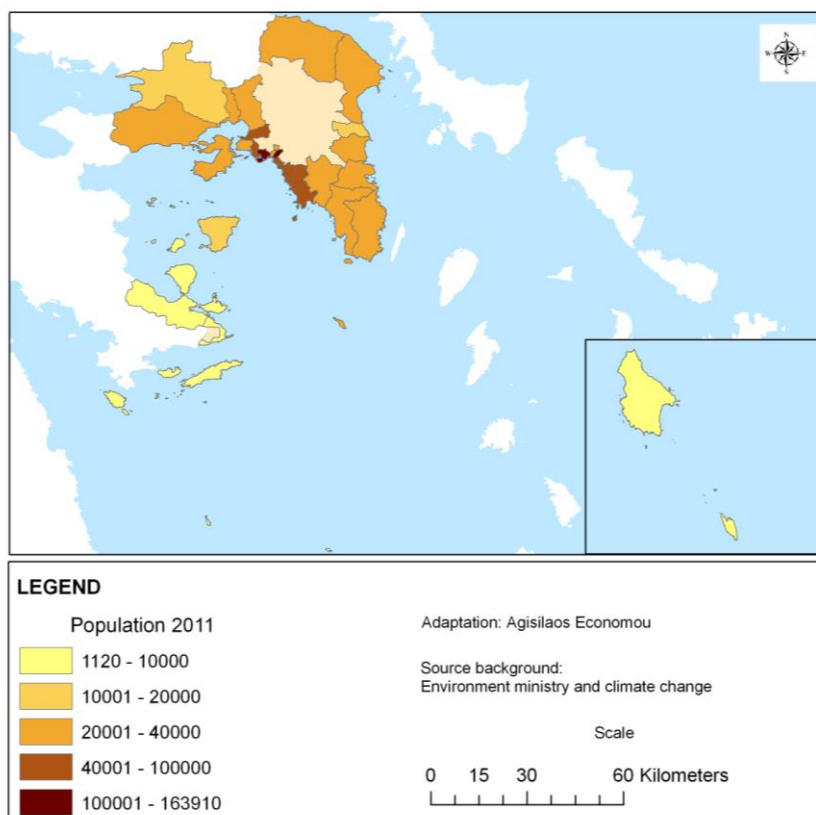
The coastal region of Attica has an area of 3092.9 Km2 and covers 81.22 % of the total area. According to the nomenclature of Territorial Units for Statistics (NTUS), belongs to category NUTS II. In this region lives 4,335,110 inhabitants, a number that corresponding to 62.09 % of the total population in the region of Attica (HSAG, 2012a) (Fig.1).


Fig.1: Population in the region of Attica.

The importance of the coastal region of Attica is great because:

- It presents good climatic conditions, mild and wet winters and relatively warm and dry summers, a high rate of sunshine and an average annual temperature ranging from 16 oC to 18 oC (HNMS, 2012).

- It presents great biodiversity. Many areas are included in the lists of the European Union as a highly valued landscapes, habitats Corine, area Natura and National Parks. The main areas that have been included in the protection Network are the Mount of Parnitha, the area of Oropos and the estuaries of Asopos, the area of Schinias, Vravrona, Sounio with the Islet of Patroclus, the mount of Hymettus, the Vouliagmeni lake and the National Park of Parnitha (Fig. 2).

- It has remarkable natural resources, such as the plain of Mesogion and Marathon.

- It has remarkable cultural resources such as global monuments, Temple of Poseidon (Sounio), Temple of Amfaias (Aegina)

- It includes a great number of sports facilities and Olympic facilities that were created to serve the 2004 Olympic Games. The Olympic projects are not sufficiently utilized so it order to contribute to tourism development.

- The region of Attica includes four ports of National Importance (Piraeus, Eleusis, Rafina and Lavrio) which are associated with the Trans-European Transport Network. It also includes the largest airport in the country Elefterios Venizelos, airport, which establishes the region of Attica as a primary national and international hub of Greece.

- It presents a strong growth of coastal areas driven by residential and tourism development. Tourism is oriented to tourism for water recreation in coastal areas (Fig. 3).
Fig 2: Protected areas in the Region of Attica
Fig .3: Number of overnights stayes of tourist during the year 2009 in the coastal area of Attica

According to the statistics data, the number of overnight stays in the coastal area of Athens presents an upward trend during the period time 2005 – 2009 (Fig. 4). The higher number of overnight stays of tourists is presented in coastal municipalities with have remarkable hotel potential.
Fig.4: Number of overnight stays of tourist during the period 2005-2009 in the coastal area of Attica (HSAG, 2012).

The results showed that the municipalities of Piraeus, Glyfada, Vouliagmeni, Faliro and Megara present the higher rates of tourism, in contrast to other areas which present fewer overnights stays. It is underlined that, the tourists movement in the Municipality of Piraeus is supported by passenger and commercial traffic of the port. Also, the area of Glyfada is a center for entertainment and commercial traffic for the southern suburbs

and an attraction pole thanks to its beaches. Vouliagmeni presents big hotel units due to the large area of beaches and the remarkable natural environment that it has.

4.1 Problems in the coastal urban area

The urban environment of Athens faces a number of problems associated with the evolution of the urban network and the spread of the conurbation Region. The reason for this expansion was the degradation of the central area of Athens.

This fact has a result to push residents to look for new housing near the center which also present remarkable natural resources.Thus, the coastal area of Attica and especially from the area of Paleo Faliro to Vouliagmeni, became a place for the accommodation of people who look for a better quality of life.

In this survey an interview with the staff that is responsible for coastal municipalities from Moschato to Vouliagmeni, took place. Our research aimed to identify the main problems that the area presents and which are officially registered by the responsible authorities which manage them. The survey showed that:

- The coastal road has cut off the coastal area of the urban fabric.

- There are incompatible land uses in the coastal zone.

- •The Presidential Decree that determines land uses and limits of construction, has not been applied except from the Alimos area.

- A little recycling rate (20 %) has taken place in some municipalities.

- There is a lack of solid waste transfer stations, resulting in the increase of transportation costs.

- Circulatory problems (noise, congestion) due to the continuing increase of cars, the lack of parking and the fact that the means of stable track do not serve all areas of the Capital, appear.

- Noise pollution from nightclubs is presented.

- The involvement of many authorities often creates problems for regulations of land uses.

- Land use intensity problems and increasing pressures for the expansion of construction in search of new residential areas, are presented.

- The inadequate flood protection system, the sewage, wastewater ,and rainwater problems, as well as the covering of the two rivers of Attica, Kifisos and Ilisos and the excavation and construction in their streams, had as a result the appearance of flooding phenomena.

- The land use plans do not cover the entire area so that areas which are outside the plan undergo heavy pressures to expand construction.

However, it is noted that the region's coastal area presents remarkable natural resources, despite the large construction development that it suffered from the 60s and onwards (Fig. 5). Nowadays, natural resources are receiving heavy pressure from the continuous construction and the high intensities of land uses.
Fig.5: Building in coastal area of Attica (HSAG, 2010).

4.2 Construction in the coastal area of Attica

Many of the above problems occur in the rest of the coastal area of Attica, with different intensity. For example, coastal areas in the eastern region, face wastewater problems due to their remoteness from the major sewage treatment plant in Psyttalia and the lack of sewage treatment plants.

Other areas face problems of illegal construction (area of Sxinia) and other area face degradation problems due to the existence of industries (Area of Aspropyrgos). Also, coastal areas host ports and shelters, which are threatened with pollution due to the movement of boats.

A large number of areas are under protection status, due to their natural and cultural resources. Nowadays these areas are threatened by human activities such as forest fires, logging, illegal construction, construction expansion and others.

Green problems also appear on dense urban areas. Many of these areas have a low proportion of green areas per inhabitants, while the lack of open spaces as well as their improper utilization, makes the situation worse.

However, there are also examples of actions such as regeneration, planting, cleaning of the area and others that have upgraded many areas and have improved the quality of life for their residents .

A typical example is the area which hosted the Olympic works. The supporting works that have been constructed in order to serve the Olympic Games, have contributed significantly in improving the environment and the quality of life.

It is underlined that apart form the environmental problems, many areas present other problems such as unemployment, poverty, immigration and crime. According to the latest statistical data of the National Statistical Service, in the region of Attica, the unemployment rate for the third quarter is 26.8 % (HSAG, 2013).

From 2009 until today, due to the global economic crisis, the Attica region shows a decline in all sectors. Moreover, the poor fiscal policy had as a result the swelling of the external debt of the country, which has affected the region's economic growth and the welfare of its residents.

The tough fiscal policy and the cut-backs in the public sector have major economic consequences on the private sector as well, resulting in reducing incomes and job losses. Thus, intra-regional disparities such as demographic inequalities, rising unemployment, population movements in search for work and others, increase. The economic crisis has affected the construction activity in this specific area, which is currently in decline.

4.3 Measures in order to face problems and growth prospects

The measures which are proposed to address the problems in the study area are:

- Implementation of legislative decrees
- Utilization of areas with present remarkable natural resources.
- Increase recycling and expansion of recycling programs
- The utilization of natural resources (wind and solar). Nowadays, taking into account the installed capacity (wind and solar) in the region of Attica, it is found that the penetration rate of electricity production from renewable energy sources is very small. This means that there is great potential for expansion of both photovoltaic systems and wind farms, especially in areas with significant wind resources.
- Rehabilitation of degraded areas
- Traffic regulations and take measures for noise pollution.
- Expansion of sewerage and rainwater networks.
- Creation of bicycle routes and encouragement of people to use more environmentally friendly means of transport such as cycling.
- Better use of beaches, protection from arbitrary structures, cleanliness and development of other maritime activities.
- Utilization of open spaces and increase of green areas.

- Increase on the use of natural gas and expansion of the existing gas network, with the aim of reducing emissions of air pollutants

- Utilization of abandoned areas in order to limit construction

- Connecting the beachfront with the urban fabric (subterranean access)

- Utilization of all Olympic sports facilities which are located in the coastal area (organized sporting events, exhibitions, use by the local residents).

- Use of public property. Nowadays at the coastal region of Attica there are large areas of open space that could be used appropriately by attracting new businesses or even by creating green spaces.

- Strengthening of tourism development, by means of upgrading hotel accommodation in order to provide high quality services.

- Strengthening of rural economy. In the Attica region there are many areas that could be used appropriately and increase agricultural production.

- Creation of additional wastewater treatment plants for areas that have none, as it is necessary for water pollution prevention.

4.4 Other actions and measures

In the region, 94 General Urban Plans have been approved. Also, Development Control Zones have been approved for areas that are outside the boundaries of these plans, and laws relating to the permitted land uses in protected areas have been passed. Such examples are the area of the mount of Egaleo, Hymettus, Penteli, Lavreotiki and Parnitha.

Many works in the coastal area have been funded by European programs. For example, in the period 1994-1999, the Region of Attica was supported with 950.1 million euros for projects that were included in the Regional Operation Programmes (ROP) for Attica. The ROP for Attica projects were focused on priority axis, such as human resources, support in productive activities in the region, transport infrastructure improvement, improvement of the quality of life and technical assistance.

Also, the coastal area is supported by the National Strategic Reference Framework (NSRF) for 2007-2013, which aims to stimulate the development of better quality of life, strengthen accessibility infrastructure and infrastructure in general, increase competitiveness and revitalize urban areas (MDCITN, 2007).

5 CONCLUSION

By recording the current status quo, the advantages and disadvantages' of the study area, the following conclusions have been reached.

The main features of the coastal urban environment in the Region of Attica are, unregulated urban sprawl, traffic problems, insufficient urban and suburban green areas, lack of public open spaces, air pollution, poor sanitation rainwater and wastewater infrastructures, and shrinkage of the unstructured urban environment.

As noted above, the coastal area has remarkable natural resources. These natural resources are currently receiving heavy pressures from human activities and are threatened by degradation. The measures that have been taken through the spatial plans for land use regulation and restriction of construction, are not sufficient. There are many areas that are outside these land use plans, which are under heavy pressures from existing land use intensities many of which have been degraded.

The survey showed that new measures and new actions are necessary for further protection of the coastal area. The conservation of natural resources is a top priority, because it is due to them, that the coastal areas will remain sustainable. Otherwise, by degrading the natural resources, in addition to the degradation of the quality of life, these areas lose the advantage for economic growth, as well.

Nowadays, due to the economic situation of the country, new initiatives for the growth of the economy which is in recession, are sought. The conservation and utilization of natural resources, of such favored by nature regions, such as the coastal urban area of Attica, is becoming particularly important, as this area is a valuable asset on many levels.

Urban Health in India: a Challenge to Policy Making

Indrani Gupta, Swadhin Mondal

(Indrani Gupta, Professor, Institute of Economic Growth, University of Delhi, India, ig.indrani@gmail.com)
(Swadhin Mondal, Consultant, Institute of Economic Growth, University of Delhi, India, kumar.swadhin@gmail.com)

1 ABSTRACT

Urban health has received relatively less focus compared to rural health in India, especially the health of the urban poor. Rapid urbanization has been accompanied by an increase population in urban slums and shanty towns, which are also very inadequately covered by basic amenities, including health services. This paper presents existing and new evidence that shows that health inequities exist between the poor and non-poor in urban areas, even in better-off states. The lack of evidence-based policies that cut across sectors continues to be a main feature of the urban health scenario. While the problems of urban health are more complex than that of rural health, this paper argues that it is possible to make a beginning fairly quickly by (a) collecting more evidence of health status and inequities in urban areas, and (b) correcting major inadequacies in infrastructure – both health and non-health – without waiting for major policy overhauls.

2 INTRODUCTION

The share of the urban population in global population has crossed the 50 percent threshold in the year 2009 (Keating and Natella 2012). By 2030 urban population will be more than 60 percent of the global population (UN 2006). Urbanization rate is rapidly increasing in Asia, South America and Africa. More than 95 percent urban growth will occur in developing countries, with over 60 percent occurring in Asia (McGee 2011). South Asia will see the largest growth with an increase of urban population by more than five times (USAID 2006). Over 2001-2011, the growth of urbanization (2001-2011) was 31 percent in India, which is somewhat lower compared to other south Asian countries (Dutta and Noble 2004). However, given that around 31 percent of the total population lives in urban town and cities (Census 2011), in absolute terms more than 377 million people live in urban areas in India. Out of world's ten largest urban agglomerations, three are in India (Delhi – 22,157,000; Mumbai – 20,041,000; and Kolkata – 15,552,000) (World Demographic Profile 2012). Projections suggest that India will have more than 700 million urban populations by the 2040s (GoI 2011), with continuous increase of urban population in Class 1 towns or cities with 100,000 or more population.

Urbanization is an important indicator of economic development and social transformation. Rapid urbanization potentially creates enormous economic advancement and gives an open environment to the urban as well as rural communities to prosper in a modern way (Redman and Jones 2004, Ding 2009, FIG Commission 3 2010). However, there are significant environmental, social and public health implications of a burgeoning urban population in cities and towns ill-equipped to deal with such rapid change. The first visible impact of this process is the formation of slums and shanty towns which results from cities not being able to accommodate migrants in habitable areas well-served by basic amenities.

Evidence exists to indicate that lack of basic infrastructure like proper water supply, electricity, sanitation and health facilities including health coverage lead to outcomes such as increases in infectious diseases and limit access to adequate health care (Kessides 1997, Gupta and Guin 2012). However, the impact of this on the health of the urban poor continues to be somewhat sparse.

Rapid urbanization, therefore, calls for major shifts in approaches to tackle urban health issues that recognize the dichotomy that exists between the status of the urban poor and the non-poor. To what extent has India been able to make this shift in policy? This paper explores to what extent India has been able to carry out this shift in its policy by carrying out an exploratory analysis of the current urban health issues, the policies that exist to deal with urban health, and implications for the future.

3 DATA AND METHODS

India has no national database on the health of the urban poor, indicating lack of proper recognition of this issue at the policy level. The clubbing together of slum and non-slum populations under the label "urban" prevents a proper analysis of health outcomes. While further regional and geographic nuancing is possible, at the very least it is important to do separate analyses for rural, urban slums and urban non-slum areas. The usual rural-urban analysis is inadequate in the current context of rapidly changing urban scenario, which is

increasingly bringing to focus the almost parallel sub-economies of original and earlier settlers and later migrants (WHO 2011, ICSU Planning Group 2011).

The only comprehensive source of statistics on disease patterns in India is the Central Bureau of Health Intelligence (CBHI) under the Ministry of Health and Family Welfare (MoHFW). However, the report on health status indicators (MoHFW 2010) does not separate disease data by residence for communicable diseases – a serious omission that prevents analysis of even rural-urban trends. There are a few others sources of national data like the National Family Health Survey (NFHS) and the District Level Household Survey (DLHS) that do some disease reporting by residence, and these can be cross-tabulated by economic status to get some insights into how the urban poor are faring. The subsequent analyses are based on a variety of sources such as these, in an attempt to do a situational assessment of the health situation in urban India.

4 EMPERICAL RESULTS

4.1 Changing Disease Patterns in India

India has been witnessing an epidemiological transition with increasing burden of both communicable and non-communicable diseases. Around 52 percent of total life years lost is caused by communicable disease, with 35 percent from non-communicable disease and the remaining from injuries (WHO 2012). While morbidity and mortality from NCDs are rising quite rapidly, communicable diseases still remain a very important part of India's disease profile. The top 5 causes (among infectious and parasitic diseases & respiratory infections) by estimated Disability Adjusted Life Years (DALYs) lost in India are: lower respiratory infections, diarrheal diseases, childhood-cluster diseases, tuberculosis and HIV/AIDS, indicating the fairly preventable nature of the current disease profile in the country (WHO 2009), signifying the potential role that rapid urbanization can play in the current disease profile of the country.

4.2 Urban and Slum Population in Indian States

Census 2011 (Government of India 2011) indicates that among the major states, Tamil Nadu and Kerala have the maximum share of urban population to total population (48.4 % and 47.7 % respectively). In fact, other major states like Maharashtra, Gujarat, Karnataka, Punjab, Haryana, Andhra Pradesh (AP) and West Bengal (WB) all have share of urban population above the national average of 31.1 percent. Interestingly, Jharkhand, Chhatisgarh and Orissa have fairly low share of urban population. However, owever, Hodfdfhjfh do these states also have a high share of slum population in their urban areas, compared to other states? The National Sample Survey (NSS) Office of Government of India conducts nationally representative surveys periodically on a variety of topics. Table 1 is based on the 65th Report of the NSS on the characteristics of urban slums in 2008-09.

The table shows only those states that have significant slum populations. Among these Maharashtra has the maximum share of slum population in India (34.7 %), followed by Andhra Pradesh (10.7 %) and West Bengal (10.3 %) respectively. The other states listed are also high in slum population compared to the rest of the states not listed in this table. It is important to note the presence of three Empowered Action Group (EAG) states in this group: Madhya Pradesh (MP), Orissa and Uttar Pradesh (UP). Clearly, high share of urban population in total population need not always indicate high ratio of slum populations.

In India, notified slums are those that are recognized by municipalities, corporations, or any other local authority, and are, therefore, under policy ambit, at least on paper. By comparison, non-notified slums have almost no legal standing, making these vulnerable to policy omissions. Greater the share of non-notified slums in total slums, greater will be the possibility of inadequate policy targeting and greater will be the vulnerabilities to a variety of shocks, including health shocks.

As Table 1 shows, almost all the states except AP have 50 percent or more slums that are non-notified. Orissa has as many as 68 percent of the slums in the non-notified category. This brief analysis throws up the possibility of bigger and economically better off states like Maharashtra contributing to the disease burden in the country. However, mere presence of a large slum population is not a sufficient; whether the states can effectively deal with the various ramifications of having significant slum populations is explored below.

States	Notified slum (%)	Non-notified slums (%)	State share of slums in India (%)
Andhra Pradesh	75.5	24.5	10.7
Delhi	33.8	66.2	6.4
Gujarat	40	60	6.9
Karnataka	49.7	50.3	4.6
Madhya Pradesh	34.3	65.7	4.5
Maharashtra	54.5	45.5	34.7
Orissa	32.3	67.7	4
Tamil Nadu	50.7	49.3	6.9
Uttar Pradesh	55.7	44.3	4.9
West Bengal	49.1	50.9	10.3
All India	50.6	49.4	100

Table 1: Percentage of notified and non-notified slums in different states & India. Source: NSS 65th Round on "Some Characteristics of Urban Slums 2008-09", (2010)

4.3 Basic Amenities in Urban Slum Areas

Are states are able to provide the slum areas with basic amenities like water, electricity, sanitation and facilities like schools and hospitals? We look at four basic indicators: (a) water-logging during monsoon months, (b) presence of latrine, (c) garbage disposal arrangement and (d) presence of hospitals, all of which can potentially lead to health hazards, especially the spread of infectious diseases.

For notified as well as non-notified slums, Orissa, Tamil Nadu, Gujarat and UP are doing quite poorly in terms of basic amenities (Table 2). Some of the other states like West Bengal and AP are also not doing that much better. In absolute terms, all the four indicators are much worse for non-notified slums compared to notified slums, in all the states. If these amenities were the only determinants of health outcomes, then all the states listed should show unfavourable outcomes. Clearly, the economic development of the state also matters in this context. Before we turn to a more nuanced picture of development in these states, we present some evidence on inter-state differences in health outcomes.

States	Notified Slums				Non-notified Slums			
	Waterlogged during monsoon	No Latrine	No Garbage disposal arrangement	No hospitals within 1 KM	Waterlogged during monsoon	No Latrine	No garbage disposal arrangement	No hospitals within 1 KM
Andhra Pradesh	18	8	3	41	43	27	40	69
Delhi	14	0	0	10	77	11	20	46
Gujarat	59	39	62	52	53	48	33	60
Karnataka	45	0	0	19	28	17	15	56
MP	24	18	48	85	81	24	24	20
Maharashtra	37	1	3	45	58	6	6	47
Orissa	99	49	33	67	38	36	48	75
Tamil Nadu	57	27	12	34	56	40	39	83
UP	60	1	16	47	66	16	54	86
West Bengal	52	13	11	55	40	10	22	71
India	41	10	10	46	54	20	23	58

Table 2 : Basic amenities in slums, by type of slums. Source: NSS 65th Round on "Some Characteristics of Urban Slums 2008-09", (2010)

4.4 Selected Health Outcomes Across States

4.4.1   Infant and Under-5 Mortality Rate: Sample Registration System (SRS)

Concerns have been raised about India's ability to meet the Millennium Development Goals (MDGs) and the unresponsiveness of the infant mortality rate (IMR) to further prevention efforts (Deolalikar 2005, Paul et al 2011). Relatively much less focus has been on the extent to which urban India contributes to the lagging IMR and MMR in the country. How are states placed in terms of IMR and U5MR, two important indicators of the MDG goals? Table 3 presents the 5 worst performing states for IMR and U5MR based on the SRS Bulletin (SRS 2011).

Clearly, Assam, Orissa, UP, MP leads the group of laggard states on these indicators. States formerly part of UP, MP and Bihar (Uttarakhand, Chattisgarh and Jharkhand) also fall in the same category. That this Empowered Action Group (EAG) of states are doing poorly is not a surprise, given their other socioeconomic indicators. The states are doing well are led by Kerala, but there remains a large gap between Kerala's performance and the other states. For example, in 2010, IMR in Kerala was 13, followed by Tamil Nadu at 24. While this scenario pertains to mother and child health, it will be interesting to see whether similar patterns are observed for other diseases as well.

	Worst performing major states	Best performing major states
Infant Mortality Rate	MP, Orissa/ UP, Assam, Rajasthan, Chattisgarh	Kerala, Tamil Nadu, Maharashtra, Delhi, West Bengal, Punjab
Under-5 Mortality Rate	MP, Assam, UP, Orissa, Rajasthan	Kerala, TN, Delhi, Maharashtra, WB
Maternal Mortality Rate	Assam, UP/Uttarakhand, MP/Chattisgarh, Bihar/Jharkhand, Orissa	Kerala, Tamil Nadu, Maharashtra, AP, West Bengal

Table 3: Performance of states in IMR, U5MR and MMR. Source: Various bulletins of Sample Registration System, India

4.4.2   Central Bureau of Health Intelligence (CBHI)

CBHI is the only source of national health data, it was important to use it to see the trends, with the caveat in mind that the data is based on less than full reporting across states. The National Health Profile 2010 reported by the CBHI indicate that among the various communicable diseases, acute respiratory infections and acute diarrheal diseases reported the highest cases during 2010. In addition, pulmonary tuberculosis, malaria, enteric fever, pneumonia and gonococci infection are the other diseases that saw more than 100,000 cases. Among these, pulmonary TB reported the maximum number of deaths. While the data the data is not presented by residence, the high cases of these infectious diseases in the country does raise the very real possibility of contribution of areas such as slums contributing to the total case load.

An analysis of the top 5 states contributing to water-borne and vector-borne communicable diseases in the last 10 years indicate that Orissa has been in the top position in vector-borne diseases. Other states like Jharkhand, West Bengal, Chhatisgarh, Madhya Pradesh have also been frequently in this group, and even bigger states like Maharashtra have shown up more than once in the top 5 list. For water-borne diseases, AP, Karnataka, Maharashtra, West Bengal showed up frequently in the top 5 for the last 10 years. While the data does not report prevalence, presumably high burden states would definitely drive the total disease burden in the country.

In sum, the evidence on MDG indicators and other infectious diseases indicate that while the EAG states continue to do poorly on all fronts, states like Maharasthra and West Bengal do not seem to be doing as well if other indicators like infectious diseases are looked at in terms of total case load.

4.4.3   Other Evidence on Disparities in Health Outcomes

There is mounting evidence that the health outcomes for the urban poor and non-poor are highly unequal even in the better off states. Evidence from an 8 city study (IIPS 2009) indicates that IMR for slums and poorest quintile are always worse than those for the city as a whole as well as non-slum population. The study included cities from the better-off states like AP (Hyderabad), Maharashtra (Mumbai) and Tamil Nadu (Chennai). Similarly, stunting was seen to occur at a much higher rate among the city poor and slum-dwellers compared to others. Similar evidence of inequality between urban poor and non-poor women in terms of their health status also now exists from a variety of sources (Agarwal 2011). As for service delivery,

available evidence does indicate that, for example, antenatal visits were much lower at 54.2 percent for the urban poor compared to the 83.1 percent for the urban non-poor (UHRC 2007).

As for home deliveries and vaccinations, a 4 city recent survey conducted among 2000 households covering 10,929 individuals in Ludhiana, Jaipur, Mathura and Ujjain on access to health services indicated lack of government facilities and services, a very high preference for private health facilities, high expenses in both private and public facilities and a perception that private facilities were offering high quality services (Gupta and Guin 2012).

We contend that even economically better off states need to watch out for infectious diseases where both urban and rural areas remain vulnerable. Due to the very nature of congested areas such as slums, states like Maharashtra, AP and West Bengal – that are dealing with such large settlements – need to be alert to relatively adverse health outcomes from such areas, in both maternal/child health as well as infectious diseases. Evidence exists to indicate that overcrowding makes outbreaks of respiratory diseases such as tuberculosis much more likely (Shetty 2011). Other studies have documented that urban areas contribute about 15 percent of the total malaria cases in India and are primarily associated with construction activities and migrant population (Dash et al. 2008). Continuous construction activities and increasing slum populations with poor sanitation have been contributing to increasing cases of malaria in urban areas (John and Thomas 2011). While the CBHI show a sharp increase in dengue cases in the last 4 years, there is enough evidence of frequent outbreaks of dengue in urban areas. It is now well known that dengue is more prevalent in urban and semi-urban areas, particularly in Asia, with mosquitoes breeding water storage containers in households (Sommerfeld 2011).

Below we present some fresh evidence from the DLHS-II on TB and Malaria for rural and urban areas as well as by economic categories in Figures 1 and 2. Clearly, the top contributors for both the diseases are the EAG states. To compare with more developed states, two major states that contribute significantly to the total disease load have been taken as well. In terms of estimated prevalence the North-Eastern (NE) states top the list for both malaria and TB, but do not necessarily add significantly to the total disease burden in the country. However, Orissa has a high prevalence as well as it contributes a high share to the total malaria cases in India. Apart from NE states and Orissa, Madhya Pradesh, Chattisgarh and Maharashtra also have high prevalence compared to the other remaining states. For TB, the major states with high prevalence are Bihar, AP, West Bengal and UP in that order.

Figure 1 show that the all-India estimated TB prevalence per 100,000 population was 366 for rural areas compared to 225 for urban areas respectively in 2002-2004, indicating fairly high burden of TB in urban areas. However, if we look at prevalence among economic categories, we see that the prevalence of TB among low income groups is highest relative to the middle and high income groups for both rural and urban areas. Looking at these high burden states, one can see that the low economic categories had a higher prevalence in almost all the states including economically better off states like AP and to a lesser extent for Maharashtra for both rural and urban areas. For example, in urban areas of UP, Bihar and MP the prevalence is significantly high among the low economic categories.
Figure 1: Persons suffering from TB (per 1,00,000 population) by Economic Class in Selected States. Source: District Level Household Survey-3, Govt. of India, 2007-08.

Similarly, Figure 2 for malaria shows higher prevalence for rural areas, but within both urban and rural areas, the prevalence is relatively higher for low economic categories. Again, this is true in most cases except for urban UP (where the middle economic category has slightly higher prevalence compared to the low category).
Figure 2: Persons suffering from Malaria (per 1,00,000 population) by Economic Class in Selected States. Source: District Level Household Survey-3, Govt. of India, 2007-08.

4.4.4 Socioeconomic Development and Health

Clearly, while a complex issue; urban health would definitely be impacted by the level of development of states by varying the extent to which states will be able to carry out prevention and control. Basic statistics on per capita GDP, poverty, inequality and female literacy rates in all the states mentioned in the previous discussion are presented in Table 4.

Major states like AP, Gujarat, Karnataka, Maharashtra are doing relatively much better on all the economic development fronts compared to states like MP, Orissa and UP; these also have a much higher per capita expenditure on health, unlike the three other states. Clearly, the health outcomes in these states are expected to be relatively better despite concerns like large slum population and lack of suitable amenities for such populations. In other words, the relative welfare of the worse off in these states is better than the welfare of similar individuals in poorer states. This is supported by evidence that indicates, for example, that neonatal mortality among urban poor in Maharashtra was 21 compared to that in MP, which was at 54.8 (Agarwal 2011).

States	Per capita SDP 2011-12	Poverty (2004-05)	Lorenz (relative rank of states indicated in parenthesis)		Female literacy (2011 Census)	Per capita health expenditure
			Rural	Urban		
Andhra Pradesh	71540	29.9	0.261(27)	0.360(28)	59.7	402
Gujarat	75115	31.8	0.236(18)	0.305(12)	70.7	320
Karnataka	69493	33.4	0.241(21)	0.338(23)	68.1	405
MP	32222	48.6	0.277(31)	0.366(29)	60.0	214
Maharashtra	83471	38.1	0.232(16)	0.378(33)	75.5	351
Orissa	46150	57.2	0.249(24)	0.354(26)	64.4	303
Tamil Nadu	84058	28.9	0.255(25)	0.323(18)	73.9	421
UP	29417	40.9	0.229(15)	0.377(32)	59.3	269
West Bengal	55864	34.3	0.221(13)	0.376(31)	71.2	292
India	60972	37.2	0.270	0.362	65.5

5 DISCUSSION AND POLICY IMPLICATIONS

It is critical to collect and analyze data that would enable evidence-based policy-making around urban health. There is a need to separate the health outcomes as well as mapping of health services for urban and rural areas, and within urban areas for the poor and the non-poor. The peculiar nature of urban habitats necessitates cross-cutting and multi-sectoral policies that can be effective only if backed by solid evidence on status and reasons for health disparities and access to services.

The need for a more nuanced health policy that is more consistent with the regional and local realities is not new (Gupta & Mitra 2002, Peters et al 2003). The fact that increases in income in urban areas does not necessarily ensure improvements in living condition are now increasingly being recognized (Madhiwalla 2007). The Planning Commission's report of the Steering Committee On Urban Development For Eleventh Five Year Plan (2007-2012) states that "Due to burgeoning urban population growth, the big cities viz., metropolitan (million plus) and mega cities are under severe strain particularly in terms of making access to infrastructure services to the inhabitants. Overall the urban dwellers in the country have low access to infrastructure services such as water supply, sanitation, power supply and solid waste disposal" (Eleventh Five Year Plan 2007-12). In December 2005, the Jawaharlal Nehru National Urban Renewal Mission (JNNURM) was launched to give focused attention to integrated development of urban infrastructure and services in select 63 cities with emphasis on provision of basic services to the urban poor including housing, water supply, sanitation, road network, urban transport, development of older cities etc. However, it has been argued that the progress has been slow, though some cities did benefit greatly from the focused attention. The reasons for slow progress have to do mainly with inadequate financing, governance and capacity especially at state levels (Ahluwalia 2011).

There remains too little focused attention on urban health. While much of the ills come from the inadequacies and inefficiencies recognized above, the government still has no proper implementation plans for the urban health. The planned National Urban Health Mission (NUHM) visualized in 2010 (Government of India 2005) has yet to take off, and while there are indications that the government may revise the earlier NUHM blueprint (ToI 2012), it is not clear what the timeline on this will be and how soon one can expect serious policy actions. In any case, there is no evidence that serious urban health data collection is going to precede the launch of such a mission, raising concerns about its effectiveness.

Generally, the state of policymaking in India's health sector is very evident by the recent stand-off between the Ministry of Health and Family Welfare and the Planning Commission around proposed meager allocation to the health sector in the 12th Five Year Plan and its interpretation of the role of private and public sector in the report of the High Level Expert Group (HLEG) on Universal Health Coverage(PTI 2012, Nigam 2012). Clearly, the coordination that is required to make that quantum jump in citizen's health across ministries and sectors is lacking as of now. The multiplicity of authorities for urban development in general, and therefore, for health specifically makes the challenges even harder. The HLEG's report on universal health coverage itself has been criticized for being somewhat of an academic wish list of things that should be righted in the health sector without an operational plan attached to it (Rao 2012, Baru 2012), yet again preventing an immediate operationalization of a sound health plan for the country.

There are some bright spots however, in the form of non-government organizations taking the lead together with government bodies to improve basic amenities in urban poor areas as well as making sure that accessibility to health services improve in such areas. The use of public-private partnerships in improving availability and accessibility of health services is now quite visible and usual (Ghanashyam 2008). That such models are also coming into urban areas is relatively less well-documented and known; there are examples of organizations such as Urban Health Resource Centre (UHRC) – a well-known organization working on the health of the urban poor – teaming up with government bodies in urban areas like Agra to propose models that can work to increase accessibility and availability of health services (UHRC 2012).

The most recent example of such public-private partnership (PPP) is the Government of National Capita Territory of Delhi's (GNCTD) Mission Convergence Programme, locally called Samajik Suvidha Sangam. This USAID funded programme is an innovative public-private partnership that teams up with local community organizations to improve the health and well-being of the urban poor of Delhi (USAID 2012).

However, it is not clear whether such instances are scalable and replicable to address the humongous problem of urban health, which must remain the primary responsibility of the government. It is probably

relatively easier to fix the supply side issues of health care in urban areas than to stem the flow of migrants or curb urbanization. If urbanization is going to continue in the pace it has, the government authorities cutting across multiple sector must wake up to the fact that the health issues go beyond the responsibility of the health departments. Having said that, the departments of health in states and the MoHFW must realize how severely inadequate the supply of health facilities and services are in the urban areas. Most recent reports indicate that there are 1083 Urban Family Welfare Centers[1] (UFWCs) and 871 Health Posts[2] (HPs) catering to 377,105,760 (Census India 2011) urban population of the country, which translates to one UFWC/HP per 192,992 urban population, compared to the norm of 1 centre for every 50,000 population, indicating severe accessibility issues (MoHFW 2006, Agarwal et al 2007). Other estimates indicate the need for an additional requirement of 500 urban health and family welfare centers to meet the current needs of urban poor (ASSOCHAM 2009).

Rectifying this does not require big missions or five year plans. The lack of vision and planning around urban health on the one hand and lack of accountability from those who are in-charge of all the civic amenities on the other will probably ensure that urban health would continue to contribute a disproportionate share to the total disease burden of the country.

[1] It provides family welfare services in urban areas since the early 1950s, and is equipped to provide contraceptive supplies. Based on the population covered by each UFWC, it is classified in three types, and has different staffing patterns. Type I covers a population of 10-25 thousand, Type II between 25-50 thousand and Type III above 50 thousand.

[2] It was introduced in 1983 with a view to provide service delivery outreach, primary health care, family welfare and MCH services in urban areas. Unlike UFWC, it is also classified into four types; A, B, C and D, but with lesser population.

1 BACKGROUND

"Heat all over Austria" – "Dog days of summer in Vienna" – "Survival tips for the heat wave" – "This week is getting hot" – "Cooling in the city". These have been the headlines in the Austrian but also European media in the past few years accompanying the summer in Vienna (Allex et al., 2011). Many studies already refer to the increase of heat days (daily maximum temperatures of at least 30° C) and heat periods in cities with dense building and few green spaces (Formayer et al., 2008). Kysely et al. (2000) define heat periods as a minimum of three consecutive days with a maximum temperature of at least 30° C. The period is considered to be continuous if the maximum temperature of each succeeding day is not less than 25° C, and the average maximum temperature during the entire period does not fall below 30° C (Kysely et al., 2000). The increasing of the daily maximum temperatures also leads to an increase of very warm nights (tropical nights).[1] This is important, because the minimum night temperature has more impact on the wellbeing of the people as well as the increase in mortality than the daily maximum temperature (StartClim, 2006). As shown in figure 1, in August 2001 the evening temperatures of Vienna were already around 20° C or even higher, especially near and in the city centre.

A comparison of the number of hot days in the period 1961-2010 showed an increase for Vienna by an average of 9.6 to 15.2 days. Also for the number of summer days (25° C or more) in Vienna climate models calculated a 30 to 50 percent increase of summer days for the period 2071 to 2100 (ZAMG, 2012) which can result in a rise of the Urban Heat Island phenomenon.

Vienna is a dynamic and growing city. Forecasts expect an increase in population to over 2 million by 2030. Urban expansion and re-use of large brownfield sites will be particularly relevant in this respect (MA 18, 2012). Densification of the urban structures without additional measures, however, increases the UHI effect.

Urban Heat Islands concern both urban residents and tourists. Persons who have to spend much time in open space as well as health-impaired and elderly people are, however, particularly affected by the impacts. This becomes manifest, for example, in a reduction of activity due to heat (Dune et al., 2013). According to a study by Robine et al., the 2003 heat wave caused around 70,000 deaths across Europe (Robine et al., 2008).

In relation to these developments and trends, the city of Vienna has early and strategic decided to elaborate options for mitigating or preventing these effects and to take part in an international research project.

---

[1] Nights with a minimum air temperature higher than 20°C are regarded as tropical nights (ZAMG, 2011).

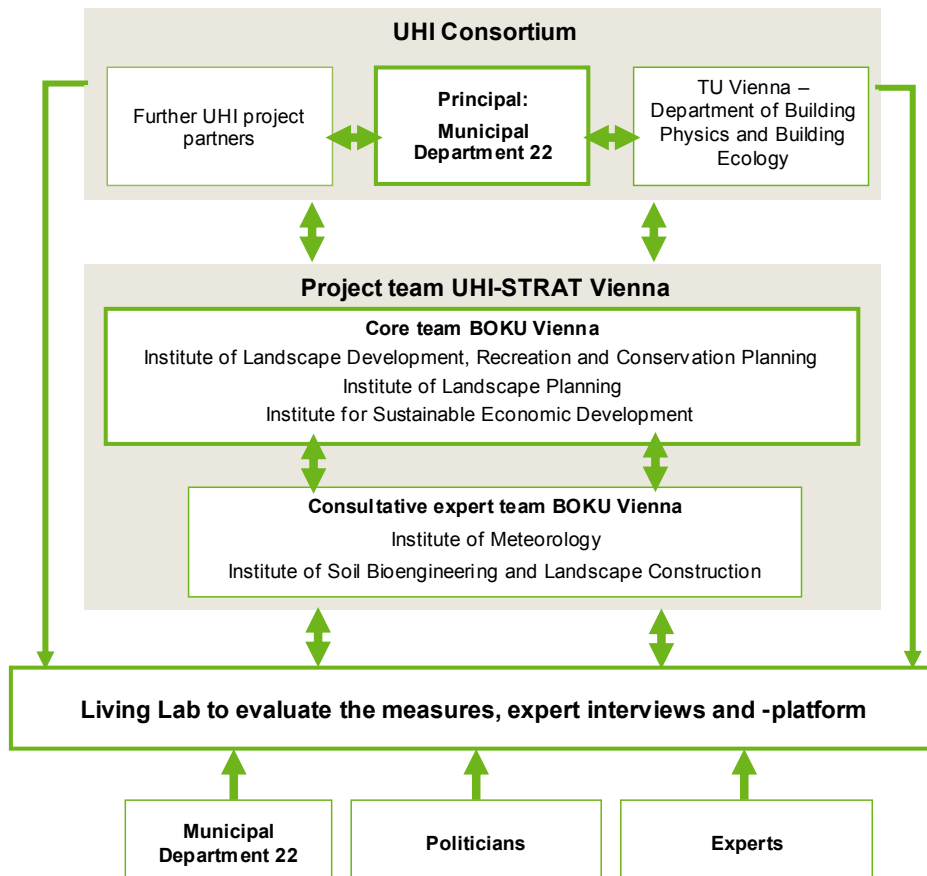

Fig. 2: Organisation of collaboration and networking

2 AIMS OF THE PROJECT

The project "Urban Heat Islands – Strategy Plan Vienna" is part of the international CE (Central Europe) project "Urban Heat Islands – Development and application of mitigation and adaptation strategies and measures for counteracting the global Urban Heat Islands phenomenon" (duration 2011-2014). Within the framework of the international project eight metropolises are examined. Along with Bologna/Modena, Venezia/Padova, Stuttgart, Lodz/Warsaw, Prague, Budapest and Ljubljana, Vienna is one of the study areas.

The aim of the project "Urban Heat Islands – Strategy Plan Vienna" is the identification of measures and adaptations to reduce the negative aspects of urban warming. The intention is to develop a strategic plan for the City of Vienna to implement urban and open space planning measures as well as urban ecology measures

Christina Czachs, Florian Reinwald, Doris Damyanovic, Christiane Brandenburg, Birgit Gantner, Brigitte Allex, Jürgen Preiss, Ursula Liebl

that reduce the negative aspects of urban warming. Based on planning tools and instruments of the different control levels of urban planning and development, possibilities of action for the City of Vienna and in addition, opportunities to raise awareness and promote acceptance of measures that reduce urban heat effects will be identified.

The scientific approach is based on inter- and transdisciplinary cooperation. Figure 2 gives an overview of the collaboration and networking in the project. On the one hand, the core team of the UHI-STRAT project is integrated in the overall CE-UHI project, and on the other hand, the UHI-STRAT team cooperates closely with the relevant departments of the City of Vienna and scientific experts. The findings obtained during the project work are reviewed in expert workshops for their relevance and applicability in the everyday management of the City of Vienna.

3 WORKFLOW AND METHODS

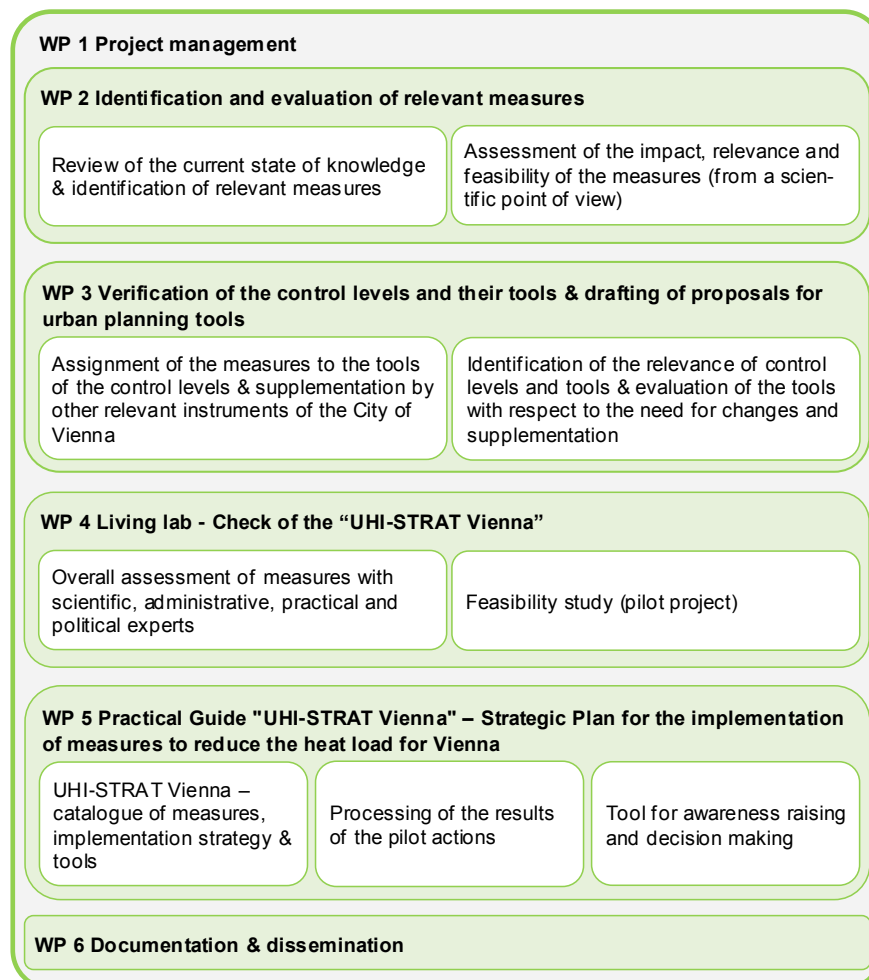
In methodological terms, the project includes a mixture of planning, urban ecological, socio-scientific and economic methods. The applied research project is carried out in close cooperation with the responsible municipal departments of the City of Vienna and consists of six main work packages (WP). Figure 3 provides an overview of the UHI-STRAT workflow. First results of WP 2 (Identification and evaluation of relevant measures) and WP 3 (Verification of the control levels and their tools & drafting of proposals for urban planning tools) are described in this paper. The additional work packages have not processed yet.


Fig. 3: Workflow "UHI-STRAT Vienna"

4 IDENTIFICATION OF RELEVANT MEASURES

The elaborated measures are of different temporal relevance. In the short term, preventive measures such as heat warning systems can be established or the individual behaviour of people can be changed by providing information. Other approaches such as the increased consideration of UHI effects in urban planning or an

adaptation of the building technology have a long preliminary lead time, i.e. in many cases they cannot be implemented that fast, but are characterized by a long-term impact.

In the project, measures are defined which refer to information and public relations or which can be implemented either by planning tools (e.g. overall concepts of urban planning, zoning and development planning) or by technical or structural means.

Technical measures to reduce UHI effects

Based on the previous knowledge and preliminary studies of the project consortium UHI (including the measures identified by the Environmental Protection Department Vienna, Municipal Department 22) and the project team UHI-STRAT Vienna, measures for the City of Vienna were identified, using a simplified SWOT (Strengths, Weaknesses, Opportunities and Threats) analysis (e.g. Terrados et.al., 2005). These have been supplemented by relevant measures that have been investigated in a comprehensive literature search of scientific papers. The catalogue of measures thus compiled serves as a basis for further work steps.

Fig. 4: Possible measures to reduce UHI effects (Allex, Damyanovic, Reinwald)

A total of about 370 possible measures have been identified so far by the UHI-STRAT Vienna team. Some examples are shown in figure 4. The measures can be roughly classified into technical and non-technical measures and categorized by subject area. The identified technical measures, for example, were summarized into the following categories (figure 5). The summarization of the non-technical measures information and public relations as well as control levels and instruments is currently in process.
Fig. 5: Categories of technical measures

To each category, measures as well as associated explanations and instructions were assigned. Table 1 shows an example of the catalogue of measures concerning the category "buildings".

Christina Czachs, Florian Reinwald, Doris Damyanovic, Christiane Brandenburg, Birgit Gantner, Brigitte Allex, Jürgen Preiss,
Ursula Liebl

category	UHI-STRAT – technical measures	Nr.	measures – explanations & instructions
buildings	active/passive cooling of buildings (e.g. ventilation, long-distance cooling, component activation, insulation, ...), (temporary) use of brownfield sites as green and open spaces	1	comfort ventilation (system, providing a constant supply of fresh filtered air)
		2	cross ventilation
		3	night ventilation
		4	solar cooling
		5	ventilation systems – cooling of the incoming air by low ground temperatures
		6	geothermal cooling technologies
		7	thermal component activation / concrete core cooling
		8	reduction of the percentage of glass facade
		9	thermal insulation, thermal renovation
	shading devices on buildings (e.g. blinds, sliding shutters, photovoltaic systems, ...)	10	shading devices on buildings (e.g. blinds, sliding shutters, …)
		11	shading roofs (e.g. by photovoltaic systems)
	water cooling of buildings	12	roofs with water cooling / Blue Roofs
		13	vertical cooling surfaces on buildings

Table 1: Excerpt from UHI-STRAT catalogue of measures – technical measures

The categorized and summarized measures will be evaluated with regard to their impact, relevance and implementation according to the categories: climate (micro-/mesoclimate), urban ecology (biodiversity/quality of life), feasibility (e.g. in the control of the City Council of Vienna, private/public, new/old stock, long-term realisability > 5 years/ short-term realisability: within 5 years) and acceptance (politicians, builders, residents) during the next work steps of the project. The assessment will be based on scientific evidence and will lead to a categorized ranking, so that both quantitative and qualitative results can be incorporated in the assessment.

Subsequently, the identified relevant measures will be analysed and evaluated under consideration of their efficiency in terms of urban planning, open space planning, urban ecology and economy. This assessment is essentially based on scientific knowledge from literature research. In addition, the evaluation results will be cleared with representatives from the fields of landscape ecology as well as urban and landscape design. The impact on the physical and mental quality of life of the people will be assessed by expert interviews. Aspects of ecosystem services, such as the habitat function, will likewise flow into the urban ecological assessment. The measures will thus also be evaluated in close relation to the conservation and enhancement of biodiversity.

The variety of possible options for action of all stakeholders and actors will be further structured and analyzed by economic criteria. Through the systematic environmental-economic approach of view, an involvement of perspective of the users can be achieved. In this context, interviews will be conducted to determine the acceptance of measures and the amount of the hypothetical individual willingness to take action themselves. This allows a qualitative assessment of costs and benefits of the elaborated measures.

The review of selected relevant measures takes place in an iterative process. Depending on the topic, experts of the project team with expertise in the relevant subject areas (e.g. planning, economics, meteorology...) will be consulted for the development of criteria for each measure or category.

Furthermore, expert interviews with people outside the project team will be conducted.

5 ASSESSMENT OF (EXISTING) REGULATIONS, TOOLS AND INSTRUMENTS

In the first step, all relevant legally binding and non-binding levels of control and tools for implementing the various measures to reduce heat effects have been identified and analysed.

Moreover, the relevance of the control levels and the individual instruments identified before will be evaluated under the aspect of urban planning, open space planning and urban ecology based on the effectiveness and importance in the implementation of the measures. In order to ensure sustained implementation of the "UHI-STRAT Vienna", experts from responsible Municipal Departments are involved in the process for information and expert interviews.

On the basis of this, suggestions will be made for modifications and extensions of the instruments and tools for implementation.

The City of Vienna's relevant tools to reduce UHI effects

The possibilities and instruments to implement UHI measures are manifold. They range from a legal basis to strategic programmes and approaches, different planning processes and procedures all the way to direct granting of subsidies or regulation by standards. Furthermore, they may be differentiated by the level of regulation. There are already approaches and tools on EU[2] , Austrian[3] and Viennese[4] level dealing with climate change – especially the increase of temperatures – or UHI phenomena directly.

Considering the importance of superior strategic approaches such as the urban development plan or the climate protection programme and the requirement of legal implementation, planning processes which lead to the development of overall concepts of urban planning or master plans, zoning and development planning, developer competitions as well as granting of subsidies have turned out to be essential points of reference and tools.

The level of urban master plans in particular has major influence on further planning and project development steps. In the City of Vienna this planning level has successfully established itself as (informal) planning tool. At this level different public and private interests can be coordinated – especially also in view of a market-driven urban development (MA 21B, 2010). In master plans and urban planning concepts the prerequisites for further planning steps are created (MA 18, 2013). The consideration of UHI matters at this level is important in order to have a basis for further implementation (especially as regards zoning planning).

The zoning and development plan is an essential tool in the City of Vienna, serving to establish a legally binding framework for development. In this planning document all future uses and the type of development of urban areas are bindingly codified. Analyses of this tool show that already with the possibilities in existence urban heat effects can be reduced. Also the realisation of zoning so far shows that climate relevant aspects have already been partly considered or used as justification for planning decisions. Apart from orientation, height and dimension of buildings, legal provisions regarding e.g. tree planting, the degree of soil sealing and development as well as green roofs can be implemented mandatorily.

Another essential level at which the City of Vienna can exert influence on the quality of development structure represents the so-called developer competitions. These have been carried out in Vienna already since 1995. From 200-300 accommodation units onwards, public invitations to tender are issued in subsidised housing for reasons of quality control (Liske, 2008). Apart from architectural and planning qualities also economic and ecological aspects have to be considered. Moreover, these competitions are partly carried out with reference to specific thematic focuses – social topics such as multi-generational or integrative housing as well as constructive topics such as passive house or multi-storey timber construction. In the case of publicly funded projects, the City of Vienna has major influence on the built quality.

It is also by granting subsidies that the City of Vienna has the possibility to control quality in terms of reducing UHI effects. In doing so, two major approaches are being pursued: the support of courtyard and vertical greening as well as the greening of roofs. These have among others micro-climatic impacts and facilitate the implementation of UHI-relevant measures (MA 22, 2013).

6   DISCUSSION OF FIRST RESULTS

In the course of research for the UHI-STRAT catalogue of measures a variety of different measures (~ 370) has been identified. On the one hand, these concern different scales (city-wide to single objects) and disciplines (e.g. engineering biology, architecture, materials research, public relations), on the other hand, different time frames will become effective in the implementation of short-, medium- and long-term

---

[2] E.g. Directive 2001/42/EC on the assessment of the effects of certain plans and programmes on the environment, Directive 2002/91/EC on the energy performance of buildings, Thematic Strategy on the Urban Environment, 2nd European Climate Change Programme …

[3] E.g. Federal Law on the presentation of an Energy Performance Certificate (BGBI. I Nr. 137/2006), Austrian federal climate strategy, klima:aktiv – the Austrian climate protection initiative …

[4] E.g. Vienna residential construction and renovation act, Strategy Plan for Vienna, The City of Vienna's climate protection programme …

Christina Czachs, Florian Reinwald, Doris Damyanovic, Christiane Brandenburg, Birgit Gantner, Brigitte Allex, Jürgen Preiss, Ursula Liebl

measures. Thus, in order to coordinate the various measures, detailed knowledge about their effects, impacts and corresponding action is needed.

Due to the different levels at which the measures are to be classified, a variety of actors and sectors are affected. An important issue in the realisation of the measures, therefore, is the inclusion of the different perspectives of the actors involved in the implementation, who come from the public, the semi-public and the private sectors. A huge difference in acceptance regarding the implementation of the measures is to be expected from the departments responsible for the implementation as well as from policy makers and citizens. For example, the introduction of a driving ban in the settlement area would indeed be a very effective measure for the motorised private transport, which due to the expected low acceptance, however, is not feasible. The assessment of the impact, relevance and feasibility of the measures must therefore be carried out from the perspective of all stakeholders.

For a better understanding a cost-benefit analysis is helpful, which makes it easier for stakeholders to assess the direct monetary benefits of the measures and the willingness of the population to accept or pay for additional measures.

In order to develop and implement the UHI strategy plan an environmental analysis of the Vienna City Administration has been carried out. The outcome was that a total of 4 administrative groups, 13 municipal departments, 5 superior units and institutions related to the City as well as the 23 districts were affected in their scope of operation or should take part in developing the UHI strategy plan. In addition, an analysis has been conducted of the different planning levels and tools that could be useful for the implementation of the elaborated measures. It turned out that all kinds of different legal regulations, strategic programmes and projects, spatial concepts, master plans as well as planning processes and procedures, granting of subsidies or standards have an influence on the development and implementation of measures to reduce UHI effects. Numerous planning levels and (legal) matters are affected.

The reduction of UHI effects is a "longitudinal and cross-sectional matter". The chronological sequence of a planning process has to be taken into account and the different levels of decision making and tools have to be adjusted and implemented in a coordinated way in order to reduce UHI effects successfully.

Furthermore, planning which is partly carried out separately (regarding e.g. nature conservation, zoning, public space, streets) and the individual steps of a planning process – from the creation of a master plan to zoning and development planning as well as project development all the way to the concrete construction – lead to intersections. These have to be transformed into junctions in order to consider necessary qualities in planning and design that contribute to the reduction of UHI effects – from the first strategic planning to the concrete implementation. An intensified cooperation and coordination therefore is of major importance.

There are also partly conflicts between the different strategic aims of the City of Vienna regarding urban planning and development and the approaches to reduce UHI effects. Competing interests have to be balanced – between measures to adapt to climate change such as fresh air corridors or larger green spaces in cities, and other political and planning aims such as densities suitable for the location or city of short distances.

Yet there are synergies as well between measures to adapt to climate change and other strategic aims of the City of Vienna. Planting activities, for example, create cooling effects but also support improved rain water storage or an increase in biodiversity.

An important aspect of the discussion is the evaluation and development of effective measures such as information and involvement of the residents as well as the establishment of information and early warning systems. It is assumed that the political commitment and the acceptance by the population will support a sustainable implementation of the defined measures. Therefore the cooperation with scientific, administrative, practical and political experts is given high priority in the whole project.

The results will be processed in a practical and hands-on guidance thread. The guide will consist of the following three modules

(1) Summary of policies and measures and the results of the evaluation

(2) Representation and processing of the two pilot actions

(3) Creation of a tool for awareness raising and decision making

and will address the scientific society, politicians, decision-makers, the administration as well as the general public.

The reducement of UHI effects on the inhabitants of the City of Vienna is challenging regarding the mainfold driving forces causing UHI effects as well as the broad spectrum of mitigation and adaption measures. To develop a balanced set of effective measures, which meet the needs of the City of Vienna, a multilevel and multidisciplinar approach is needed.

But before concrete measures are developed and implemented a mainstreaming of the topic is necessary. Awareness rising is required to show which effects and impacts climatic changes and increasing densification of the city have on the entire population and the quality of life of the citizens of Vienna. It is also important to show that with existing instruments and measures steps against UHI effects can be set effectively.

1 ABSTRACT

In Italy, especially in large urban centers, the public building stock represents a large portion of the consolidated city that is in a state of disrepair due to the aging and to the processes of degradation and marginalization.

In addition to the well-known difficulties derived from residential prevalent use in these residential complexes, however, there is a considerable number of spaces at ground floor raised on "pilotis", places designed for the community but nowadays spaces of transit, without a specific destination use and without specific qualities, residual or abandoned in most cases and therefore perceived as dangerous by the inhabitants.

A departmental research conducted on the case of Rome and developed at DIPSA of the University of Roma Tre has highlighted the problems common to Piani di Zona made accordingly to Law n.167/1962 but also the potential for transformation of space porches free.

From this research, the international design competition PASS- Plan for Social and Sustainable Housing – has identified the project themes from which to increase, and specify, the number of flats, to achieve a sustainable energy behavior of existing buildings, with the 'overall goal of initiating a process of wider redevelopment, as well as the procedural steps through which the institution ATER Roma in an exemplary manner is beginning the process of upgrading the complex Tiburtino III.

The contribution of the report is to present and share the issues identified, the specific competition procedure used and the results obtained, such as references to a possible and practical method of intervention in the consolidated city.

2 INTRODUCTION

In 2010, the Housing Association of public housing stock in Rome (ATER- Roma) has adopted the main elements of a long process of research undertaken by the Department DIPSA Roma Tre University on the subject of redevelopment of public housing stock built in Rome, launching the international design competition PASS – Project for Social and Sustainable Housing.

From a first phase of the investigation it was found that the residential housing stock realized with the first Plans for Economic and public housing (PEEP) presents many porches spaces (approximately 222,000 square meters), today underutilized and devoid of quality, a second phase has made it clear that these spaces, together with those present on the roof top of the buildings, if properly converted, could accommodate new functions or increase the housing stock of public assets.

Fig. 1: Buildings at Tiburtino III in Rome.

For the important implications of this analysis and application of recent regional standards, the case study of the plan area Tiburtino III (Fig. 1) was chosen from ATER Roma as a framework for testing an international design competition.

3 THE ITALIAN SCENARIO

The Italian public social housing stock has been built mainly in three phases. The first historical period coincides with the decade known as post-war reconstruction period (1945-1950), in which huge public investments were applied. The intent was to rebuild more than one million rooms destroyed by the war.

Between 1950 and 1970, the State supported new housing developments by extensive investments. In the social sector the first important resolution was the INA-CASA programme (part of the Employment Act 1949). In a six months time, 649 building sites were posed. When the plans were fully completed 2.800 dwellings per week were realized, enabling to give house to 560 households a week.

With the aim of employment of often underqualified personnel, all the technological innovation was expressively restrained in these programmes; all the INA CASA districts are characterized by small buildings, small neighbourhoods and vernacular themes.

A second important national programme is given by the GESCAL Trust Funds (GEstioneCAse Lavoratori) between 1967 and 1973.

Both the two programmes are at the base of a widespread homogeneity for typological and constructive solutions within the Italian building stock of those early years.

A first variety is introduced with the housing programmes in several larger cities that follow the national law on social housing in 1962. In the city of Rome i.e. most of the public housing stock planned between 1960 and 1980 has been realized using two programmes of 1967 and 1985 based on the said law (Piani per l'Edilizia Economica e Popolare, P.E.E.P.). The P.E.E.P. instruments allowed the realization of 67 districts with a total of 551.073 rooms equivalent to 44.085.840 cubic meters of built volume. P.E.E.P. districts are built by prefabricated system, present tall buildings with a lot of public space.

Public social housing is also designed for an abstract model of the average family, an idea that we can no longer recognize in today's society. Young couples, the elderly, extended families are just some of the new users who need accommodation.

3.1 Academic reaserch at University of Roma Tre

The Dipartimento di Progettazione e Studio dell'Architettura of University of Roma Tre (DIPSA) has focused its researches on rehabilitation of the housing stock built in Rome under the first programme law n. 167 of 1962.

An initial fact-finding investigation[1] on a residential complex has identified the main issues of the aging building stock and the possible strategies to be applied not only to solve the obsolescence of the building elements but also to counter the deterioration of the city: marginality, monofunctionality, low maintenance etc.

The procedures identified in order to obtain an organic project that redesign entire look of the district Tiburtino III chosen as case study are: interventions at the base of the building, the wrapping, the roof and re-distribution of existing dwellings. The district shows all the characteristic signs of decay, abandonment and isolation common to many other public districts made in those years.

A subsequent research undertaken by Barbara Del Brocco (2008) has investigated the potential for transformation of the free spaces at the base of buildings, recurring theme of architecture of public districts. The ground floors, generally designed with porch, conceived as places of community, are rapidly transformed in areas without a precise destination and without quality, transit sites becoming neglected or, at worst, residual spaces avoided by the people because they are perceived as dangerous. The research investigates possible transformations of these spaces in relationship to the environmental and social context, particularly by infill development with selected functions. These interventions, with its point and one-off

Andrea Vidotto, DIPSA Dipartimento di progettazione studio dell'architettura, Università Roma Tre. B. Del Brocco, M. De Matteis, C. Frazzoni, M.L. Olivetti. S. Pollak, F. Riccardo.

approach, could constitute a "micro-network" spread in the urban fabric in order to start a bigger process of urban regeneration. The objective of this investigation is to stimulate local Administrations, Housing Associations, inhabitants and media to consider porch floor an important resource for renovation of housing stock, and, if it will be conveniently filled, it could become the flywheel of outskirts rehabilitation.

Research shows that the ground floor can be considered a resource for the transformation of the stock of public housing built with the first PEEP between 1967 and 1985 in Rome. In particular, the porch floor appears to be a recurring theme of architecture built in those years, although it declined in different ways and in spite of specific conditions.

In the first we have tried to determine the amount of free space at the foot of the buildings available for processing. The lack of collaboration ATER and, perhaps, the real inability to know the areas of overall porch floor of their assets, has meant that it was necessary to adopt an alternative strategy.Assuming that the architecture is an expression full of technical regulations has been proposed a cross-reading of public housing with the laws and regulations that have generated to determine the amount of space available for processing.

If ground porch floor takes its origin from the "5 points of Architecture" of Le Corbusier, it is important to find out its first appearance in social housing stock in Italy. So it is of prime importance to analyze the principal laws and regulations on social housing in Italy, especially in Rome chosen as context of reference of research.

4 EVOLUTION OF SOCIAL HOUSING IN ITALY

4.1 The urban block and the garden city (1900-1930)

With Luzzatti Laws n. 254/ 1903, the Italian government intervenes directly in the field of social housing, in fact, after this law enables public and private bodies and cooperatives in moral or autonomous institutions to build housing. The goal is to promote and coordinate the philanthropic and spontaneous initiatives.

In the first period of expansion after the unification of the country the reference model is the city block, and social housing, sets against private construction, differs from these in terms of habitable, greater distance between the buildings in a same block, the greater amplitude of the courtyard in order to respond to new requirements for ventilation and natural lighting, such as Testaccio in Rome by Magni (1910-1913) (Fig. 2).

Fig. 2: Testaccio in Rome by Magni (1910-1913)

The language of social housing is almost identical to that of private construction: basements, architecture, pilasters and cornices are common to both nineteenth-century taste.

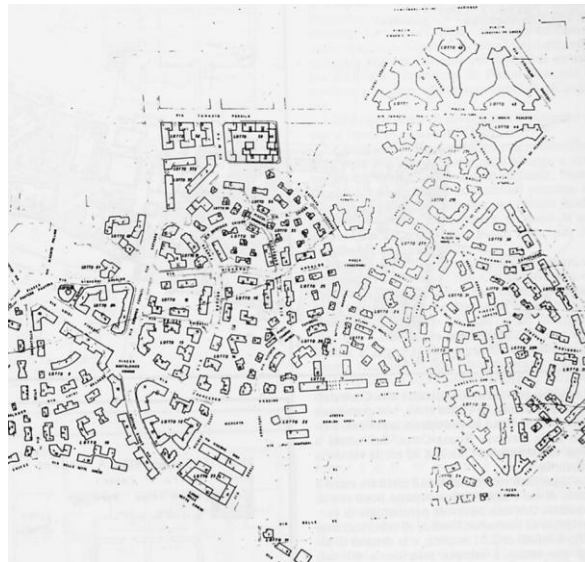
If the language remains the same, the urban grid pattern gives way to garden city, as Garbatella (1926) (Fig.3) or Aniene (1920).


Fig. 3: Garbatella in Rome (1926)

The basement rooted to the ground, for structural reasons, is characterized by small windows and rusticated in some cases with the presence of shops and stores, the dwellings start from the first floor.

In Europe the principles of the Modern Movement begin to assert and in Italy is called Rationalism; the social housing in Rome, however, is not affected by these influences.

The 1930 season marks the end of the largest residential building and in 1939 there is a drastic reduction of the decorations.

From that moment, the role of Housing Association will always be more tangential to the functioning of the market and increasingly influenced by urban policy of fascism. The area of intervention will be to immigrants and their barracks or some of the people expelled from districts with the most rapid liberalization of rents and the intensification of the politics of demolition.

4.2 The INA-CASA programme – The first seven years 1949-1956

With the aim to solve simultaneously the problem of unemployment and the house comes into force the Law n. 43 of 28 February 1949 "Employment growth plan working", known as the Law Fanfani or INA-CASA Programme. The INA CASA Programme (1949-1963) can be divided into two periods of 7 years each. To support the design, the INA CASA prepares a manual consisting of 4 issues, 2 for every seven years. The famous Italian architect Adalberto Libera will be the curator of the first 2 issues and be supported among others by Gorio and will be design office manager from 1949 to 1954 and later consultant.

The first volume of "Suggestions, rules and schemes for the preparation and presentation of projects – Announcements of competitions" (INA CASA, 1949) presents a set of blueprints for 4 building types: multi-storey building, isolated multi-storey building, one-storey row house and the row house.

The second " Suggestions, examples and standards for urban design. Projects Type " (INA CASA, 1950) shows a series of Anglo-Saxon and Scandinavian examples, such as garden city and new empirism.

If the internal organization of the accommodation suggested by the manual reflects the studies of the Modern Movement, urban facilities recommended are more bound to respect the site and the history of the country.

The two Guidelines text-books contains several suggestions for designers and they allow dwellings at ground floor. We can assert that Unité d'Habitation of Tuscolano designed by Adalberto Libera in 1950 is the only realization with porch floor in Rome in that period.[2] (Fig.4).

4.3 The INA-CASA programme – The second seven years 1956-1963

From 1955 INA CASA starts a revision of standards for the design, following the referendum and surveys of recipients of housing, and organizes a conference attended by the most important exponents of Italian

---

[2] We can notice that Libera is the designer of other two semipublic districts with porch floor, Villaggio Olimpico 1957 and Decima district 1960 and he is also one of the architects involved into guidelines working out.

architecture, including Adalberto Libera and in 1956 publishes the third booklet "Guide for the examination of the INA CASA projects to be implemented in the second seven years.

Fig. 4: Unité d'Habitation of Tuscolano in Rome -Adalberto Libera in 1950

Tall buildings are not allowed more than 3 floors, flats at ground floor are forbidden unless measures to avoid introspection and the unpleasant effects of moisture. Therefore recommend that the basement floors are at least 60 cm above the ground level, below which there are well-ventilated basements. It is encouraged to use the ground floor for remittances for local scooters and bicycles, or areas for children's play (INA Casa 1956, p.12).

In this period we found in Rome only two buildings with porch floor: the 1957 Ponte Mammolo by Vaccaro who has worked with Libera, and the 1958 Acilia by Del Debbio.

4.3.1   In search of pilotis: a hypothesis

In the projects of Adalberto Libera is common the use of porch floor at the ground floor; for him is an essential sign of innovation, as he asserted during a conference in Florence .

The porch floor, in the architecture of public housing in Rome, appears for the first time in 1954 in the Unité d'Habitation of Adalberto Libera at Tuscolano III. It can be found in other projects prepared by the architect: project of the district Pineto in 1957 with eng. G. Vaccaro; project of the residential district at Grottaperfetta in 1957-60 with the other architects Monaco and Luccichenti; Olympic Village in 1957-1960 designed with Cafiero, Monaco e Luccichenti e Moretti; and the district INCIS at Decima in 1960-1966 with Cafiero, Guidi e Moretti.

It is important to note that Vaccaro, who had worked with Libera in the project for the neighborhood Pineto in 1957, is the author of the other district of the second seven years of INA CASA programme in which appear the porch floor, Ponte Mammolo (1957-62). Libera has been manager of the technical office of INA CASA from 1949 to 1954 and then plays the role of outside counsel, but in the first two volumes of Suggestions for the design there is no reference to porch floor. However, we should consider the incessant search for Libera on Unité d'Habitation, especially when compared with Le Corbusier's theories.

So we can easily state that the appearance of the porch through the second seven years of INA CASA is primarily due to the architect Adalberto Libera.

4.4 The ten-year plan GESCAL (1963-1973)

With the end of the INA CASA Plan are established GESCAL Trust Funds (GEstioneCAse Lavoratori) for the implementation of the ten-year plan. The Law 60/1963 establishes the Central Committee with responsibility for overall planning and management of houses for workers . In 1963 is enacted GESCAL technique legislation with the primary objective of addressing, through detailed provisions, the implementation of action plans in the building of districts named Piani di Zona.

The technical legislation incorporates some topics of the rules of the INA CASA Plan, in particular reaffirms the prohibition to have ground floor accommodation and, in fact, requires the arcade at the ground floor of buildings. The architect Pietro Barucci, in an interview (Del Brocco 2008, p. 79), says that the porch floor inside GESCAL technical standards can be considered a "victory" of architect Moroni, designer of Spinaceto, one of the districts built in this period, who insisted that this sign of modernity was inserted in the rules.

The Article n.27 affirms "Ground floors in the covered area, free spaces surrounded by walls, shall not be less than one third of the total area of the building, and allow ample communication between the areas surrounding the buildings". The ten years Programme of GESCAL (1963-1973) and its technical Regulation confirms the prohibition to build dwellings on the ground floor and it forces the passing portico.

The law n.167 1962 sets up the Piani di zona (districts), where local administrations has to locate areas for social housing. The first programme, in Rome i.e., allows the realization of 67 districts, 21,1 millions of residential cubic meters equivalent to 273.487 rooms.

Other national laws modify the way of designing buildings: the law n.513 of 1977 and n.457 of 1978. They reduce common spaces and passing porch disappears. The introduction of the "virtual height", an abstract value, suggests to have ground floor on pilotis close to cellars or small stores.

4.4.1 First Plan for and Economic and social Housing in Rome

In 1962 Law 167 is enacted, it requires municipalities with populations greater than 50,000 inhabitants to prepare Piani di zona (districts), for public housing and in the same year in Rome is adopted the new General Master Plan. Two years after, February 26, 1964, the municipality of Rome launches its first Plan for Economic and social Housing (PEEP). The program identifies 70 areas to house 700,000 people covering an area of 5,000 hectares. The plan will be subsequently reduced to 460,000 rooms and at the end (1985) it will be realized only 270,000 rooms. It is the greatest plan in Italy.

We can identify three main stages in the schematic that coincide with three different approaches to the design of new neighborhoods.

In the startup (1968-71) is very strong the influence of utopias of mega-structuralist movement and all the projects, including Spinaceto Tor de Cenci, Casal de Pazzi Nomentano, Tiburtino, represent a formalization of the "town-design", urban design in large scale

In the first neighborhoods the passing porch is always present, as noted by the critic Sergio Lenci "earned in those years, a standard abstract, which acted negatively, as, for example, to prescribe the general adoption of the porch on the ground floor. This rule has caused hectares of arcades unnecessary, harmful to the creation of urban spaces in the maintenance and management has not been attributed to the individual, but was entrusted to institutions that have given up immediatly." (Bossalino and Cotti, 1992).

The 70s, central phase, are characterized by large "architectural objects", a large building types that integrate their internal spaces and service spaces. This is the case of Corviale, Laurentino and partly Vigne Nuove in which seems to end the morphology of the whole configuration of the main building, in a coincidence between building type and morphology of the" urban "part".

The third generation of districts (1977-1980) sees the presence of two opposing trends project: the first that refers to previous research on the large urban signs Torrevecchia, and a second looking for a relationship with the urban fabric of the traditional type.

The research investigates only the districts made with the GESCAL technical Regulation up to 1977. So If we exclude the last period, the districts built of up to 1977 in Rome are 25 and the porch floor according to the legislation had to be equal to 25 % of the built-on area, amounts to 222,000 square meters. These space is empty and available to be transformed and can be filled with new selected functions.

If we take into account that all these settlements still suffer the lack of public services , principally due in the first phase to the unwillingness of the administration to take charge of management and in the intermediate stage, the lack of funding. We can conclude that the huge surface of empty space at the ground floor can be used to regenerate all the district.

5 CASE OF STUDY TIBURTINO III IN ROME

Tiburtino III 15 bis (1972-75) is one of the districts built during the law n.167 and it has been chosen as a specific case of study in order to check the interventions in relationship with the goals. Its empty spaces at ground floor are: not fully utilized; in most of cases neglected and dirty; not well lighted; often place of micro-criminality; only in one case are maintained by inhabitants. (Fig. 5)

The research takes into account the recent investigation made by CRESME-Center for Economic Research Social Market for Building and Land-, on suburbs of Rome (AeT. and CRESME, 2007) in which it emerges

a new demand of residential quality in the areas build under the social housing law of 1962 n.167. It expresses a demand of maintenance of old housing stock on one hand, and on the other hand a demand of facilities.

Fig. 5: An example of empty space at ground floor at Tiburtino III

The facilities wished by inhabitants are: Office for Fiscal Adviser; Office for administrative practice; Energy point and advisory services for energy saving; kindergarten for children; bicycle rent.

The available surface of the district, less than 25 % of built-on area is 2.000 sq. If we consider that for 1784 sq to rehabilitate it is necessary about 890.000 €.

A final phase of the investigation has probed the possibility of involvement of the inhabitants. The desire to take care for these spaces was already inherent in the district, are in fact many of the signs that reveal a desire for redemption of collective space: limited appropriations, fences consist of vases, chairs arranged so well. A two-month workshop was led eventually with students at the school of Arts located in the district. They, left free to interpret the empty spaces at the ground floor along the main street, have identified the first functions to be placed and then have showed elementary but effective proposals for redevelopment.

6 INTERNATIONAL COMPETITION

In March 2010, ATER Roma (Housing Association of Rome) welcoming the opportunity to reuse the free spaces at the ground floor of the buildings, with the support of the Lazio Region and from the new provisions of the regional legislation, has given the world the professional challenge of providing a concrete and feasible answer about the densification of the consolidated city, launching the procedure of the international design competition, whose care and scientific organization was assigned to DIPSA.[3] The international design competition PASS – Plan for Social and Sustainable Homes is an application of the specific results of a long process of research undertaken by DIPSA – Department of Design and study of Architecture of University of Roma Tre on the topics of rehabilitation of public housing stock in Rome. Thanks also to the new regional law – Piano Casa- that allows the increases in cubic volume to regenerate the public urban stock.

The competition is coherent with regional regulatory guidance that allow the intervention on existing buildings with the aim of increasing the housing supply in the area of public social housing.

Subject of the international design competition "PASS – design for sustainable social housing" is the redevelopment of the portion of E.R.P. (Public Housing) compound located in P.d.Z. (District Plan) n. 15 bis – Tiburtino III – lots included between via Grotte di Gregna and via Mozart – through gain of approx 120 new public housing units, new services equipment for the district, redevelopment of public spaces, integrated interventions to improve the energetic behavior of existing buildings (consisting in approx 450 housing units), in order to improve housings living quality, the energetic performance, innovate equipment systems for a sustainable management.

Some 50 project proposals developed by groups of professionals, have declined in different and innovative ways the architectural quality, with the issues of energy sustainability, environmental and economic.

---

[3] SCIENTIFIC CONSULTANCY OF COMPETITION PROCEDURE UNIVERSITY ROMA TRE- DIPSA – Department of Design and architectural studies- Scientific Coordination and drafting of Preliminary Design Document: arch. Mariella Annese, arch. Barbara Del Brocco. Technical and administrative planning arch. Mariella Annese.

The exchange of professional experience has reopened the cultural debate about re-densification the consolidated city and has generated several ideas on how to transform public housing stock.

The competition was won by the group led by the Spanish office Espegel-Fisac, with other two winning projects (2nd place by the group led by SMTstudio Associates Architects, 3rd study Molestina Architekten), and 3 mentioned (Parasite study, NEXT architects , 3TI Progetto italia).

Characteristic of the winning project is to undermine the rigid system of Tiburtino III filleting the courtyards and public space with the ground floor of the buildings, set at 70 cm, with an organic design with ramps.

As for the new housing, penthouses on floors and porches have been proposed distinct types (Fig.6).On the roof there are two types of composition: the first type, located on the exterior of the buildings sector, has a configuration introverted, with its areas shielded from the terrace surfaces and distributed along "corridors bright", so as to give each of them a direct relationship with the open space in private rooms at the second type, provided on the inner buildings of the complex, all rooms have aggregated around a patio, a private open space from which you access the housing units (quote of the Roman impluvium houses) .

The unit plans at porch floor, however, is formed instead of a central core that contains all the technical installations and wetlands, while the living spaces open onto private terraces, private conceived as ideal extension of the public green in front of the rooms bed, facing instead on areas behind, protected by vegetation belts. For the redevelopment of the existing facades has been proposed a modular prefab that clips to the existing structure, a ventilated flat panels. In correspondence of the lodges and the windows, the system allows to create "blades" openable and closable to adjust the amount of solar radiation, the ventilation and the level of external view.

Fig. 6: The project of Espegel-Fisac

The project 2nd place (SMTstudio Architetti Associati) gives to the public space a dominant role. The open spaces between the buildings are transformed into parterre replacing the vehicular traffic, reorganized on the fringe. The design of the paving trace the footprint on the ground of buildings and detects the insertion of several programmable functions according to the needs of the inhabitants (Fig. 7). The base, particularly in the courtyard, it expanded into squares conceived as outdoor living rooms that resolve differences of quotas by improving accessibility through the fitting of a plane sloping green that covers the volumes of the existing cellars. To obtain the shielding for private open spaces, the dwellings at porch floor are obtained by reformulating the existing service volumes, volumes that become translucent colored, strongly recognizable. On the roof, however, the settlement system involves the aggregation of prefabricated modules with a clear formal identity of pitched roofs, configure a new urban fabric held together by a kind of main street and small public squares in height.

The proposal of the Molestina Architekten firm, 3rd place, begins from a careful analysis of the site in terms of use of space and from the belief that the evident signs of obsolescence must somehow be preserved, even put on display. For this reason, the project envelops all built in a new polycarbonate skin that gives a new identity to the neighborhood, while preserving the visibility of the status quo (Fig. 8).

The "greenhouse" defines a unique space, penetrated by light and air, transitional space between public and private, it becomes a meeting place for residents which also contributes to the energy balance of buildings; plants that grow in it improve the microclimate and purify the air and, depending on the season, connote the

look through colors and scents . With regard to housing, those places in the plans arcades are characterized by high flexibility: each unit has secured a double cross ventilation, exposure to light and great views. The accommodation located on the roofs are equipped with balconies on both sides and are open on the greenhouses of the common terraces.

7 CONCLUSION

The result of the competition, contrary to what is usual, has been followed with the award to the winning team of the assignment for the final design, which ended in 2011. Waiting for regional funds for subsequent phases of design and construction, an initial assessment of the whole process can be expressed.

The great variety of proposals received and the wealth of presented architectural solutions evidence that reflection on possible intervention in the city built is very large and full of themes and facets. The procedure of the design competition also proves to be the ideal range for a fertile exchange of professional experience on the issues, but also an opportunity for research institutions and the policies to define effective collaborations and partnerships, through which assume a survey methodology and of concrete intervention in the consolidated city.

Urban Planning Implications of Changing Land Use Structure of Metropolitan Lagos, Nigeria

Leke Oduwaye

(Prof. Leke Oduwaye, Department of Urban and Regional Planning, University of Lagos, Lagos, Nigeria, aoduwaye@unilag.edu.ng)

1 ABSTRACT

The changing land use structure of metropolitan Lagos has many implications on the land use prospects of the city. The nature of the implications manifests in various shades of socio-economic, physical and environmental dimensions. This paper unravels the different dimensions of the changing land use and their implications on land use development of the city. The paper discusses the nature of the changes and their implications on land use type's namely residential, commercial, industrial, educational and institutional, religious, circulation, parks and recreational land uses. The research methodology involved the collection of primary and secondary data. Data were collected on determinants of urban land use which the paper classified into economic, sociological, cultural, environmental, infrastructure and institutional factors. A total of 755 questionnaires were administered to collect data on determinants of land use in order to establish their influence on Lagos changing land use structure. The application of factor analysis and principal components analytical techniques shows that infrastructure and economic factors are the major factors influencing land use in Lagos. Also, there exist high levels of correlation between these variables, influencing land use of Lagos. The research concludes that significant distortion of the Lagos Metropolitan Master Plan has taken place which led to the unforeseen physical land use structure problems. The paper suggests that there is urgent need for the preparation of new land use development plan for Lagos with special attention to provision of infrastructure and economic policies that will improve the people's quality of life. There is also need to improve the land use administration of the city, harmonization of the roles of various levels of land use management agencies with adequate provisions for citizens and stakeholders participation in the planning process. Electronic planning permit approval system should be introduced. This will improve the time for approval of land use plans and prevent official corruption as the need for physical contacts between prospective developers and planning officials will be eliminated.

2 INTRODUCTION

Studies on the problems and prospects of metropolitan areas are usually of great concern to scholars and policy makers. This has been confirmed through the works of many researchers such as in the work of Mabogunje (1968) who examined the distribution and characteristics of residential districts in Lagos. He noted that areas that are districts in social and physical patterns can be found in Lagos. These areas are classified into low, medium and high quality residential areas. Also Ayeni (1979) researched into the spatial interaction and structure of residential areas in Lagos. Sada (1979) attempted a study of land use classification of cities in developing countries. He identified four major physical divisions of cities in developing countries. These are the Government Reservation Area (GRAs), which in most cities generate positive effects, because they are always planned. The second are the private layouts which often generate both positive and negative effects as the quality of life in the area depends upon the monitoring system by the planners. The third is the old traditional residential areas and the fourth the uncontrolled and unplanned fringe residential areas. The last two types he stated are notorious for their negative effects on development due to overcrowding and urban sprawl. Frishman (1979) examined the growth pattern of cities under the Hausa-Fulani, the British rule and the Independent Authority. Specifically on Kano he noted that the growth of the city was determined by the nature of land tenure law in contrast with the European and American cities. Use of land in Kano was mixed in every area and segregation by income and wealth did not occur. Instead, each ethnic group developed her own sub-city, as own sector and expanded outward along its fringe. Okpala (1981) study was on residential mobility in Nigerian cities with Enugu and Onitsha as case studies. The study by Okpala (1981) showed that residential mobility plays a very important role in the smooth functioning of urban housing market. Residential nobility facilitate the phenomena of filtering down process which is very important in improving access to urban housing.

In a study by Okewole (1997), on environmental restructuring in Bodija Estate, Ibadan, increasing environmental restructuring in the planned residential estate, was found to be due to the fact that the designed environment does not satisfy residents aspiration. Adindu and Ogbonna (1998) study was on the nature of urban expansion with Owerri as case study. They concluded that the future growth of the city

depends on the nature of the fringe areas as Owerri city development is circular in nature. Omirin (1998) analysis of residential land accessibility in Lagos showed that there exists an interplay of many factors most prominent among which are low rate of new housing production, increasing competition in the demand for cheap accommodation in the metropolis, drastic fall in the exchange value of the naira vis-avis the currencies of foreign countries from which most building materials are sourced. Other recent research works on Nigeria urban land use include the study by Oyesiku (2002) on the city consultation process paradigm and urban poverty alleviation in which he concluded that the incidence of poverty in the developing countries is on the rise and very remarkable in sub-Sahara Africa, having serious implications for the world and regional economy, growth and physical development. Fawehinmi (2002) researched into property conversion in Nigeria with Akure as case study. He concluded that property conversion is essentially economic to the extent that it is predominantly done for profit maximization. To discourage this phenomenon he suggested that the national economy should improved as this will stimulate commercial property development. Efforts should also be made to increase the supply of formal rental units, as this is the only way to reduce the dominance of the formal property market. A research on the implication for land market transactions, globalization or investment and land market was carried out by Aluko and Amidu (2005) in which they concluded that globalization depends on a well functioning land market, the availability of land, information, secure tenure arrangements and appropriate registration or recording system. Oduwaye (2006) researched on the effects of globalization on Lagos cityscape and concluded that formal commercial land uses are reducing while massive informal commercial land use are now in fragments and predominantly along major roads. Ofogba (2011) study on land tenure in Nigeria stated that there is much of overlap of functions in the land administration process resulting in confusion of rules. Alade and Oduwaye (2012) identified capacity building on urban land use management as a major constraints to land use efficiency in Nigeria.

In the light of the foregoing, there is no existing work on the implications of land use changes in Lagos, thus this paper essentially investigates of the implications of the present fragmentation and abuse of land use in metropolitan Lagos. It unravels the consequences of this on the quality and optimum utilization of scarce lands in metropolitan Lagos. In a situation where land, the most fundamental resources of all is being developed and exploited without critical and scientific assessment, it is imperative that land use planning and development should become of prime concern of the Lagos community and the government. The pride of place desired by efficient urban land use planning development, administration and development control has been stressed by many urban land use scholars and practitioners. For example, Olajuyin (1997) reiterated the need for efficient town planning practice and professional responsibility in Nigeria. Ibitoye (1997) also presented a similar view in his study on intra-regional planning implications on the provision of physical and social facilities in local government headquarters and their settlements in Ondo State of Nigeria. Makinde (1998), analysis of the state and local government roles within the context of the Lagos State Urban Regional Planning Board and Town Planning Authority, Edict, 1997 concluded that there is need for efficient and smooth inter-government relationship at all levels in order to achieve efficient land use planning and development in Lagos. In line with the view of Makinde (1998); Kadiri (1998) identified the need for good relationships between the state and the local planning authorities as basic prerequisite for successful land use planning in Lagos. The import of these planning experts centered on the fact that land use planning problems in Nigeria cities is more of management and administration of land use. There is need to appreciate the consequences of uncoordinated and unethical practices in the area of land planning, control and development. Specifically this paper discusses the physical development process of different land uses with residential, commercial, industrial, educational and institutional, circulation, parks and gardens. The implications of the present physical development process in Lagos are also discussed with suggestions on how to improve the present nature of physical development.

3   THE CASE STUDY AREA AND RESEARCH METHODOLOGY

Lagos Metropolis is located in the south-western part of Nigeria. It is the largest metropolitan area in Nigeria (Ayeni, 1979). Lagos metropolis lies generally on low lands, with about 17500 hectares of built-up area. The approximate population of this area is more than 18 million people. The projected population by the year 2015 by the United Nations is 24.5 million. The projected average population density of the built-up area of Lagos metropolis is about 20,000 people per square kilometer. The significance of the role of Lagos is due partly to her historical and cultural background and partly to her former role as the seat of the Federal government. It also owes its growth and development to European colonial influence.

The data used were from both primary and secondary sources. A total of 755 questionnaires were administered covering all categories of land use types in the study area. Data collected were analyzed through the use of correlation analysis with the aid of Spearman's correlation to establish the relationship between socio-economic characteristics of respondents and land use in the study area. Further analysis on the determinants of residential land values was done with the use of principal component technique. The outcome of the analysis shows that out of the six variables economic, sociological, cultural, environmental, infrastructure and institutional factors, infrastructure and the economy are the major factors influencing land use in Lagos.

4 DETERMINANTS OF URBAN LAND USE

There are many factors influencing urban land use. These factors can broadly be classified into six. They are social, cultural, economic, environmental, infrastructure and institutional factors (Litclifield, 1974). Socio-economic factors influencing urban land use can be viewed from the sociological, geographical, and economic perspectives. To the sociologist, it is the human being, his psychology, which is the key to the process structure and pattern. Other specific social factors influencing land use are quality of neighbourhood, security, prestige, taste, ethnic and social factors. The geographer places emphasis on such things as relief, elevation, climate, location and geology. The economist suggests that it is the economies, which are to be obtained from using a particular piece of land, for example from its accessibility, and centrality that influence land use. The economist also considers the issue of scarcity, demand, nature of use, agglomeration economies, expected revenue, speculation and intervening opportunities. Also cultural factors influencing land use include ethnic origin, religion and tradition. Rapoport (1977) noted that individual aspiration to achieved culturally derived satisfaction, also affect land use.

Environmental factors influencing land use are nature of environment, climate, soil, topography, drainage and quality of water bodies. For example, topography affect amenity ranking though this could vary from family depending on their composition and preference. Topography could have a bearing on land use through its effects on development cost. Also the nature of existing land uses such as seaport, airport, institutions and business areas which generate employment increase demand for land and therefore property value. Critical to urban land use decision is also the level of infrastructural facilities in different parts of the city (Litclifield, 1974). The influences of these factors have been supported by Ayeni (1979), in his study on Lagos during which he attempted a study on the spatial interaction and structure of Lagos. Also in a study by Olaore (1981), during which he established the land value trend in Kaduna, the influence of infrastructural facilities was also confirmed. Basically the following facilities are critical to determination of urban land use, namely, access roads, good drainage, electricity and public water supply. Where these facilities are adequately available, the land values will be high in such areas. Institutional factors affecting urban land use include local customs, traditions, law, organizations and other institutions of human society. Among planning instruments which influence land use are the master plan, zoning regulations, rent laws, land acquisition policies, sources of title and type of tenure.

5 DATA ANALYSIS

The research analyzed the determinants of land use in Lagos with the use of principal components analytical technique (see Table 1). Since the principal components technique produces components in descending order or importance, therefore its adoption in this study is an aid in reducing the variables into fewer numbers which account for as many possible variations among the original variables. The results of the application of these techniques are discussed in the following section.

VAR1	Economic factors as a factor influencing land use
VAR2	Sociological factors as a factor influencing land use
VAR3	Cultural factors as a factor influencing land use
VAR4	Environmental factors as a factor influences land use
VAR5	Infrastructural factors as a factor influencing land use
VAR6	Institutional factors as a factor influencing land use

Table 1: Variables used in Factors Analysis. Source: Field Survey, 2012

Table 2 shows the correlation matrix of the linear association between the variables. The coefficient that is + 0.500 or greater shows a high level of co-variation between the variables involved. Also, coefficient ranging between + 0.400 shows the moderate level of correlation, while those between + 0.100 and + 0.200 indicate a weak level of correlation. Those lower than +0.100 shows little or no linear correlation.

Variables	1	2	3	4	5
1	1.00				
2	.709	1.000			
3	.530	.633	1.000		
4	.722	.504	.594	1.000	
5	.693	.512	.601	.582	1.000
6	.711	.495	.482	.703	.762	1.000

Table 2: Matrix of Correlations. Source: Field Survey 2012

First, it is necessary to state that 95 variables were used for the analysis. For the purpose of this paper the six variables have been isolated as basis of analysis in this study, thus the moderate level of correlation observed in Table 2.

The results obtained in the matrix of correlation in Table 2 shows that all the variables have high degree positive relationships with one another. This is a confirmation of the validity of the determinants of urban land use as established in literature. The score on the relationship between infrastructure and institutional factors shows the highest positive association with a figure of .762. This means that improvement in infrastructural facilities especially roads has been due to pronounced institutional support in the study area. Also the relationship between the following recorded very high degree of positive relationship: economic and sociological factors (.709), economic and cultural factors (.722), economic and institutional factors (- 711). The implications of the above is that improvement in institutional support and infrastructure will be expected to bring about sustainable land use, while improved economic situation will result into effective implementation of planning regulations and land use. Generally the lowest correlation interrelationship figure recorded as .504 is for the relationship between sociological factors and environment. This is still within the range of high coefficient level of co-variation. This means that all the factors identified as basic to influencing land use in Lagos have high level of co-variation relationships.

A further analysis of these variables was done through the application of principal component technique aimed at making each factors independent of each other.

Factors Number	Eigen Value	% of Variance	Cumulative % of Variance
1	4.231	60.471	60.471
2	1.742	17.134	77.605

Table 3: Extraction of Initial Factors (Components)

Table 3 shows the result of the extraction when the six variables (determinants of the land use) were subjected to principal component analysis. The six factors have been reduced to two which give accounts of all the other factors. The first components are renamed infrastructural facilities and the second component renamed economic factors. It can be observed in Table 3 that the first factor has an Eigen 4.231 which is the relative magnitude of variance accounted for by the first variable. Usually the first Eigen value accounts for the highest variance in the data set. The first components also explain 60.471 percent of the variance in the data, while the first two components account for 77.605 percent of the variance in the data. As discussed earlier that the aim of the principal components is that of data reduction, thus not all the components or factors influencing land use in the study area are retained in the final rotation solution. The first two components which account for 77.605 % of the variance is retained. This is based on the criterion that the two factors components have at least 5 % of the total variation based on Spence's specification (Spence, 1968).

Variable		Factors	
		1	2
VAR5	Infrastructure Facilities	.871	.263
VAR1	Economic Factors	.862	.157
Eigen Values		4.286	1.264
% of Total Variance		60.141	17.314
Cumulative % of Total Variance		60.141	77.455

Table 4 revealed the component loading for each primary variable of each of the components when they are subject to varimax rotation. Note: Loading that is equal or greater than 0.40 are considered to be high.

The interpretation of the loading is the same as it was done is the correlation coefficients. Factors loading of 0.401 and more are considered to be high. This is also in agreement with Spence (1968) who considered 0.40 as a cut off level for high factor loading. Based on this, the first factor which accounts for 60.141 of the total variance loads highly on both infrastructural facilities and economic factors, whereas the second factors which accounts for 17.314 % of the total variance loads relatively low on both infrastructural facilities and economic factors with figures .263 and .157 respectively. The implication of these figures is that

infrastructural facility improvement and economic factors are highly related in factor 1, while they are weakly related in factor 2. The implication of this is that where there is improvement in infrastructural facilities there is expected to be improvement in economic variables, usually this will manifest in form of increase in revenue on landed properties.

6 LAND USE DEVELOPMENT PROCESS IN LAGOS METROPOLIS

The land use and settlement pattern of Lagos in the last twenty-five years can be highlighted through the review of different land use categories namely: residential, industrial, commercial, industrial, educational and institutional, religious, circulation, parks and recreational areas.

6.1 Residential Land Usr

The noticeable major determinant of residential development in Lagos is that of accessibility infrastructure (road) and land value. This is in agreement with what has been identified in literature and these are among the variables identified and analysed through the principal component technique. The land value could be in terms of rent, cost of purchase of apartment/house and cost of residential land plot. Motorway corridors are major determinants of urban residential growth. The Lagos-Badagry, Lagos-Abeokuta and Lagos-Epe expressways attract indiscriminate physical development in all directions. The nature of the indiscriminate development is further compounded due to the mass land acquisition by both the state and federal government, which in most cases are not followed up with appropriate schemes through which the people can easily purchase land and develop in compliance with such schemes. Thus, illegal land development, predominantly of residential use continue to spring up in response to ever-rapid population growth especially in the fringe areas of the metropolis. The phenomenon is common in the urban fringe of Isheri in the north; Ikorodu and Ajegunle in the north east; Ojo-Badagry Axis in the south-west; Alagbado, Ipaja in the north/west and Lekki region in the south-east. However it does not mean that all residential buildings springing up in these areas are not approved by relevant government planning agencies of either the local, state or federal government. The case is that most of these structures are not in approved layouts. Some of them are also on acquired government lands.

Land which residential building can be built without contravening exist planning regulations are scarce or are not in accessible locations therefore, the policy of government towards residential land development should be re-examine to take care of these noticeable deficiencies. Another type of residential units and support facility phenomenon is the filling-in of existing un-used spaces especially in older inner city areas. For example the second Republic civilian government (1979-83) regime in an effort to achieve the policy of Universal Primary Education (UPE) was confronted with acute shortage of classrooms. The government embarked on quick response through construction of classrooms on available urban open spaces. These spaces were areas earmarked and use as public open spaces and recreational areas in many residential neighbourhoods. Thus urban open spaces have virtually been eliminated from the Lagos landscape.

6.2 Commercial Land Use

Lagos is not only the leading commercial nerve center of Nigeria but also that of West Africa. Lagos metropolis, has the potential of becoming the leading Africa center of trade. Many areas specifically earmarked in the metropolitan Lagos master plan for commercial development have not been developed. This has been due to the low level of economic activities in the country generally. Hence, the demand for high quality commercial premises, which could have emerged from such schemes, could rather be low. Therefore these have led to a situation where illegal conversions of buildings especially those along major roads and streets have generally been embraced by property owners. This is common in residential areas especially in traditional core areas and high-density residential areas. Lagos is presently characterized by commercial ribbon street development such that virtually all high-density areas are in a chaotic state with indiscriminate mix of commercial, light industry, transport and religious land uses. The phenomenon of chaotic land use mix deserves special attention in any future regional and master plan scheme of Lagos. Also, existing commercial places especially markets mainly under local government administration in the city are being expanded without due compliance with appropriate planning regulations such as car park requirement, set-backs among others.

6.3 Industrial Land Use

Except for the new Ikorodu Estate and Lekki Free Trade Zone there is no new industrial estate development in the last two decades. Again, the reason for this is not farfetched. It has been mainly due to the economic downturn of the country and government's lukewarm attitude. Existing industrial premises are characterized by sealed up factories, factories being converted to mere warehouses and to religious worship centers especially churches. The reasons for this is that the operation of most of the existing factories require very huge amount and the import liberalization policy of government in compliance with globalization principle has made local production unprofitable, thus manufacturers prefer importation of finished goods. The few operating factories are not operating at full capacity of their installations. The implication of this is that there has not been remarkable industrial land expansion in the city. This will require special attention, as industrial operation is the engine of growth and development because of their multiplier effects on income, savings and development of other land uses. However, the Lekki Free Trade Zone implementation construction commenced recently. Judging by the political will and commitment by the Lagos State Government there is prospect for the physical manifestation of the idea.

6.4 EDducational and Institutional Land Use

As earlier mentioned in the section under residential land use development, the state government encouraged the development of physical structures to provide more classrooms mainly at the primary and secondary school levels. Also the liberalization of education at all levels in which the private sector is allow to establish and manage educational institutions has increased substantially the land area occupied by educational uses. However, land space for most of the private sector educational institutions are through the conversion of existing buildings especially residential to educational uses. Few buildings are approved and constructed for educational use. Most of the new buildings specifically approved for educational uses are on plots earmarked for residential apartments thus compromising appropriateness and efficiency of location of educational facilities. Any meaningful future plan of the city should detail the pattern of their locations and enforce planning standard requirements of existing educational facilities at all levels. This problem is more pronounced with nursery/primary, vocational and secondary schools.

Institutional land uses also witnessed significant landmark effects in two areas the construction of the new Lagos State Secretariat at Alausa and the movement of the nation's capital to Abuja. Therefore, the spillover effects of the state secretariat on other land uses has been remarkable. Ikeja, the location of the State Government Secretariat has witnessed tremendous growth of commercial and institutional uses while traffic congestion has become a major problem. In the case of the seat of the Federal Secretariat at Ikoyi, the area has witnessed significant drop in traffic due to the movement of the seat of Federal Government to Abuja. The establishment of the Lagos State University in Ojo has its impact on trip generation and distribution, around the Ojo origin. Aside from these three major landmarks of institutional changes, Lagos has no other significant institutional land use changes.

6.5 Religious Land Use

Historically, this has always been part of residential facilities in the land use structure of Lagos except for few religious locations within commercial districts such as in Lagos Island and Ikeja. The major and significant phenomenon recorded in this land use class has been tremendous development of religious places in every nook and corner of the city especially in built-up residential areas. Churches and mosques are the most prominent features. An average of about ten places of worship of various sizes can be observed per square kilometer of any built-up residential area except in government and private estates. The number is higher in high-density residential areas. This is a major problem especially when consideration is given to the mode of worship with loud speakers, which are installed outside the buildings, thus generating high level of noise during services. Other problems arising from these unapproved places of worship include vehicular congestion and heavy human traffic problems of which car parking is a major aspect.

6.6 Circulation

By the turn of the 19th century bridges constructed mostly of timber had been completed to link Lagos Island with Iddo known as Carter Bridge and Denton Bridge, both are no longer in existence. Both bridges have been replaced by new dual carriage ways with concrete median separators. The Lagos railway started under the management of the Nigeria Railway Corporation in 1896, with its terminus at Iddo. The rail lines run in a

north-south direction and still maintains the steel track of the pre-colonial type. It still maintains the steel gauge tracks of the pre-colonial type. Road network development started in the second half of the 19th century with the initial opening up of the Marina. The administration of governor Glover opened up the Broad Street in Lagos. He also linked up then Victoria Street (now Nnamdi Azikwe Street) with the mainland in 1866. By 1900 the city had about 15 kilometers of road over which horse drawn carriage were pulled. By 1946 two main arterial roads of greater Lagos had become prominent links with the hinterlands. They are the Ikorodu Road and Agege Motor Road both of which run in north-south direction with the Agege Motor Road running parallel with the railway line.

Road network in Lagos can be classified into three broad types namely the expressways, major arterial roads and other roads which serve as access and collector roads. Existing express roads are Ikorodu Road, Fusho Williams Avenue-Agege Motor Road-Abeokuta Express Road and Apapa-Oshodi-Oworoshoki Express Road. The complex network of bridges on the Lagos lagoon connect various parts of the island to the mainland with the most important line being Eko Bridge which links the commercial core of the Idumota on the island to Oyingbo in the mainland with a length of about 11/2 kilometer. The Third Mainland Bridge completed in 1991, is about 10 kilometer long. It is reputed to be the longest bridges in Africa. It links the Oworoshoki end of the mainland to various parts of the island of Ikoyi, Victoria and Lagos Islands. The Third Mainland Bridge is the busiest of all the bridges with a peak periods of between 7-10a.m and 4-30p.m, respectively during the working days on Monday to Friday. It has increased tremendously accessibility and economic activities in Lagos. The Lagos-Ibadan Expressway is in the northern boundary of the metropolis. It serves as the major link of vehicular traffic out of Lagos to other parts of Nigeria. The Lagos-Epe Express and the Lagos-Badagry Express Way located and runs towards the east in the south/east and the latter towards the west in the south-west are also major traffic routes. The recent commencement of the construction of light rail running parallel to the Lagos-Badagry expressway will enhance development along this region. Two airports serve Lagos, Murtala Muhammed Local and International Airports with both of them located at Ikeja, the capital of Lagos State. Also two major seaports serve Lagos. They are the Apapa Wharf and the Tin Can Island Port. They are both linked with the Apapa-Oshodi Expressway.

6.7 Lagos Parks and Recreational Land Use

Prior to the development earlier mentioned regarding educational institutions, the construction of schools on open spaces were common in the late 1970's. Ample parks and open spaces existed in Lagos despite the fine texture of the urban morphology. During the colonial periods more attention was devoted to the development of Ikoyi as a garden suburban coupled with the development of private commercial and club recreational grounds such as the Race Course now Tafawa Balewa Square, the King George IV Stadium now Onikan Stadium, the Ikoyi Golf Course and the Government House Garden, the National Stadium and the recently completed Thunder Balogun Stadium at Surulere. The earlier forms of European gardens which later influenced greatly the present landscape style of Lagos existed before colonization. They were the gardens and plantations developed around the traditional forts built by the European Merchants. They were mainly utilitarian gardens devoted to the cultivation of exotic food crops and fruit trees. Few of them had summer houses. During this time the forces and taste influential to the development of Renaissance gardens in Europe were already at work. Some of these early gardens had traits of the garden styles peculiar to the countries of the European merchants who built them.

The colonial landscape of Lagos will not be complete without the mentioning of the government reservation area (GRA). The principle of the GRA development can best be illustrated by the description given to its by Lord Lugard in 1904. According to him the European Reservation Areas now known as GRA should be developed as a cool fruit and flower garden where one could sit on a shady verandah in the privacy of one's own home. Extensive public open spaces with recreational grounds and sports field would be near both office and home, reached by shady pathways. The GRA's were the European government version of the garden city in Nigeria. The products of these are houses to be seen in the older GRA's such as in Ikeja. They were built in the then remote areas but have been surrounded by built-up neighbourhoods due to urban sprawl.

After independence in 1960, new landscape features continued to reflect the British styles. Many landmarks to commemorate the independence anniversary were built in form of statues and gardens. The early post-colonial landscape features include the Tinubu Square fountain, the remembrance arcade and the Tafawa

Balewa Square. The Ibrahim Babangida Boulevard Obelisk was built in 1991. Unfortunately, modern Nigerian landscape movement started in Lagos, today it has very little to show for it in the area of public gardens and parks. Existing parks and open spaces can be found along Lagos Marina which has been blighted by the construction of hard concrete fly-overs. The beaches of Bar Beach, Lekki, Badagry are areas that should be improved. A few recreational grounds and local parks have been developed in recent times by private clubs, social and non-governmental organizations and many private residential estate developers. These renewed efforts should be sustainable through government facilitation effort. Recently government embarked on city-wide massive landscaping and this has significant impact on the greenery of Lagos. Many new parks are constructed, among which are Gani Fawehinmi and Moshood Abiola Garden.

The "Nigerian Urban Planning Decree No. 88, 1992" is a rescue mission legal framework which should substantially improve the quality of the environment in all parts of Nigeria including Lagos. The establishment of the Lagos State Urban Regional Planning Board and the various Local Planning Authorities will no doubts lead to sound land use planning in all parts of Lagos. The prospects of good landscape rest solely on the local planning boards. Local Planning Authorities should exercise the enforcement power provided in the law establishing them in order to achieve remarkable level of land use compliance by the public. Reduction of taxes and levies by government for environmental friendly organizations could be used as incentives to encourage environmental improvement.

7 DISCUSSION ON LAND USE CHANGES IN LAGOS

Land use changes have been gradual over twenty-five years and sporadic in the past ten years across the entire Lagos Metropolis. However, the genesis of the dynamic land use structure has a humble beginning as at 1910. The society was simply not properly monitored because there was no formal planning authority in place. Thus spatial coverage of Lagos was limited around the present day Lagos Island Local Government Area.

The land use structure has changed from the former simple pattern to a complex pattern. This was as a result of intense and widespread urbanization. Though, as at this period planning and development activities were guided adequately by the Lagos Executive Development Board that later transformed to Lagos State Development and Property Corporation. Socio-economic characteristics played major roles in the ordering of the land uses. The result of this was segregation of human settlements based on socio-economic status. The spatial extent of Lagos Metropolis has greatly increased, likewise intensity of land use. The land use pattern that ensured in 1970 revealed a linear settlement pattern using the major roads and the railway line as points of origin. Again, the land use structure had a central business district in Lagos Island and the intensity of use has also improved. In the 1980s land use structure for a potential metropolis has ensured. The land use structure before the preparation of Lagos State Regional Master Plan and subsequently Metropolitan Lagos master plan was beginning to generate attention because there were widespread urban problems as a result of uncoordinated urban development and inadequate development control. The roads network was extended and improved upon to cater for the prevailing urban problems. The districts were characterized by diverse socio-economic conditions (such as income, population density, building conditions, poverty level, development potentials, economic base and predominant land use). A multi-nuclei urban center was in its embryonic stage. The spatial coverage was largely influenced by population size and development needs. Lagos Metropolis witnessed one of the highest levels of urbanization between the periods of 1980 to the present time. This is due to globalization trend in economic activities fuelled by advancements in science and technology in the area of information technology, the global economy, telecommunication, resources utilization and management.

Specifically, the most noticeable effect of globalization within Lagos cityscape is radical shift in the land use pattern. The high dependency of the city economy on imported goods, has led to a massive depletion, within a decade, of industrial enterprises with its attendant erosion of job opportunities. While industrial land uses are decreasing however, alternative uses, chief among which are religious in nature, are rapidly taking the place of industries, churches especially are in the forefront. It is thus a common phenomenon to see churches occupying entirely an area hitherto used as factory or partially occupying a significant portion of such premises. Such religious places have their peculiar complementary accompaniments such as weekly heavy traffic. Many commercial premises in different parts of the city have also given way to religious land uses. The reason for this is that churches seems in the prevailing circumstances, to be the land use capable of

affording the rents demanded by property owners, the service sector having been economically weakened as it were, by forces of globalization. These phenomena can be described as change of use of existing buildings.

Change of use of existing land use zoning plan is common feature. The city is now dotted with uncomplimentary land uses in many areas. This is common with uses such as multistory office blocks within residential neighbourhoods. This is contrary to basic urban land use theories, which discourage intrusion into privacy of residential areas. This aside from being an intrusion into household's privacy is also a security risk. The heavy traffic which accompanies such invasion also violates residential neighbourhoods. Aside from multistories within residential areas, petrol filling stations and fast food outlets are other common features observable within the Lagos cityscape. Surprisingly however, most of these anomalous land uses have the approval from appropriate government planning agencies. In a sense, physical planning contradictions in the city are exigent response to the negative impact of globalization on Lagos economy. With industries being frustrated out of business and jobs drying up, government revenue through company tax and personal income tax is correspondingly dwindling. In search of new sources of revenue, government, it may be argued, is forced into unorthodoxies in revenue generation. Since these new uses are capable of paying the necessary levies, taxes and other financial returns to government naturally, they are supported by government. It is however mandatory for these new uses to apply for change of land use, process the new building plan, pay specific fee for the changes as well as pay company and personnel taxes. Thus the changed landscape is the result of economic needs on the part of government and individuals. Again as identified in literature and confirmed in the analyses economic factors and institutional variables have significant influences on the Lagos land use structure. The influence of infrastructure is more pronounced, especially with its negative effects on industrial land use.

With the decline in the formal sector of industrial and formal service industries, the informal sector has emerged as the dominant feature of the cityscape. Usually in the form of scattered small-scale service points. The bulk of the informal sector usually operates along major roads and within neighbourhoods. This sector has also assumed the services formally provided by supermarkets, furniture sales shops, electronic stores, hardware shops etc. Following the demise of the formal sector, which these units of business were a part, it is important to reiterate here that the collapse of these formal service units is due to globalization, which has eroded local industries, which used to produce the goods sold at these shops but which can no longer do so because of their non-competitiveness within a globalize economy. Since the informal sector can afford to offer similar services at lower prices made possible by relative lower overheads, of the doubtful quality of the goods, they become the only available avenues for consumer, even at high risk. The Lagos streetscape is dotted with small scale sale shops offering a wide range of services from household items, electronics, furniture, hardware, and cobbling, packaging and sundry cottage manufacturing industries. In the market sector hawking, itinerant salesmanship and home trading thrive while in the service sector catering, telephony service, hair-care, vulcanizing, motor mechanic etc dominate. The city landscape is in fragments of dirty production and service points with no regard for land use zoning. As with changes in land uses, the informal sector is now a major source of revenue for government at the local level. Informal enterprises are closely monitored to pay sales tax by local government authorities. It can be concluded therefore that the informal sector is currently a major provider of employment in Lagos.

All these have profound impact on the land use structure that ensured. Presently, a multi-nuclei urban pattern has emerged with its spatial coverage extending greatly into the hinterlands. The recent land use trend produces lateral expansion into neighbourhoods sub-urban centers (Mowe, Ikorodu, Sango-Ota, Okokomaiko, Ajah etc). The possibility of a conurbation is being studied with regards to other urban center such as Sagamu, Abeokuta, Ifo among others within the next ten years. The land use structure has grown to a very complex nature with associated dynamic urban problems.

8 PLANNING IMPLICATIONS OF FINDINGS AND SUGGESTIONS

The only major comprehensive master plan of Lagos was prepared in 1985 but unfortunately the detailed district plans were never prepared. The master plan was reviewed two years ago but attempts to prepare a new one has not been initiated. The uncontrolled urban sprawl prior to the preparation of the master plan continued. Rapid development continues to feature prominently especially at the northern part where land is firm and not as water-lodged as it is in the southern end where this led to high cost of physical development. The Lagos-Badagry, Lagos-Ibadan and Lekki-Epe expressways continue to attract physical development

indiscriminately in all directions. The nature of expansion is further complicated by government mass land acquisition policy which is not followed up with appropriate schemes through which the people can purchase land and develop in compliance with legal requirements. Therefore illegal structures continue to spring as the increase populations have to respond to natural need for shelter.

Previous government policies do not improve the situation as illegal building owners are made to pay penal fees which they are always ready to pay. Therefore unplanned neighbourhoods continue to emerge. Tremendous invasion of the suburb in many-regions such as Lekki in the south-eastern part continued. Towards the north-west, the situation in Ikotun, Ipaja, Agege, Abule-Egba, Ojokoro are worse mainly with residential buildings. Towards the north-east the nature of the riverine serves as a check against indiscriminate construction. Nonetheless pronounced illegal building constructions are common. All these do not necessarily mean that buildings are not approved by the planning authorities. Land on which people can build without contravening existing regulations are scarce, therefore the policy of government towards land development deserve immediate overhaul, if the people are to build houses without contravening planning legislations. The second types of development are the filling-in of the existing un-used spaces within the urban fabric. Abuse has been from both government and the people. For example the second republic civilian regime in an effort to achieve the policy of Universal Primary Education (UPE) was confronted with acute shortage of classrooms. It embarked on quick response through construction of classrooms on available urban open spaces earmarked as public recreational spaces in old neighbourhoods layouts. The state civilian government has filled in such spaces with classrooms blocks in virtually all parts of the metropolis. Thus, virtually all open spaces in the urban fabric disappeared leaving no meaningful community recreational open spaces in Lagos Metropolis. Today Lagos appears practically full of hard landscape in the built-up areas without any appreciable neighbotirhood open spaces, neither parks nor gardens. This has serious consequences on the recreational life of the inhabitants.

Most of the negative observations such as conversion of open spaces to other uses, non-implementation of plans, abuse of planning standards can only be overcome through the preparation of either a new master plan or preparation of schemes at local or subject plan levels eventhough piece meal district plans are currently embarked upon by the government. This will require sustainable strong political will and building of appropriate human capacity, modernization of development approval and monitoring system. There is also need for effective public participation. The complexities surrounding the mechanism sustaining Lagos physical development have become more difficult to understand.

9 CONCLUSION

From the discussion above it is clear that appreciable physical development have taken place in Lagos from the pre-colonial period to the present lime. A critical study of the land use shows that they have largely been influenced by western styles. The indigenous planners are yet to come-up with distinct style rooted in our traditional land use planning. However we can appreciate the complexity of the problem through the historical background of modern education in Nigeria which was based practically on British background. Also other problems that should be resolved in order to overcome the present constraints include adequate finance, social factors, manpower, cultural factors, geomorphic and legal problems. Majority of the people are poor therefore emphasis should be on functional physical development such as prevention of flooding, housing, environmental sanitation, parks and gardens, paved pedestrian walkways, tree planting amongst others.

Valuation Cycles Of Pre Industrial Townscape

Jürgen Lafrenz

(Prof. Dr. Jürgen Lafrenz, Universität Hamburg, Institut für Geographie, Bundesstr. 55, 20146 Hamburg, Germany, juergen.lafrenz@uni-hamburg.de)

1 ABSTRACT

The townscape is the morphological expression of urban life in its local individuality and its historical complexity. It has a holistic structure, and the formative parts penetrate to different degrees. Human conscio¬usness always evaluates the urban physical structu¬res anew. The aesthetic and documentary component will change with the spirit of the time.

The shape of occidental towns was formed in pre-industrial building periods through

- a high degree of continuity of the ground plan patterns since the times of settlement
- an adaptation of the architectural styles of the pre-industrial eras in a specific local manner.

Whereas in pre-industrial times the physiognomy of occidental towns was characterized by high degrees of persistence, there were more degrees of freedom between radical transformation and adjoining regulations in the further development since the beginnings of the industrial era. These topics brought the fundamental question about the reflection of pre-industrial townscape due to the later building periods. In a heuristic manner the model of a cycle theory has been tested for the change of paradigm.

The fundamental fact of the evaluation is the identification of almost two synchronic cycles, which started with a period of disregard and later turned into a period of adaptation of the local architecture. The inner break of the two cycles in Central Euro¬pe can be dated about 1957, the inner changes around 1900, and around 1970 with slight changes in different regions. The two cycles show some similarities in their inner development. However, in the second cycle the proceedings for disregard were characterized by a more drastic vigour, and the instruments to main¬tain tradition were much more careful.

In analogy of both cycles, one could visualise that the present confession of the public towards the hi-storic repertory of forms may lose its fascination, and a change to a third cycle will take place. There are opinions that a certain inflationary protection of monuments and a much less creative architecture of adaptation has arisen from the genius loci. In the present time, the human-interest pretence of history is even effective, nevertheless it is not only contrary to historic mentality, but may also be the germ that at any time could cause people to turn away from history again.

2 INTRODUCTION

The townscape is the morphological expression of urban life in its local individuality and its historical complexity. The configuration has a holistic structure and the formative parts penetrate to different degrees. Human consciousness always evaluates the urban physical structures anew. The townscape itself may be a significant viewpoint of such an evaluation .The aesthetic and documentary valuation will change with the spirit of the time, or to quote Faust in Johann Wolfgang von Goethe's drama:

"What you call the spirit of the time

is in reality the own spirit of men

in which the times are mirroring themselves".

The shape of occidental towns was mostly formed in pre-industrial building periods by means of:

- a high degree of persistence of the urban pattern got underway after the time of settlement
- the adaptation of the architectural styles of pre-industrial eras, in a specific local manner.

There were more degrees of freedom between radical transformation and homogenizing regulation at a later date. These given facts should be followed by the fundamental question about the reflection of pre-industrial townscape due to the later building times. In a heuristic manner, the hypothesis of a twofold cycle has been tested for a change of paradigm, with respect to the further influence on the traditional townscape.

The immediate past, the perspective of which is often not seen very clearly due to a lack of distance, was often fiercely criticized. In the analysis, the adaptation of the townscape tradition swung between "yes" and

"no" and therefore, a detached attitude is taken, particularly as a momentary point of view could prove to be a transitional one.

The findings are based on an analysis of the townscape of selected occidental urban cores in Northern und Central Europe. This paper will explicate the model of the town of Lübeck, former Head of the Hansa, the core of which is particularly suitable for such a consideration, for three reasons:

- the town centre has been changed only in such a way that the pre-industrial shape is highly persistent up to the present day, despite impacts of urbanization.
- precise order and functional conciseness in the townscape could suggest the possibility of a later interference in a normative comparison in the present building fabric.
- local literature and planning material could elucidate epochal intentions regarding the townscape.

3 THE CASE OF LÜBECK

The configuration of the townscape of in the core of Lübeck results, on the one hand, from a continuity of only few planning ideas during a time of intensive settlement in the Late Middle Ages and, on the other hand, from an increasing lassitude as a consequence of a lack of economic growth forces during the early modern times. The townscape of Lübeck on the hill between Trave and Wakenitz was fixed by a precise urban pattern, not schematic, but nearly regular:

- Types of streets

The only incomplete regular network consists of backbone streets, rib-streets, and transverse streets beset by fringe streets and it is additionally extended in the more peripheral areas by aisles (Gänge) into the blocks.

- Types of plots

The pre-industrial pattern of plots is formed out of elongated broader and narrower non- standard plots whose former backside plots are cut off in many cases, as small plots to the borders of the streets and as plots of the Gänge within the blocks.

- Types of houses

The pre-industrial stock of houses of civic building blocks exposed to these streets consists of big and small gabled houses as well as of eaves houses exposed to the streets and Gänge. The houses of the different building phases are differentiated by modified division into compartments and changing architecture of the facades within almost unchanged constructions.

- Street space

The continuous alignment out of mostly the same types of houses with façades of different building phases results in widened cross profiles and curved longitudinal profiles in connection with the relief in well-proportioned and fully changing arranged spaces of streets.

- Roof space

The dominant attribution of the gabled and eaves houses to the forms of the street produced due to the ascending relief, is a sliding overlapping scale of almost equally oriented roof ridges into a roof space that is almost only disrupted in its uniformity in the backbone streets and along the north-western fringed streets.

- Skyline

As the basis for the topographically distinctive distribution of the monumental structures, the roof space is part of the skyline that is heightened in its impression by the surrounding watercourses and former fortifications.

3.1 The First Evaluation Cycle

3.1.1   Period Of Disregard

In Lübeck, the beginning of urbanization coincided with the abolition of the function of the town gates in 1864. After a long period of economic stagnation, the community began to grow at an increasing pace. The degree of change was especially dependent on the capital at hand. In the expanding agglomeration, the city centre initially developed along the main roads of the old town. A construction boom began in the business area as well as on the periphery in a few speculative objects, such as tenement houses which replaced traditional houses. Most of the large scale public institutions were built on the sites of former cloisters and curiae – whose old building substance was often integrated.

Before the turn of the 20th century, in the Bismarck era (Hochgründerzeit), disregard the pre-industrial structures with new forms and on a large scale was considered liberation. Under most generous standards of building codes of 1865 and 1881, the density of the inner town expanded vertically rather than horizontally. The height of the houses was raised to such an extent that the scale of the traditional townscape was broken at many places. The new houses with tall and bare fire protecting walls were in disorder to the relatively homogenous sequence of houses in the streets. The steep tile roofs were mostly intermingled with the (nearly) flat ones of non-local materials. The facades of lavish historicism were broken by the almost plain front walls of the traditional houses. However, this was seldom the case with the speculative objects of tenement houses near the periphery, where simple facades with less ornamentation arose. The new large public buildings reflect international, more eclectic style elements. However, a crossover of traditional forms with a regional touch was not unusual in the process of vital history adaptation.

3.1.2   Period Of Adaptation

The construction periods from 1900 to 1950 are a strong commitment to tradition and a critical reaction to the intrusions of the Bismarck era. At the beginning of the 20th century, an awareness of the importance to continue the irretrievable historical townscape of the long established urban cores arose. This was not directed exclusively at the structures of highest historical and artistic value as in the past, but paid attention also to less significant buildings which bear witness to the pre-industrial period. The principle was adopted that an outstanding structure and its immediate environs enhance each other and that the townscape would be formed by the totality of all individual structures of different orders. With the "discovery" of the ensemble of buildings, entire historical city cores were declared monuments.

In Lübeck, the new appreciation of long-established culture was based on the complementary instruments of preservation of monuments and sympathetic architecture (Anpassungsarchitektur).

- In 1915, the first preservation order (Denkmalschutzgesetz) was passed and shortly thereafter, a significant number of pre-industrial houses were affected by the statute. The strength of the law lay in the fundamental preservation of the buildings; its weakness lay in the tight financial situation of the communes.

- The efforts to promote traditional architecture were underscored in 1901 with a "competition of facades" (Fassadenwettbewerb) which was announced by an "Association of Friends of Art". The outcome of 80 contributions was a locally specific metamorphosis of stylistic elements of historicism. However, a local traditional style (Heimatschutzstil) which was orientated on pre-industrial forms in a simple performance and only intended to emphasize the "traditional connections in character of the essential" soon became standard practice. In the 1930's, buildings of historicism so were classified as "construction sins" and some facades were "purified" of their décor.

From about 1900, the appreciation of tradition coincided with urbanization influencing the historical ground pattern more incisively. Plots were aggregated to larger units and streets were widened. The particular functional challenges which had repercussions on the townscape, apart from the growing location pressure on the main business streets, resulted from the following objectives:

- In 1905, in order to cope with the flowing traffic, several alignment plans (Fluchtlinienpläne) to broaden the streets were drawn up. In the process of new building construction, the main traffic streets were set back in conformity with the projected alignment.

- In 1935, a flexible programme for the comprehensive renewal of run-down districts away from the main streets was initiated, which materialised quite pragmatically when dealing with the established building substance. Front houses were rationally converted to flats while the building density in the inner blocks was substantially reduced.

Much of the original townscape was given up as a result of these measures, despite all the confessions of heritage preservation.

Since the 1920's, the potential preservation of valuable building substance was made possible by increased planning options. A counterbalance planning (Auffangplanung) was capable of influencing the location structure by stipulating the land use. In a protective manner, it was possible not only to divert the street traffic but also to relieve the city core structure. In this connection, the idea arose to relocate certain functions to semi-central locations outside the former town gates, but this could only be realised to a limited extent.

3.2 Second Evaluation Cycle

3.2.1 Period Of Disregard

In 1942, in Lübeck almost 20 % of the buildings in the core area, mostly in the main business streets, were destroyed by air-raids. The first decades after the war, the maxim was: city planning according to functional criteria. During the post-war reconstruction the following targets had priority:

- The historical core should become the main business centre again, although a semi-central location for many a function would have been sufficient that time.

- The historical core should be aligned to current flowing and stationary traffic, whereby in the long run, a system of peripheral roads should reduce the through traffic.

The widening of the streets, which occasionally occurred in the early 20th century by successive piecemeal replacement, was now tackled resolutely. Contrary to the former intention showing the frontage lines, the streets were now widened considerably. By re-groupment of plots and the coring of inner blocks, courtyards (Blockbinnenhöfe) were created, particularly for stationary vehicles. .

The consciousness of the city planners to restore the pre-industrial landscape still existed in the initial years following the war but could only put into action with considerable restrictions during the reconstruction of the inner core. The preservation was confined to the traditional isles (Traditionsinseln) and monumental buildings were reconstructed almost authentically.

The architecture of the new houses no longer represented the home style movement. The use of bricks for the facades and tiles for the (more or less) steep roofs still had a certain affinity with the building tradition. Most

of the gable-fronted houses were substituted by houses with the ridge parallel to the street. The new houses were sometimes wider. The traditional façade with separate inlets for the windows was frequently replaced by a flush façade with rows of windows. The sequence of the house facades often broke up the convention of traditional metric. The spatial patttern of the roofs, which were still traditionally steep, were changed to the extent that instead of many former gable houses the new buildings got ridges parallel to the streets.

The total break with tradition materialized at the end of the 1950's. With the dynamic economic development since the 1960's, the main business zone, which had experienced successive post-war reconstruction and local pressures, expanded into the neighbouring areas of the urban core. The types of construction followed multiple architectural styles with an international character using cubistic form and non-local material.

3.2.2   Period Of Adaptation

The attention to traditional townscape in Lübeck dawned again about 1975, at a time when the renewal of blighted areas of the old core became a current issue. Despite certain inner conflicts, a complex programme for the redevelopment concentrated on the following aims:

- The historical core shall be preserved completely in its cultural, historical and its townscape protecting elements.

- The historical core shall be promoted as a location for central functions for the population in the urban area and its hinterland.

- The historical core shall be increased in value as a location for potentially diverse models of flats which would be suitable for different population groups.

In this respect, the urban core as a monument was discovered for the second time and again, the reaction was to achieve a dualism of historical preservation and sympathetic architecture.

- The protection of historical buildings was extended. Many more objects were classified under the preservation order than in earlier times, even some that had been built during the industrial era, constructed before 1900.

- Sympathetic architecture was tried once again. Since 1981, after a period of vagueness, townscape regulations have been passed for public town space. Basically, it is the standardization of the types of buildings, the shape of the roofs and the structures of façades in their urban connection (Planungsgruppe mbH URBA 1977). The construction of the interior of the houses has seldom been laid down but every current building project is preceded by a total stock-taking.

During the realization of the programme, the consciousness for the authenticity of the townscape heritage has been sharpened. Defensive measures have been taken to influence the land use in order to facilitate the inner town preservation. Private traffic has been restricted considerably, in particular the through traffic in the core area. Substantial parking space has been established on areas of the waterfront at the fringe of the old core.

The revitalization of the core has resulted in a wave of public and private activities. The initial dispersion of objects brought about further initiatives in the neighbourhood and thus stimulated "snowball effects".

4   THE DUAL CYCLE: A COMPARISON

The fundamental fact of the evaluation is the identifica¬tion of almost two synchronic cycles, which started at a time from a period of disregard, and turned into a period of adaptation of the local archi-tecture. The inner break of the two cycles in Central Euro¬pe can be dated about 1957, the inner changes around 1900, and around 1975 with slight changes in different regions. When comparing several European cities, the analysis shows similar such periods that might only differ from each other by a short time lag. In times of economic prosperity and technical belief in progress, a distinct intermission materialized, while in times of depression, a growing uneasiness led to vital changes of mind.

The two cycles show some similarities in their inner course. However, in the second cycle, the proceedings for disregard were characterized by a more drastic vigour, and the instruments to maintain tradition were much more careful.

The two "periods of disregard" evolved differently, namely:

- The architecture in the time of historicism was lavish but it was rather meagre in the time of functionalism because the new construction techniques showed their rational effects.

- The multiplicity of new buildings broke up the structure of the traditional metric in both cycles. But still, the dimensional break was more radical through the second period.

The architecture of historicism, which was valued negatively in the first period of adaptation, was regarded in a positive way in the second period of adaptation. Nevertheless it is a kind of architecture that disregarded space and time in an ecclesiastical manner, similar to a current collage architecture, that has all kinds of historic motives available, but which are not derived from local tradition.

In both periods of adaptation, a dual strategy was applied to the cores, namely the heritage protection and the sympathetic architecture.

- The consciousness with a positive attitude towards the originality of the townscape and the instruments of preservation are pursued more consequently in the later cycle.

- The understanding of planning has also changed fundamentally in the sense of adequate townscape preservation, when contrary to former principles, now the defensive maxim is "form follows function".

- In the first period of adaptation, the interest in the townscape was only later linked with processes of urban redevelopment, however, in the second period of adaptation, urban redevelopment preceded and through its intervention in traditional structure, the question of preservation of heritage and sympathetic architecture was provoked.

5   ON THE WAY TO A THIRD CYCLE

In both cycles, the respective period of disregard was considerably shorter than the respective period of adaptation, which already manifests itself in the last cycle, too. In analogy of both cycles, one could visualise that the present public respect for historic repertory of forms might lose its fascination, and the preserving redevelopment would consequently wane, so that a change to a third cycle will eventually take place. There are opinions that a certain inflationary protection of monuments and a much less creative architecture of adaptation will arise from the genius loci. The arbitrary adaptation of any given pre-industrial design re¬sults in a pseudo-historic townscape in many places – even in places outside the historical districts. At the present time, the human-interest pretence of history is very effective. Nevertheless, it is not only contrary to historic mentality, but may also be the germ that at any time, as result of overreactions, will cause people to turn away from history again.

The cycle theory of a building conduct based on tradition manifests itself in comparable heuristic swings of the pendulum since the boom of the industrial age. The American city planner Albert Guttenberg postulates that, in principle, more attention should be paid to the cycle aspect of city development when he says:

"..planners ought to pay more attention than they do to the cycle aspect of their professions' history.." (GUTTENBERG 1990, p.694)

Abandonded Churches in European Countries: a UK Perspective

Peter Aiers

(Peter Aiers, The Churches Conservation Trust, Society Building, 8 All Saints St, London, N1 9RL, paiers@thecct.org.uk)

1 ABSTRACT

The ownership of churches greatly affects how they are dealt with when they are no longer required for regular worship. The Church of England, Catholic Church and Non Conformist churches have different processes and legislation that considers the redundancy of their churches.

We consider The Church of England's redundancy process. It has around 16,000 churches of which 12,000 are protected due to their historic importance. The Churches Conservation Trust (CCT) plays a key role in managing the redundancy of those churches of historic importance. CCT cares for those historic churches which no longer required for regular worship, if no other use can be found.

There are increasing pressures on CCT. It has an increasing portofolio of churches to manage while also suffering financial cutbacks. Therefore, as part of reducing the overheads and maintenance costs, CCT developed a process for the active reuse of historic churches. This seeks to re-unite the church with the community, not necessarily as a place of religious worship, but always with reference to this, as the buildings remain consecrated. Our approach considers three major areas; the potential to attract capital funding (grants, charitable donations or commercial investment); the ability of the building to bear architectural intervention and; the potential for the building to generate long term revenue and be self sustaining.

2 CASE STUDIES

Four case studies will be provided which show that a creative approach can result insuccesful regeneration in many different types of churches and local contexts:

- St Mary at Quay Ipswich, an urban site in a relatively deprived neighbourhoods http://www.visitchurches.org.uk/AboutCCT/Regeneratingcommunities/Projectsexamplesofourregenerationwork/AplaceforwellbeingrelaxationIpswich/ ,

- All Saints Benington, a rural deprived site http://www.visitchurches.org.uk/AboutCCT/ Regeneratingcommunities/Projectsexamplesofourregenerationwork/AthrivingheartforvillageBenington/

- St Nicholas Kings Lynn, rural town site http://www.visitchurches.org.uk/AboutCCT/ Regeneratingcommunities/Projectsexamplesofourregenerationwork/AculturalvenueKingsLynn/

- St John, Hanley, Stoke on Trent, urban commercial site

- http://www.midlandsheritage.co.uk/churches-chapels-etc/229-st-johns-church-hanley-stoke-trent.html

3 CONCLUSION

Our four very different case studies how community engagement can be harnessed to find sustainable futures for the churches. We highlight what has worked, what has been more challenging and how time consuming it is to develop these community based solutions. We conclude that the community element is central as church buildings have always been, on the most part, a resource for local people and they tell the story of that particular place. It is not just the continued presence of the church building in an area but also that building's continued relevance, in some way, to the local community which retains the cultural identity

4 THE CHURCH OF ENGLAND REDUNDANCY PROCESS AND THE CHURCHES CONSERVATION TRUST ROLE

4.1 When a Church Building Closes

When an Anglican (Church of England) Church has to close for whatever reason, lack of congregation, large repair bill, it is in the wrong place, then there needs to be a scheme created under the provisions of a piece of legislation called the Pastoral Measure 1983.

The Pastoral Measure is concerned with finding suitable alternative use for these buildings, many of which are protected (listed) buildings. The process is that the Diocese appoints agents to market the church building and try to find potential new uses. If a suitable use and purchaser is found then there is a public consultation. Secular planning permissions, either planning permission and/or Listed Building Consents, will be applied for and advice also given by the Statutory Advisory Committee of the Church Buildings Council. If no suitable use can be found and the building is of significant historic value then consideration is given to vesting the church building with the Churches Conservation Trust.

This process can take several years and the church building can be stuck in the "waiting period", a sort of church building limbo for this time. The maintenance of the closed church building is the responsibility of the Diocese but frequently they will only do the minimum necessary to maintain the building during which time the condition may deteriorate and there is no congregation to care for the building. If there are any local people to the church building who still have a connection, the "waiting period" can mean that this connection is lost as the local community are no longer responsible for it.

4.2 The Churches Conservation Trust

The Churches Conservation Trust was established in 1969 as the Redundant Churches Fund and was a partnership of church and state with both contributing, as they still do, towards the cost of the upkeep and repair of the portfolio that the Trust holds. Since 1969 the CCT has acquired 342 churches. Over the past several years the CCT has worked hard to generate more income outside those of the church and state, around £1.4m per annum is from the Church Commissioners, £2.9m from Department of Culture, Media and Sport and around £2m is self generated.

In order to cope with the continued growth of the portfolio, the CCT takes on at least one or two more historic churches each year, the CCT has developed a process for the active reuse of churches. This process seeks to re unite the church with the community, not necessarily as a place of worship, but always with reference to this. Our approach considers three major areas; the potential to attract capital funding (grants, charitable donations or commercial investment); the ability of the building to bear architectural intervention and; the potential for the building to generate long term revenue and be self sustaining.

4.3 The process

There are essentially 5 key stages our approach to community-led regeneration projects for our buildings, which aim to simplify the process for all partners, whilst creating strong decision-making evidence to take a project forward.

 Project start up – commissioning

- Establishing a project team
- Creating a memorandum of understanding about the partnership, its objectives and responsibilities
- Collecting important background information
- Establishing whether there are any existing ideas for the use of the church

Community profile and background research

This stage generates information on the people, the place and the opportunities for a church. A community profile is intended to provide a quick snapshot of local people and will enable the project team to better understand its community and their needs. It should also be used to provide an evidence base for future funding bids. The additional background research should help provide a further overview of an area's priorities and should include:

- Reviewing key documents for the area including any local plans
- Researching key local people and organizations that may need to be consulted on project ideas Initial consultation

The purpose of this stage is to generate further project ideas and to test reactions to any existing proposals. People should be consulted in a fun and accessible way, to reach as wide as possible audience. Consultation could take the form of:

- An open day that includes entertainment and consultation

- Surveys with local people
- Attending existing events to speak to people about the project ideas

Options development

Options development requires initial ideas to stand up to more robust testing. We develop mini-proposals for feasible ideas identified in the earlier stages, testing each against:

- capacity and interest from potential delivery partners – contacting and establishing links
- ability to generate capital – assessment of funding availability
- ability to generate revenue – an outline business plan
- scope for adaptation of the building – production of an Assessment of Significance by one of our Conservation Managers

The intention is that from this process, a preferred option will be established. More consultation may be required to establish the preferred option. Assuming there is a sufficient business case to move forward, this is then can be taken into stage 5.

 Full project development

This is the most detailed stage and includes:

- detailed business planning – producing a plan
- grant & finance applications – sourcing funding
- project development & design – designing and delivering any necessary adaptation works
- project management and operation – finalising clear governance structures

Once a project has been developed then it will need to be delivered and evaluated.

5   CASE STUDIES

The four cases below will show that a creative apporach can result in successful projects and that a failure to connect an historic church to the community can cause long term planning problems.

5.1 St Mary @ Quay, Ipswich, urban site

This church dating from c 1450 has been redundant since the end of the Second World War. It was brought back into use after the war as a home for the Boys Brigade until the 1970's when it became the responsiblity of the CCT.

The Church is located in the port area of Ipswich which has struggled over the last few decades and led to a major regeneration of the waterfront in the 21st century. This regeneration stalled due to the recession and the building is still stranded in a poor road scheme behind a partially regenerated waterfront.

In 2007 the CCT actively sought a partner to develop a project to secure the long term future of the church as there was a significant repair need for the building. A mental health charity, Suffolk Mind, became our partners in the project and we have developed a well being centre based around the concept that people repsond positively to good historic buildings. This is not going to be a centre for actue mental health care but rather to highlight the need for everyone to take care of thier mental health. All aspects of the project make reference to mental well being, even the proposed interpretation on the site.

The project has raised £5.5m to create a new build extension which will house the economic driver of the project, complimentary therapies and the main body of the church will be open to be used for events and cafe and other hires. The church will be available for the local community once more and will be regenerated before the regeneration area in which it sits. This shows the powerful combination of hertiage and community effort.

5.2 All Saints Benington, rural village site

This church was closed in 2003 and is in the "waiting period" still. The church closed as the population was declining as well as the church attendance. There was also a large repair bill for the repair of the roofs which

ensured its' closure. The local community formed a Building Preservation Trust in 2007 in order to find a use for the church. In 2009 the CCT started to support the Benington Community Heritage Trust (BCHT).

All Saints Benington is a church dating from the early 13th century and sits in a small rural village located on a busy main road. The traffic is all through traffic. The local shop has closed, the pub has struggled to find a tenant and butchers shop is now up for sale. The village also hosts a village hall.

The CCT have asssited the BCHT by taking them through the process outlined above to try to establish how the church building might be used for the benefit of the local community whilst still respecting the historic building. Following considerable community consultation and hard work the project has now raised over £2m to create a mixed use (including a church use) for the historic church. The church will remain in community ownership and will have a sustainable economic and social purpose.

5.3 St Nicholas, Kings Lynn, rural town site

This is the largest chapel of ease in England and was rebuilt c.1380-1415. This Perpendicular style chapel is vast and due to a declining congregation it closed and was passed to the CCT in 1989. Due to the scale of the building there are considerable repair needs and also for the building to have a more postive community ownership. Although there are a group of people in the community who do care for the building they need to expand their membership and attract new people. The building also needs to find some way to raise more income to support its' long term maintenance needs.

Once again the CCT has worked with the local community to develop a project for greater community use of the building for concerts and events, using the process outlined above. This project has now raised around £2.5m with over £210,000 being raised locally. This money will improve the building for concert use and repair the roofs as well as seeing the installation of solar panels to help with the long term energy costs for the building.

5.4 St John Hanley, Stoke on Trent, urban site

This is an 18th Century church in Hanley. The church was closed in the late 1980's and very soon afterwards a shooping centre was built adjacent to this church. The shopping centre effectively blocks out this church which has been something of an urban blight. There has been a real struggle to find a use for the building due to large strucural problems and the location. Finally the building was sold to a developer in the 2008. There is an estimated cost of £1.5m to bring the building back into use and convert to restaurant use.

There has been opposition in the community for the commerical solution proposed for this building and consent has been denied to re house the peal of bells in the tower. This leaves the building without a use and demonstrates how not engaging with the community is a danger to the future of historic church buildings.

6   CONCLUSION

Our four very different case studies how community engagement can be harnessed to find sustainable futures for the churches. We highlight what has worked, what has been more challenging and how time consuming it is to develop these community based solutions. We conclude that the community element is central as church buildings have always been, on the most part, a resource for local people and they tell the story of that particular place. It is not just the continued presence of the church building in an area but also that building's continued relevance, in some way, to the local community which retains the cultural identity.

Abandoned and Re-Used Churches in Germany

Kerstin Gothe, Stefan Netsch

(Prof. Kerstin Gothe; Karlsruhe Institut of Technology, kerstin.gothe@kit.edu)

(Stefan Netsch, Karlsruhe Institut of Technology, stefan.netsch@kit.edu)

1 ABSTRACT

Abandoned and reused churches are a current societal issue that has achieved considerable public attention in Germany. A growing number of churches, other buildings in the parishes or land owned by the church have been on offer for sale more frequently in the past years. Caused by a decline of church members in the last decades the result is a continuous shortage in the available budgets, which are necessary to maintain the property. The general treatment of abandoned churches is discussed among professionals in a broad way with different perspectives. One of the main problems is to find appropriate solutions which suit the different participants who are involved in the process of reuse. To keep the church building maintained a form of mixed use is a necessary solution. Within this process new forms of cooperation between the different participants are developed to create a mix of different usages.

2 INTRODUCTION

In Germany churches are vacated or not used to their whole extent. Main reason for this trend is the declining number of church-goers. An excess amount of sacred buildings ensues, all of them in need of new uses in accordance with the building substance. The Protestant and the Catholic Church have to find functional solutions which are structurally and economically sustainable.

In the near future both of them will not be able to maintain their property economically.The scope of follow-up uses is broad and ranges from changes or extension of use to demolition as a last solution.

There are diverse types of churches and parishes. Two main differences are for example the position of the church building in town is variable or the financial framework of a parish. This leads to an inability of finding standardised solutions, making spacial context and involved player's vital components in the process.

3 SITUATION OF THE CHURCHES IN GERMANY

Both churches have abundant spaces at their disposal: The Protestant Church owns approximately 75'000 buildings of which about 21'000 are churches and chapels. Out of this number over 16'600 are listed buildings.[1] The remaining buildings serve profane uses: as rectories, trust homes, nurseries etc. The Catholic Church owns approximately 60'000 building of which about 24'500 are churches and chapels. Out of this number over 23'000 are listed buildings. [2] The preservation, the restoration and the maintenance, especially of the listed buildings, effect major costs[3].

The high percentage of listed buildings put into focus the immense cultural value of parish buildings while causing high maintenance costs. Plus, these buildings need to answer to new standards like accessibility as well as user demands like heated service rooms and state of the art utilities management.

The number of church-goers is declining. In between 2007 and 2010 both congregations have lost nearly a million members each.[4] The chief factor of influence is the demographic change, whereat other factors like lost faith and deficient identification with the church also present important figures. In the long run this decline will cause lower church tax gains and as a result severely affect the financial situation of the churches. We can today assume that in 30 years time the Protestant Church will have lost a third of her

---

[1] EKD 2012: 35

[2] EKD 2012: 35

[3] Around 12,3 % oft he anual budget by the Protestant Church in Germany is invested in the maintanance and enovation of church building.

The total amount is 1,23 billion euros. (Dagmar Reiß-Fechter (Hrsg.) Kirchliches Immobilienmanagement - Der Leitfaden (2009), p.40)

[4] Statistisches Bundesamt, Statistisches Jahrbuch 2012, p.65, The churches have 23,9 million (protestant) and 24,6 million (catholic) members.

members and half of her current tax income[5]. A similar development is to be expected from the Catholic Church.

Already only a small part of members takes part in church activities. Only 4% of Protestants in Germany regularly attend Sunday service and 14.8% of Catholics attend the Holy Communion. [6]

This trend is expected to carry on in the future. The impacts of this development are still small at this stage. Only 202 protestant churches have been sold and 75 have been demolished between 1990 and 2010. [7] [8] In the past 242 catholic churches been taken out of use. Only 30 of them have been demolished. The expectation is that around 3% of have all catholic churches will be loosing their function as a sacred place.[9]

4 CONSTRUCTIONAL SOLUTIONS FOR CHANGES OF USES

The existing excess amount of vacant buildings in both congregations makes them unable to put their whole property to good use and forces them to develop solutions and concepts for their extended use. Apart from constructional operations which require financial investments, organisational concepts for more dense or extended uses are being researched. Well known are the following:

- Organisational solutions: By merging multiple rectorates single church buildings can be used more efficiently and to a heightened capacity. To extend this way of usage, communal functions can be added and combined in church buildings.

- Densification of uses: various parochial functions previously accomodated in profane buildings are transferred into church buildings. This way of integrating and densifying church-related uses reduces the number of local church buildings in the long term. [10]

- Extension of use: New functions are added inside the church buildings. This can be achieved temporarily, for example with a profane usage during the week and a sacral usage on the weekends (example Kulturkirche Hamburg Altona[11]), as well as spacially by dividing the sacral room (example Müncheberg). For many churches this can be the first step to a thorough reuse. [12]

- Reuse of churches[13]: The complete change of a sacred to a profane use of the church building markes the last step. Hereby conflicts ensue mainly out of the kind of use and the resulting constructional transformations.

- Closure: If no further use can be found, a sensible temporary solution can be the preservation and closure of the building.

- Demolition as a last solution: To prevent a damage of the church image by alien uses, the parish can also choose to demolish the church building.[14] [15]

In practice of reuse of a church there are little differences between the two congregations[16]. The main difference between the catholic and the protestant church is that the Catholic Church is a sacred place, which can only be used by a profane user after a process of desecration has taken place.[17]

[15] Beste (2010):61

[16] The most important difference is that in the Catholic church is not allowed to share the sacred room with a profan user.

[17] Deutsche Bischofskonferenz (2003):26ff.

5 POSSIBLE RE-USES OF CHURCHES

New uses of churches are judged differentially in society, depending on their adequacy. In case of sacred buildings most people perceive almost any kind of reuse as degradation. [18] The bad popularity of reuses originates from the high value of church buildings as icons of identification in the general opinion. The question of compliance cannot be answered unambiguously. Futural usage by other congregations or congregational institutions[19] [20] is possible, although many parishes (both congregations) rather (tend to criticise and) disapprove of a transformation into a mosque.[21]

Thinkable solutions are for example cultural uses (exhibitions, concert venues, lecture rooms, libraries), offices and other work spaces (studios, workshops). Also examples for accomodation, sports venues (e.g. climbing walls, gymnasia, wellness or baths) as well as gastronomy or hotels can be found. Parishes and citizens tend to rather accept the various forms of cultural uses and most of them are spatially compatible with the sacral spatial structure. Alas, not all abandoned church buildings can be reused this way.

Churches are not only a predominant component of a village or township as a building; they first and foremost take on an important role as a communal institution. In line with national urban development politics the recently concluded cooperational project „Kirche findet Stadt" [22] made it clear that by bringing together multiple stakeholders more sustainable solutions can be found. Churches with all their structural and social potentials present important partners in the development of use concepts on village or district level.

The communal perception and judgement of the reuse with focus on the symbolical value of the building presents a central element of the discussion. The more unique and larger the iconicity, the harder an adequate follow-up use will be found. [23] It will be easier to accept a new use for a post-war church in an urban quarter than for a listed central city church. Aside from the sort of use public accessibility takes on an important role as well. A reuse as a concert hall or museum will be well-received because public accessibility remains possible. A major difference is made between church-related and unrelated uses. Church-related reuses on behalf of the congregation or superior congregational institutions are much better tolerated, also mixed usages or sacral custom solutions such as "city churches"[24] or youth churches. In summary, commercial solutions are looked upon with great reserve, for example has the transformation into a gymnasium for a congregational school as St. Maxim in Trier been much better received than a non-congregational reuse such as a climbing wall venue.

The discussion about adequate forms of use can not be ended concordantly. It is expected that the rising number of vacant sacral buildings will heighten the acceptance for profane solutions.

6 CONCLUSION

The broad range of church building types in a specific local context refuses standardised solutions. Albeit, there are various subjects that need to be investigated more closely to yield possible solutions:

- The impeding demolition could be avoided in most cases if the pressure was taken down on the process of transformation. An interesting aspect was brought forth by the new eastern states of Germany to temporarily shut the buildings down and thus take them from the real estate market. This way their impression in the urban space can prevail.

[24] Citykirche is an oecumenical project of churches, which are usually located in the inner city. The aim oft he project is to motivate passersby to visit the church or to have a short rest.

- The significance of church buildings in an urban context is also a visual one. They make great impact on the townscape and are often found in central locations where they vitally add to local identification and genius loci.

- Strategies of reuse differ and depend on their application in cities or in rural areas. The significance of a church building is usually higher in villages which complicates profane reuses.

- A church building inventory should be established on a communal level. [25] The goal should be the portrayal of all disposable spaces for the community and their individual use intensity and capacity. New concepts and strategies for reuse can subsequently be found in cooperation with all congregations.

Not only do both churches have to think about spatial and architectural concepts, they also have to be open to new concepts in their church work. Only then they will stand a chance to preserve the church as buildings and as an institution and fill them with life anew.

About Historical Centers: Is the Trend towards Decor Really Irresistible?

Olivier Lefebvre

(Dr Olivier Lefebvre, Olivier Lefebvre Consultant, 4 rue Rollin, 75005 Paris, France, o.lefebvreparis05@orange.fr)

1 ABSTRACT

We argue that the projects in the historical centers of European cities are characterized either by truth, either by authenticity and either by spectacle (décor). There is always a formatting of space and behaviors, but for culture or entertainment. This is confirmed when companies using Internet, which are specialized in the industry of "events", manage historical monuments. Also, a monument can be used for entertainment, as if it was a piece of décor. To deal with the topic of the limits of the trend towards décor (in historical centers) we use the ideas of the French philosopher Lipotevsky. In a society with three characteristics, democracy, individualism and consumption, when in a group tastes and desires are shared, it can obtain decisions in accordance with the preferences of its members. Therefore the set of the projects in the historical center of some city should be somewhere inside a triangle truth – authenticity – spectacle. It is because if there is need of entertainment, there is also a need of authenticity. This ambiguity exists for a long time in tourism and architecture.

2 INTRODUCTION

We see in the historical centers of the large European cities two trends at work, which are in conflict:

- One is preservation of Heritage. The goal is Culture.

- The other is adapting the city to décor (fairs, parades, urban scenography, "events" …). The goal is entertainment.

In any case, some space and behaviors are formatted. A space is formatted either for culture either for entertainment. This is confirmed when companies, using Internet, specialized in the industry of "events", manage historical monuments. More, historical monuments can be used for spectacle, and the preservation of Heritage leads to … décor. Therefore there is this question which is posed: what are the limits to the trend towards décor?

We deal with this topic in this paper.

One can present some features of the two trends in a kind of tableau:

	Heritage	*Décor*
Personalities and professionals	*Julien Benda[1], Marcel Poete[2], Guy Debord[3], Viollet le Duc, professionals of Heritage preservation*	*Barneys[4], advertisers, specialists of marketing, specialists of scenography*
Kinds of places and examples of sites	*Museums, cultural quarters, historical cities.* *Cité de Carcassonne, Mont Saint Michel …*	*Thematic parks, quarters devoted to entertainment.* *Euro Disney Land, Las Vegas …*

Our method will be to use examples, which allow showing three trends:

---

[1] Julien Benda was a French philosopher. He thought that intellectuals have to tell the truth, always. He quoted the famous French philosopher Renan: "one has always to tell the truth, no matter the price".

[2] Marcel Poete was a French urban planner. He set out the notion of "Mysticism" of a city. It means that all the monuments of a city "translate" some chosen values: the Religion, the King, the Nation, Science … He was a proponent of the value of reconciliation of social classes.

[3] In his book "Comments on the Society of the Spectacle" Guy Debord tells how "the Spectacle" hampers "historical knowledge" and imposes the "perennial present". Also, he speaks of "irrefutable fake". According to him, the Spectacle is the consequence of Medias in the context of mass consumption boosted by advertising. Guy Debord was a proponent of self-organization and autonomy.

[4] This intellectual was a forerunner in the twenties, when he argued that any method efficient to sell goods was good. He invented the modern tools of advertising and marketing.

- The choice is between two formattings (of space, of behaviors). The "historical truth" has to be interpreted. There are rival doctrines. And décor corresponds to some formatting: the reactions of consumers are conditioned by Medias and specialists of shows (and scenography).

- A trick is that décor can follow Heritage. One knows how to use historical settings to mount entertaining shows. Therefore the preservation of Heritage can finally lead to décor.

- There is a limit to the adaptation of the City to décor. To show it we shall use the ideas of the French philosopher Lipovetsky.

The limit between Heritage and décor is blurry. In the Conclusion we show that this ambiguity is not new: it exists for a long time in the case of tourism and architecture, for instance.

3   HERITAGE OR DÉCOR? SOME EXAMPLES

We shall present four examples.

3.1 "The birthplace"

It is the title of a short story from the famous American novelist Henry James. A guide is in charge of the visit of the house where a famous poet is born. There is nothing interesting to view, so he is asked to imagine and tell attractive anecdotes. Being honest, he refuses. But after some reflection, he accepts and all the people are pleased: himself (he wins more money), his wife, the proprietaries of the house and … the public (more tourists visit the house). Even if it is irony, the spectacle wins, no matter the historical truth is.

3.2 The House of Slaves

The so-called House of Slaves is in the Gorée Island in Senegal, near Dakar. According to the guide Joseph Ndiaye, who launched it, it was there that thousands and thousands of people left their country to America on ships, to be sold as slaves. The historians deny: the house belonged to a rich Senegalese woman having a dozen of servants, the only slaves in the house, and Gorée was only a marginal center of slave trade. Now Joseph Ndiaye is dead but the tourists are still told this story. Clearly, it is spectacle (not truth or authenticity).

3.3 Illumination of cathedrals in France

One started to illuminate the Notre Dame de Paris cathedral with funny colors (purple, pink …), but it ceased soon. Instead, the illumination highlights the architectural features of the monument. But the spectacle had its revenge, which concerned other cathedrals in France. Thanks to chemical analyses of the remaining pigments, researchers discovered the real colors with which the statues of the façades of the cathedrals were painted in the Middle Ages. Using very much sophisticated cameras one projects these colors on the façade of cathedrals (like the cathedral of Amiens) while there is an aesthetic and historical comment, and music which are listened to. The spectacle has been a great success for ten years. In this case, it is historical truth the winner, not authenticity or spectacle. Indeed, it is an entertaining spectacle, but in accordance with historical truth.   Note that historical truth is preferable to authenticity. If we believe what the historian Leon Poliakov tells in his book "The history of anti-Semitism", the Mysteries played on the squares of cathedrals in the Middle Ages were vulgar, violent and anti-Semitic. They were great success, all the people living in the city attending them, except … the robbers. Also, Viollet le Duc suggests that every year the cathedral was given to the populace for a few days, and strange actions occurred. For all these reasons, today the choice of historical truth seems preferable to the choice of authenticity.

Today the gothic monuments are restored in accordance with a doctrine set out by Viollet le Duc.   To explain the influence of Viollet le Duc is easy. There is no reason to not apply the ideas set out by the American sociologist HS Becker in his book "Art worlds" to the milieu in charge of preservation of Heritage. This milieu is made up of several groups, each of them having a role (architects, artists, craftsmen, critics, administrators …). This milieu is pleased with two Viollet le Duc's ideas: the necessity of popularity (of restored monuments) and the role of architects in the past. Viollet le Duc praises the role of the group of architects at the time of gothic art (from twelfth century to fifteenth century). Even, he uses the Hegelian parable of the Master and the Slave. They were commoner, secular, working and talented people. They greatly contributed to the recovery of Europe in the twelfth and thirteenth centuries. They triggered the rise of building castles, palaces, city halls etc. Before, there was Roman Art, which was remarkable, but was not

unified and monastic. Gothic art was useful to the unity of France, triggered by the power of the King. Viollet le Duc died in 1879, he did not see modern art and that is why he thought that gothic art was the best of art in France (with a short period in the beginning of the seventeenth century). Further in the paper we shall describe the rules of "good style" according to Viollet le Duc.

3.4 Napoléon Peyrat: a mix of deeply thought history and poetic imagination

Napoleon Peyrat is a famous French historian of the nineteenth century. Being born in the South of France and protestant, he was fascinated by the heretic people having lived in this region (Cathars, Protestants) and studied their history. He "discovered" the role of the castle of Montségur, which was the headquarters of the Cathar church from 1232 to 1244. After the Treaty of Paris (1229) the lands belonging to the Count of Toulouse were no more secure for Cathars, and many of them found a refuge in the castle. They surrendered in 1244, many of them being the victims of the Inquisition. Peyrat discovered also the deep penetration of the Cathar religion in the society of this region, and the role of women among the believers. But he imagined the role in the Cathar church of a Countess of Foix, Esclarmonde. He imagined an underground Montségur, room, crypts, "holy pools" etc. More seriously, he imagined the story of a "second Montségur": according to him, around 1330, the last Cathars, hundreds of men, women and kids, died because of hunger and thirst, walled in the cave of Lombrives, in the valley of Ariège. They preferred this fate to abjuring their faith. Their bodies were covered by limestone and stalagmites etc. According to Peyrat, this kind of suicide was common among Cathars, but this also has been never proved. When Peyrat has imagined stories, no documents or clues have been found by historians, since his death in 1881. But the guides told tourists the story concerning Lombrives. Only in the fifties and sixties the story was removed from guidebooks. Today the guides only evoke the legends concerning the cave at Lombrives. Napoléon Peyrat has done very much to launch touristic sites in the region of Ariège: it is justified in the case of Montségur, and Mas d'Azil (a site with a cave where Protestants victoriously resisted the troops of Louis XIII in 1625, an event studied by Peyrat), but not in the case of Lombrives. This is an example of historical truth winning.

Today Internet is popular for twenty years and there has been some thought on rumors. One can use, to understand how a rumor is diffused, a word (the "buzz"), a metaphor (the "snowball") and a notion (viral process). The notion of viral process shows how a rumor is disseminated, benefitting from several variants (or changing forms), each of them being adequate to some group which believes the rumor and propagates it. Historianshave ideas on the process of dissemination of the rumor on the cave at Lombrives. These ideas are set out in a book which presents the communications at a congress on the works of Napoléon Peyrat (Cabanel and De Robert, 1998). The process could have been:

- First, a tale which concerns the cave at Lombrives is published in a local review.
- The guides at Lombrives tell the tourists the story, but presenting it as a true story.
- Napoléon Peyrat visits the site, believes the story told by the guide.
- He has the idea of a similar story, but which would concern Cathars. If the first story (which concerns robbers) is true and believed, the similar story (on Cathars) will be believed.
- He imagines the story of the Cathars at Lombrives, and tells it in his book onCathars.
- The readers of the book of Napoléon Peyrat believe the story on Cathars.
- Etc.

These examples show that the struggle between authenticity, historical truth and spectacle is very ambiguous. It results in historical truth or spectacle winning, depending on circumstances.

4   THE IDEAS OF LIPOTEVSKY AND THE LIMITS TO THE TREND TOWARDS DÉCOR

According to the French philosopher Lipovetsky, there has been during the second half of the twentieth century a Revolution which was democratic, egalitarian and individualistic (Lipovetsky, 2000). Individuals make the choices they want: in their personal affairs, as consumers, when political and social stakes are considered (since they are part of an Opinion omnipotent because of the influence of Medias) … The rights of minorities (sexual, ethnic …) are respected. When there is some stake, a majority appears and decisions are taken which protect the rights of individuals and groups. For instance, consumers are protected against the bad quality of products. Now we can speak of the conflict between Heritage and décor. There are

contradictory needs. A large city has to be vibrant, allow entertainment. But there is also a need of authenticity and memory. As the destruction of monuments is unconceivable, the alternative, if one wants to adapt the city to décor, should be to imagine a new identity for them, to speak of them in a new way thanks to marketing and Medias. [5] But people do not like lies and mystifications. Therefore the trend towards décor in the historical centers should be limited. The result could be neither the "mystical" city in the Marcel Poete's meaning (displaying some chosen value thanks to every monument), neither a city completely devoted to spectacle.

Lipovetsky thinks that cinema pervades Society. Theway in which it deals with topics, relying on drama, hyperbole, spectacle and stars, is imitated in many fields of social life, including urban planning (Lipotevsky, 2011). For instance, one can imagine a city covered with high towers, each of them being a hallmark of the city and having a characteristic and funny shape, and an identity of "personality" built up thanks to marketing and Medias … Surely, the adaptation of the City to décor owes very much to cinema. But the complete adaptation of the city to décor, scenography and cinema seems improbable.

5 CONCLUSION

We argue that the set of the projects in the historical center of large European cities, should be somewhere inside a triangle authenticity – historical truth – spectacle. In other words, these projects should remain in some ambiguity.

This ambiguity exists for a long time in the fields of tourism and architecture.

5.1 The ambiguity exists in tourism

Tours are not a quest, except in rare cases. Tour as a quest has been defined by the German philosopher Keyserling (a well-known intellectual at the time of the Weimar Republic): "I toured around the world to find myself". Exceptions are, for instance, Goethe [6], Liszt [7], and Nietzsche [8]. There are several traditions, concerning guidebooks. Of course, each of them has been founded. One can take the example of the Stendhal's travel books [9]. If one considers his confidences, it is only a mix of false and true. But errors and even plagiarism are forgiven when he speaks of art. When he examined the social, historical and political conditions of culture, he was a forerunner, his works heralding those of Burckhardt and Nietzsche. He had a deep intuition of what is production of culture (in the case of books, paintings, statues …) one century before the Frankfort School's works. He initiated a tradition for guidebooks. Even in the fifties, when car and photo were popular, a well-known French writer, Gabriel Faure [10] wrote the guidebook "Aux lacsItaliens" ("At the Italian lakes"). The goal of such a guidebook is, besides giving practical advices, to trigger the sharing of tastes.Problems of aesthetics are posed and discussed, the author displaying his own choice. Indeed there is a spectrum of guidebooks, from the diary or travelogue (today it is called "travel writing") to the guidebook giving only impersonal and objective advices. But there is always some formatting (of the vision of the visited country). An example of a tradition for guidebooks is the guidebooks examined by Edward Said in his book "Orientalism". They present people in Oriental countriesin the same way: they have a great past but their present state is poor and dull, they are passive, fatalist, lazy, sensual, either very much loyal either deceitful etc.

In any way the modern guidebooks (including those on Internet) describe (if they do not recommend) spectacles for tourists: fairs, parades, carnivals, scenography [11] and thematic parks … This shows the ambiguity in tourism. The guidebooks pay attention to what is authentic, true or spectacular in the countries visited by tourists.

---

[5] In Paris, a little park à la Indiana Jones will be seen, soon.

[6] The poet was initiated into beauty of art thanks to a tour in Italy.

[7] The musician, who became a monk when he was old, made tours in Italy in the same spirit than a pilgrim.

[8] The philosopher touring in Italy was ill and his only preoccupation was to achieve his works.

[9] One of themis "Promenades dans Rome" ("Walks in Rome") which was the most popular book from him, during his life.

[10] He was not the famous French musician Gabriel Fauré. They were friends and toured Italy together.

[11] To obtain a nicer view of the monument, one changes the surroundings.

5.2 The ambiguity exists in architecture

The aesthetics of authenticity postulates that the best is when the monument remains exactly what it was before its restoration. Thus it remains the same in the imaginary. One often quotes the restoration of the castle of Haut Koenigsburg in Alsace, in France, by the architect BodoEbhardt, around 1900.

The proponent of the aesthetics of historical truth is Viollet le Duc. He interprets the style of the architecture of a particular time, thanks to a doctrine. The historical and social context is taken into account. The success is when the solutions of the problems are made visible by the architect, these problems being the program of the monument (or building), its stability, how it is integrated in the landscape, and the choice of the materials which are used … Decoration and color and even some scenography have their role. Also, the "scale" (today the human being), geometrical proportions and symmetry, matter. For instance, Gothic Art displays the equilibrium of pressures and counter-pressures, decoration (dramatic statues, local plants on capitals) and color completing the scenery.

It is not Viollet le Duc, but his followers, who were criticized for having changed the restored monuments, too much.

The conflict between authenticity and historical truth remains. Architects specialized in the restoration of monuments have accepted some principles which are set out in the Chart of Venice (1964):

- The changes have to remain visible thanks to some signs (for instance one uses another material than the material used to build the monument, when one makes changes during the restoration).
- The changes have to be reversible.
- The original state of the monument should be respected if it is possible.

Also, traditional and local materials should be used.

When big changes in historical centers of cities are considered, the choice of authenticity, truth or spectacle is a stake which is often intertwined with other ones.

For instance, in many cities of Northern Italy, inhabitants like Heritage. But they also want to keep the conditions of life in the city, as they are. They do not wish their city attracting too many tourists. It is as if they feared attractive Heritage leading to décor. The outcome is a reasonable exploitation of the resource that Heritage is.

Are the Netherlands Shrinking or Just Changing?

Stefan Netsch, Niels Kropman

1 ABSTRACT

Since the 1990's years we have seen a sharp year to year growth in the production of real-estate in the Netherlands. The realization of 80.000 houses a year for instance was considered just as normal as the year on year increase in the value of those same houses, or any type of real-estate for that matter (Shenk, Gool: 2010). But since the start of the financial crisis in the summer of 2008 and soon thereafter the economic crisis that followed real-estate prizes have started to decline at an ever rapidly rate. As a direct result the demand for new houses has dropped dramatically and homeowners and institutional owners of real-estate are being confronted with losses when selling their property. Combined with the stricter rules concerning mortgages the demand for real-estate is even stronger declining.

This is in sharp contrast with the last 20 years when rising prices for real-estate where taken for granted. But this change is not being fuelled by economic and financial processes alone. There is also a demographic and labour shift in the Netherlands that causes a regional concentration of employment in the more urbanized western part of the Netherlands, also known as the Randstad. Young people are moving away from the more rural areas in the periphery of the Netherlands and relocating where there are more possibilities in finding employment. Increasingly the country is developing at two different speeds where the western part of the country is still growing both economically and demographically and the more rural areas located in the eastern and southern part of the country have to deal with a shrinking population. Direct result of this shrinking population is of course a shrinking real-estate market and a strong decline in the number of houses being realized in those regions that have to deal with a shrinking population. This has been made worse by the economic and financial crisis. And lastly and most importantly there is a demographic shift caused by the generation that was born just after the Second World War, also known as the Babyboom-generation. All these economic, financial, demographic, urban and social processes are influencing our cities and villages throughout the country and therefore the real-estate market. The question can therefore be asked if the Netherlands, after decades of growth, are now in a process of decline or a process of change? Or are the decline and change strongly intertwined with each other and should they be considered as one?

At the moment it is clear that the spatial effect of a regional shrinking population and the related economic consequences are being strengthened by the way the Dutch finance and subsidize their houses. The majority of the homeowners have their home fully mortgaged firstly because of lack of direct financial means and secondly made possible and stimulated by the Dutch regulations and rules concerning financing real-estate. A Dutch homeowner with a mortgage applies every year for a tax-refund based on the paid interest on their mortgage during the year before. This refund has stimulated ownership in the Netherlands, made even more attractive by the taken for granted year to year increase in value of real-estate and therefore the apparent minimal risk there was for the homeowners. This has led to a situation where, on average, houses were being sold 5 to 10 years (TU Delft: 2010) after buying it. The profit made on the sale of the house was then used to buy a new and more expensive house. This process has been the engine behind the strong real-estate market of the last 2 to 3 decades, but the engine is no more. The financial crisis and the economic crisis that followed suit have brought the market to a crashing standstill. The decline of the real-estate market has been made even worse by the surfacing effects of the demographic transition. The shrinking economy and lower demand because of it made selling your house and ever increasing daunting task. Next to a shrinking demand in general it is becoming ever more difficult to get a new mortgage caused by a direct shortage of available credit and secondly because in a lot of cases the actual value of the house is less than the original mortgage. The traditional Dutch system of using the profit of the sale of your house to buy a newer and bigger house is no more and is replaced by the realization that unless you have savings you can no longer change houses as easy as before. All this has led to stagnation in mobility of the Dutch, both on the real-estate market as on the labour market while at the same time there is re/urbanisation by both labour and people.

To summarize there is at the moment an exceptional situation in the Netherlands where the economic stagnation and demographic change strengthen each other and the influence they both have on the Dutch real-estate market. Houses are harder to sell, especially in the shrinking regions and the drop in value is an

obstacle for owners to get e new mortgage. At the same time we also see a shift in labour where both business and the labourers themselves increasingly move away from the rural periphery and relocate in the more urbanised parts of the country, mainly the Randstad. This shift in labour causes the real-estate market to shrink even more at a local/regional level with further stagnating mobility of homeowners and vacant houses and other buildings as a consequence that leads to even less labour and a declining attractiveness of the region leading to an even greater relocation of labour and people. Selling your real-estate is being hindered by both the demographic change and the economic crisis and this particularly the case in the periphery of the Netherlands (CBS: 2011) and the real-estate market in the Netherlands seems to be grinded to standstill for ever. But is this indeed the case? This paper will identify the different processes that are at work at the moment and the relation there is between them. How is the Dutch real-estate market being affected by the economic and financial crisis and what role are demographic changes and apparent re-urbanization playing in this process of decline and shrinkage in one part and growth in the other part of the country? What does this all mean for our cities and villages and is there a real-estate market left in the near future?

2 DEMOGRAPHIC DEVELOPMENT IN THE NETHERLANDS

Before the role and influence of the demographic changes on the real-estate market and the re-urbanisation can be explained we will look more closely at the demographic development of the Netherlands over the last couple of decennia. The Dutch population as a whole will grow on the long term. In sharp contrast with the before mentioned shrinking population it is expected that the current population will grow from 16,7 million people to almost 18 million people in the year 2040. After that the population will slowly stabilize (CBS, 2012).
Fig. 1: Development of the population (CBS, 2011)

This prediction of lasting growth of the total population is in sharp contrast with the forecasts for regions located in the rural periphery of the Netherlands. Therefore it can be concluded that there is national demographic growth and local demographic shrinkage at the same time. The Netherlands are showing signs of being a country with clearly two different paces of developments. This development is not new in the Netherlands, the national spatial program published in 1966 already spoke of precisely such a process. The national program tried to mitigate the expected consequences only to discover a couple years later that this process never had gotten foothold and a period of unprecedented growth had arrived.

Another important demographic change is the ageing of the general population. The build-up and the division by age is shifting at the moment to a large group that's 65 years old or older. This particular group is at the moment 16 % of the total population but in the near future this will increase to 20 % of the total population and some cases even higher. The group in the age 0 to 20 years old will be a stable 20 % of the population during the same period. The increase in people over 65 years old will come at the cost of the population between 20 and 65 years old, the most economically active persons. This group will consistently be under 60 % of the total population. In absolute numbers there is an increase of 2.500.000 people over 65

years of age also the age when people retire from work. And with this ageing population we see an increasing effect on the economy, interest rates and health costs. (Eurostat Baseline, 2011).
Fig. 2: Inhabitants per household (CBS 2011)

So how is it possible that the Dutch population is shrinking and growing at the same time while at the same undergoing a process of increasing ageing of the population. To clarify this seemingly complicated process a closer look needs to be taken at the immigration and birth-death statistics. In the period between 1995 and 2011 there is a clear surplus in immigration, not only caused by family reunification but also because the positive economic situation created a demand for labourers (CBS, 2012) that was bigger than the local availability. The immigrants did not come from the traditional countries as Morocco, Surinam and Turkey but increasingly from other European countries (Buursink, 2013).

Next to immigration there are also more people being born each year then people passing away and this of course has a positive influence on the population growth. On average the population in the Netherlands increases by 40.000 persons a year when looking at the difference between births and deaths. The cause is twofold, over the last years the average number of children per woman has risen from 1,7 children to 1,8 children. But an even bigger influence is the quality of healthcare and the Dutch healthcare in particular (Demos, 2009).
Fig. 3: Birth rate (CBS 2011)

The numbers indeed show that the general population will keep on growing for the coming years, from 16,7 million people to 18 million in the year 2040. But still the public debate in the Netherlands is being dominated by the general idea the population is in fact shrinking. Looking at the regional forecast 2010 as published by the Planbureau voor de Leefomgeving it is clear why this general opinion is dominating the debate in general and the in the press in particular. The reason is the local and regional differences in population build-up. During the period between 1998 and 2010 the rural areas like the northern part of Groningen of Limburg already showed a clear decline in actual growth of the population. This decline is expected to continue and will be focused mostly in regions outside the Randstad. The Netherlands will be divided between a densely populated and economically strong urban area (the Randstad) with urban connections to the larger urbanized areas in the more distant areas and the periphery of the Netherlands that will shrink both in population as in economic weight. Most affected are those regions that have a long tradition of agricultural production or where in the past the economy has shifted strongly, like when the coalmines closed in the 1980's. At the same time there is an increase in the number of households since the 1998's because the average occupancy of houses or average size of a Dutch household has dropped to 2.2 persons per household (CBS 2007).When a population is shrinking and growing at the same time it is interesting when this process is accompanied with a rising of the number of households. This increase in number of households is caused by a combination of the ageing of the population and social changes in general. As more and more people belonging to the babyboom generation pass away the number of 1 person households within this demographic category will rise. Together with social changes like divorces and more different ways of living together the demand for one-person houses will increase over time. The combination of increasing relocation to the Randstad and the rising demand for one-person houses will strengthen the real-estate market in the more urbanized areas in the Netherlands while the market in the periphery will shrink.

3 HOUSING SUPPLY SINCE 1990

In order to fully explain the current status of the Dutch real estate market a closer look needs to be taken at spatial and tax policy developments since the 1990's. Over the last two decades the Dutch housing market was one of the most dynamic in Europe in terms of both number of houses developed on a yearly basis as well as the year to year increase in the value of houses. After the end of the Second World War there was a shortage in available houses and somewhere in the region of 500.000 houses needed to be (re)build or repaired (van der Cammen & de Klerk, 2010). Since the end of the world war the Dutch spatial policy has been strongly focused on rebuilding and solving the shortage of available houses. One of the largest and most influential projects aimed at building houses is the VINEX-program of the 1990's that was a direct

result of the implementation of the Fourth National Policy Document on Spatial Planning (VINAC) and its supplement the VINEX. This building program was devised during a time where the economic situation was not all that different from the one the Netherlands and Europa are in at the moment.

During the recession between 1979 and 1984 Dutch policymakers and politicians tried to define what spatial planning could contribute to the economic recovery. The central theme of the Fourth National Policy Document on Spatial Planning (VINAC, 1988) was internationalization, economic perspectives, opportunity development and improving existing qualities. In short the VINAC tried to prepare the spatial development for the 21st century from an economic perspective. The focus on improving the most important economic sectors by the national spatial policy was an important change (Wagenaar, 2011). Improving the locational factors for (inter)national businesses and the strengthening of the Dutch transport and distribution sector were the key elements within the spatial policy (Klundert, 2008). Due to policy changes and early elections the VINAC never got implemented and the new government added two new tasks to spatial planning in the Netherlands. Next to the before mentioned tasks Dutch Spatial policy should also deal with the increasing use of automobiles and spatial and environmental problems needed to be approached integrally. Proximity and secondly accessibility became therefore leading in new developments (Klaassen, 2000).

The VINAC and VINAC tried to find an answer to the apparent huge demand for houses and labor. According to research 835.000 houses and 530.000 jobs needed to be located in the period between 1995 – 2015 and most of the demand was located in the Randstad. The Dutch planning system needed to be prepared to facilitate the expected huge rise in mobility and adopted the rule proximity first and accessibility second. This translated in focus on existing urbanized regions as prime candidates for the expansion of cities and after those options where explored the edges of the city. "Proximity first" also became the rule for the search for new work locations and a new typology was developed for labor locations where the type of accessibility was used to categorize all labor locations. To support the policy as stated in the VINEX the government added several charts that showed for each province and city-region the possible locations for expansion combined with the transportation network, both existing and planned. Such a level of detail was never before being done. The message in the VINEX was clear: build as much as possible in and on the edges of existing cities that have good connectivity in order to improve urban vitality and environmental qualities. As a direct result Dutch cities showed an enormous expansion in the following year, especially at the edges of the existing urban fabric because of the better connectivity when comparing to the city centers. Secondly investments in the city center and the improvement to the urban quality of cities in general caused land values in the inner-city to rise making the locations situated at the edges of the cities even more attractive for development.

When in the 1990's the Dutch economy started to grow again it led to an increasing decentralization of the government and a greater role for the market. Secondly the demand changed from quantity to quality because of the growing wealth of the Netherlands as a whole and its inhabitants of course in particular. The recently politically accepted VINEX was not capable to accommodate and facilitate the changing market. As a direct result of these political and economic changes real estate development increasingly became the sole responsibility of municipalities and developers alone. Developers increasingly bought grounds destined for building projects and traded those with the municipalities for the right to develop the location. Local governments more and more were forced in the role of being the subsidizer and project developers and corporations the actual developer. This combination of decentralization and a bigger role for the market led to a decreasing influence in the actual spatial development by (local) governments (Bureau Beerschot, 1999). As such the VINEX-program changed into an integrated planning concept that got fragmentally implemented and directed by the market instead of the government. The market dictated both quality as well as the quantity of the housing development. The VINEX program is therefore synonymous for too little quality and too much quantity. Since implementation of the VINEX, in 1995, on average 50.000 houses a year have been built. Sometimes this number was even as high 100.000 a year. In general the developments can be divided in two different categories, namely the redevelopment of the old inner city harbor areas with a focus on high density development while in the rest of the country there was a more traditional expansion by the development of large numbers of single family homes.

Fig. 4: Impression Kop van Zuid (Stefan Netsch)

Fig. 5: Impression VINEX neighbourhood (Stefan Netsch)

4 CONSEQUENCES

For more than a decennium the Dutch real estate market was used as an economic instrument by the Dutch policy makers "to build the Netherlands out of the economic crises". Fueled by low interest rates the different Dutch governments were able to buy large quantities of land with the goal of developing it. The governments sold the land to the developers and in return they took care of the infrastructural development of the location. This is one of the major problems nowadays. While the governments are responsible for the infrastructural development of the location the developers were only committed and responsible for the

building program. In a market under the influence of an economic recession governments no longer have the financial means to develop the infrastructure and as a result they are held responsible by the developers.
Fig.6: Build houses and sold houses (CBS 2011)

As a result of the economic crisis combined with the financial risks governments took on the Dutch real estate market there are now roughly 60 municipalities facing bankruptcy (Jacobs, 2011). Land bought in economic good times with the aim of turning it into land to be developed is not sellable anymore. As a result many municipalities are facing negative balance sheets because the real estate prices have dropped and the market has come to a standstill while the investments are already made.

There are many reasons why the Dutch real estate market has come to a standstill. As before mentioned Dutch spatial policy helped create an unhealthy market. But also the financial market and the Dutch consumers have contributed to the present day crisis. The Dutch private homeowner has enjoyed a very profitable tax refund ever since the end of the 1970's. The same way policymakers used spatial policy as a means to improve economic growth the tax system was designed to improve home ownership. Both instruments were instrumental for the economic growth the Netherlands needed so much. Dutch home owners got a tax refund on the interest paid for their mortgage and as such banks and financial institutes advised potential home owners to invest savings in their own real estate. After all, the home owner got a tax refund every year and real estate prices will increase year by year. The average mortgage in the Netherlands has risen over the years to 107 % of the actual value of the real estate (Elsevier, 2012). Not only you were able to loan more then you owned you only needed to pay the interest of the mortgage. After all after 30 years the value of the home you just bought will be significantly higher than the original mortgage. As mentioned before the Dutch policymakers implemented this tax rule in order to promote home ownership in the Netherlands. The combination of spatial policy and tax benefits led to an exploding real estate market that showed year after year that the notion of always rising real estate prices to be true. Over the last 10 to 15 years this has led to a 300 % rise of the value of real estate (CBS, 2011) and home ownership became the natural and financially most sensible goal for every Dutch. And after you bought a house you bought a new one, often more expensive, every 5 to 10 years. After all it was just a matter of selling the old house with a profit and use the profit to buy a new, more expensive house. The apparent scarcity of new houses, fuelled by the tax system and spatial policy, gave the Dutch the opportunity to buy ever more expensive houses.
Fig 7: Value of houses in Amsterdam and the Netherlands (CBS 2012)

This process of year to year growth in real-estate prices and parallel the increase of the average total mortgage came to an end with the financial crisis in 2008. The resulting economic crisis has resulted in less available credit and stricter rules concerning the capital buffers made the financial institutes more and more reluctant to sell people mortgages. This has led to stagnation of the real estate market because housing prices started to drop and building projects to be postponed or cancelled.

Especially in the economic les developed regions in the periphery of the Netherlands the results of the shrinking real-estate market can be seen. Because there are less economic opportunities those regions often fall in the category of shrinking regions but now the combination of economic crisis and dropping real-estate prices makes it harder to leave those regions in search for a new home and often a new job in the Randstad. But selling your home for less than the mortgage value is almost not possible in the Netherlands and if you are able to sell your house you have to accept the fact you are left with a debt to the bank. In general people with jobs are financially capable to relocate to other parts of the Netherlands leaving older people behind.

The consequences of the Dutch financial system in times of crisis combined with huge demographic changes concerning the ageing of the population and demographic shift of labour from the periphery to the Randstad are all contributing to the present day standstill of the real-estate market. The question still remains are the Netherlands and the real-estate market in particular just shrinking or are they changing.

5 THE CHANGING REALESTATEMARKET

It is reasonable safe to assume that the economic recession is of temporarily nature. But when the economy starts to grow there are still the demographic changes like the ageing of the population and the demographic and labor shift to the more urbanized parts of the country influencing the market.

When looking at the population in general there is no problem with a shrinking population The Netherlands are still growing and are predicted to keep growing till about 2030. This growth is fueled by immigration and the positive birthrate. But on a more local scale there is a strong divide between shrinking and growing regions and this process has started well before the economic crisis. The shrinking population cannot be explained by demographic change but is just a matter of economic opportunities.

So local and regional orientated shrinkage of the population is expected to continue and will offer the real-estate market huge challenges to deal with. Empty buildings, low real-estate prices, less infrastructure and cancelled building programs are the results of this process. This process will fuel itself because the shrinking population means less income for the local government and therefore less financial means to keep important

functions in the community. This will in return lead to more people leaving, an increasingly ageing population and less people working. As a result the local real-estate market will shrink.

Fig. 8: Shrinking population and real-estate (www.veendammer.nl, 2012)

As mentioned before the population as a whole will keep on growing, mainly in the western part of the country. Predictions are that over the years 1.500.000 people will be in need of a home in the Randstad. The demand for new homes will also be more strongly focused on the cities instead of the VINEX neighbourhoods of the past. Therefore the Dutch real-estate market will have two faces for the coming years, both shrinkage and growth at the same time.

The biggest problem the market needs to face is the changing demand typology of houses. The VINEX program was strongly focussed on developing the single family home. The ageing of the population and the risen popularity of living in the city will increase demand for high density housing. Over the past decades the realization of high density housing was neglected because of denying the changes in demographic composition of the population by focussing on general data concerning population growth. Also the ever increasing housing prices, fuelled by the financial system in the Netherlands, has kept the focus on the development of single family homes on new building land.

6 CONCLUSION

To answer the question will there be a real estate market left in the future, the answer is yes. The new market will be like the two sides of a coin. On one side there will be a shrinking market, located in the periphery of the Netherlands. The process of locally shrinking population will continue and will lead to a locally very challenging real estate market that has to deal with shrinking and changing demand, empty buildings and low incentives for investment. On the other side there are those regions that will keep on growing where the market needs to cater for in increasing demand in both low and high density housing. The market needs to refocus on the city again because the huge development plans for new low density houses, like the VINEX neighbourhoods, will be something of the past. Instead there will be a focus in intensifying the existing urban centres and transformation of buildings within the city limits in order to accommodate the changed demand by the shift demographic and labor shift and the ageing of the general population.

The paradox is that in the 1960´s there was fear for a divide in the Netherlands where the periphery would shrink both economically and demographically and the Randstad would grow both economically and demographically. Fearing uncontrolled growth of the cities Dutch policy makers tried to accommodate and counter the threat of uncontrollable city growth by appointing regions and municipalities that should develop and expand in order to accommodate this growth (Ministerie van Ruimtelijke Ordening 1966). It was these

plans that would 15 years later mature in the VINEX-program that would in the end lead to the present day situation.

1 ABSTRACT

People with visual impairement have striking needs for trustfully navigation systems enabling for efficient mobility services, mainly considering safety and autonomy. Navigation technologies are being implemented in innovative personal navigation devices, but existing products fail because they lack accuracy and do not provide a suitable and efficient man-machine interface adjusted to this user segment, or rely on costly infrastructure.

The ARGUS project focuses on a satellite based navigation (GNSS/EDAS – EGNOS Data Access System) terminal for people with impaired visually capabilities, guiding them along pre-defined tracks using specifically designed HMI (Human Machine Interface) such as tactile, acoustic and haptic signals. It introduces the opportunity to develop an innovative guidance support system for visually impaired people based on the provision of a virtual-lead-line perception to the end user that can be perceived and followed. This will provide "track navigation" instead of the classical "waypoint or route navigation" which is used for car navigation or people with all visual capabilities.

This system will be also usable for professional, scientific and sport activities developed in reduced visibility scenarios that could require accurate guidance on normal or emergency situations, as well as for other people working in reduced visibility environments needing guidance and assistance.

This paper explains the features of the ARGUS device and expands on the Proof of Concepts that was carried out with the potential users.

2 INTRODUCTION

Almost 300 million people in the world are visually impaired. About 90 % of the world's visually impaired live in developing countries, and about 65 % are aged 50 and older, with an increasing elderly population in many countries, more people will be at risk of age-related visual impairment.

The global response to prevention of blindness have had specific results in areas of progress over the last 20 years including prevention, eye care servicies, development of policies and strategies, campaigns to raise awareness, and stronger international partnerships with engagement of the private sector and civil society.

But this global response has also had one of the main areas of progress on the developmentet and implementation of technical assistance to the users. Despite the technology state of the art many questions remain open concerning autonomous navigation, acuracy, integrity.

3 MAIN OBJECTIVES OF THE PROJECT

The ARGUS project focuses onto the development of a service platform and a satellite based navigation terminal for people with impaired visually capabilities, to guide them along a pre-defined track, using acoustic and audio-haptic signals. In this sense, the ARGUS system provides a virtual guidance rope for blind and partially sighted persons or people working in environments with low visibility (emergency and rescue services, etc.). Based on GNSS systems, ARGUS acts as a leading climber providing a safety rope to the persons following, leaving for them a secure path.

The main goal of the project is to develop a GNSS based mobility service for people with impaired visually capabilities, to guide them along a pre-defined track, using acoustic and audio haptic signals, which meets

the level of accuracy, integrity and reliability they need in urban and outdoor environment for improving their day to day life autonomy.

ARGUS project primarily retrieves benefits from satellite navigation services and technologies to increase the level of positioning accuracy and reliability as well as the level of service availability. But the ARGUS project will also develop a whole set of services aimed at pragmatically support visually impaired people in their day-to-day life mobility. For this purpose, some specific objectives are considered:

- To build up a commercial navigation product for visually impaired people which guides them with acoustic and audio-haptic signals along a secure, pre-defined track. The positioning component uses satellite based positioning

- To develop tactile signals, acoustic and audio-haptic ones, for providing a non-visual track perception and mental map of the path, and supporting the guidance of visually impaired people along a pre-defined track.

- To develop an application for authorised third parties. With the application software, stored pre-defined tracks can be transmitted to the user terminal on demand.

- Provide an intelligent navigation and guiding portable device to support ageing population and visually impaired people.

- Provide updated data through a public Web services sharing information collected by ARGUS users with other ARGUS users or with general public

4   HOLOPHONIC SYSTEM

What is "binaural"?

Binaural sounds create the illusion that sounds produced by stereo headphones come from specific directions and distances, based on the interaural differences (arrival time and amplitude between the ears). This allows users perceiving 3D sound positioning, which can be used to guide visually impaired persons following a route (controlled via GNSS) giving a sense of 3D navigation.

To understand what binaural hearing is, we must know how we perceive the sound from those two "inputs", our ears.

The sound waves with their directionality and their amplitude make our ear/brain system locate sounds using our two ears. We use three different cues between our ears when locating a sound source: level, phase and spectrum (loudness). These differences are used in the ARGUS Project to generate virtual sounds creating another reality layer, corresponding to the direction that the user must follow. Although, none of these differences acts alone, the spatial location depends on many factors such as sight, location awareness, experience, environment, and even the state of mind are important for sound localization.
Image 1: Diagram explaining how sounds reach both ears in Holophonic system

The ARGUS User Terminal incorporates an Acoustic System, which receives the user's position from the Positioning Unit. The user perceives an additional reality layer of useful information, giving all the necessary stimuli to guide users naturally through a virtual pathway. Not just with a virtual 3D sound, but also with detailed audio descriptions of Points of Interest, services, and many environmental information.

Users can customize the system choosing among different sounds and adjusting parameters like volume, or speed of sound. Others will be automatically set up depending on the usage context and environment. The system will self-adjust its loudness to be heard but not disturbing in any area.

Oihana Otaegui, Estíbaliz Loyo, Eduardo Carrasco, Claudia Fösleitner, John Spiller, Daniela Patti, Adela Marcoci, Rafael Olmedo, Markus Dubielzig

In addition to the navigation system an online service will support in-situ routing assistance and a web-based collaborative environment including a social network will be used.

5 USER REQUIREMENTS GATHERING

The ARGUS project tackles a problem faced by many people with visual impairment in getting from one place to another. The project team wanted to check that the initial assumed user requirements were correct and if not to suggest alternatives. A survey was conducted using a questionnaire answered either in a face-to-face interview or online. There were 82 replies in total coming from Spain, UK, Germany, Italy and Austria.

Additionally to the user requirements, use cases were identified as well. The results of the questionnaires were analyzed and then discussed at a user workshop at UK.

The user survey of requirements showed that there was a need for a system, which would enhance the mobility and independence of blind and partially sighted people.

The main points of emerging from the survey were:

- The monetary value of such device and how it should be paid for.
- Users will not use ARGUS alone but as an aid to route finding.
- The security and safety of such a vulnerable group is important.
- Most beneficial when used in conjunction with public transport information.
- The helpfulness of a sound interface had to be validated by a Preliminary Proof of Concept test.

The survey confirmed the main requirements initially proposed for ARGUS.

6 WIZARD OF OZ PROTOTYPE

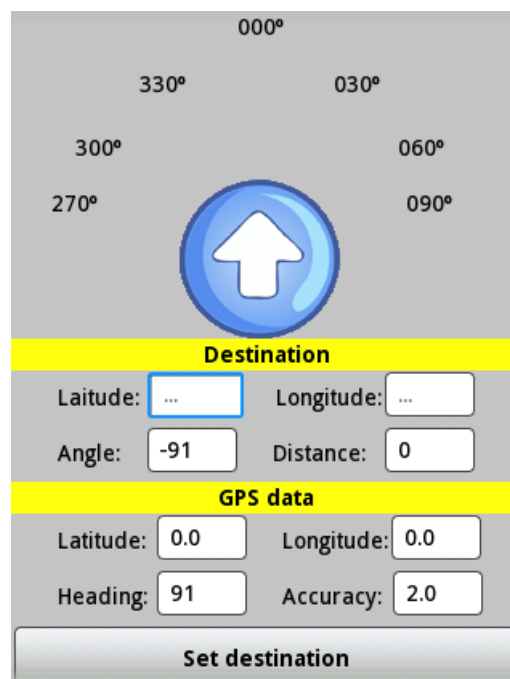
In parallel to the user requirements, the ARGUS team has developed a tool that allows testing the system setting up different parameters to configure the binaural sound and different User Interface options in an easy way. The Wizard of Oz tool helps to validate requirements, and can be also tested to train test subjects.


Image 2: Screen of the Wizard of Oz application

7 USER TERMINAL

Within ARGUS, the users play a major role. Based on interviewing sessions with them, the matter came up that they do not want another device but use their Smartphone.

Due to the fact that current Smartphones do not support the position accuracy and integrity required in ARGUS, the project decided to develop a separate localization and navigation module as a black box without

any visual user interface. The localization and navigation module is aimed at providing information like the high accuracy position, heading and velocity to the Smartphone supplying the precision needed by the ARGUS device.

The main user interface is realized in the ARGUS application on the Smartphone which is capable of guiding the user along pre-defined routes, using acoustic 3D sounds and haptic signals, and allowing Internet access for remote service supply and navigation position augmentation. Finally, it has to be stressed that the application for the Smartphone has been designed in order to be portable to current dominant mobile platforms such as Android, iOS and other mobile OS.

Key localization features:

- Position augmentation for precise positions.
- Quality check to indicate position accuracy.
- Safety-relevant integrity check.
- Additional measurements to bridge GNSS signal outages.

Image 3: User Terminal diagram: GNSS + Localization and navigation module + Binaural Guidance + Smartphone

8 ARGUS WEB SERVICES

The route calculation is one of the main ARGUS features. In order to generate the route from the origin to the destination, two options are available: pre-recorded tracks that can be used and a routing algorithm that calculates the best path to reach the destination from the origin point.

The optimal route is determined taking into account the restrictions or preferences of stored POIs. Pre-recorded tracks can be natural routes which are available in the multilayer cartography, or those previously generated by other users of the ARGUS system and published on the social network for other users to make use of them.

Furthermore, routes can be supplied with surrounding protection levels areas through the web-based application. The GEOCorridor® function enables additional route supervision by providing the possibility to define safety zones around given routes. An alarm is generated if the user leaves the safety zone marked by the GEOCorridor® function.

Additionally, by means of the dedicated social network, users can include their feedback and publish their experiences while using the ARGUS system. This personalized annotations become part of the multilayered data, thus the route calculation algorithm can consider it in further path generations.

9 PRELIMINARY PROOF OF CONCEPT TESTS

Preliminary Proof of Concept [PPoC] user tests have been carried out in Paderborn (Germany) in September 2012.
Image 4: map section with a route surrounded by a safety zone

A preliminary functional prototype with basic functionalities and using beta developments was tested by four expert users with different visual impairments who participated in these tests to technically assess the concept and to feed the project with the results obtained.

The outcomes of this PPoC have been very encouraging. All users successfully accomplished assigned navigation tasks, and low deviations from control points were achieved.

Only 5 minutes training on users was required to obtain good performance with the ARGUS system.

Key citation: "Before the test, I have to admit, I was very sceptic that this would work. I was very positively surprised after the first test with the Vibe. The headphones still allowed me to hear ambient sounds without missing the direction from where they were coming and the guidance sounds were not interfering with the ambient sounds. The navigation itself was very easy to follow and so precise that I hit two of the cones marking the track to follow. The GPS signal communicated via the binaural sounds was steady and kept me straight on the path to follow"
Image 5: User and route of proof of concept test

10 CONCLUSION

During testing and conversations with the potential users, most said that they would be interested in buying the ARGUS solution.

The interesting thing about the ARGUS product is that it will enable a larger accessibility of users to the city as it is useful to various sub-users groups.

ARGUS for most users will not be an alternative to the solutions already used, but an additional aid to support confidence and autonomy when moving around the streets.

It will not eliminate the use of some available solutions like the cane or the guide dogs. The cane will still be useful for detecting the closet obstacles but ARGUS will mean an additional aid to support confidence and autonomy when moving around the streets. Persons with guide dogs outlined that the system would allow them to choose additional ways to their destination instead of relying only on the trained route of the guide dog"

For example, ARGUS is of interest also for people with guide dogs. They outlined that the system would allow them to choose additional ways to their destination instead of relying only on the trained route of the guide dog. This does not imply that the ARGUS solution will be able to substitute a guide dog; it recognizes obstacles and guides them around road works while the ARGUS system would take over the guidance. Furthermore they outlined that they even would like to use ARGUS when walking accompanied by an assistant.

Even on familiar routes the system would make their lives easier, as it is a comfortable way to find the right directions without the need to count meters or crossings which is exhausting, especially after a long day at work.

The system significantly reduces the required mobility training of people with visual impairments since they can walk unfamiliar routes alone – even for the first time.

1 ABSTRACT

According to ESPON "ATTREG" project, "attractiveness is intended as the interaction of a complex set of characteristics based on the presence/absence of certain forms of Territorial Capital with the attraction of various "audiences". Effective territorial monitoring system of territorial capital assets and better coordination among different development and sectoral policies are basic conditions for achieving territorial cohesion and territorial development goals on transnational, national, regional and local level. The South-East-Europe project ATTRACT-SEE will support policy makers to achieve better coordination of territorial attractiveness policies – based upon place-specific assets – as well as their implementation and evaluation. The aim of the project is to establish a framework concept of territorial attractiveness at SEE scale as well as to develop tools useful for policy makers to enhance the quality of decisions concerning territorial cohesion and growth.

Firstly, a common territorial monitoring framework will be established, based upon a shared concept of "territorial attractiveness" as well as upon its assets. The objective is to create a model of a monitoring system suited to the needs of policy and decision makers, in view to provide outputs useful for supporting policy development and implementation. Through the establishment of a shared system of indicators, the model will then be applied to monitor territorial quality and attractiveness. Secondly, a policy coordination process will be designed, promoting, supporting and actively moderating participation and involvement of policy and decision makers from different sectors and administrative levels.

Concrete outputs such as a common territorial monitoring framework, transnational as well as trans-national/national/regional territorial quality and attractiveness reports, policy coordination process handbook, and stakeholder involvement workshops will create and/or strengthen permanent stakeholder networks in spatial and regional planning.

The paper gives an overview of the design of this research project and the implementation of a territorial monitoring system for South-East Europe. It focuses on the question on how to describe territorial attractiveness. It presents considerations and first results on the description of a concept of territorial attractiveness which will be the basis for the definition of common monitoring indicators.

2 BACKGROUND

2.1 Regional characterisitcs

South-East Europe is one of the most heterogenous and complex regions in Europe. Transformation processes and new boundaries have changed political, economic, social and cultural patterns and relations. The region has been undergoing a fundamental change in economic and production patterns since the 1990s. While some regions, especially the capital cities, are adapting well to the new challenges, others are trying to re-orientate themselves. Significant for the programme area are regional disparities in terms of economic power, innovation, competitiveness and accessibility between urban areas and rural areas. In the European transportation network, South East Europe is acting as a bridge between North, South, East and West Europe. The existing networks however cannot keep pace with the rise in demand and the increasingly

demanding standards specifications. A large number of instruments and concepts like the Trans-European Networks (TENs) and the Pan-European Transport Corridors cross the area, but need to be further developed. There are rivers suitable for freight transportation, maritime borders and the Danube, an important international inland waterway and integrating factor in many fields, such as transport, trade and environment. South East Europe is characterised by broad biodiversity and natural resources of high environmental value. The potential for the use of environmentally friendly technologies and the assets for future economic and social development are the strong points of the area, but inherited environmental damage has to be addressed as well (URL 1). Current challenges and driving forces for the spatial development are growing impact of globalization and structural changes after the recent economic crisis, demographic and social challenges and the (upcoming) EU-integration (EU 2011).

Figure 1: South-East-Europe according tot he SEE Transnational Cooperation Programme (Source: URL 1).

2.2 Territorial Cohesion of the European Union

Based on the Territorial Agenda 2020 of the EU one major objective of the European cohesion policy has been to strengthen economic and social cohesion. The main issues of cohesion are to (URL 2):

- Capitalise on the strengths of each territory so they can best contribute to the sustainable and balanced development of the EU as a whole;

- Manage concentration – Cities have both positive and negative impacts – intensifying innovation and productivity at the same time as pollution and social exclusion;

- Better connect territories – People should be able to live wherever they want, with access to public services, efficient transport, reliable energy networks and broadband internet throughout the territory;

- Develop cooperation – The effects of climate change and traffic congestion do not stop at traditional administrative borders, so new forms of cooperation are needed between countries and regions. The EU Strategy for the Baltic Sea Region and the EU Strategy for the Danube Region are examples of new, macro-regional approach;

- Foster Urban-Rural linkages.

2.3 Current situation of monitoring in South-East-Europe

In practice, the implementation of the objectives of territorial cohesion is partly slowed down because of a lack of coordination between decision makers from different sectors and administrative levels. For example, there is only little awareness of how sectoral decisions can influence the region as a whole. Even though a number of good practices exist on local or regional level, harmonised methodologies and tools to analyse and monitor the spatial development and spatial trends are missing on national and transnational level. Nevertheless, monitoring can provide useful results for the establishement of evidence-based and strategic developments. A monitoring system is a tool for a comprehensive observation of the implementation of territorial and sectoral policies (ROYAL TOWN PLANNING INSTITUTE 2008; UNITED NATIONS 2007) and the need for a common monitoring system, transparent planning and decision making as well as stronger cooperation between regions is growing. These requirements were in the centre of discussion at several transnational workshops and conferences such as at the conference on "Potentials of territorial

Julia Neuschmid, Christian Eizinger, Blaž Barborič, Graziella Guaragno, Tomaž Miklavčič, Stefano Marani, Ljiljana Živković, Francesca Altomare, Đorđe Milić, Gianandrea Esposito, Alessandro Selva

cohesion in western Balkan" organized in 2010 by the Ministry of Evironment and Planning in Slovenia. A second impulse was given one year after in Ljubljana during an event organized between the South-East-Europe Programme and the project Plan4all (URL 3) that contributed to the harmonization of spatial planning data according to INSPIRE – the European Directive for the establishment of a spatial data infrastructure in Europe (URL 4). In this context the question rises how a monitoring system can be established in South-East-Europe.

3 ATTRACT-SEE PROJECT ACTIVITIES AND STATUS OF THEIR REALIZATION

3.1 Project aims and structure

The project Attract-SEE – Assessing Territorial Attractiveness in South East Europe deals with the above question. The aim of the project is to develop a transnational monitoring system that supports the establishement of policy coordination framework in concerned regions and to develop tools for policy and decision makers enhancing the quality of their development decisions. It is funded under the European South-East-Europe Programme between October 2012 and September 2014. The consortium has ten project partners. These are Geodetic Institute of Slovenia (lead partner), CEIT Alanova (Austria), Office for National Economic Planning (ONEP) (Hungary), Emilia-Romagna Region (RER) (Italy), Ministry of Infrastructure and Spatial Planning (MzIP) (Slovenia), The Regional Environmental Center for Central and Eastern Europe (REC) (Slovenia), Republic Agency for Spatial Planning (RAPP) (Serbia), Network of Associations of Local Authorities in South-East Europe (NALAS) (Former Yugoslav Republic of Macedonia), Institute of spatial planning of the Koprivnica-Križevci County (ZAVOD) (Croatia) and Federal Ministry of Physical Planning (FMPU) (Bosnia and Herzegovina). Further one associated, strategic partners from the EU, and several observers are involved in the project.

Project Attract-SEE is designed out of two parallel in several worksteps interlinked activities. First tier of activities is set out to develop a common territorial monitoring framework (TMF) applicable in partner countries and regions. Second tier of actions is developing and facilitating a policy coordination process promoting interaction among territorial monitoring and policy making. Stakeholders involved into a policy coordination process – mainly through project`s workshops – will participate in designing TMF providing their needs for information, their expectations as the manner in which territorial information could be presented in the most suitable way.

The project consists of six work packages (WP), covering the transnational project and financial management (WP1), communication activities (WP2), common territorial monitoring framework (WP3), attractiveness of SEE territories (WP4), development of common territorial monitoring reports (WP5), and policy coordination (WP6). WPs are divided into several activities which are being implemented in parallel. The project started 1st October 2012. According to the timeline of the project (first period of five is finished), most of the activities have been started and some of them have already been finished. Activities in WP2 started with the common project visual identity. The project website (http://www.attract-see.eu/) and some promotion material were prepared, too. The Project Communication Strategy is in preparation. Creation of the common territorial monitoring framework (WP3) has started with an overview of the EU territorial monitoring best practices. ESPON (URL 5) Programme and EUROSTAT (URL 6) solutions (e.g. NUTS classification), INSPIRE Directive (eg. data harmonization and interoperability models) will be applied. The Inquiery on Territorial Monitoring Systems was delivered to all the project partners and results were analysed to get the common denominator of needs, expectations, and feasibility of the project implementation. Common set of attractiveness indicators for SEE region is being prepared. The final version of the Report on Territorial Attractiveness (WP4) was prepared and is presented in the text below. Development of the common territorial monitoring (WP5) started with collecting information on spatial datasets. Data overviews for each country/region involved were prepared. Their analysis got answers concerning available spatial datasets in SEE region. Dataset sources, dataset regulations, accessibility of datasets, and dataset maintenance periods were explored. Policy Coordination Process Handbook (WP6) is in preparation and will serve as a common methodological support for all the project partners.

Based on the analyses of existing monitoring systems in partner countries as other good practices TMF will be developed in the project, supporting observation of existing territorial development and territorial trends.

TMF will define overall process of territorial monitoring including data gathering and analysis, indicator preparation and calculations and territorial report preparation.

A transnational attractiveness synthesis report will be developed as the project output. Territorial reports provide information and knowledge on territorial structures, potentials and trends. The report will be based on the quantitative results from the analyses of established harmonised indicator system on the territorial level of the partner countries and regions. Where applicable and available, data for other SEE countries will be used and presented. Project aims to inform policy and decision makers and draw their attention about wider territorial picture and encourage them to take it into account when developing and implementing various sectoral policies. The report will be presented to stakeholders at the transnational level at the transnational stakeholder involvement workshop, which will be organised alongside the final project conference.

In different pilot areas more detailed separate territorial reports will be prepared on the basis of available indicators and on the basis of existing national/regional analysis in the field of territorial attractiveness and quality. In order to ensure comparability of reports on transnational level, common methodology for territorial attractiveness report will be used. This methodology will define draft content and form of the report. The policy coordination process is very important result of the project and is described in next chapter.

3.2 Project stakeholder involvement

The policy coordination process is expected to result in a more long term coordination network. To support the activities a Policy coordination handbook will be prepared at early project implementation stage and aims to guide territorial development experts in establishing stakeholder networks, and in coordinating the process in their pilot areas with engageing stakeholders. This document will define the strategy for involving stakeholders: the aproach, the principles and guidelines for implementation. It will also present the benefits, the drivers and the barriers for effective involvement.

Equipped with appropriate knowledge and skills, and following the methodology defined in the policy coordination process handbook, the relevant project partners will develop the stakeholder involvement plans in each project region/country. In fact these documents will be the action plans for implementation of stakeholder involvement in practice. Stakeholder involvement will be implemented at national workshops. Each partner should organize four national workshops where objectives and results will be discussed and verified. Such a concept of stakeholder involvement will enable regular verification of intermediate results and will strenghten the stakeholder networks.

4 DEFINING TERRITORIAL ATTRACTIVENESS

4.1 Concept and operational implications

"Attractiveness": what are we talking about? Although more and more frequent in development plans, programmes and other policy documents, not always the appeal of the word goes together with a clear meaning. Attract-SEE assumed as a starting point the previous ESPON ATTREG Project (URL 7), that after considering several European case studies, provided a framework definition of attractiveness "as the interaction of a complex set of characteristics based on the presence/absence of certain forms of Territorial Capital with the attraction of various "audiences" varying in their level of transience in place from long-term residents as working population to short-term visitors and some hybrids mobilities between the two". In this sense, attractivess becomes "a place-specific asset that guarantees some kind of socio economic stability", referred to the different dimensions of Territorial Capital (Environmental; Economic and Human; Anthropic; Socio-Cultural and Institutional Capitals).

According to Attract-SEE partners, this perspective attributes to the concept of attractiveness a clear "territorial" dimension. In concrete terms, territorial attractiveness grounds on a mobility concept and implies the capacity of a place to attract and retain subjects from other places, due to its advantageous features. We can consider that building an "attractive region" needs to focus two complementary dimensions:

- the home internal side, made of quality settlements and ecosystems, able to regenerate social cohesion, reproduce knowledge, create decent jobs and make good value of entrepreneurship: it is key for retaining citizens, skilled workforce, enterprises, etc. already living in the "place";

Julia Neuschmid, Christian Eizinger, Blaž Barborič, Graziella Guaragno, Tomaž Miklavčič, Stefano Marani, Ljiljana Živković, Francesca Altomare, Đorđe Milić, Gianandrea Esposito, Alessandro Selva

- the external side, made of international acknowledgement of these territorial qualities, linked to the capacity to attract and hold talents and investments, to attract visitors/tourists for different purposes (culture, nature, business, etc.) and ensure their "loyalty" as availability to return to the "place".

This approach allows to operationalize the concept within EU cohesion policy and to make it assessable at SEE scale, considering both the trans-national perspective and the internal one, at country/region scale.

4.2 Methodology

The methodological approach to reach this objective included three steps, developed complementarily and through three operative tools adopted and provided to project partners (PPs) and to stakeholders.

Step 1 focused on the assessment of the concept of "Territorial Attractiveness" adopted by PPs country/region, making specific reference to official Spatial Policy Documents (strategic and/or operational Plans and Programmes). For the purpose it has been developed a "Tool of Inquiry" addressing on one hand the territorial monitoring systems in use in partners' countries/regions and the identification of specific best practices and on the other focusing on the concept of attractiveness adopted, the supporting assets and the specific indicators utilised. The questionnaire was provided by e-mail.

Step 2 was aimed at assessing the answers provided by partners on the concept of Territorial Attractiveness according to their relevant strategic and/or operational Plans and/or Programmes as well as at identifying the assets considered as strategic. The results were subsequently re-elaborated and returned to project partners and to project international stakeholders during the Ljubljana conference and partner meeting (December 13-14, 2012). During these events partners were provided with a first outlook of the concepts of Territorial Attractiveness in use in each context while a first characterization of the concept was attempted, specifying in particular the features that explain the actual meaning of Territorial Attractiveness ("attracting whom, where, how?"). Secondarily, a preliminary classification of the Territorial Capital assets to be considered was presented. The potential relationships between local visions/policies adopted by partners and the main EU strategic documents for development were also explored (i.e. EU 2020 and the Territorial Agenda 2020).

Step 3: international stakeholders and partners were asked to express their opinion on the relevance of the Territorial Capital assets identified for Territorial Attractiveness assessment, to obtain a revised picture of the concept and a framework of the assets to be considered, adjusted to the perspectives of each partners. This was done using two types of questionnaire aimed at evaluating the relevance of any asset, including the possibility to suggest the introduction of new assets considered relevant. In particular, international stakeholders questionnaire (directly distributed during Ljubljana Conference) were asked to provide a "qualitative" assessment of the assets identified (in terms of relevance/non relevance) while partners questionnaire (sent by e-mail) provided a "quantitative" assessment (assets ranked from 1 to 5, according to a growing relevance) as well as a double level of assessment, to be held at national and transnational level.

After a wide debate, the assets indicated by partners were grouped into macro-themes and put in relation with specific target groups ("audiences"), in view to give evidence to their different level of interest in each assets and – in some cases – to the real trade-offs (see tab. 4.1 in the next paragraph). Attract-SEE partners are presently facing the job to identify proper indicators for attractiveness assets, to be considered at trans-national and national scale, in view to produce, in the forthcoming months, specific reports that will pave the way for the establishment of a Common Territorial Monitoring Framework.

4.3 Results of the work process

First of all, Attract-SEE partners agreed on some specific features of the concept:

(1) Quality of places gains high importance: cohesion/inclusiveness, culture, public services, effective governance are key for attracting and retaining a specific "audience". E.g. in the case of cities seen as "engines of regional development", attractiveness depends not only on the sum of its structures and infrastructures but also on its capacity of attracting and retaining people.

(2) Territorial scales and diversity of places are the key to assess attractiveness: it is on diversity that depends the generation of flows from one place to another and the effectiveness of different strategies – such as specialization or balance of mixed factors – depends on the context and dimension of the area considered.

(3) Drivers for "attractiveness" are different: Territorial Capital assets should thus be considered in relation to "who is attracted by what". E.g.:

- environmental capital, including good climate and a high quality landscape, attracting "silver migrants";

- economic/knowledge capital – concentrated in core European cities – attracts both investments and talents;

- social inclusion capacity as well as good governance arrangements reinforce flows of migrants, both new citizens and enterprises, facilitating the birth of new initiatives by "contamination" of ideas and resources,.

(4) "Plurality" of needs/expectations grounds the demand for diversified policies targeted to different actors that, while commonly looking for "quality of places", do not always share the same concept of what quality actually is, e.g.: natural and/or cultural tourism development policies may strongly conflict with heavy infrastructure policies (e.g. industrial/logistic poles), if pursued on the same territory. This calls for "good governance" of spatial development processes, also ensuring the management of objectives trade-offs.

(5) (Un)stability of factors of attractiveness: positioning of the territories should rely on stable features that allow a long term strategy but, while some drivers for attractiveness may prove to be volatile (e.g: big events) if not included in a wider vision, also the same understanding of territorial attractiveness may change. E.g.:

- many territories become very "fragile" after 2008 crisis, with social capital supporting innovation capacity of a local system (e.g. an industrial district) breaking down;

- knowledge capital may be attracted elsewhere as well as financial capital, according to more favourable conditions;

- climate change can determine strong changes in territorial quality and make e.g. a territory less attractive for tourists/visitors; financial crisis can make the management of cultural/natural resources less reliable discouraging both fruition and the implementation of proactive environmental prevention policies.

Targets / TC asset		Companies/ Investments	Tourists	Residents	Migrants
Environmental capital					
Environmental quality	Environmental quality (air, water, waste, greenhouse gases, etc.)		x	x	x
Territorial/ecosystem integrity	Territorial/ecosystem fragmentation		x	x	
	Biodiversity		x	x	
	Risk management	x		x	
Natural resources and energy	Natural resources management (renewable/non renewable)			x

	Internationalization	x			x

Table 1: Matching assets with different group of targets.

To conclude, "Territorial Attractiveness" is not an absolute concept: "attractiveness" of a territory can change according to the targets and the assets of the Territorial Capital considered and positioning a territory in its external context implies a matching between specific assets and targets to attract. These two orientations have to be related to the different goals/visions of the overall territorial development strategy.

5 MONITORING FOR SPATIAL DECISIONS

5.1 Building territorial monitoring tool

Public policies and other sectoral/strategic decision-makers need monitoring tools to continually and easily follow-up and understand effects and trends within local, regional, national and/or transnational levels produced by their actions and plans, which are aimed at sustainable and balanced territorial development.

From spatio-temporal perspective, these monitoring tools should provide platform for collection and storing various types of data and information on different territorial development conditions, statuses and events through time periods; from public policy process perspective, monitoring tools should support territorial development knowledge creation, using analysis, comparison, interpretation and presentation methods, needed for informed and timely decision-making. Due to described territorial development character and needs of policy creation and management process, territorial monitoring tools are usually supported by GIS technology advantages, which are in some cases further enhanced by particular expert or decision-making systems (based on multicriteria analysis or system dynamics approach).

Therefore, following the EU's Territorial Agenda 2020 aimed at territorial development cohesion by appropriate policies development and implementation throughout member and candidate/neighbouring states/regions, Project would propose territorial monitoring tool that should support territorial attractiveness policies and decision-making processes coordination within the South East Europe region.

5.2 Design and implementation of the monitoring framework

In building monitoring tool for attractiveness policy development/implementation and coordination within the project area, both social and technical dimensions of common information platform would be considered and designed to involve each project partner country's specifics, on one side, and to provide basis both for local as well as SEE-wide attractiveness development decision-making process, on the other.

Starting from the current territorial development practices of project partners as well as SEE Programme objectives and EU initiatives falling within the technical and social domains of the project scope, common territorial monitoring framework (CTMF) would be built. Its outlines would be positioned among the relevant European initiatives and programmes results and recommendations, like ESPON, INSPIRE/Plan4all and other relevant approaches (OECD, UN).

On the technical side of common territorial monitoring tool for attractiveness assessment, project partners would develop as outputs:

(1) Common methodology for territorial attractiveness indicators identification based on OECD and UN approache's principles "pressure, state, response" for those events or processes identified as relevant for attractiveness development within each project partner's territory and SEE in general. Also, policy interrelation matrix would be developed for policy effects evaluation and strategic decision-making against identified attractiveness trageting values and groups; and

(2) Common data and metadata model for territorial attractiveness indicators definition based on INSPIRE/Plan4all recommendations and data specifications, and adjusted to project partners' existing

experience as well as specific needs. Additionally, interpretations of attractiveness indicators' values would be done against relevant ESPON projects' results. On the social side of territorial attractiveness monitoring tool for SEE, national stakeholders communities consisting of policy and other sectoral/strategic decision-makers would be involved in the project acitivies at the four workshops during the project duration. The main objectives of those workshops are to present project aim, activities and results to stakeholder communities, but also to build capacity in domain of territorial monitoring results understanding and utilization, building thus ownership over the project outcome and its results' sustainability.

Finally, based on gap analysis of existing territorial monitoring experience in each project partner against developed CTMF, sustainability of the project results would be additionally secure by action plans where each partner would identify steps needed for achieving territorial monitoring goals.

6 OUTLOOK

The results of Attract-SEE should be used by politicians and decision makers to improve cooperation and networks between European countries, to support territorial cohesion and development in South-East-Europe. Next steps of Attract-SEE are the finalisation of the design of the common monitoring framework, the final definition of monitoring indicators based on a defined methodology, and the development of the common data model. The main aspects of all project phases are a policy coordination process as well as the involvement of stakeholders.

1 INTRODUCTION

The Centrope region is situated at the mutual borders of Austria, the Czech Republic, Hungary, and Slovakia. Its aim is to foster cultural, ecologic and economic development in an area that had to suffer enormous disadvantages during the decades of existence of the Iron Curtain and is now ready to catch up.

To help planners and stakeholders to get an overview of the Centrope region, the geoportal CentropeMAP went online in 2005 and was soon extended by a cross-border statistics database which is linked to the map view. This powerful tool allows you to convert statistic data into easily legible thematic maps and various types of charts on the fly.

CentropeMAP is an online geoportal, which means it collects web map services (WMS) from all parts of the Centrope Region and presents all these services to the user compiled into one single map. CentropeMAP emphasises on datasets that are of interest for spatial planning and similar professions, comprising multiple data layers from the fields of biota, boundaries, elevation, imagery/base maps, inland waters, planning/cadastre, structure, and transportation.

Planners and stakeholders receive a great help from maps. Also, statistic data is important to analyse a region. So why not combine maps and statistics and create a combined view of statistic data directly in a map? CentropeSTATISTICS joins data from the regions Vysocina, Jiho-moravsky, Bratislavsky, Trnavsky, Györ-Moson-Sopron, Burgenland, Lower Austria, and Vienna and features readymade thematic maps as well as an expert mode which gives full access to the whole Centrope cross-border statistics database. Note that you can also download these data and, for example, use it in a spread-sheet. Almost all datasets are collected in a time series so that the development of the region can be explored in yearly steps since 2001; the data range comprises various fields like population statistics, population development and projection as well as land use, educational statistics, tourism or migration.

2 THE BASIC MODE

The CentropeSTATISTICS Basic Mode allows you to create a couple of thematic maps which have been predefined by the CentropeMAP team. It is mainly for quick queries or for people who do not have much experience in creating thematic maps or charts from statistic tables.

All available statistics themes are collected in a menu tree on the left part of the CentropeSTATISTICS window. After selection, it may take a couple of seconds until a map preview appears in the right half of the window. In the meanwhile, the theme you selected is prepared to be displayed as web map service image in the CentropeMAP window. Now you can hit the "Create Map" button. The map, which has been precalculated in the background, is now brought into the CentropeMAP window, and the CentropeMAP window is automatically brought to your desktop.

3 THE EXPERT MODE

3.1 Creating maps and charts

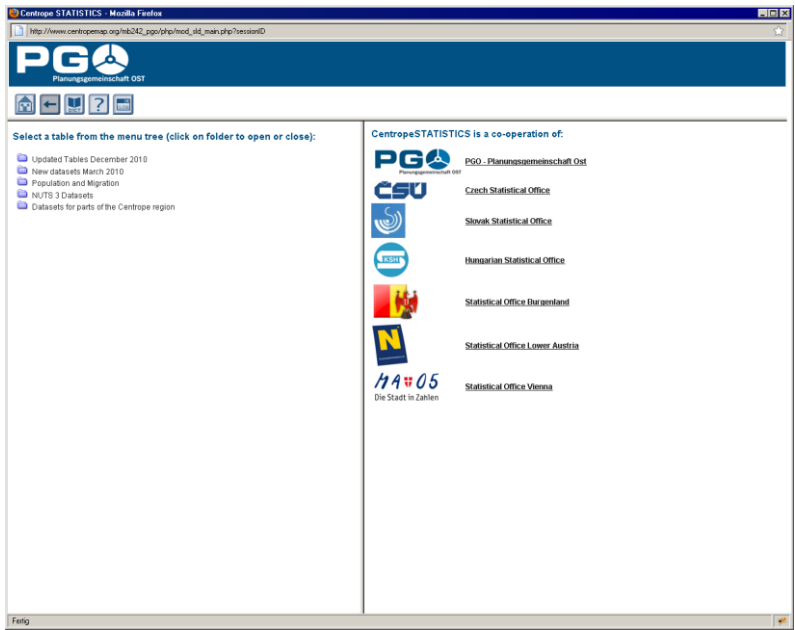
The CentropeSTATISTICS Expert Mode gives you full access to the whole Centrope cross-border statistics database, you can download these data and set several options while creating your thematic map or chart. The expert mode is meant for planners, statisticians and other professionals who know how to create meaningful thematic maps and charts.


Fig. 1: CentropeSTATISTICS start screen.

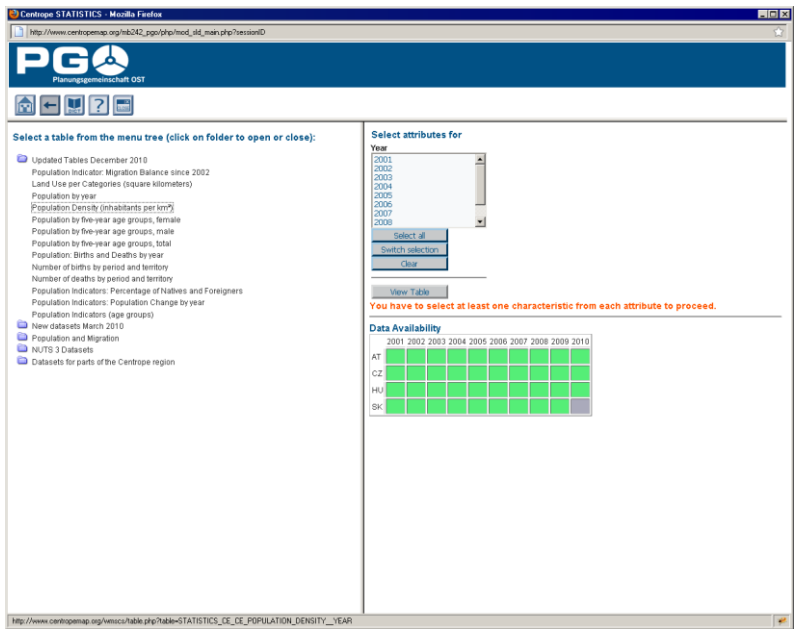
Looking at the CentropeSTATISTICS Expert Mode start screen, you will see that it is divided into three parts. At the top you have the title bar with some buttons, and below the screen is divided into a left and a right half. If you like, you can resize the whole window or move the grey border that separates the left and right screen parts. All available statistics themes are collected in a menu tree on the left part of the CentropeSTATISTICS window. To select a theme, click on it. After your click, the availability form is loaded into the right half of the statistics window. It shows you which attributes are available for selection. In most cases, this will be the year only as we tend to prepare the statistics table in a way that similar themes are shown in separate tables and not altogether in one large table. Another example for an attribute to be selected is whether the number shall be shown as absolute values or, for instance, per 1,000 inhabitants.


Fig. 2: CentropeSTATISTICS start screen after table selection.

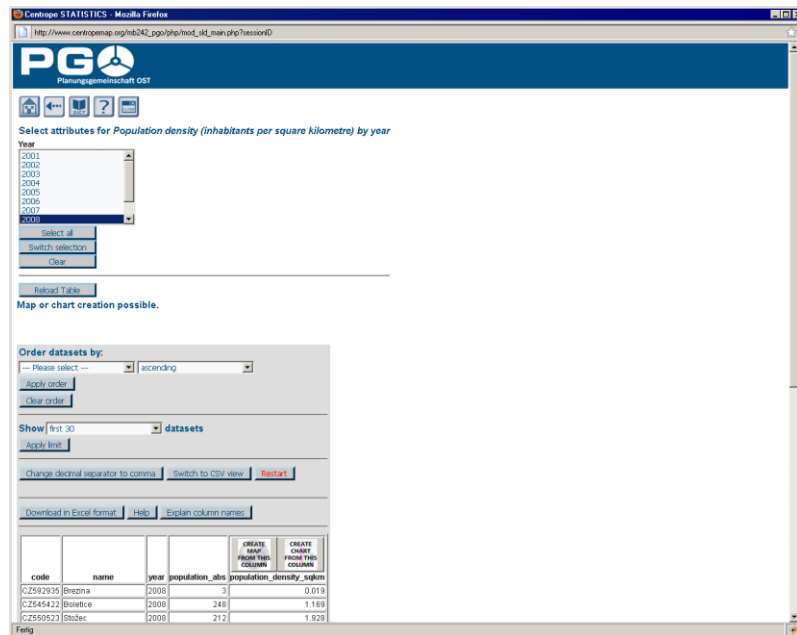
A green square means that data is available, a grey square indicated that data is not available in a certain part of the Centrope region for a certain year. Clicking the "View Table" buttons opens the selected table in the statistics window. The division between left and right half of the window does not exist further on.


Fig. 3: CentropeSTATISTICS table view.

From this point, you are ready to

- create maps,
- create bar/line/point charts,
- create pie charts,
- create symbol maps.

The result may look like this:
Fig. 4: Example results: thematic map (left), pie chart (right).

3.2 Working with user-defined tables

You are not restricted to the given tables in CentropeSTATISTICS. There is also a possiblity to combine data from more than one table, put it together in a custom table, and even calculate your own indicators. First of all, if you want to work with a custom table, you have to create one. The "Create custom table" button is situated below the table tree menu on the start page of the CentropeSTATISTICS expert mode. After table creation, if you press the "View custom table" button, the same happens as if you selected any other table from the menu tree. It is still empty, so in the next step you have to add columns to your custom table. Return to the start page and select any table you want from the menu tree. Open it as usual. You can see that an additional button appears on the top of each column: "Add to custom table".

Map calculations and map output are done only for the geographic intersection of the data added to your table. E. g. if you add a column containing data for the whole Centrope region and another column with data

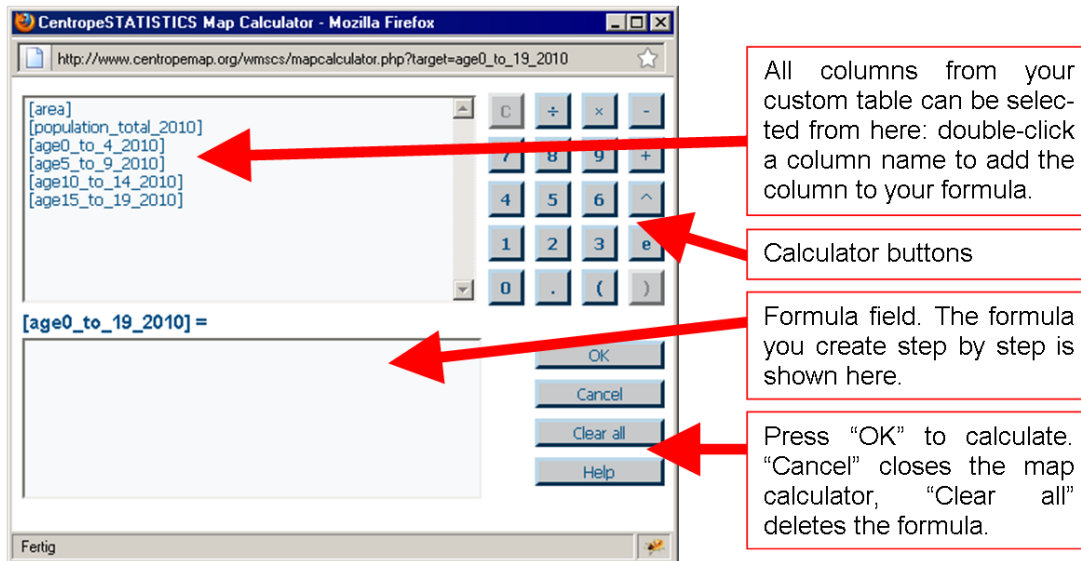
for whole Austria, all following operations will only be performed for the Centrope part of Austria. If you try to add a column which would set the intersection to null, CentropeSTATISTICS will notice this and prevent you from adding this column.


Fig. 5: The map calculator.

The map calculator works similar to any standard desk calculator. The "C" button lets you undo your last calculator action, i. e. remove a digit, an operator or a column name from the formula field. If you press "OK", the formula will be checked for errors and executed, resulting in a new column within your custom table.

4 PERSPECTIVES

Behind CentropeMAP and CentropeSTATISTICS there is a cross-border database for both geodata and statistics. This database is growing – slowly, but steadily. Approximately twice a year experts from all partner regions meet to discuss the further extension of this database. For various reasons, the extension of the cross-border database is not an easy task:

All incoming datasets have to be checked on their compatibility and comparability with existing data. This is extremely important for statistical data because it has to be verified that datasets from different countries were collected in the same way before they are put together in one table. Otherwise, they cannot be compared with each other.

This situation may improve in the future: The statistic offices of the partner regions are more and more following guidelines of the European statistical office EUROSTAT, so their data output is automatically comparable between different regions and countries. Data delivery from each EU country to Eurostat has already been running for many years; however, these datasets are not on municipality level but often on a quite rough regional level which is good for a pan-European point of view, but to general for the Centrope region.

Cities for All: All-Inclusive Collective Urban Spaces for the Public – a Case of a Successful Interactive Model

Eric R. P. Farr, Poorang (Amir E.) Piroozfar

(Dr Eric R. P. Farr, Independent Researcher, Critic and Consultant, 3 Montgomery, Irvine, CA 92604, USA)
(Dr Poorang Piroozfar; Senior Lecturer in Architectural Technology, School of Environment and Technology, University of Brighton, UK)

1 ABSTRACT

In theory bringing a diverse range of the public together into a locality in a city and satisfying a broad spectrum of expectations is what public spaces are designed to satisfy. However, in reality this has proven to be a challenging task for both designers and planners. There are predominant factors that determine who would spend their time in a public space and to what extents they would be satisfied with their time spent. Those include age, gender, ethnicity, social class, needs, wants and personal preferences to just name a few.

Having encompassed a wide range of activities, all-inclusive urban spaces may impose substantial costs to the city from inception through to the completion stages. However, such spaces can successfully be launched, and reimburse their costs, if they are carefully set up to absorb the mass of their peripheral communities and inhabitants on a regular basis. Offering relief for senior citizens, amusement for the youngsters and toddlers, entertainment for the teenagers, all in chorus, provide interactive atmospheres that resonate with the initial purposes of all-inclusive public spaces.

This paper aims to investigate Niruye-Havaei, an established urban square, in Tehran as one of the most successful exemplars in provision of an overarching urban public space, overcoming the aforementioned problem. The paper begins with general background information of the place and the space, and the communities in the surrounding vicinities, and how they have been formed over the years and how they are in a dynamic interaction with each other, leading to introduction of such successful pattern. Utilising overt and covert participant observation (ethnography) methods, it will then contemplate on the potentials of place and space, and explores how the entire urban district has been 'orbitalised' around this featured space and why it has found such a prominent role in the area. Finally, it concludes with a framework model for all-inclusive public spaces and suggests its application to similar situations for acquiring a record of success in urban developments.

2 ON PLACE AND SPACE: THE OPENING

'There is no specific theory of space, but quite simply a deployment and specification of the theory of social structure, in order to account for the characteristics of the particular social form, space, and its articulation with other historically given, forms and processes' (Castells 1977:124). Castells (1983) had to retract from his radical Marxist take on space to assert that space is in fact the society itself as opposed to a reflection of the society (Hubbard 2004).

Despite being heavily criticised by Manuel Castells, for naively equating spatial propinquity with social emancipation (Hubbard 2004:74), 'as if there were no institutional organisation outside arrangement of space' (Castells 1977:90), Henri Lefebvre played a pivotal role as a theorist of social space with critique of the 'Everydayness' as a soul-destroying feature of modernity, when the social interaction takes place in the material environment. His critique developed from domestic life in a household to the neighbourhood and to the urban life where his reading of 'the urban' conforms to the Hegelian form in a phenomenological sense. In his view 'the urban' is social 'centrality' where capitalist's aspects intersect in the place even for a short period of time; what contradicts with Castells' dichotomy of place and the space of flows (Castell 1977 in: Shields 2004:209). The 'City-ness' in his view, Shields (2004) asserts that, is the simultaneous gathering and dispersing of goods, information and people. In 'The Production of Space' (1991) and 'Writing on Cities' (1996), Lefebvre departs from a synchronic discourse on space to a diachronic one where culture finds a quintessential role as a result of the history of change.

Lefebvre's 'abstract space' of capitalism was later on challenged by Bourdieu's advocacy for habitus; a vague but authentic, and culturally-rich 'place' (Bridge 2004:60). Later works attempt to investigate the validity of the concept within the fast pace of globalisation by investigating it at different levels. Leach (2002) and Dovey (2002) for instance explore the relationships between habitus and formation of identity by

highlighting the architectural profession as a responsible party for reproducing the dominant social divisions through forms of 'place-making' (Bridge 2004)

Drawing on Alfred Schutz (Schutz and Luckmann 1974), Bauman (1993: 145) maintains that our very sense of objective, physical space derives from the 'phenomenological reduction of daily experience to pure quantity, during which distance is "depopulated" and "extemporalised"' (in: Clarke and Doel 2004). They continue to state that cognitive spacing derives from modernity's desire to master space; to determine a place for everything and ensure that everything is in place – so that surveillance might readily reveal whatever is 'out of place' (Clarke and Doel 2004:36)

'Spaces of dispersion' which draws a principle, a meaning, a spirit, a worldview, an overall shape, etc. – what Foucault categorises as 'all phenomena' – around a single centre; a space of dispersion deployed by a general history (Foucault 1972:10 in Philo 2004:124) is perhaps Foucault's most important contribution to the formation of space and place in the post modernity era beyond his concept of power and theory of governance. The interactions across time and space was later used by Giddens (1984 in Warf 2004:130-132) as time-space distantiation as a fundamental concept to exertion of power; in his 'structuration theory', more ontologically than epistemologically though.

3   THE USE AND THE PURPOSE OF THE PUBLIC SPACE

Carmona et al. (2008) categorise the benefits of the public space into 'economic' i.e. positive impact on property prices (Colin Buchanan and Partners 2007, Luttik 2000, Peiser and Schwann 1993 and CABE 2005a), boosting commercial trading (DoE and ATCM 1997) or regional economic performance (Frontier Economics 2004), land value and investment (Luther and Gruehn 2001, Phillips 2000); 'human health' by encouraging exercise (Hakim 1999, Diabetes Prevention Group 2002, Slattery et al. 1997, Grisso et al. 1991), influence a longer life (Takano et al. 2002), providing space for formal and informal sports and games (Woolley 2003, Woolley and Johns 2001), reducing stress and enhancing mental health (Hartig et al. 2003, Halpern 1995) and child health (Taylor et al. 2001); 'social' by delivering learning benefits to children (Fjortoft 2001, Taylor et al. 1998), nurturing social and cognitive skills (Pellegrini and Blatchford 1993), reducing crime and asbo (McKay 1998, Conolly 2002, Painter 1996, Loukaitou-Sideris et al. 2001, CABE 2005b), promoting neighbourliness and social cohesion (Baulkwill 2002, Massey 2002, Quayle and Driessen van der Like 1997, Kuo et al. 1998, Appleyard 1981), providing venues for social events (Schuster 1995), reducing child mortality by avoiding car-dominated environments (Living Streets 2001, Maconachie and Elliston 2002), providing venues for social interchange and supporting social life of communities (Mean and Tims 2005, Dines and Cattel 2006, Jones et al. 2007, Watson 2006); and finally 'Environmental' by encouraging the use of sustainable modes of transport (Gehl and Gemzøe 1996, 2000), improving air quality through reducing heat island effects, pollution and water run-off (Littlefair et al. 2000, Whitford Ennos and Handley 2001, Shashua-Bar and Hoffman 2000, Upmanis 2000) and creating opportunities for urban wildlife to flourish (Shoard 2003).

Figure 1: Public Space, the Kit of Parts (Carmona et al. 2008)

Similar to the division developed for Urban Amenity Indicators for New Zealand by Bell (2000: 21), Carmona et al. (2008: 9) conceptualised three key dimensions that together define the character of the public space:

- The key elements that constitute public space – in other words, the 'kit of parts';
- The particular characteristics of public spaces – the 'qualities' that different spaces possess;
- The range of socio/economic and physical/spatial contexts – or the 'context for action'.

The key elements of the public space or the 'kit of parts' are developed into four key elements as seen in Figure 1:

4   THE DECLINE OF THE PUBLIC SPACE

Carr et al. (2009:67) assign the 'flight' to the suburbs and 'abandonment' of the centre cities to the mid C20th boom in economy which provided the middle class with an opportunity to move out from the cities to the suburbs with a dream of owning their affordable private outdoor green spaces.

A general decline in public space realm has been realised by most scholars who have written on the issue (Carmona et al. 2008). They continue to state that the reasons recognised and solutions recommended are commonly very diverse. The administrative of many best-known cities choose to concentrate their efforts on what they tend to refer to as over-management of public spaces, what results in commodification of space (Sorkin 1992, Boyer 1994, Zukin 1995, Loukaitous-Sideris and Banerjee 1998). Others mainly emphasise what is understood as under-management of the public space as a consequence of poorly designed and insecure public spaces. Public spaces of the latter have been described, rendered and criticised in Jacob (1961) and Newman (1973) among many others who explain the relationships between the design/planning quality and the quality of neighbourhood, and the public space.

5   NIRUYE-HAVAEI 2ND SQUARE: A CASE OF AN INTEGRATIVE MODEL

The public space subject to this study is an urban square which combines a wide variety of 'kit of parts' – both physical and non-physical – mostly for the local users. In addition, it also acts as a traffic node in form of a city roundabout where the local traffic merges with the commuters' flow to work which starts or ends somewhere in the neighbourhood and passes through this traffic node.

There is no doubt that the quality of buildings, landscape or infrastructure – the three physical compartments of the 'kit of parts' – is very ordinary if not lower than average and by far even less sophisticated than what the city and local authorities normally expect them to be. For example, urban design of the square is not even to the level to be considered as a 'design'; the buildings surrounding it and their façades are average developers' works, meaning that there is no sign of significantly cultivated artistic aspects or architectural merit. On the other hand, the issue of noise as a result of passing-by traffic and the significant number of mopeds seems to be unsolvable. Since there is a unanimous covenant on lack of high quality of the aforementioned compartments – buildings, landscape or infrastructure – the main question of this research arises as to: what actually makes this case so worthwhile, viable and workable.

Figure 2: Map of Tehran and Niruye-Havaei neighbourhood. Courtesy of Google Map

Located in north-east part of Tehran, Niruye-Havaei is a part of Borough 13 in modern Tehran. It has a background history as a Qajar Royal hunting ground (known as Doshan-Tappeh), scattered settlements in form of small villages and one of the new urban developments outside the old city fortress of 1889, and a formal new urban district for over 70 years in its today form. It is named after an air force base which is located to the north of the neighbourhood (See Figure 2).

Some twenty years ago, the square which had a series of tall fences around, with four entrance gates to keep it safe over nights for years, like many others lost its protective barrier through Tehran's municipality act of revitalisation of public spaces. As a result the space became open to the public day and night. Once the fences came down, the square, equipped to an ample of lamp posts, was kept luminous, and night police patrolled regularly to make the area safe and secure. Although the whole area was considered to be fairly safe at the time, the initial safety belt plan successfully minimised the gangs' and drug dealers' opportunities to accommodate in the square and its vicinity. The closest similar public space with a level of importance nowhere near that of Niruye-Havaei 2nd Square, is the 1st Square, where the size, the scale, the level of intervention and socio-cultural exchange between the users are significantly lower (See Figure 3). Despite the close proximity of the two squares, the 1st square never found such a crucial and intra-regional role as of the 2nd squares. In fact the 2nd Square has found such social 'centrality' way beyond the mere intersection of the capitalist's aspects in brief periods of time; a centre for orbitalisation of the urban context deep into the urban texture behind the physical boundaries of the square surroundings. The orbitalised urban district around the square interact with it in more than three dimensions of the space but also in the fourth dimension of time, fifth of memories and sixth of cross-gender, cross-generation, cross-cultural interaction of the spatial user groups.

Figure 3: Map (left) /Aerial view (right) of the vicinity indicating 1st and 2nd squares locations in Niruye-Havaei. Courtesy of Google Map

After the revitalisation act, the 2nd square was mainly used as an urban park with limited uses, scopes and activities, similar to its role before the act; central pond and fountains, sitting areas around the pond, outer pedestrian ring, sitting benches, working together as a public leisure space. During the next 15 years, the municipalities were given more devolved task and autonomy resulting in dedicated budget for restoration of public spaces centrally managed through a newly established organisation known as Tehran's Beautification Organisation. What was first added to the public spaces was in form of seasonal and temporary ornaments, festive decorations, planters and planting beds and hangers. Gradually some of the temporary decoration and landscape ornaments turn into more permanent ones. Added to those were some renewed infrastructures and some new proposed functionalities on a trial and error basis, some of which became permanent over a period of time, while the other less successful ones were modified, abandoned, or replaced. Ultimately what can be seen today is a merger of the resultant of what has been experienced over the past 20 years spreading in over 12000 m2. Children's playground, aquarium, a book sale booth, a sandwich shop, equipped exercise areas, chess tables, ping pong tables, canopies, vegetation and plantation repository, local community centre, free blood pressure and blood sugar monitoring station are the permanent functions, spaces and services in this square. In addition a mobile police station is located in south part of the square to provide local security (See Figures 4-11).

6 SPATIAL ANALYSIS

This costly project was surveyed over a period of 70 days spread over from mid-September to mid-March, during which there were 28 people present in mornings, 56 in afternoons, in weekdays, 200-250 in the weekends, with the lowest record of a minimum of 12 during the coldest days of the year 2012. The space was used for local chess, backgammon and playing card leagues up to midnight during the warmer seasons. After the school hours the user population will be added by the school pupils. All the above figures exclude the users of the aquarium, the local community centre, book stall, and the sandwich shop.

Figure 8: A grandfather with his granddaughter. Figure 9: Senior citizens and teenagers playing chess, cards and backgamon in a cold day

Figure 10: An aged man exercising in a cold morning. Figure 11: The central pond and fountains of the square

While being self-sufficient in a sense, the square also works interactively with the local shops including a pharmacy, a bakery, a confectionary, several banks, and news agents, etc. which adds to liveability, usability

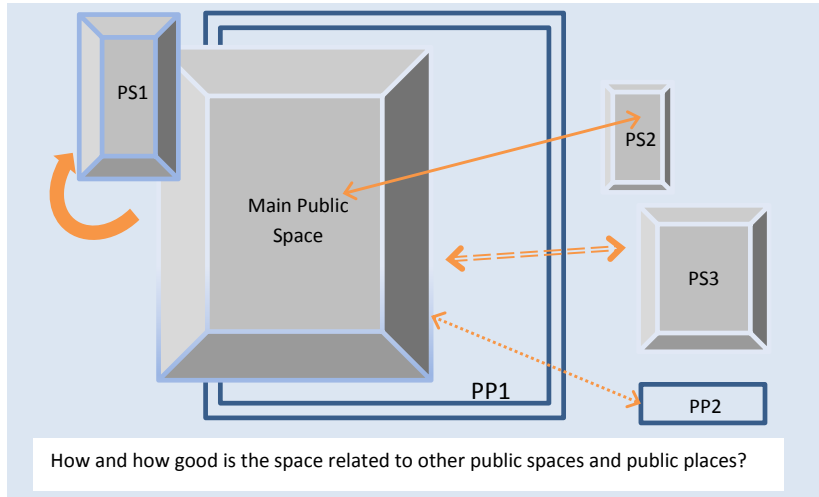
and comprehensiveness of users' demographic pattern during the different hours of a day, transforming 'public place' to 'public space' and transferring the vibe and ambience of the public space into several blocks deep into the urban fabric surrounding the square (See Figure 12). This has resulted in creating temporary car parks around the roundabout and reduction of the vehicle traffic speed improving the livelihood and the pedestrian use of the space. Moreover, this has added to diversification of the ethnographies using what the square has to offer, from those who can access it on-foot to those driving in from more distant neighbourhoods.


Figure 12.

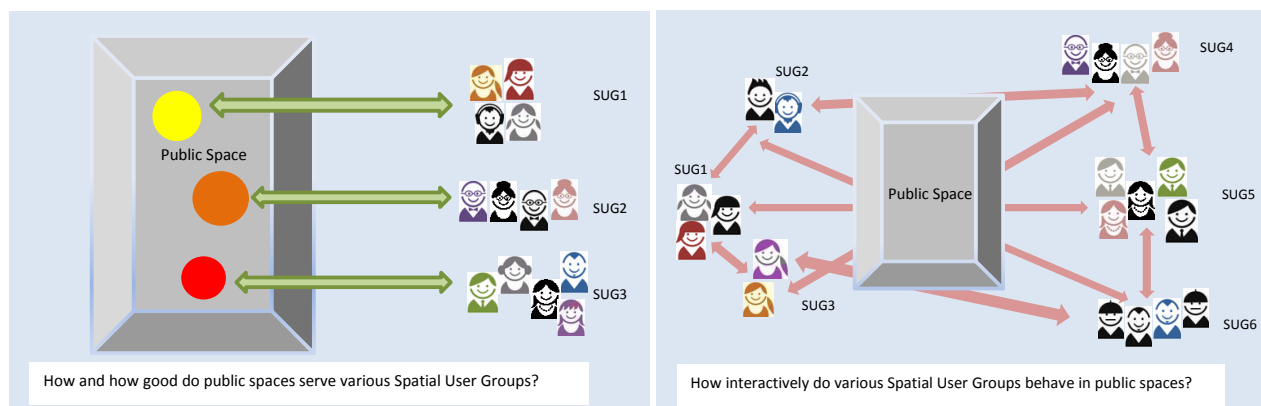
The spatial variation, and diversification of fucntionalities absorbs a broad range of spatial users groups meaning that users in different age brakets, genders, backgrounds, having various tastes and spatial expectations find their needs and wants (at least partialy) fulfilled simultaneously with those of the others' within one urban setting (See Figure 13). This simultaneity provides an atmosphere for different users groups to share their spatial use experience, for instance grandparents can and do use the space at the same time as their very own grandchildren with very little conflict of interest priorities if any and maximum coalition between the spatial user groups. This has turned the square into a 'social hub' for senior citizens where they can enjoy a lively interaction with other spatial users, fresh air, outdoor exercise and sports or simply the companionship of their friends or family members. This not only has helped renew the links of the senior citizens to the society but also has integrated their roles, values and benefits into the space dimensions and facilitated a context to use their potentialities towards creation of socio-cultural sustainability (See Figure 14). This interaction has been developed into and between other spatial users groups.


Figure 13, Figure 14.

7 CONCLUSION

Although under-management or over-management have been understood to be the main reasons for the decline in the urban space, it seems that the main reason for urban space decline lies in the principles and approaches to the 'Production of Space', where production of a socio-cultural space is achieved through

maximising of the functionality with an aim to increase the absorption of the masses and to encourage the diversification of the spatial user groups. This means if and when the public space is to be able to offer satisfaction for its local community, it will need to be successful in absorbing the mass; what differs fundamentally from the quality in the mere design process as it is classically understood. All-inclusiveness of the urban space will mean creating equal and wider opportunities for participation of all parties to keep the public space lively. To provide an all-inclusive solution for prevention of the urban space from decline, the planners and designers should develop a systematic feedback loop to transfer the learning experience of the public space from the post-occupancy/operation stages into planning and design stages.

A theory of 'Orbitalisation' of the urban district around a public space was drawn where the dimensions of space are developed beyond the traditional three dimensions further into what the effect of time, experience and diversification of the spatial user groups is added to the collective memory of the urban space; what is conveyed through means over and above the physical entities of the space.

1 ABSTRACT[1]

The world is in a continuous change. People lived according to different norms in different periods, with the development of technology, the accelerated time people's learning and knowledge have required/demand a continuous change. Learning and knowledge have played/play an accentuated role in the development and everyday life of mankind. Education, and especially tertiary education is still in a key position today, when in its strategies Europe is laying emphasis on the fact that knowledge and innovation could be the driving force of competitiveness. (Tamándl 2012)

The world's tertiary education – including the Hungarian tertiary education system as well – has undergone a huge change in the last two decades. Functions which are said to be traditional have changed significantly, the supply range has transformed – it is offering new things for both the students and the teachers -, it is playing different roles in the life of people, professions, careers, as well as in that of the regions. (Fábri 2005) The carriers of knowledge are the institutions of higher education. Encouraging innovation and innovation have priority, because they contribute to development. That is the reason why it is necessary to create harmony between the needs of companies and the output of educational institutions. (Filep 2009) The domestic regional science is increasingly turning towards tertiary education; moreover, competition as a new factor has appeared in the life of universities. New institutions have shown up on the supply side (private, religious, non-profit, foreign), while on the demand side professions, trade groups are being created, or are disappearing from the "spotlight". (Rechnitzer 2010) Institutions, performers are multiplying knowledge as well as innovation have begun decentralization, and they are more and more integrating into the local, regional economies, as a result of which the structures of this process have also entered the phase of transformation. (Grosz-Rechnitzer 2005)

Taking he above ideas into account, it can be declared that the alteration of the economy and the society, namely the phenomenon of globalisation has impacted the segment of tertiary education and it has resulted in its transformation. There is a competition going on for the free capital, more exactly today it is a crucial issue which region or area can attract the capital necessary for the production of products and high technology (Barakonyi 2009), in the process of which higher education institutions can play a significant role.

One of the most important structural problems of the national tertiary education is the weakness and disability of the relationship between the education and the labour market, the inadequate nature of the information flow between the two spheres. The demands of the labour market are not built in the content, output expectations and requirements of courses offered by universities and colleges, although there is a need for the information systems revealing the labour market position of graduates, for objective ranking methods and for conveying information about the labour market to the students. Efficiency, economy, transparency and traceability are irreplaceable elements of the operation of higher education institutions in the 21st century. The Hungarian higher education institutions can become competitive in the uniform European Higher Education Area only if they necessarily employ the latest ICT-based (Information and communication technology) services. The planned activities make possible to modernize the control and management systems of the institutions in order to make them efficient and flexible, with the support of IT devices, moreover, they can help the efforts aiming at the introduction of modern, integrated services.

In recent years several experts have analysed and presented that in Hungarian tertiary education the geographical location of institutions can mean an advantage and a disadvantage as well, namely the capital represents the leading role from every aspects (number of students, range of courses, etc.) Until now there have not been any rankings or indicators with the help of which institutions could have been compared. In order to be able to decrease the differences of the above analysis, the causes of the difference have to be explored. By setting up the competitiveness model, we are presenting the indicators, the categories according

---

to which the institutions on the countryside can be as competitive, or even more competitive than universities in the capital.

Due to their huge numbers, the competition between the institutions – both in space and size – is definitively considered to be lively on the relatively small Hungarian higher education market. The regional commitment of the institutions on the countryside are supposed to be higher than those in Budapest where the institutions have significant national scope and they also have needs to appear at an international level. (Kovács 2012)

2 RESEARCH METHODOLOGY

With the research we are trying to find the answer to questions like how the present position, competitiveness of European universities can be connected to their role in the region, how rankings can be used in determining the quality of institutions, how the results of graduate career tracking researches (output indicators) can be interlinked with university rankings, and what kind of positive effect can be derived from such a new kind of ranking.

In the last years, decades – similarly to more fields – rankings have appeared in the tertiary education as well, which make international comparison possible. (Shanghai Academic Ranking of World Universities – ARWU, Times Higher Education World University Ranking, World's Best Universities Ranking – US News and World Report, CHE University Ranking, U-Multirank ranking, Performance Rankings of Scientific Paper for World Universities, Webometrics Ranking of World Universities) University rankings have and can have an important role in justifying or confuting the governmental, institutional, corporate and family decisions made on the supply and demand side of tertiary education services. The appearance of rankings have been followed by numerous debates, which mainly questioned the methodology, criteria and indicators of these lists, although most of them have agreed in the fact that at present this is the best method to measure the competitiveness of higher education institutions from a professional and scientific aspect. Besides these, the rankings can be fixed in value in the long run only if they represent the institutional quality, prove to be capable of comparing the scientific level of institutions, can reflect the position of universities in the competition for students and resources; moreover, they provide exact information about graduate feed-backs and the value of the degree.

More and more theoretical and practical research is dealing with the competitiveness of countries, regions, both internationally and nationally. There are several examples showing that – besides enterprises and nations – the question of competitiveness is present in today's tertiary education. There is a competition for the students, teachers, R&D work and for the finances necessary for the education. In the previous year I tried to set up a model suitable for the measurement of university competitiveness on the basis of a special methodology, the pyramid model of competitiveness by Lengyel (2010). The third chapter is presenting the further consideration, methodological elaboration and test of the model. In the model I mostly relied on the textual accounts of the NEFMI, the AVIR, the Educatio Nonprofit Kft., the OTDT, the TEMPUS Public Foundation, the OH, the FTT[2] and the higher education institutions. While setting up the model, from a methodological point of view I found it important to base it on an economic theory, to make it consequent from a mathematic-statistic point of view, to direct it to the method of achieving competitiveness and the future development of competitiveness. Among the further aspects I considered the fact that it should be suitable for the comparison of higher education institutions, and should be useful for the purposes of scientific research and practical application. From a technical aspect I considered transparency, extensive nature, authenticity, usability (informal and research) and proportionality important. The tertiary education competitiveness model has a greater spectrum than the existing – either Hungarian, or international – rankings. Taking the above points into account I classified the 42 indicators into 3 basic categories and 5 basic factors in which the indicators of the trifold unity of education, research and service. The basic categories contain the student-, alumni- and labour market satisfaction, and I characterized each of the basic categories and the basic factors with more indicators. We carried out the examination with nine selected institutions. The three basic categories and the five basic factors were each characterized by more indicators. We summed up and took the average of the standardised (transformed to a scale between 0 and 1) values of

---

[2] NEFMI – Ministry of National Resources, AVIR – Data Warehouse-based Management Information System, OTDT – Council of National Scientific Students' Association, OH – Educational Authority, FTT – Higher Education and Research Council

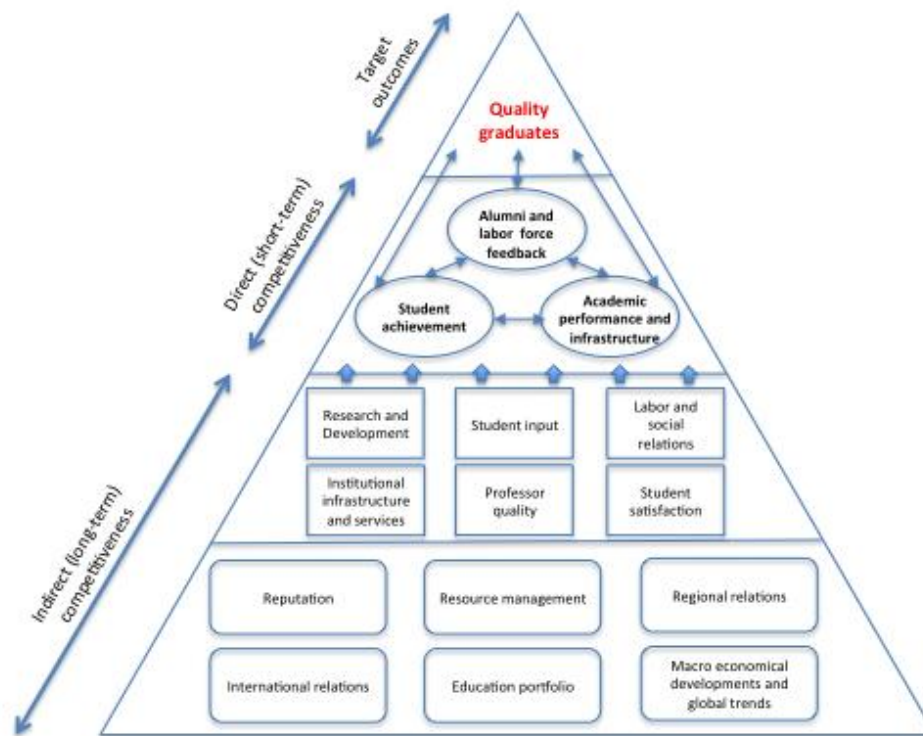
the indicators belonging to the same basic category (and basic factor). The final static measurement of competitiveness was carried out by considering the indicators of the basic categories and basic factors with the methodology specified weighting, and then the final result was developed by transforming the resulting values between 0 and 100 once more.


Fig. 1: Ranking of higher education institutions on the basis of the competitiveness model. Source: Filep-Kovács-Tamándl 2010.

Although no comparative examination of universities, higher education institutions have been made on the basis of the method, we still consider it a model which can have results in national and international researches as well by collecting the data if it is used systematically All this can mean the possibility of the comprehensive expansion of the research.

3   RESULTS OF THE RESEARCH

In recent years, similarly to other sectors, competition has also appeared in tertiary education. It is marked by the fact that besides state institutions more institutions (mainly private, non-profit, and religious ones) have been established. Institutions have made attempts to refresh the range of their courses with new methods (distance learning, e-learning). Parallel with this, as a result of socio-economic trends majors, professions have been appreciated and depreciated, new fields of professions have been given more attention. Students' expectations have been transformed and institutional services, institutional infrastructure, distance from the place of living, and future possibilities of work close to the institution have appeared with greater emphasis in the selection of institutions.

Institutions on the countryside have to struggle with the additional difficulty of a bigger significance given to institutions in the capital by the professionals. What aspects could or can be behind this statement? The number of institutions on the countryside has decreased while the number of state instituions has remained practically the same, the number of institutions in the capital has slightly increased, which can be explained by the integration. The leading role of institutions in the capital is permanent concidering the number of students (nearly 40 % of students study in the capital) and the diversity of courses, furthermore they can put pressure on politics forming tertiary education due to their importance. (Rechnitzer 2009)

Under the above circumstances, I have undertaken the task to verify with the competitiveness model the fact that rural institutions can compete and sometimes stay ahead in the competition of the universities in the capital.

Previously we had a review of the competitiveness indicators of the 9 selected universities in detail; furthermore, their positions on the basis of the tertiary education competitiveness model can also be seen. The cumulated results are included in Table no. 1 and Figure no. 2.

Name[3]	BCE	BME	DE	ELTE	NYME	PE	PTE	SZE	SZTE
Basic categories	5.	4.	3.	1.	9.	7.	6.	8.	2.
Basic factors	5.	1.	2.	4.	9.	8.	6.	7.	3.
Competitiveness (total)	*5.*	*1.*	*3.*	*4.*	*9.*	*8.*	*6.*	*7.*	*2.*

Table 1: Position of higher education institutions on the basis of the competitiveness model
Fig. 2: Ranking of higher education institutions on the basis of the competitiveness model

The basic categories and the basic functions of competitiveness verified the asumption. By four out of the eight categories of competitiveness rural institutions had the best performance. In relation to the basic categories and the basic factors, we can tow-two rural institutions among the three best ones. In the first three places of the final ranking there are again two rural universities (SZTE, DE), with their final points just slightly less than the leader of the ranking, the BME (2-3 points less).

To sum up, rural universities can compete with the institutions in the capital regarding tertiary education indicators and competitiveness. Hungarian institutions, independently of their geographical location (either in the capital or in a rural city) can be equally competitive, namely the regional position does not always adversely influence the competitiveness.

4 CONCLUSION

The higher education institutions are taking an increasingly bigger role in the development of their regions and cities, in turn, the the cities and regions are also making attempts to do their best for the economic, social and cultural development of tertiary education. From the point of view of the university regional role-taking is important because in this way it has the opportunity to show its contribution to the civil society, and can verify its values formed by education and research with which it repays the investments of society. However it must be noted that not every Hungarian higher education institution has only regional embeddedness. The greater institutions in the capital (ELTE, BME, BCE) have nationwide coverage and relationships, while regional binding is characteristic of the rural institutions (SZTE – Szeged, SZE – Győr, DE – Debrecen, PE – Pécs).

Collecting data was the most difficult task during the application of the tertiary education competitiveness model set up on the example of the pyramid model. Many data cannot be found at institutional or national level, which makes the analysis and the testing of the model more difficult. The time series study, related to a longer period, would provide more information about the processes, but in that case less data can be taken

---

[3] BCE – Corvinus University of Budapest; BME- Budapest University of Technology and Economics; DE – University of Debrecen; ELTE – Eötvös Loránd University; NYME – University of West Hungary; PE – University of Pannonia; PTE – University of Pécs; SZE – Széchenyi István University; SZTE – University of Szeged

into consideration and the data selection at the suitable level has to be well devised. Thus the resulting analysis reflects a static state, which shows the given state projected to the nine higher education institution, but the time series study is necessary and it has to be carried out in the future.

There have been and there are still studies abot competitiveness carried out in a lot of fields (comparison of countries, regions, cities, professional fields, enterprises, etc.) in both national and international literature, but it is a novel attempt to compare universities, higher education institutions on the basis of indicators, and to define and determine their competitiveness despite the existence of several tertiary education rankings.

It is clear on the basis of the data of higher education institutions that the increase and competitiveness of the Hungarian tertiary education differs from institution to institution and it changes unevenly. On the basis of these ideas I believe that it is especially important for experts and certain offices and administrative organizations (NEFMI, Educatio, ÁSZ, KSH) to cooperate in the interest of the success of future comparisons, as exact and extensive samplings, surveys and analyses are inevitable in order to get authentic data.

In summary it can be said that the modell and the GCTS survey offer a unique possibility to reveal the labour market position of young graduates, it has an indisputable national significance, and it points at young people's social background and lifestyle, labour market opportunities, intention of further trainings, and with the annual repetition of the survey, there will be a possibility to follow up on the tendencies. It is not easy to find a way as it requires considerable efforts from leaders, teachers and researchers as well. (Szekeres 2008)
